The very successful Herschel space mission observed in the important wavelength range between about 60 and 600 microns, most of which is completely inaccessible from the ground. After its conclusion and with no similar major space observatory becoming available in the near future, the Stratospheric Observatory for Infrared Astronomy, SOFIA, is the one facility that can still provide the astronomical community on a regular basis with new observations in the large spectral gap left betweeen JWST and ALMA. In addition, SOFIA allows for instrument augmentations, as new state-of-the-art photometric, spectrometric, and polarimetric capabilities have been added and are being further improved. The fact that SOFIA provides ample mass, power, computing capabilities as well as 4K cooling, eases the constraints on future instrument design, technical readiness, and the instrument build to an extent not possible for space-borne missions. We will review and compare the existing legacy data from Herschel with the growing instrumental capabilities of SOFIA and highlight specific science areas where the stratospheric observatory will be able to significantly advance Origins science topics.

E1.18-0010-18 THE C+ UNIVERSE

Alexander Tielens, tielens@strw.leidenuniv.nl Leiden Observatory, Leiden, Netherlands

The interstellar medium (ISM) is central to galaxy evolution over cosmic time. Interstellar gas is known to exist as atomic (HI) clouds and star forming molecular clouds. Recent observations have revealed that half of interstellar gas is in so-called CO-dark molecular gas (hydrogen is H2 but carbon is C+). Atomic and CO-dark gas have so-far eluded detailed characterization because of lack of suitable tracer and the physical conditions of these components and their relationship to the molecular reservoir are largely unknown and their role in galactic ecology is wide open.

The combination of sensitive THz heterodyne receiver arrays with a nimble telescope on SOFIA enables large scale, [CII] 158m surveys of regions of massive star formation. This line is the main cooling line of the diffuse ISM and therefore a key diagnostic of interstellar gas energy balance. In addition, the high spectral resolution inherent to heterodyne techniques allows us to study in detail the kinematics of photodissociation regions, which separate ionized from molecular gas. I will present the first results of the [CII] 158m square degree Orion Survey, its analysis and implications for large scale [CII] 158m emission from galaxies.

E1.18-0011-18 SOFIA FAR-INFRARED FIFI-LS OBSERVATIONS OF CO-RICH KNOTS IN THE SUPERNOVA REMNANT CAS A

Jeonghee Rho, jrho@seti.org

SOFIA/USRA, Moffett Field, California, United States

Supernovae are key drivers of the evolution of the interstellar medium of galaxies as they are main sources of heavy elements and kinetic energy. Dense, fast-moving ejecta knots in supernova remnants (SNRs) are prime sites for molecule and dust formation. Whether dust is survived from the reverse shock is one of the unsolved fundamental problems in understanding dust evolution and a large amount of dust detected in high-redshift galaxies.

We present SOFIA far-IR spectrometer FIFI-LS observations of CO-rich knots in Cas A in the [OIII] 52 and 88 microns and [OI] 63 micron lines. The observations covered 1 arcmin area. The FIFI-LS spectra show the line widths of [OIII] and [OI] similar to those of the Herschel PACS [OIII] and CO lines. We find that [OIII] maps show very different structure from the [OI] map. The [OIII] maps show diffuse, large-scale structures and the ratio of the two [OIII] lines implies a range of density 100 - 10,000 per cm3. In contrast, the [OI] map shows bright emission from dense CO-rich knots. We will discuss characteristics and evolution of the dense knots, the implication of [OI] cooling, reformation of CO molecules, and to the dust in the early

Universe.

E1.18-0012-18 SHOCKED AND SCORCHED: A GREAT INVESTIGATION OF [CII] AND [OI] EMISSION FROMFREE-FLOATING EVAPORATING GAS GLOBULES IN MASSIVE STAR FORMATION REGIONS

Raghvendra Sahai, raghvendra.sahai@jpl.nasa.gov JPL, Pasadena, California, United States

Mark Morris, morris@astro.ucla.edu

University of California, Los Angeles, Los Angeles, California, United States Mark Claussen, mclausse@nrao.edu

NRAO, Socorrow, New Mexico, United States Thomas Bisbas, tbisbas@ufl.edu

University of Florida, Gainsville, Florida, United States Nimesh Patel, npatel@cfa.harvard.edu

Harvard-Smithsonian Center for Astrophysics, Cambridge, Massachusetts (USA), Cambridge, Massachusetts, United States

We present first results from a GREAT program to study the atomic component of select members of a new class of tadpole-shaped free-floating evaporating gas globules (frEGGs) in massive star-formation regions. Since discovering the most prominent member of this class in an HST imaging survey, we have now identified substantial populations of such objects in several massive star-forming regions using Spitzer IRAC 8 micron images. By virtue of their distinct, isolated morphologies, frEGGs are ideal astrophysical laboratories for probing star formation in irradiated environments. Our molecular-line observations (e.g., CO, 13CO J=2-1 HCO+ J=3-2) reveal the presence of dense molecular cores associated with these objects, with total masses of cool (50 K) molecular gas exceeding 0.5-5 Msun, and our radio continuum imaging of a few reveals bright photo-ionized peripheries in these objects. Our GREAT study of 3 frEGGs has allowed us to detect the warm (few x 100 K) atomic gas that is expected to exist in a photon-dominated region surrounding the molecular gas and determine its mass, and probe the photoevaporative flow that is expected to drive the evolution of these objects. Our SOFIA data (together with existing multiwavelength data), when compared with results from sophisticated 3-D numerical simulations, will provide a unique window into the dynamical and chemical evolution of these irradiated dense gaseous globules, and the star-formation process within them.

E1.18-0013-18 MID-INFRARED MAPPING OF THE GALACTIC CENTER REGION

Nadeen B. Sabha, sabha@ph1.uni-koeln.de University of Cologne, Cologne, Germany

The center of the Milky Way is the closet laboratory for studying nuclear stellar clusters, star formation under extreme conditions, and the immediate surroundings of a supermassive black hole. This Galactic Centre (GC) harbors three massive clusters that allow studying cluster-based star formation history over the past 8 Myr. I will present our recent mid-infrared observations of the GC region obtained in 2010 and 2016 with the ground-based instrument VISIR on the ESO Very Large Telescope. The high-resolution multi-epoch N -band data cover a large field of view of selected regions within the central tens of parsecs of the Galaxy. Photometric and astrometric analysis of mosaics of the nuclear star cluster, the Quintuplet cluster, and regions in the Arched Filaments and the Sickle provide a census of faint compact (disk candidates, YSO's, and bow shocks) and diffuse emission sources in the mid-infrared. Their spatial distribution and concentration is studied and combined with existing multi-wavelength surveys in the infrared and the X-rays. The Galactic Center is one of the targets planned to be observed with the MIRI instrument GTO time aboard the James Webb Space Telescope (JWST). This data is hence of importance in the preparation and interpretation of the upcoming MIRI observations.

E1.18-0014-18 POSTER HIGHLIGHTS SESSION

Jeonghee Rho, jrho@seti.org

NASA/ARC, Moffett Field, California, United States Randolf Klein, rklein@sofia.usra.edu

USRA, Moffett Field, California, United States

Poster contributors will have an opportunity to present their posters as a short talk in one or two minutes. Please prepare for one slide of the summary of your poster and provide to the event organizer and your session chair.

E1.18-0015-18 SOFIA/HAWC+ FAR-INFRARED STUDIES OF MAGNETIC FIELDS AND PROSPECTS FOR SPACE

C. Darren Dowell, charles.d.dowell@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

The HAWC+ instrument, designed for far-infrared (Λ = 50-220 μm) imaging and linear polarimetry with SOFIA, was commissioned in 2016 and has begun science observations. Many of the ongoing and upcoming observations, in support of the community through the SOFIA Guest Observer process and also by the HAWC+ Guaranteed Time science team, are utilizing the alignment of interstellar dust grains to make maps of magnetic fields in nearby molecular clouds, the Galactic center, and infrared-bright galaxies. We show a sample of the first maps obtained with HAWC+, review the physical effects that are being studied, and discuss the capabilities and limitations for HAWC+ as an airborne instrument. We use the results from HAWC+ to predict potential outcomes from far-IR polarimetry from space with mission concepts such as the Origins Space Telescope.

E1.18-0016-18 FIR OBSERVATION OF THE POLARIZED DUST EMISSION IN GALAXIES WITH PILOT

Jean-Philippe Bernard, jean-philippe.bernard@irap.omp.eu

Institut de recherche en Astrophysique et Planétologie, Toulouse, France Anne Hughes, annie.hughes@irap.omp.eu

IRAP - Institute of Research in Astrophysics and Planetology, Toulouse, France

Understanding the role played by the magnetic Field in shaping ISM structures and ultimately forming new stars in galaxies is one of the next observational challenges of modern astronomy. In particular, sounding regions where stars actually form requires using dust polarization measurements, which are difficult to obtain. I will discuss this in the context of the recent Planck all-sky map of the polarized dust emission. I will also present preliminary results of the PILOT balloon-borne instrument regarding the magnetic field structure and dust properties in regions of the galactic plane and possibly the nearby Large Magellanic Cloud. These regions were observed recently in polarization of the Far-IR emission of dust grains, during the second flight of the PILOT instrument that took place from Alice Springs, Australia, in April 2017.

Star formation, the most fundamental process in the universe, is linked to planet formation and thus to the origin and evolution of life. We have a general outline of how planets and stars form, yet unraveling the details of the physics and chemistry continues to challenge us. The infrared and submillimeter part of the spectrum hold the most promise for studying the beginnings of star formation. The observational landscape recently shaped by Spitzer, Herschel and ALMA, continues to challenge our current theories. SOFIA, the Stratospheric Observatory for Infrared Astronomy, equipped with state-of-the-art infrared instrumentation to a vantage point up to 45,000 feet (13.7 km) flight altitude that is above 99.9% of the Earth's water vapor, enables observations in the infrared through Terahertz frequencies not possible from the ground. Examples of future SOFIA science frontiers include: (1) Establishing the role of magnetic fields on sub-parsec scales in giant molecular clouds, and in filamentary star formation regions within, with 50-200 micron polarimetry, when combined with VLT/GTC, Planck, ALMA, and Herschel data, will provide a huge leap in our understanding of the role of magnetic fields on various size scales in our Galaxy. (2) Velocity resolved imaging spectroscopic surveys of massive star formation cloud complexes in the Milky Way in ionized carbon at 158 micron and other FIR emission lines to revolutionize our understanding of the role of environment and feedback in star formation and its link to galaxy evolution. (3) Studies of the fundamental ground-state transition of 112 micron

HD and water (vapor and ice) in a survey of several protoplanetary disks to measure the mass of planet-forming matter in the Galaxy and push the planet-formation field forward.

E1.18-0018-18 CHEMISTRY IN PROTOSTELLAR REGIONS: NEW IMPLICATIONS FOR JWST MIRI/ NIRSPEC

Liton Majumdar, liton.majumdar@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Pierre Gratier, pierre.gratier@u-bordeaux.fr University of Bordeaux, France, Bordeaux, France Valentine Wakelam, valentine.wakelam@u-bordeaux.fr University of Bordeaux, France, Bordeaux, France Emmanuel Caux, emmanuel.caux@irap.omp.eu Universite de Toulouse, France, Toulouse, France Karen Willacy, karen.willacy@jpl.nasa.gov

NASA Jet Propulsion Lab / California Institute of Technology, Pasadena, California, United States

M. E. Ressler, michael.e.ressler@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Observation of CO2 in exoplanet atmospheres is one of the major science themes for James Webb Space Telescope (JWST). CO2 cannot be observed in the gas phase through rotational transitions in the far-infrared or submillimeter range due to its lack of permanent dipole moment. It has to be observed through its vibrational transitions at nearand mid-infrared wavelengths. We will show how observation of protonated form of CO2 in a solar-type protostar help us to better understand the overall temperature structure, ionization structure, H2O and CO2 snow lines, and overall C/O ratio. Implications of our study to the chemistry of CO2 ices using JWST-MIRI and NIRSpec will be discussed as well.

E1.18-0019-18 THE ORIGINS SPACE TELESCOPE (OST)

Charles Bradford, matt.bradford@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Presented on behalf of the OST study team, with engineering support at Goddard Space Flight Center.

The Origins Space Telescope (OST) one of the four science and technology definition stud- ies supported by NASA Headquarters to prepare for the 2020 Astronomy and Astrophysics Decadal Survey. OST will operate in the midand far-infrared where galaxies emit most of their energy; it offers massive sensitivity gains in this relatively unexplored regime with a large, actively-cooled telescope and background-limited far-IR detector arrays. OST will provide a complete picture of star formation, black hole growth, and interstellar processes across the arc of cosmic history; from the first proto-galaxies and emergence of heavy elements in the dark ages, through the peak of star-formation activity, to the present-day conditions in deeply-obscured regions of the Milky Way and nearby galaxies. The formation of habitable worlds is a key OST theme, and the observatory is designed to chart the trail of water from the interstellar medium through protoplanetary disks to planetary systems, including water transport in our own solar system. A particularly unique OST capability is the identification of life-bearing worlds through a dedicated mid-IR exoplanet transit spectroscopy channel targeting co-existence of methane and ozone: a combination indicating life. We will present the science drivers and broad capabilities of OST, and describe our Concept 2, a 5.9 m telescope cooled to 4 K with an integrated passive (sunshade) and active (cryocooler) systems. Concept 2 is designed to have minimal deployments to mitigate risk and reduce integration costs, while still fitting into a 7m fairing. OST instruments include the Origins Survey Spectrometer (OSS) a backgroundlimited wideband R=300 spectrometer covering 28 to 600 microns with high-resolution modes providing R up to 105, a Mid-Infrared Imager, Spectrometer and Coronagraph (MISC) offering imaging and spectroscopy from 5 to 28 microns and the dedicated exoplanet spectrograph, a Far-Infrared Imaging Polarimeter (FIP) providing broad-band imaging polarimetry from 40 to 240 microns, and possibly a HEterodyne Receiver for OST (HERO), providing R 106–107 for kinematic studies of water and other key species in disks and the interstellar medium.

E1.18-0020-18 STAR FORMATION IN THE GALACTIC CENTER: FORCAST OBSERVATIONS OF SGR B1

Angela Cotera, ascotera@gmail.com

SETI Institute, Avondale, Arizona, United States Janet Simpson, janet.p.simpson@gmail.com

SETI Institute/NASA Ames Res. Center, Mountain View, California, United States

The proximity of the center of our Galaxy enables us to study star formation under conditions commonly found in other galaxies, but at spatial resolutions unachievable elsewhere. The Galactic Center (GC) provides unparalleled opportunities to test theories of the interrelationship of massive stars, warm and hot gas and dust, turbulent giant molecular clouds, large-scale magnetic fields, and a black hole. The region known as Sagittarius B is one of the most complex star-forming regions in the galaxy, containing a massive molecular cloud, dozen of HII regions, and numerous young stellar objects (YSOs). It is composed of two distinct regions (Sgr B1 and Sgr B2). Although much of Sgr B is unobservable at IR wavelengths due to extinction, Sgr B1 has lower extinction. We will present data of Sgr B1 taken with the Faint Object InfraRed Camera for the SOFIA Telescope (FORCAST) at 19, 31, and 37 microns. We will present colortemperature maps of the region, which enable us to explore variations in the dust temperatures throughout the region and any relations to the known massive stars and massive YSOs in the region. We will also combine the newly obtained data with archival data to create spectral energy distributions (SEDs) for compact sources throughout the region, to better understand the type, temperature and extinction for these sources. These results will enable us to address the complex issue of the relationship of Sgr B1, Sgr B2, and proposed sequential star formation occurring as the giant molecular clouds in the Central Molecular Zone (CMZ) orbit the black hole Sgr A*.

E1.18-0021-18 STRIATIONS IN MOLECULAR CLOUDS: “HEARING” THE 3D SHAPE OF MUSCA

Konstantinos Tassis, tassis@physics.uoc.gr University of Crete, Heraklion, Greece Aris Tritsis, aris.tritsis@anu.edu.au

Australian National University, Canberra, Australia

Dust continuum and molecular observations of the low column density parts of molecular clouds have revealed the presence of elongated structures which appear to be well aligned with the magnetic field. These so-called striations are remarkably ordered structures in otherwise chaotic-looking clouds, so understanding their physical origin and the information they encode is expected to be revealing of the properties of their parent clouds. We probe possible mechanisms of striation formation through a series of ideal magnetohydrodynamic simulations. We demonstrate that magnetosonic waves, ubiquitous in molecuar clouds, are the most probable cause of striations, since they are the only mechanism that can reproduce quantitatively their observed properties. If indeed striations are the interstellar ripples caused by the passage of magnetosonic waves, then profound consequences are implied for their ability to reveal hidden, important information about molecular clouds. I will present a specific example: striations in the Musca molecular cloud are found to encode normal modes of the cloud’s global magnetosonic vibrations, allowing the reconstruction of it’s 3D shape.

E1.18-0022-18 NISS: NEAR-INFRARED IMAGING SPECTROMETRIC SURVEY MISSION

Woong-Seob Jeong, jeongws@kasi.re.kr

Korea Astronomy and Space Science Institute, Deajeon, Korea NISS Team

Woong-Seob Jeong, Sung-Joon Park, Bongkon Moon, Dae-Hee Lee, Jeonghyun Pyo, Won-Kee Park, Il-Joong Kim, Youngsik Park, Kyeongyeon Ko, Mingyu Kim, Duk-Hang Lee, Minjin Kim, Jongwan Ko, Myungshin Im, Hyung Mok Lee, Jeong-Eun Lee, Goo-Hwan Shin, Jang-Soo Chae, Toshio Matsumoto

The NISS (Near-infrared Imaging Spectrometer for Star formation history) have been developed by KASI as one of the scientific payloads onboard the first small satellite of NEXTSat program (NEXTSat-1) in Korea. The both imaging (spatial resolution of 15”) and low spectral resolution spectroscopy (R 20) in the wide near-infrared range from 0.95 to 2.5μm is a unique capability of the NISS for the study of star formation in local and distant Universe. It will perform the near-infrared imaging spectroscopic survey for scientific targets such as nearby galaxies, galaxy clusters, star-forming regions and low background regions. The NISS will be launched in 2018 and operated to make the spectrophotometric survey covering up to an area of 200 square degrees during around 2 years.

E1.18-0023-18 THE BALLOON EXPERIMENTAL TWIN TELESCOPE FOR INFRARED INTERFEROMETRY (BETTII): A BALLOON-BORNE INTERFEROMETER FOR EXPLORING THE FORMATION OF STARS

Stephen Rinehart, stephen.a.rinehart@nasa.gov NASA/GSFC, Greenbelt, Maryland, United States

The Balloon Experimental Twin Telescope for Infrared Interferometry (BETTII) is an 8-meter far-infrared interferometer designed to provide spatially-resolved spectroscopy in the 30-100 micron regime. The high angular resolution provided by BETTII, as well as the spectral coverage, complements both ground-based and space-based observations with unique FIR data that is critical for understanding the intrinsic luminosity of individual protostellar cores. BETTII had a successful engineering flight in 2017, but at the end of the flight an anomaly resulted in the loss of the payload. The team is currently working to rebuild the payload for a 2020 recommissioning flight, to be followed by science flights in 2021 and 2022 focused on nearby star formation regions.

E1.18-0024-18 THE MID-INFRARED IMAGER/ SPECTROMETER/CORONAGRAPH INSTRUMENT (MISC) FOR THE CONCEPT 2 ORIGINS SPACE TELESCOPE

Thomas Roellig, thomas.l.roellig@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States Itsuki Sakon, isakon@astron.s.u-tokyo.ac.jp

University of Tokyo, Tokyo, Japan Kimberly Ennico, kimberly.ennico@nasa.gov

NASA Ames Research Center, Mountain View, California, United States

The Origins Space Telescope (OST) is one of four potential future flagship missions that have been funded by NASA for study for consideration in the upcoming Astrophysics Decadal Review to be conducted in 2020. The OST Concept 2 telescope will be 5.9 meters in diameter, cooled to 4K, and the mission will be optimized for efficient mid and far-infrared astronomical observations. An initial suite of four focal plane instruments are being baselined for the Concept 2 observatory. The MISC instrument will observe at the shortest wavelengths of any of these instruments, ranging from 5 to 28 microns, and consists of two separate optical modules providing imaging, spectroscopy, and (potentially) coronagraph capabilities. The first module covers a 4.5' x 4.5' field with filters and grisms from 5-28 microns. We are also studying the feasibility of adding a coronagraph optical path in this module that would cover 6-28 microns in five broad bands. In addition to the imager module there is a separate densified pupil spectrometer module that would be used for R 100-300 exoplanet transit and emission spectroscopy from 6-26 microns with very high spectro-photometric stability. As the shortest wavelength focal plane imager the MISC instrument will also be used for focal plane guiding as needed for the other OST science instruments.

E1.18-0025-18 MEASURING STAR FORMATION, BLACK HOLE GROWTH AND GALACTIC FEEDBACK WITH THE ORIGINS SPACE TELESCOPE

Lee Armus, lee@ipac.caltech.edu

Caltech / IPAC, Pasadena, California, United States Alexandra Pope, pope@astro.umass.edu

University of Massachusetts, Amherst, Wyoming, United States Charles Bradford, matt.bradford@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Alberto Bolatto, bolatto@astro.umd.edu

University of Maryland, College Park, Maryland, United States

Since a significant fraction of star formation and black hole growth occurs behind dust, our understanding of how and why galaxies evolve will remain incomplete until deep, wide area spectroscopic surveys in the Far-Infrared can be carried out from space. The Origins Space Telescope (OST), a mission concept being studied for presentation to the 2020 Decadal Survey, represents an enormous leap over any existing infrared mission, and will uniquely measure black hole growth and star formation in dusty galaxies over more than 95% of cosmic history, generating a 3D map of the extragalactic, infrared sky. With wide wavelength coverage (5-600 microns), a large primary mirror actively cooled to 4K, and a capable suite of imagers and spectrometers, OST will be an extremely sensitive probe of the power sources in galaxies, and the effects of feedback on the multi-phase ISM, through measurement of key tracers such as OH and H2O lines, atomic fine structure emission lines, and PAH dust features. Energetic feedback from AGN, young stars, and supernovae can regulate galaxy growth over a wide range in mass and be important for the enrichment of the interstellar and circumgalactic medium, yet the existence and type of feedback as a function of redshift, luminosity, and environment is poorly constrained. With OST we can directly observe the role of feedback in quenching galaxies, derive the wind kinetic energy and mass outflow rates, and correlate these with key galaxy properties (AGN or starburst power, environment, mass, age). We will explain how blind and targeted surveys with OST will have an enormous impact on our understanding of the duty cycle and basic physical properties of feedback in AGN and starburst galaxies over the last 12 Gyr of cosmic time.

E1.18-0026-18 INFRARED VIEW ON THE HOT MOLECULAR CORES IN THE M17-SW PDR

Zhiwei Chen, zwchen@pmo.ac.cn

Purple Mountain Observatory, Chinese Academy of Sciences, Nanjing, China Rolf Chini, chini@astro.rub.de

Ruhr-Universität Bochum, Bochum, Germany Wei Sun, sunwei@pmo.ac.cn

Purple Mountain Observatory, Nanjing, China

We present the results of an extensive infrared study of the hot molecular cores in the massive star-forming region M17-SW PDR. The data cover information in the wavelength rage from 2 to 850 μm, kinematic motions of water masers obtained from the VERA parallax measurements, and the X-ray images from Chandra space telescope. From the VLT/JHKL multiband images, we identify two infrared counterparts of the two hot molecular cores, which are physically associated with water maser emissions. These two infrared counterparts are also associated with two Chandra/X-ray point sources within 1" radius. The compiled spectral energy distribution of the two infrared counterparts cover broad-band data in the K, L, Spitzer/IRAC1-4 bands. The infrared fluxes and the X-ray properties are favor of two high-mass protostars embedded in the two hot molecular cores. One infrared counterpart is found to be the driver source of a dozens of water maser spots, which show kinematic motions in expansion phase. From the kinematic motions of these water maser spots, we estimate the momentum rate of the flow as 3.7 × 10−4M0yr−1, which is comparable to that of outflow driven by massive protostars.

E1.18-0027-18 PDR ANALYSIS WITH FAR-INFRARED DIAGNOSTIC LINES IN M17-SW

Randolf Klein, rklein@sofia.usra.edu

Photo-dissociation regions (PDRs) are the places where molecular clouds are destroyed by UV radiation of forming massive stars (eg. Hollenbach Tielens 1999). The molecular gas is photodissociated and then ionized by UV radiation. Photo-electric heating heats the gas in the PDRs. Cooling happens through the dust continuum and a handful of far infrared (FIR) fine-structure lines. FIFI-LS (Colditz et al. 2012), the FIR spectrometer onboard the US-German airborne observatory, SOFIA, can map these main cooling lines efficiently.

To study the heating, cooling, physical conditions and destruction rates, we observed the wellstudied edge-on PDR, M17-SW with high spatial resolution in all major FIR cooling lines of the ionized and neutral medium. In this presentation, we discuss the fine-structure line and continuum maps observed by SOFIA/FIFI-LS showing the layering in this edge-on PDR. The data allows us to infer physical conditions and the energetics of the interface regions. The continuum maps together with literature data allow us to construct complete spectral energy distributions of the PDR material and the sources embedded in the PDR.

The dataset presented here and its initial analysis is a comprehensive FIR view of the PDR M17-SW from the dense cloud into the ionized region at thempeak of the SED. It is a dataset to study the feedback of young massive stars on their parental cloud as it shows the ionization and dissociation front eroding the molecular cloud.

E1.18-0029-18 A COMPLETE QUANTIFICATION OF PHOTON-INDUCED DESORPTION PROCESSES: MORPHOLOGY EFFECT ON CO2 ICE

Ni-En Sie, angelnnrita@gmail.com

National Central University, Zhongli, Taiwan, China Rafael Martín-Doménech, rmartin@cab.inta-csic.es Centro Astrobiologia, Madrid, Spain

Guillermo Manuel Muñoz Caro, munozcg@cab.inta-csic.es Centro de Astrobiologia, CSIC-INTA, Madrid, Spain

Yu-Jung Chen, asperchen@phy.ncu.edu.tw

National Central University Taiwan, Zhongli, Taiwan, China

According to literature, different deposition temperatures of CO2 ice lead to distinct structures of CO2, which possesses an amorphous structure below 35 K and a crystalline structure at temperatures higher than 35 K. In Öberg et al. 2009, the photodesorption yield of CO2 ice depends on its morphology. For the purpose of investigating the relationship between the photodesorption yield of CO2 ice and its morphology, the CO2 ice was deposited at 16, 30, 40, 50, and 60 K respectively, and all of these ices were irradiated with vacuum ultraviolet (VUV) photons at 16 K. In this work, we will introduce a novel method to quantify the photodesorption yield of CO2 ices by a calibrated quadrupole mass spectrometer (QMS). The experimental results show that the photodesorption yields of CO2 ices deposited at different temperatures mentioned above are almost the same, meaning that the photodesorption yield of CO2 ice is irrelevant to its morphology, which is inconsistent with what was reported in Öberg et al. 2009.

E1.18-0030-18 LAB AND ON-ORBIT CALIBRATION FOR THE KOREAN NEAR-INFRARED SPACE TELESCOPES

Jeonghyun Pyo, jhpyo@kasi.re.kr

Korea Astronomy and Space Science Institute, Daejeon, Korea KASI Space Astronomy Group

Wonyong Han, Woong-Seob Jeong, Il-Joong Kim, Kyeongheon Ko, Dae-Hee Lee, Bongkon Moon, Sung-Joon Park, Won-Kee Park, Youngsik Park, Hyunjong Seo

Korea Astronomy and Space Science Institute (KASI) so far have developed two near-infrared space telescopes for astronomical studies. MIRIS (Multi-purpose InfraRed Imaging System), launched in 2013 November, had observed pole regions for near-IR background studies and the Galactic Paschen-alpha emission by 2015 May. NISS (Near-infrared Imaging Spectroscopy for Star forming history) will be launched soon and perform imaging spectroscopic observations for one year. As the name says, NISS is designed to survey extragalactic and Galactic objects to study star forming process over various scales. We calibrated the instruments and developed the data reduction pipelines based on the analysis of the ground lab experiment and the onorbit observation data. This contribution will report the efforts for calibration of the Korean near-IR astronomical space telescopes.

E1.18-0031-18 THEORETICAL AND OBSERVATIONAL STUDY OF PAHS UP TO TEN RING HEXAGONS

Mahadevappa Naganathappa, swamimahadev25@gmail.com GITAM University, Hyderabad Campus, Hyderabad, India Mahadevappa Naganathappa, swamimahadev25@gmail.com GITAM University, Hyderabad Campus, Hyderabad, India

The present study reports the theoretical infrared and optical absorption spectra of neutral hexagons. The one to ten membered hexagons have considered for the study. These hexagons have isomers based on the structural arrangements. The cata, peri-condensed and branched structures of these hexagons have considered for the study. The five member benzene ring has 22 isomers viz 02 branched, 10 peri and 10 cata-condensed structures. All these structures are optimized at B3LYP/TZVP level of theory to confirm lowest energy structure. The closed peri-condensed structure is the lowest energy isomer for five membered hexagons. This type of structures for one to ten membered hexagons have considered for the study. The significant change has been observed in their vibrational and electronic absorption spectra of ions. The geometrical parameters such as dipole moment, symmetry and energies for these isomers are reported. We have also reported the optical spectra of for one to ten membered hexagons using TD-DFT approach at the same level of theory. The electronic transition, oscillator strength, and HOMO-LUMO gap also reported. The present study also is to understand emission features of the 217 nm (2200) astronomical UV bump. We have compared this theoretical study with the available observational data.

E2.1-0001-18 UNDERSTANDING FORMATION AND STRUCTURE OF SOLAR PROMINENCES VIA MULTIDIMENSIONAL SIMULATIONS

Chun Xia, chun.xia@ynu.edu.cn Yunnan University, Kunming, China

Rony Keppens, rony.keppens@kuleuven.be KU Leuven, Leuven, Belgium

Solar prominences are one of the most common activities in the corona. The formation of magnetic and plasma structures of prominences is far from fully understood. Observations and theoretical studies suggest that typical prominences are hosted in helical magnetic flux ropes. With the aid of multidimensional magnetohydrodynamic (MHD) simulations, we provide numerical models to explain the formation of flux ropes driven by photospheric motion and magnetic reconnection at footpoints of sheared magnetic loops. The physical mechanism responsible for prominence plasma formation is believed to be thermal instability, which may be triggered by thermal nonequilibrium process with strong heating and chromospheric evaporation near footpoints of magnetic loops or by compression resulted from the topological change of magnetic field via coronal reconnection. Both scenarios are presented by multidimensional MHD simulations. The observed ubiquitous dense downflows and light upflows in quiescent prominences are difficult to interpret as plasma with high conductivity seems to move across horizontal magnetic field lines. Multidimensional MHD simulations on a local portion of prominence with parallel field lines, suggest magnetic Rayleigh-Taylor instability is responsible for the phenomenon. Our full prominence model, as a result of in-situ plasma condensations in a magnetic flux rope driven by continuous plasma evaporation from chromosphere, reproduced a fragmented, highly dynamic state with continuous reappearance of multiple blobs and thread structures that move mainly downward dragging along mass-loaded field lines, which may explain the dense downflows of quiescent prominences. With steady footpoint heating, the modeled prominence established a dynamic balance between the drainage of the prominence plasma back to the chromosphere and the formation of prominence plasma via continuous condensation.

E2.1-0002-18 FORMATION AND ERUPTION OF CORONAL FLUX ROPES

Rui Liu, rliu@ustc.edu.cn

University of Science and Technology of China, Hefei, China

Solar corona is frequently disrupted by coronal mass ejections (CMEs), whose core structure is believed to be a flux rope made of helical magnetic field. Although its presence after solar eruptions has been verified by spacecraft measurements near Earth, its formation process on the Sun remains elusive, yet is critical to understanding the physics of solar eruptions as well as a broad spectrum of heliospherical and astrophysical phenomena. Here we present the observations of dynamic formation and subsequent eruption of coronal flux ropes. The formation process can be either directly observed above the limb in the high corona or derived from the imprint on the surface. Based on these observations, we propose a new mechanism, in which the flux rope originates from the coalescences of plasmoids that are ubiquitously present in current layers. The buoyant rising of this seed flux rope induces plasma inflow underneath to drive magnetic reconnection, which establishes a positive feedback through which the seed flux rope grows into a CME.

E2.1-0003-18 CAN 3D WHOLE-PROMINENCE FINE STRUCTURE MODELS BE USED FOR ASSESSMENT OF THE PROMINENCE PLASMA MASS AND DISTRIBUTION PRIOR TO THE ONSET OF CMES?

Max Planck Institute for Astrophysics, Garching, Germany

Two complex 3D models of entire prominences including their numerous fine structures were recently developed. The first 3D Whole-Prominence Fine Structure (WPFS) model was developed by Gunár and Mackay. The second 3D WPFS model was put forward by Gunár, Aulanier, Dudík, Heinzel, and Schmieder. These 3D prominence models combine simulations of the 3D magnetic field configuration of an entire prominence with a detailed description of the prominence plasma. The plasma is located in magnetic dips in hydrostatic equilibrium and is distributed along hundreds of fine structures. The assumed prominence plasma has realistic density and temperature distributions including the prominence-corona transition region.

These 3D WPFS models allow us to study the distribution and the mass of the prominence plasma contained in prominence magnetic field configurations. These can be crucial during the onset and early evolution of CMEs. Moreover, prominence plasma represents a bulk of the material ejected by CMEs into the interplanetary space. Here, we investigate the potential of using the 3D WPFS models for assessment of the role the prominence plasma plays in the initiation and evolution of CMEs.

E2.1-0004-18 DYNAMICS IN QUIESCENT PROMINENCES OBSERVED BY THE IRIS AND MSDP SPECTROGRAPHS

Observatoire de Paris Meudon, Meudon, France

Quiescent solar prominences are generally considered to be stable. However, these prominences consist of a multitude of small-scale structures or threads that are often significantly dynamic. To understand the nature of the plasma dynamics we use the high spatial, temporal and spectral resolution observations obtained by IRIS during coordinated campaign with the MSDP spectrograph at the Meudon Solar Tower. Mg II h and k lines observed by IRIS represent a good diagnostic tool for investigation of the prominence fine structure dynamics, as they are optically thick under the prominence conditions. We will present detailed IRIS observations of Mg II lines. We explain significant asymmetries in the observed Mg II spectra by the presence of several threads located along the line of sight with different velocities. In such a case, the decrease of the intensity of individual components of the observed spectra with the distance from the central wavelength can be explained by the Doppler dimming effect. To interpret the observed Mg II profiles in terms of dynamics we use 1D or 2D radiative transfer models including a prominence-corona transition region. We also show that the H-alpha line which is optically thinner than the Mg II doublet is an important constrain for the radiative transfer radiation modelling.

E2.1-0005-18 UNAMBIGUOUS EVIDENCE OF FILAMENT SPLITTING-INDUCED PARTIAL ERUPTIONS

Xin Cheng, xincheng@nju.edu.cn Nanjing University, Nanjing, China Bernhard Kliem, bkliem@uni-potsdam.de

University of Potsdam, Potsdam, Germany

Coronal mass ejections are usually believed to be produced by the full eruption of a magnetic flux rope (MFR). However, it is recently recognised that the MFR may only release part of flux during once eruption, leading to a partial eruption. Here, we investigate two partial eruption events, the first one appears as a failed filament eruption, while the second manifests as a successful hot channel eruption. Thanks to the high resolution, high cadence, and multitemperature capability of the Atmospheric Imaging Assembly, it is found that both partial eruptions are a consequence of the splitting of an intact MFR-filament system caused by the internal reconnection. For the failed one, the internal reconnection, most likely induced by the rising and writhing motions of the filament, initially appears as EUV brightenings in the middle of the filament. Quickly, it evolves to the current sheet reconnection in the wake of the eruption of the upper filament. For the successful one, the internal reconnection initiates prior to the eruption, which is also evidenced by obvious heating in the middle of the filament. As the internal reconnection proceeds to the current sheet reconnection, the filament is split into two; the upper flux escapes as an erupting hot channel. As a result, regardless of being failed or successful, both of them produce hard X-ray sources and cusp-shaped loops below the erupting flux but above the surviving flux, as well as two ribbons at two sides of the latter.

E2.1-0006-18 MULTI-WAVELENGTH ANALYSIS OF A HELICAL PROMINENCE ERUPTION

Haiqing Xu, xhq@bao.ac.cn

National Astronomical Observatories, Chinese Academy of Sciences, Beijing, China

We use H image observed at Huairou Solar Observing Station of National Astronomical Observatories of China and multi-wavelength images observed by Atmospheric Imaging Assembly (AIA) onboard the Solar Dynamics Observatory (SDO) to analyze a prominence eruption on 14 October 2012. During the rising phase of the prominence, some twist convert to writhe. The kink structure is obvious in AIA 131 Å and 94 Å images. The twist of the prominence is estimated at least three turns (6) which reaches up to the threshold of the kink instability. So we suggest the prominence eruption is triggered by kink instability. The cusp structure in AIA 131 Å and 94 Å images is coincident with the RHESSI X-ray source location which is the feather of magnetic reconnection.

E2.1-0007-18 MAGNETIC RECONNECTION WITHIN A MULTI-FLUX-ROPE SYSTEM DURING THE PRECURSOR PHASE OF A CONFINED FLARE

Arun Kumar Awasthi, arun.awasthi.87@gmail.com University of Science and Technology of China, Hefei, China Rui Liu, rliu@ustc.edu.cn

University of Science and Technology of China, Hefei, China

The core structure of a solar eruption is believed to be a flux rope made of helical magnetic field. While the post-eruption “standard” picture of the flux rope has been largely studied, the flux rope formation and its evolution toward eruption remain elusive owing to subtle activity and emission during this phase. Here we investigate the pre-eruption morphology of a complex ejecta and associated activities during the precursor phase of a confined C1.1 SOL2015-06- 22T16:45 flare exhibiting multiple intermittent brightenings along the polarity inversion line (PIL). Spectral analysis of X-ray emission recorded during the precursor phase revealed the presence of non-thermal electron with a spectral index -6 while the plasma temperature during this phase reached to 20 MK as also confirmed by the DEM maps synthesized using EUV observations. The coronal magnetic-field topology, derived from the NLFFF extrapolations revealed a multi-flux-rope system comprising of at least five branches spanned across 25 Mm altitude. A combined map of magnetic twist-number and squashing factor revealed the release of the twist after the flare, confirming the reconnection taking place within the flux-rope system spatially linked with the excursions observed during the precursor phase. Further, EUV images revealed bi-directional outflows of the plasma blobs from the reconnection site. In summary, our investigation of a rare flare precursor with definitive signatures of magnetic reconnection within a system of multiple braided flux-rope branches with different degree of coherency signifies the importance of internal structure and reconnection in understanding CMEs.

E2.1-0008-18 COOL AND HOT FLUX ROPES, THEIR HELICITY

Alexander Nindos, anindos@uoi.gr University of Ioannina, Ioannina, Greece

We will review recent indirect and direct evidence for the existence of magnetic flux ropes in the solar atmosphere. Magnetic flux ropes may appear as S-shaped or reverse S-shaped (sigmoidal) structures in regions that are likely to erupt, and may also show in nonlinear force-free field extrapolations that use data from photospheric vector magnetograms as boundary condition. The availability of high sensitivity data recorded with unprecedented spatial and temporal resolution in hot EUV wavelengths by the Atmospheric Imaging Assembly (AIA) onboard the Solar Dynamics Observatory (SDO) has revealed the existence of coherent structures identified as hot flux ropes. In this presentation, we will review the properties of both cool and hot flux ropes with an emphasis on the frequency of their occurrence in large flares and on their magnetic helicity content.

E2.1-0009-18 A STUDY OF EXTERNAL MAGNETIC RECONNECTION THAT TRIGGERS A SOLAR ERUPTION

Guiping Zhou, gpzhou@nao.cas.cn

National Astronomical Observatories of Chinese Academy of Sciences, Beijing, China

External magnetic reconnection (EMR) is suggested to play an essential role in triggering a solar eruption, but is rarely directly observed. Here, we report on a filament eruption on 2014 October 3 that apparently involves the process of an early EMR. A total of 1.7 × 1020M x flux was first canceled along the filament–related polarity inversion line over 12hr, and then the filament axis started to brighten in extreme ultraviolet (EUV). An impulsive EUV brightening began 30 minutes later, and we attribute this to EMR, as it is located at the center of a bidirectional outflow with a velocity of 60-75 km/s along large-scale magnetic loops from active regions NOAA 12178 and 12179, respectively, and over the filament mentioned above. Following the EMR, the filament was activated; then, partial eruption occurred 6 minutes later in the west, in which the decay index above the magnetic flux rope (MFR) reached the critical value of 1.5. The observations are interpreted in terms of underlying magnetic flux cancelation leading to the buildup and eventual formation of the MFR with a filament embedded in it, and the MFR is elevated later. The activated MFR rises and pushes the overlying sheared field and forms a current sheet causing the EMR. The EMR in turn weakens the constraining effect of the overlying field, leading to the arising of the MFR, and subsequently erupting due to torus instability.

E2.1-0010-18 MAGNETIC RECONNECTION DURING ERUPTIVE MAGNETIC FLUX ROPES

Rony Keppens, rony.keppens@kuleuven.be KU Leuven, Leuven, Belgium

Zhixing Mei, meizhixing@ynao.ac.cn

Yunnan Astronomical Observatory, KunMing, China Jun Lin, jlin@ynao.ac.cn

Yunnan Astronomical Observatory, Kunming, Yunnan, China

Using highly resolved magnetohydrodynamic simulations, we follow the eruption of a kinkunstable magnetic flux rope in 3D. Our grid refinement allows to zoom in on the reconnection sites within the current sheet. At an estimated Lundquist number of 10000, we retrieve the 3D generalization of Petschek slow shocks, tubular substructures indicating tearing disruption, and turbulent interaction of the ejection flows with the closed magnetic structures above and below the extended current sheet. The 3D simulations allow synthetic views from varying line of sight orientations, and show many morphological aspects known from actual observations.

E2.1-0011-18 THE ORIGIN OF MAJOR SOLAR ACTIVITY - COLLISIONAL SHEARING BETWEEN NONCONJUGATED POLARITIES IN SOLAR ACTIVE REGIONS

Georgios Chintzoglou, g.hintzo@gmail.com

Lockheed Martin Solar and Astrophysics Laboratory, Palo Alto, California, United States Jie Zhang, jzhang7@gmu.edu

George Mason University, Fairfax, Virginia, United States

We present observations suggestive of a new scenario for the origin of activity in solar Active Regions (ARs). ARs that exhibit compact Polarity Inversion Lines (PILs) are known to be very flare-productive. However, the basis for this statistical inference has not been demonstrated conclusively. We show that such PILs can occur due to the collision between two emerging flux tubes within the same AR. The flux tubes may emerge simultaneously or sequentially, initially each producing two opposite conjugated polarities at the surface. The proper motions of the polarities lead the nonconjugated opposite polarities into a collision course, producing shearing and cancellation of opposite flux. We name this process "collisional shearing" to emphasize that the shearing develops due to the collision. Collisional shearing is a process different from the concept of flux cancellation occurring between conjugated polarities of a single emerging flux tube, a process that has been commonly used in many numerical models. High spatial and temporal resolution observations from the Solar Dynamics Observatory for two emerging ARs show the continuous cancellation of up to 20% of their unsigned magnetic flux, which occurs at the collisional PIL for as long as the sunspot collision persists. The cancellation is accompanied by a succession of solar flares and CMEs, products of magnetic flux cancellation along the contact layer. Our results strongly suggest that magnetic cancellation driven by collisional shearing is a primary process that needs to be taken into consideration for the improvement of predicting solar energetic events and space weather.

E2.1-0012-18 SOLAR PROMINENCE OSCILLATIONS

Manuel Luna, mluna@iac.es

Instituto de Astrofisica de Canarias (IAC), La Laguna, Spain

Prominence oscillations have been observed for at least 80 years, yet their fundamental physics and implications for eruptive activity remain poorly understood. These oscillations not only provide a laboratory for investigating the competing processes of forcing and damping, but also open a window into determining filament properties that are difficult or impossible to measure directly (e.g. the magnetic field strength). Prominence oscillations have periods from few minutes to ultra long periods with more than 20 hours. The observed oscillation velocities range from 0.1 to 100 km/s. The oscillations damp quickly, in few periods, even for the most energetic events. In this talk, recent observational and theoretical discoveries on this topic will be presented.

E2.1-0013-18 CORONAL JETS: FORMATION, EVOLUTION, AND EFFECTS IN THE HELIOSPHERE

Nour E. Raouafi, noureddine.raouafi@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States

Coronal jets are ubiquitous solar transients that supply the upper solar atmosphere with important mass and energy input. They are omnipresent regardless of the solar cycle phase. The debate on how they form and evolve in the corona and solar wind is very intense in the last decade. The size spectrum of jets spreads from structures close or at the limit of the current spatial resolution such as spicules and jetlets to narrow CME-like features. They are also critical to the formation and energy supply that maintain larger coronal structures for long periods of time (e.g., plumes). Jet phenomena may hint to basic processes for heating the corona and accelerating the solar wind. We present an overview of the formation, evolution, and effects of coronal jets in the heliosphere.

E2.1-0014-18 COMPOUND SOLAR ERUPTIONS AND THE CAUSES

Jie Zhang, jzhang7@gmu.edu

George Mason University, Fairfax, Virginia, United States Suman Dhakal, sumankdhakal@gmail.com

Virginia, United States

Georgios Chintzoglou, g.hintzo@gmail.com

Lockheed Martin Solar and Astrophysics Laboratory, Palo Alto, California, United States

A compound solar eruption is a phenomenon of successive eruptions of two or more magnetic structures within a short period of time. The eruption of one magnetic structure may affect the other one through the interconnection of magnetic field in the corona. This is in contrast of singular eruptions, the concern of most theoretical and numerical models of solar eruptions. In this presentation, we will report a detailed study of the compound eruption occurred on 2012 March 10 from NOAA AR 11429. The eruption produced a GOES M8.4 flare that contained two distinct peaks with a separation of 12 minutes during the impulsive phase of the flare. The data from SDO, STEREO-A and GOES help identify that the two peaks are caused by eruption of two pre-existing magnetic flux bundles lying along a same polarity inversion line. The stereoscopic observations of pre-existing filaments show that these flux bundles are lying one above the other, separated by 12 Mm in height, in a so-called "double-decker" configuration. The high-lying flux bundle became unstable and erupted first, showing as a high-temperature hot channel in EUV wavelengths. About 12 minutes later, the low-lying flux bundle also started to erupt and moved at a faster speed. The two erupting flux bundles interacted with each other and appeared as a single coronal mass ejection in white-light coronagraph images in the outer corona. The "double-decker" configuration is likely to be caused by strong shearing motion and fast flux cancellation along a strong-gradient polarity inversion line. The successive eruption of two separate but coupled magnetic flux bundles, possibly in the form of magnetic flux ropes, lead to the compound solar eruption. The study of the compound eruption provides us a unique opportunity of revealing the formation process of erupting structures and the initiation mechanism of solar eruptions in general.

E2.1-0015-18 GENERALIZING THE RBSL-METHOD FOR FLUX ROPES WITH VARIOUS CURRENT PROFILES AND NONZERO EXTERNAL AXIAL FIELD

Predictive Science, Inc., San Diego, California, United States

Magnetic flux ropes (FRs) likely play a key role in prominence formation and solar eruptions. It is therefore important to develop methods for constructing FR configurations constrained by observational data. With this aim, we have recently derived a pair of regularized Biot-Savart laws (RBSLs; Titov et al. 2017) that allow one to efficiently calculate the magnetic vector potential of an FR with circular cross-sections and an axis of arbitrary shape. One of the RBSLs represents the axial component of the vector potential produced by the axial current of the FR, while the other represents the azimuthal component produced by the axial flux of the FR. The kernels of the RBSLs are regularized at the axis in such a way that, when the axis is straight, the RBSLs define a cylindrical flux rope whose structure is exactly force-free. Therefore, a curved thin FR defined by the RBSLs with the same kernels is approximately force-free.

Originally, we implemented the RBSLs only for FRs that have a parabolic profile of the axial current and a vanishing axial magnetic field at the FR surface. Here we present a twoparametric generalization of the method that describes FRs with various axial-current profiles and a nonvanishing external axial field existing in sheared configurations. To benchmark this generalization, we applied it first to simple configurations of a toroidal-arc FR embedded into a potential background field, which are geometrically similar to the model proposed by Titov & Démoulin (1999). We investigated the numerical FR equilibria reached in zero-beta MHD relaxations of these configurations in dependence of the initial axial-current profile and the strength of the external axial field.

We plan to apply the generalized RBSLs to more realistic and complex configurations. Our previous successful applications of the RBSLs for FRs with a parabolic axial-current profile suggest the following. The shape of the FR axis can be determined in more complicated cases by tracking the observed polarity inversion line of the eruptions' source region and estimating its height variation as well as other FR parameters by means of a potential field extrapolated from the observed magnetogram.

E2.1-0016-18 3D MHD MODELING OF PROMINENCE FORMATION AND ERUPTION

Tibor Torok, tibor@predsci.com

Predictive Science Inc., San Diego, California, United States

The formation of prominences in the solar corona is widely thought to be caused by plasma evaporation and condensation via thermal non-equilibrium. This process has been previously modeled by one-dimensional hydrodynamic simulations along individual field lines within static magnetic fields. A more realistic modeling of prominence formation can be achieved through the use of three-dimensional thermodynamic MHD simulations with time-dependent magnetic fields, which has only become feasible within the last few years. In this talk I will describe recent three-dimensional simulations that display the formation and eruption of prominencelike structures. The capabilities and limitations of these simulations will be discussed, along with the next steps that lie ahead.

E2.1-0017-18 MHD SIMULATIONS OF PROMINENCE ERUPTION

Yuhong Fan, yfan@ucar.edu

National Center for Atmospheric Research, Boulder, Colorado, United States

We present MHD simulations of the eruption of a prominence carrying coronal flux rope under a coronal streamer, with the thermodynamics treatment including a simple empirical coronal heating, optically thin radiative cooling and the field aligned thermal conduction. We first initialize a quasi-steady solar wind solution with a coronal helmet streamer, using an initial normal flux distribution of a simple bipolar arcade field on the lower boundary. Then into this coronal streamer we impose at the lower boundary the slow emergence of a twisted magnetic torus. As a result a quasi-equilibrium flux rope is built up under the streamer magnetic field. We find that for a sufficiently long, significantly twisted flux rope, prominence/filament condensations of an elongated sigmoid morphology form in the dips of the twisted field lines due to run-away radiative cooling. A prominence cavity also forms surrounding the prominence when observed above the limb with a line-of-sight nearly along the length of the flux rope as shown by AIA synthetic EUV images. The prominence carrying field is found to be significantly non force-free due to the prominence weight despite being low plasma. The flux rope eventually erupts due to the development of the kink instability, and we obtain the eruption of the prominence, which shows substantial draining along the legs of the erupting flux rope displaying helical structures. We discuss the role prominence mass plays in the storage of the free magnetic energy and in the dynamics of the eruption.

E2.1-0018-18 MANIFESTATION OF CORONAL MASS EJECTIONS NEAR EARTH: A REVIEW

SIDC - Royal Observatory of Belgium, Brussels, Belgium

Coronal Mass Ejections (CMEs) are launched from the Sun, as a result of magnetic instabilities, carrying away a huge amount of magnetic flux and helicity. Interplanetary CMEs (ICMEs) are their manifestations observed further away in the heliosphere. ICMEs contain different plasma and magnetic field properties, compared with those of the ambient solar wind. From the large number of observed ICMEs in the past years, we significantly increased our knowledge on several of their properties such as: their global 3D shape, the identification of the composing sub-structures, the amount of magnetohydrodynamical quantities transported, as well as how the plasma and magnetic field are typically distributed inside them. In the present talk we will present a general review of these aspects of ICMEs. In particular we will focus on the total amount of magnetic flux and helicity ejected by CMEs from the Sun along a solar cycle, and on plasma and magnetic properties of their shock/sheath/flux-rope/wake. These results can help to understand their interaction with the ambient solar wind and with planetary magnetic environments. They are particularly crucial for a better understanding of the Sun-Earth coupling.

E2.1-0019-18 THE BEST AND LAST OF SOLAR CYCLE 24 - THE GLOBAL EUV WAVE FROM THE X8 FLARE-CME ERUPTION ON 2017-SEPT-10: SDO/AIA OBSERVATIONS AND DATA-CONSTRAINED SIMULATIONS

Lockheed Martin Solar and Astrophysics Laboratory, Palo Alto, California, United States

Global extreme ultraviolet (EUV) waves are commonly associated with coronal mass ejections (CMEs) and flares. One particular EUV wave that was triggered by the X8 flare-CME eruption on 2017 September 10 was extraordinary - one of the best EUV waves ever observed with modern instruments (e.g., SDO/AIA and GOES/SUVI), yet likely the last one of such magnitudes in Cycle 24 as the Sun heads toward the solar minimum. We present here detailed analysis of SDO/AIA observations of this event and comparison with high-fidelity, data-constrained MHD simulations using the University of Michigan Alfven Wave Solar Model (AWSoM). Observational highlights include: (1) The EUV wave traverses almost the entire visible solar disk and circumference, manifesting its truly global nature. This vast range is mainly due to the exceptionally large wave amplitude, with EUV intensity changes by up to a factor of 3 (as opposed to, e.g., 30% for moderate events). (2) The large wave amplitude also leads to the novel detection of strong transmission components (in addition to commonly observed reflections) into and through both polar coronal holes, at elevated apparent wave speeds up to 2600 km/s. (3) The wave also produces significant heating, indicated by long-lasting EUV intensity changes. As such, this EUV wave offers unique magnetic and thermal diagnostics of the global, CMEspawning corona. Our MHD simulations have largely reproduced the observed features. We find that the simulated EUV wave morphology and kinematics are sensitive to the orientation of the initial flux rope introduced to the host active region. An orientation with the flux-rope axis in the north-south direction produces the best match to the observations. This suggests that EUV waves may potentially be used to constrain the flux-rope geometry for such limb or behind-the-limb eruptions, whose source-region magnetic fields cannot be directly observed, and thus offer useful implications for space-weather predictions.

E2.1-0020-18 TWO-DIMENSIONAL MHD SIMULATION FOR PROMINENCE ERUPTION WITH RADIATIVE CONDENSATION

Takafumi Kaneko, kaneko@isee.nagoya-u.ac.jp

Institute for Space-Earth Environmental Research, Nagoya University, Nagoya, Japan Kanya Kusano, kusano@nagoya-u.jp

Institute for Space-Earth Environmental Research, Nagoya University, Nagoya, Japan

We reproduced solar prominence eruption using 2.5-dimensional magnetohydrodynamic (MHD) simulations including nonlinear anisotropic thermal conduction and optically thin radiative cooling. Solar prominence eruption is a progenitor of coronal mass ejection and one of the important subjects in studies of solar physics and space weather. Only a few numerical simulation have been carried out for prominence eruptions due to difficulty in reproducing cool dense plasmas of prominence in the hot tenuous corona. In this study, we numerically modeled prominence eruption by combining prominence formation model (Kaneko Yokoyama, 2015, 2017) and flare trigger model (Kusano et al., 2012). In the present simulations, a flux rope is created by reconnections between coronal arcade fields and a newly emerging bipole. Radiative condensation is triggered inside the flux rope, leading to prominence formation. The flux rope hosting prominence erupts by MHD instability and reconnection. As a result of parameter survey, we found that momentum as well as mass in the coronal flux rope is condensed into prominence, facilitating the initiation of MHD instability responsible for eruptions. Our results suggest that the slow rise phase of prominence eruptions is maintained or extended by momentum condensation from the corona toward prominence.

E2.1-0021-18 HOT ERUPTING PROMINENCES IN CORES OF CME'S

University of Ljubljana, Slovenia Roberto Susino, sur@oact.inaf.it

INAF - Osservatorio Astronomico di Torino, Pino Torinese, Italy

Coronal mass ejections (CME) associated with prominence eruptions exhibit relatively cool material in their cores. Such prominence plasmas were frequently detected in various spectral lines by SOHO/UVCS coronagraph and in the visible light by SOHO/LASCO as well as by STEREO coronagraphs. UVCS provided excellent spectra of CME-core prominences and an extended catalogue of these data is available. We will present recent results of a hot prominence diagnostics using the hydrogen Lyman lines and the CIII line. The erupting prominence parameters are further constrained by the visible light observations from LASCO-C2. A novel non-LTE modeling based on such observations will be presented and we will highlight the diagnostic potential of the UV and visible light for future space coronagraphs like Metis on board the ESA Solar Orbiter mission. The plasma parameters of such hot prominences are compared with those obtained from numerical MHD simulations of erupting flux ropes surrounded by CMEs. Finally, we will also mention synergies with stellar analogues.

E2.1-0022-18 DYNAMIC EVOLUTION OF FLARE RIBBONS OBSERVED BY THE SDO AND IRIS

Ting Li, liting@nao.cas.cn NAOC, Beijing, China

The shape, location, and dynamics of flare ribbons, as well as their relationship to magnetic fields provide a significant amount of information about the 3D magnetic configuration involved in the reconnection process. We anlalyed the X 1.6-class flare on 2014 September 10, and found that the flare ribbon consisted of a series of bright knots that simultaneously underwent a quasi-periodic slipping motion along the flare ribbon. The spectroscopic observations of the IRIS showed that the redshifts of the Si IV 1402.77 Å line at the locations of moving knots were larger than other locations of the flare ribbon, with a value of about 30-50 km/s. Similarly, the line profile became broader at the locations of slipping knots and the width increased to 40-60 km/s. Moreover, we report flare ribbons approach (FRA) during a multiple-ribbon Mclass flare on 2015 November 4 in NOAA AR 12443, obtained by the IRIS and SDO. The flare consisted of a pair of main ribbons and two pairs of secondary ribbons. The two pairs of secondary ribbons were formed later than the appearance of the main ribbons, with respective time delays of 15 and 19 minutes. The negative-polarity main ribbon spread outward faster than the first secondary ribbon with the same polarity in front of it, and thus the FRA was generated. Just before their encounter, the main ribbon was darkening drastically, implying the suppression of main-phase reconnection that produced two main ribbons. The FRA caused the deflection of the main ribbon to the direction of secondary ribbon with a deflection angle of about 60°. We suggest that there are three topological domains with footpoints outlined by the three pairs of ribbons. Close proximity of these domains leads to deflection of the ribbons, which is in agreement with the magnetic field topology.

E2.1-0023-18 EXTENDED KILOGAUSS BALD PATCHES IN THE SUPER-FLARING ACTIVE REGION 12673

Xudong Sun, xudongs@hawaii.edu

University of Hawaii at Manoa, Kahului, Hawaii, United States Viacheslav Titov, titovv@predsci.com

Predictive Science, Inc., San Diego, California, United States Maria Kazachenko, kazachenko@ssl.berkeley.edu

Space Science Laboratory, UC Berkeley, Berkeley, California, United States Mark Cheung, cheung@lmsal.com

Lockheed Martin Solar and Astrophysics Laboratory, Palo Alto, California, United States

Magnetic field in the active region core holds the key to its eruptive potential. An interesting topological feature is the “bald patch” (BP) - a segment of the polarity inversion line (PIL) at which the photospheric magnetic field is directed from the negative to positive side, implying the presence of U-shaped magnetic loops in the immediate low corona. When accompanied by strong shear, coherent BPs can provide evidence for pre-eruption flux ropes (FRs). Here we report on an archetypical BP structure observed in the super-flaring active region 12673, which extends over 30 Mm with a typical field of 2-3 kG. The structure formed gradually over one day prior to an X9-class flare. Co-spatial photospheric downflow developed and sustained near the PIL. The coronal magnetic field inferred from a nonlinear force-free field model reveals textbook morphology of a low-lying, twisted FR. We discuss the formation mechanism of such extended BPs and its role in initiating major eruptions.

E2.1-0024-18 OBSERVATIONAL CONSTRAINTS ON STELLAR FLARES AND PROMINENCES

Alicia Aarnio, alicia.aarnio@colorado.edu

University of Colorado Boulder, Boulder, Colorado, United States

Multi-wavelength surveys have catalogued a wealth of stellar flare data for stars representing a broad range of masses and ages. Young solar analogs inform our understanding of the Sun's evolution and the influence of its activity on early solar system formation, while field star observations allow us to place its current activity into context within a statistical ensemble of main-sequence G-type stars. At the same time, stellar observations probe a variety of interior and coronal conditions, providing constraints on models of equilibrium (and loss thereof!) for magnetic structures. In this review, I will focus on our current understanding of stellar flares, prominences, and coronal mass ejections as a function of stellar parameters. As our interpretation of stellar data relies heavily on solar-stellar analogy, I will explore how far into extreme stellar parameter spaces this comparison can be invoked.

E2.1-0025-18 NEW CORONAL SCIENCE FROM NASA WB-57F HIGH-ALTITUDE AIRCRAFT OBSERVATIONS OF THE 2017 TOTAL SOLAR ECLIPSE

NCAR, Boulder, Colorado, United States Edward DeLuca, edeluca@cfa.harvard.edu

Harvard-Smithsonian Center for Astrophysics, Cambridge, Massachusetts, United States Steven Tomczyk, tomczyk@ucar.edu

High Altitude Observatory, NCAR, Boulder, United States NASA WB57F 2017 Total Solar Eclipse Team

Joan Burkepile, Thomas Anthony Casey, John Collier, Don 'DD' Darrow, Dominic Del Rosso, Daniel D Durda, Peter Gallagher, Jasmine Gascar, Leon Golub, Matthey Jacyna, David 'DJ' Johnson, Philip G Judge, Cary Klemm, Glenn T Laurent, Johanna Lewis, Charles Mallini, Thomas 'Duster' Parent, Tim Propp, Andrew Steffl, Jeff Warner, Matthew J West, John Wiseman, Mallory Yates, & Andrei Zhukov

Total solar eclipses present rare opportunities to study the complex solar corona, down to altitudes of just a few percent of a solar radius above the surface, using ground-based and airborne observatories that would otherwise be dominated by the intense solar disk and high sky brightness. Studying the corona is critical to gaining a better understanding of physical processes that occur on other stars and astrophysical objects, as well as understanding the dominant driver of space weather that affects human assets at Earth and elsewhere. For example, it is still poorly understood how the corona is heated to temperatures of 1–2 MK globally and up to 5–10 MK above active regions, while the underlying chromosphere is 100 times cooler; numerous theories abound, but are difficult to constrain due to the limited sensitivities and cadences of prior measurements. The stability of large-scale coronal structures and the extent of their reach to the middle and outer corona are also not well known, limited in large part by sensitivities and fields of view of existing observations.

Airborne observations during a total eclipse provide unique advantages. By flying in the stratosphere at altitudes of 50 kft or

higher, they avoid all weather, the seeing quality is enormously improved, and additional wavelengths such as near-IR also become available due to significantly reduced water absorption. An airborne observatory can also follow the Moon's shadow, increasing the total observing time by 50% or more.

We present current results of solar coronal measurements from airborne observations of the 2017 Great American Total Solar Eclipse using two of NASA's WB-57 high-altitude research aircraft, each equipped with two 8.7" telescopes feeding high-sensitivity visible (green line and nearby continuum) and medium-wave IR (3–5 µm) cameras operating at high cadence (30 Hz) with 3 arcsec/pixel platescale and 3 Rsun fields of view. The aircraft flew along the eclipse path, separated by 110 km, to observe a summed 7.5 minutes of totality in both visible and MWIR. These observations enable groundbreaking studies of high-speed coherent motion

– including possible Alfvén waves and nanojets – in the lower and middle corona that could shed light on coronal heating processes and the formation and stability of coronal structures. Our MWIR observations of a cool prominence and hot coronal active region plasma will be combined with spectra from the AIR-Spec instrument, flown concurrently on NCAR's HIAPER GV. We review the WB-57 eclipse mission and the current results of analysis on the visible and IR coronal measurements, along with an outlook for future analysis and missions.

E2.1-0026-18 FINDING AND INTERPRETING STELLAR CORONAL MASS EJECTIONS

Rachel Osten, osten@stsci.edu

Space Telescope Science Institute, Baltimore, Maryland, United States Michael Crosley, mcrosle1@jhu.edu

Johns Hopkins University, Baltimore, Maryland, United States

The astrophysical study of mass loss, both steady-state and transient, on the cool half of the HR diagram has implications both for the star itself and the conditions created around the star that can be hospitable or inimical to supporting life. Stellar coronal mass ejections have not been conclusively detected, despite the ubiquity with which their radiative counterparts in an eruptive event (stellar flares) have. I will review some of the different observational methods which have been used and possibly could be used in the future in the stellar case, emphasizing some of the difficulties inherent in such attempts. I will provide a framework for interpreting potential transient stellar mass loss in light of the properties of flares known to occur on magnetically active stars. This uses a physically motivated way to connect the properties of flares and coronal mass ejections and provides a testable hypothesis for observing or constraining transient stellar mass loss. Finally I will describe recent results using radio observations to detect stellar coronal mass ejections, and what those results imply about transient stellar mass loss. I will give updates on prospects using future facilities to make headway in this important area.

E2.1-0027-18 WHAT OBSERVATIONS ARE REQUIRED TO SOLVE THE CME INITIATION PROBLEM?

Andrei Zhukov, andrei.zhukov@sidc.be

Royal Observatory of Belgium, Brussels, Belgium

Despite extensive observations of solar coronal mass ejections (CMEs), the CME initiation mechanism remains unclear. The CME acceleration curve is currently measured using the combined observations taken by extreme-ultraviolet (EUV) imagers (e.g. STEREO/EUVI, SDO/AIA, PROBA2/SWAP) and white-light externally occulted coronagraphs (e.g. SOHO/LASCO C2 and C3, STEREO/COR2). The CME propagation in the gap between the fields of view of the two types of instruments is either interpolated, or measured using the data taken by internally occulted coronagraphs (Mk4, SOHO/LASCO C1, STEREO/COR1), which suffer from significant straylight. These heterogeneous observations with three different types of instruments do not allow distinguishing between different proposed mechanisms of the CME initiation. Measurements of the CME kinematics and detailed observations of the coronal restructuring during CMEs are required in the crucial region of the inner corona where the peak acceleration takes place. Future observational capabilities that will address the CME initiation problem in the next several years (e.g. Solar Orbiter, PROBA-3, Aditya-L1) will be discussed. In particular, low straylight and high spatio-temporal resolution of the ASPIICS coronagraph onboard the PROBA-3 mission will allow to determine the timing of occurrence of the fast eruption onset and the reconnection onset, which is necessary to distinguish between different mechanisms of the CME initiation, such as ideal (e.g. torus instability) and resistive (magnetic breakout) mechanisms.

E2.1-0028-18 EVOLUTION OF A MAGNETIC FLUX ROPE TOWARD ERUPTION

Wensi Wang, wensiwang17@gmail.com

Montana State University & University of Science and Technology of China, Bozeman, Montana, United States

Jiong Qiu, qiu@montana.edu

Montana State University, Bozeman, Montana, United States Rui Liu, rliu@ustc.edu.cn

University of Science and Technology of China, Hefei, China

A magnetic flux rope (MFR) is a critical component of many Coronal Mass Ejections (CMEs), yet it is poorly understood how the MFR is formed and what mechanism triggers the eruption of the MFR. To provide insight into this question, in this work, we study the dynamic evolution and magnetic structure of a MFR for five hours before its eruption on June 14 2012. The MFR is located in a sigmoidal active region (AR) 11504, which is characterized by significant sunspot rotation for two days. The CME is accompanied by a M1.9 two-ribbon flare, as well as coronal dimming adjacent to the two flare ribbons in magnetic fields of opposite polarities. The conjugate coronal dimming is therefore used to identify the feet of the MFR. We find persistent gradual coronal dimming coincident with the slow rise of a coronal structure for five hours before the eruption. This evolution appears to take place in a few stages, each preceded by a series of C-class flares, and the final eruption occurs at the onset of the M1.9 flare. We also calculate the vertical current at the feet of the MFR and estimate the mean twist of the MFR during its evolution. The sequence of observations suggests that flare reconnection plays a crucial role in the MFR evolution toward its eruption.

E2.1-0030-18 PHYSICAL CONDITIONS IN A PROMINENCE ERUPTION DURING ITS PREERUPTION AND ACCELERATION

Ping Zhang, ping.zhang@ias.u-psud.fr

Institut d'Astrophysique Spatiale, Orsay, France Eric Buchlin, eric.buchlin@ias.u-psud.fr

IAS, CNRS / Univ. Paris Sud XI, Orsay, France Jean-Claude Vial, jean-claude.vial@ias.u-psud.fr Institut d'astrophysique spatiale, Orsay, France

We rely upon the simultaneous observations of a CME-associated eruptive prominence which have been made by the Interface Region Imaging Spectrograph (IRIS), Atmospheric Imaging Assembly (AIA) of SDO, EUVI of STEREO and the ground-based K-COR coronagraph. We focus on the determination of mass flows in order to detect a possible mass loading. In order to derive the full velocity vector, we combine an optical flow method on the AIA 304 and IRIS SJI observations to compute the POS velocities in the prominence and a Doppler technique with the IRIS observations to compute the LOS velocities. Then we focus on the determination of densities through the combination of spectroscopic observations and NLTE modelling. We first characterize the Mg II h and k profiles (time and space-dependent!) through a grid of 6 typical profiles (reversed and unreversed). Then we compare them with the signatures of hundreds of prominence models through NLTE radiative transfer computations (I.A.S. PROM7 code). Much attention is paid to the exact incident radiation in various lines and continua. Having selected the best (fitting) models, we are able to derive the total (hydrogen) density and compute the mass flows. The derivation of physical parameters (e.g. velocity) also takes into account the STEREO observations to derive the 3D geometry of the prominence and K-COR to derive the density later on in the process of eruption.

E2.1-0031-18 THE RELATIONSHIP BETWEEN DYNAMICAL BRIGHT POINTS AND SURGES ON LIGHT BRIDGE OF SUNSPOT

Yuzong Zhang, yuzong@nao.cas.cn

National Astronomical Observatories, Chinese Academy of Sciences, Beijing, China

Using the detailed observations obtained by the New Solar Telescope of Big Bear Solar Observatory, we explored the motions of bright points (BPs) on the light bridge. It is found that there are three kinds of motions of the BPs on the bridge. The first kind of the BPs is along the axis of the light bridge, the second one along the direction perpendicular to the axis of the light bridge and the last one moving around a position without distinct displacement. Then we compared the dynamic properties of these three kinds of BPs with the surges on the light bridge. The first kind of BPs is tightly related to the severity of the surge. It is suggested that the formation of the surge maybe coming from the collision between the plasma on the light bridge and the moving BPs.

E2.1-0032-18 MAGNETIC FIELD DIAGNOSTICS IN THE SOLAR UPPER ATMOSPHERE AND FUTURE INSTRUMENTATION

Nour E. Raouafi, noureddine.raouafi@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States

The solar upper atmosphere manifests the key role of the magnetic field in coupling and structuring of the different layers, energy flow and dissipation, plasma heating and acceleration, and the multi-scale, explosive solar activity. Understanding these phenomena and the related physical mechanisms cannot be achieved without comprehensive understanding of the evolution (both spatial and in time) of the magnetic field through the different atmospheric layers. We present an overview of the techniques used to determine the magnetic field in the solar chromosphere and corona. The development of future instruments will also be outlined.

E2.1-0034-18 LARGE-SCALE PATTERNS OF FILAMENT CHANNELS AND FILAMENTS

Duncan Mackay, dhm@st-and.ac.uk

University of St Andrews, 8HB, United Kingdom

In this review the properties and large-scale patterns of filament channels and filaments will be considered. Initially, the global formation locations of filament channels and filaments are discussed, along with their hemispheric pattern. Next, observations of the formation of filament channels and filaments are described where two opposing views are considered. Finally, the wide range of models that have been constructed to consider the formation of filament channels and filaments over long time-scales are described, along with the origin of the hemispheric pattern of filaments.

E2.2-0001-18 ENERGY PARTITION IN STELLAR FLARES

Rachel Osten, osten@stsci.edu

Space Telescope Science Institute, Baltimore, Maryland, United States

The extremes of magnetic activity on stars in the cool half of the HR diagram exceed by large factors those exhibited by our Sun, making flares on these stars ideal probes of some of the processes which can be studied in detail on the Sun. The magnetic activity of stars helps to set the conditions present in the near stellar environment, and affects formation and evolution of planetary systems. I will summarize multi-wavelength observational constraints that point to stellar flares having the same physical processes underlying them as solar flares. I will next summarize results describing energy partition in solar and stellar flares. I will present multi-wavelength observations of two recent stellar super flares serendipitously observed by the Swift satellite and numerous ground-based facilities, and demonstrate how the multi-wavelength information is used to interpret the coronal radiation, particularly in light of what it reveals about the interplay between radiation observed in various bands, as well as energy flow by particle beams. I will examine what these flares reveal in light of continuation of solar flare scaling relations into the extremes of temperature and emission measure. I will present recent results on simultaneous radio and optical stellar flares and discuss the unique contribution to understanding the presence and action of nonthermal particles in stellar flares afforded by radio observations.

E2.2-0002-18 EXPLORING THE NON-THERMAL CHARACTERISTICS OF X-RAY EMISSION FROM SOLAR FLARES

Nipa Bhatt, nijibhatt@hotmail.com

C. U. Shah Science College, Ahmedabad, India Rajmal Jain, rajmal@prl.res.in

Physical Research Laboratory, Ahmedabad, Ahmedabad, India

Observations of hard X-ray (HXR) emission provide the most direct diagnostics of energy release in solar flares. This paper presents the study of hard X-ray (HXR) emission from ten potentially geo effective solar flares (GOES X class) observed by "Reuven Ramaty High-Energy Spectroscopic Imager (RHESSI)" mission. The flare plasma is characterized in the energy range of 13 - 100 keV. To investigate spectral characteristics of X-ray emission from solar flares, the spectra are fitted with thermal and non-thermal functions over the observed duration of the flare. The thermal part of the spectrum is fitted with the isothermal model. The non-thermal hard X-ray emission is assumed to be due to a power-law distribution of electrons emitting hard X-rays via Bremsstrahlung in a thick target. The non thermal part of the spectrum is fitted with thick target function. The spectral analysis enabled us to study the spectro-temporal evolution as well as the range of the spectral parameters for Xclass flares. Employing the thick target spectral parameters, the total non-thermal energy content of X-class flares is estimated.

E2.2-0003-18 BLUE WING ENHANCEMENT OF THE CHROMOSPHERIC MG II H AND K LINES IN A SOLAR FLARE

We performed coordinated observations of NOAA AR 12205, which produced a C-class flare on 2014 November 11, with the Interface Region Imaging Spectrograph (IRIS) and the Domeless Solar Telescope (DST) at Hida Observatory. Using spectral data in the Si IV 1403 Å, C II 1335 Å, and Mg II h and k lines from IRIS and the Ca II K, Ca II 8542 Å, and Hα lines from DST, we investigated the temporal and spatial evolution around a moving flare kernel. In the Mg II h line, the leading edge of the kernel showed intensity enhancement in the blue wing and difference between the blue-side peak and red-side one (Ih2v < Ih2r). Then, the drastic change of the intensity in the red wing occurred. The blueshift lasted for 9–48 s with a speed of 10.1 2.6 km s–1 and it was followed by the strong redshift with a speed of up to 51 km s–1

detected in the Mg II h line. The strong redshift was a common property for all six lines but the blueshift prior to it was found only in the Mg II lines. A cloud modeling of the Mg II h line suggests that the blue wing enhancement with such peak difference can be caused by a chromospheric-temperature (cool) upflow. We discuss a scenario in which an upflow of cool plasma is lifted up by expanding (hot) plasma owing to the deep penetration of non-thermal electrons into the chromosphere. In addition, at the leading edge of the final flare footpoints, the blueshift persisted in the Mg II h line, which was not followed by any large redshift

and intensity enhancement. Such long-lasting blueshift can be explained by cool upflow caused by small energy flux into the lower atmosphere.

E2.2-0004-18 A NANOFLARE EXPLANATION FOR PERIODIC VARIATIONS IN FLARE STARS

Christopher Dillon, cdillon06@qub.ac.uk

Queen's University Belfast, Belfast, United Kingdom David Jess, d.jess@qub.ac.uk

Queen's University Belfast, Belfast, United Kingdom

Several studies have documented periodic and quasi-periodic signals from the time series of dMe flare stars and other stellar sources. Such periodic signals, observed within quiescent phases (i.e., devoid of larger-scale microflare or flare activity), range in period from 1-1000 seconds and hence have been tentatively linked to ubiquitous p-mode oscillations generated in the convective layers of the star. As such, most interpretations for the observed periodicities have been framed in terms of magneto-hydrodynamic wave behavior. However, we propose that a series of continuous nanoflares, based upon a powerlaw distribution, can provide a similar periodic signal in the associated synthetic time series. Monte Carlo simulations, embodying the nanoflare signals and modeled noise profiles, produces a time series consistent with previous observations of dMe flare star lightcurves. Through an examination of nanoflare decay timescales and differing powerlaw indices, we provide evidence that periodic signals found in stellar time series can be explained by low-energy nanoflares embedded within the noise envelope of a stellar lightcurve. Implications for spatially-resolved solar datasets, including those from SDO/AIA, will also be discussed.

E2.2-0005-18 MODELING FLARE-GENERATED QUASI-PERIODIC PROPAGATING FAST MAGNETOSONIC WAVES OBSERVED BY SDO/AIA

Leon Ofman, leon.ofman@nasa.gov

CUA/NASA GSFC, Greenbelt, MD, Maryland, United States Wei Liu, weiliu@lmsal.com

Bay Area Environmental Research Institute / Lockheed Martin Solar and Astrophysics Laboratory, Moffett Field, California, United States

Fast-propagating (phase speeds of 1000 km/s) quasi-periodic, fast-mode wave (QFPs) accompanying many solar flares have been discovered by SDO/AIA (Liu et al. 2011). They typically propagate in funnel-like structures associated with the expanding magnetic field topology of the active regions (ARs), driven by flare-pulsations duration of impulsive phase. The fast magnetosonic waves provide information on the magnetic, density, and temperature structure through coronal seismology. While all previously reported QFP waves originate from a single localized flaring source, we report the first AIA observation and 3D MHD modeling of counter-QFPs originating from two 'sympathetic' flares. The waves are excited at the two sources associated with flare locations and connected by magnetic loops, by time-depended forcing, constrained by the spatial (localized) and quasi-periodic temporal evolution of the flare pulsations. With the aid of 3D MHD modeling we investigate the excitation, propagation, nonlinearity, and interaction of the counter-propagating waves for a range of key parameters, such as the properties of the flaring sources and the background magnetic topology. In addition to QFPs, we find evidence of associated waves, such as trapped fast (kink) modes in coronal loops, and slow mode waves propagating along the AR loops. Our model results are in qualitative agreement with the AIAobserved counter propagating waves providing the first direct evidence of counter-propagating fast magnetosonic waves that carry significant energy flux in low-corona magnetic structures.

E2.2-0006-18 HYDRODYNAMICAL 1D MODELLING OF FLARING LOOPS DURING A B8.3 FLARE ON JULY 04, 2009

Arun Kumar Awasthi, arun.awasthi.87@gmail.com University of Science and Technology of China, Hefei, China Janusz Sylwester, js@cbk.pan.wroc.pl

Space Research Centre of the Polish Academy of Sciences, Wroclaw, Poland Barbara Sylwester, bs@cbk.pan.wroc.pl

Space Research Centre of the Polish Academy of Sciences, Wroclaw, Poland Fabio Reale, reale@astropa.unipa.it

University of Palermo, Palermo, Italy Rui Liu, rliu@ustc.edu.cn

University of Science and Technology of China, Hefei, China

Hydrodynamical evolution of flaring plasma is crucial in understanding the response of various layers of solar atmospheres and the role of plasma energy transport and radiative loss processes. Although the insights obtained from the analysis of multi-wavelength emission are limited by the sensitivity of the observing instruments, numerical modelling constrained by observable provides a comprehensive picture of the underlying processes. In this regard, we investigate the evolution of thermal characteristics of plasma during a B8.9 flare of July 04, 2009 using Palermo-Harvard (PH) 1D hydrodynamic (HD) model. The X-ray spectra during the event, observed commonly by SphinX (1-15 keV), SOXS (4-25 keV) and Fermi (6 keV) instruments, were analysed in order to derive thermal characteristics of flaring plasma. EUV images available from SOHO and STEREO-twin satellites were used to derive projection-free geometrical characteristics of flaring loop(s) which are provided as an input to the PH model along with a number of heating profiles varying spatially across the loop and in time. Resulting temperature and density profiles along the loop were convolved with the response matrix of GOES X-ray monitors to derive respective fluxes and then compared with that observed. The PH exercise which bestrepresented the GOES observations during the flare was further used in mapping the spatial distribution of emission along the flaring loop(s) as well as the evolution of flaring plasma on the diagnostic diagram (DD; log T against log EM) as determined from the EUV and Xray channels. Moreover, a comparison of differential emission measure distribution (DEM[T]) derived from the PH model were compared with that obtained by applying the WithbroeSylwester deconvolution algorithm on the combined observation of STEREO, SphinX, SOXS and Fermi instruments. This investigation provides an exhaustive comparison of spatial and temporal evolution of thermal characteristics of flaring plasma as determined from the HD modelling with that available from the EUV and X-ray measurements.

E2.2-0007-18 WAITING TIME DISTRIBUTIONS OF SOLAR AND STELLAR FLARES: POISSON PROCESS OR WITH MEMORY?

Chuan Li, lic@nju.edu.cn

Nanjing University, Nanjing, China Sijia Zhong, sijia.zhong@seu.edu.cn Southeast University, Nanjing, China Zigong Xu, xuzg@smail.nju.edu.cn Nanjing University, Nanjing, China

The statistics of time interval between two successive flares provide information whether solar and stellar activities occur independently or with memory? Here we examine the waiting time distributions (WTDs) of solar flares recorded with the GOES satellite during solar cycle 23, as well as the stellar flares produced by a solar type star (KIC11551430) observed with the Kepler mission. Based on the Kolmogorov-SmirnovK-Stest, we make a quantity analysis of the departure of WTDs from the Poisson process as predicted by the self-organized criticality (SOC) theory. We then fit the WTDs with functions of the non-stationary Poisson distribution (Wheatland 2000; Li et al. 2014), the Levy function (Lepreti et al. 2001), and the Weibull function (Weibull 1951; Telloni et al. 2014). It is found that a certain amount of memory is characterized during periods of high solar activities, while the random Poisson process dominates during solar minimum. The production of "super flares" is statistically a random process.

Solar soft X-ray (SXR) observations provide unique diagnostics of plasma heating, during solar flares and quiescent times. Spectrallyand temporally-resolved measurements are crucial for understanding the dynamics and evolution of these energetic processes; spatially-resolved measurements are essential for understanding energy transport. A critical observational gap exists from 0.2 to 3 keV (4–60 Å), where spectrally-resolved stellar observations are plentiful but have not been routinely made for the Sun in many decades. This energy range includes spectral lines from highly-ionized atoms with both low and high first ionization potential (FIP), as well as thermal free-free (bremsstrahlung) and free-bound (radiative recombination) continua. These SXR emissions provide crucial diagnostics of plasma temperature distributions, as well as elemental abundances that probe plasma origins over a wide range of temperatures, that are not available from observations at other wavelengths. A better understanding of thermal plasma also informs our interpretation of hard X-ray (HXR) observations of nonthermal par ticles, improving our understanding of the relationships between particle acceleration, plasma heating, and the underlying release of magnetic energy during reconnection.

We discuss a proposed small satellite pathfinder mission, the CubeSat Imaging X-ray Solar Spectrometer (CubIXSS), to measure spectrallyand spatially-resolved SXRs from the quiescent and flaring Sun from a 6U CubeSat platform in low-Earth orbit during a nominal 1-year mission. CubIXSS includes the Amptek X123-FastSDD silicon drift detector, a low-noise, commercial off-the-shelf (COTS) instrument enabling full-Sun SXR spectroscopy from 0.5 to 20 keV with 0.15 keV FWHM spectral resolution with low power, mass, and volume requirements. Multiple detectors and tailored apertures provide sensitivity to SXR emission from deep solar minimum to >X5 flares. An X123-CdTe cadmium-telluride detector is also included for 5–50 keV HXR spectroscopy with 0.5 keV FWHM resolution. The precise spectra from these instruments will provide detailed measurements of the coronal temperature distribution and elemental abundances during flares and quiescent times, and, for large flares, context information of flare-accelerated electrons.

CubIXSS also includes a novel spectro-spatial imager – the first ever solar imager on a CubeSat – utilizing a custom pinhole camera and Chandra-heritage X-ray transmission diffraction grating to provide spatiallyresolved, full-Sun imaging spectroscopy from 0.2 to 10 keV (1–60 Å), with 25 arcsec and 0.25 Å FWHM spatial and spectral resolutions, respectively. Additional pinholes with tailored filters provide non-dispersed images with coarse spectral information to seed analysis of the dispersed spectro-spatial images and for improved sensitivity to quiescent conditions. MOXSI's unique capabilities enable SXR spectroscopy and corresponding temperature and elemental abundance diagnostics of individual flares and active regions over a spectral range never before accessed by any prior solar mission.

CubIXSS is a pathfinder for larger satellites with improved resolution and sensitivity. Through these groundbreaking new measurements, CubIXSS and future missions will improve our physical understanding of thermal plasma processes and impulsive energy release in the solar corona, from quiet Sun to solar flares.

E2.2-0009-18 RHESSI SWAP POST-FLARE GIANT ARCH SIGNATURES

Matthew West, mwest@oma.be

Royal Observatory of Belgium, Brussels, Belgium Daniel Seaton, daniel.seaton@colorado.edu

University of Colorado at Boulder, Boulder, Colorado, United States Brian Dennis, brian.r.dennis@nasa.gov

Goddard Space Flight Center, Greenbelt, United States Sabrina Savage, sabrina.savage@nasa.gov NASA/MSFC, Huntsville, United States

Li Feng, lfeng@pmo.ac.cn

Purple Mountain Observatory, Chinese Academy of Sciences, Nanjing, China Erika Palmerio, erika.palmerio@helsinki.fi

University of Helsinki, Helsinki, Finland

Recent observations from the SWAP EUV imager on board PROBA2, AIA on SDO and SXI X ray observations from the GOES satellite have shown that post flare giant arches and regular post flare loops are one and the same thing. However, it is still not clear how certain loop systems are able to sustain prolonged growth to heights greater than half a solar radii (> 400000 km). In this presentation we further explore the energy deposition rate above post flare loop systems through high energy RHESSI observations, combined with evidence of supra arcade down flows, indicating ongoing sustained magnetic reconnection.

E2.2-0011-18 EVIDENCE OF A DISTANT DECIMETRIC SPIKE SOURCE CONNECTED TO THE MAIN ELECTRON ACCELERATION SITE: FIRST HIGH TIME CADENCE GMRT OBSERVATIONS

Susanta Kumar Bisoi, susanta@nao.cas.cn

National Astronomical Observatories, CAS, Beijing, China Arun Kumar Awasthi, arun.awasthi.87@gmail.com University of Science and Technology of China, Hefei, China Shweta Srivastava, srivashweta@gmail.com India

We present a study of decimetric radio activity, associated with two (GOES C1.4 and M1.0 class) flares and a coronal mass ejection (CME) of 20 June 2015, using the first high time cadence (0.5s) 610 MHz observations of the Giant Meterwave Radio Telescope (GMRT). The GMRT images show strong radio sources during the M1.0 flare and CME, which are located near the flaring site, while, in contrary, a strong spike radio source during the C1.4 flare, with no corresponding coronal or magnetic features, are rather located about 500 arcsec away from the flare site in soft X-rays. Although weak radio burst sources are located near the flaring site, during the C1.4 flare maximum, associated with the spike radio source, which show a good temporal correspondence with a metric type-III burst identified by the Solar Broadband Radio Spectrometer at Yunnan Astronomical Observatory. A multi-wavelength analysis, in combination with potential field source surface extrapolation, has been carried out to investigate the genesis of non-thermal radio emitting electrons, which revealed that the distant spike radio source, noticed during the C1.4 flare, is actually connected to the main electron acceleration sites and is generated by a plasma emission instead of a loss cone maser instability.

E2.2-0012-18 FLARE-PRODUCTIVE ACTIVE REGIONS: OBSERVATIONS, MODELING, AND THEIR APPLICATIONS

Shin Toriumi, shin.toriumi@nao.ac.jp

National Astronomical Observatory of Japan, Tokyo, Japan

Strong solar flares and coronal mass ejections are known to occur in complex active regions (ARs). Then, what kind of AR structures are important for producing these events, and how can we model them? This review talk aims at answering to these questions. First, we introduce the statistical analysis on various flare-productive ARs, in which we investigated all >M5.0- class events within 45 deg from disk center for six years from May 2010. We classified the total of 51 events into four categories based on their formation processes, namely, (1) SpotSpot, a complex AR with AR-sized polarity inversion lines (PILs), (2) Spot-Satellite, in which a newly-emerging flux appears adjacent to the pre-existing spot, (3) Quadrupole, where two emerging fields collide against each other, and (4) Inter-AR, the flares occurring between two apparently separated ARs. As a result, we found that the characteristics of the flare eruptions strongly depend on the groups; for example, the flare duration of the majority group (1) is four times longer than that of another majority group (2). Second, we show the numerical attempt to model various flaring ARs, where we reproduced these four types (1-4) by conducting a series of flux-emergence simulations. We found that the sheared PILs in these ARs are created through the stretching and advection of horizontal magnetic fields due to the large-scale flux emergence. As ARs develop, free magnetic energy becomes stored in the corona, which could be released through the flare eruptions. Finally, we explore the possibility to apply these works to some particular ARs by introducing our newest work on NOAA AR 12673, which appeared in September 2017 and produced numerous strong flares including the X9.3-class event. We show the numerical modeling of AR 12673 and comparison with observations, discussing the possible magnetic structures in the subsurface layers that eventually led to the series of strong flares in this AR.

E2.2-0013-18 COMPARING TWO ACOUSTICALLY ACTIVE SEPTEMBER 6 X-CLASS FLARES OF SOLAR CYCLE 24.

Sergei Zharkov, s.zharkov@hull.ac.uk University of Hull, Hull, United Kingdom Connor Macrae, c.macrae(at)hull.ac.uk University of Hull, Hull, United Kingdom Sarah A. Matthews, sarah.matthews@ucl.ac.uk

Mullard Space Science Laboratory, University College, Holmbury St.Mary. Dorking, United Kingdom

Valentina Zharkova, valentina.zharkova@northumbria.ac.uk University of Northumbria, Newcastle Upon Tyne, United Kingdom

Two of the larger X-class flares of the current cycle have taken place on September 6, one near the peak of the cycle in 2011 and the other one approaching the minimum in 2017. We show that both have been accompanied by two sun quakes exhibiting very different properties. We analyse both events and their photospheric impact using helioseismic techniques and SDO HMI data supplemented by atmospheric observations from GOES, AIA and Hinode, and consider energies and momenta to look at possible mechanisms of sun quake generation in each case.

E2.2-0014-18 COOL LOOPS ON COOL STARS

Petr Heinzel, pheinzel@asu.cas.cz

Astronomical Institute, Academy of Sciences, Ondrejov, Czech Republic

Recently a significant effort has been devoted to systematic modelling of solar and stellar chromospheric flares which are typically manifested by bright ribbons embedded in the lower atmospheric layers. However, apart from ribbons detectable in a broad range of the electromagnetic spectrum, overlying loops are also frequently observed on the Sun. They appear in various spectral lines and can be well resolved in the so-called eruptive flares. We will show how their appearance depends on the loop plasma conditions and parameters. We will also briefly review the efforts to model the radiation properties of such loops and namely of those which cooled down to chromospheric temperatures. Light curves of the flaring ribbons may differ from time evolution of the loop brightness and this can be easily detected on the Sun. However, on cool stars the measured light curves may contain an unresolved information about the temporal evolution of both ribbons and cool loops and we will demonstrate how this can be modelled.

E2.2-0015-18 SHORT DURATION FLARES IN GALEX DATA

Clara Brasseur, cbrasseur@stsci.edu

Space Telescope Science Institute, Baltimore, Maryland, United States Rachel Osten, osten@stsci.edu

Space Telescope Science Institute, Baltimore, Maryland, United States

Flares on cool stars indicate short time-scale magnetic reconnection processes that provide temporary increases in the stellar radiative output. While recent work has focused on longduration flares from solar-like stars and those of lower mass, the existence of short-duration flares in the ultraviolet has not been systematically probed before. We will present an interesting population of short duration flares we discovered in a sample of 37,000 light curves observed from 2009-2012 by the GALEX and Kepler missions. These flares range in duration from under a minute to a few minutes and are almost entirely distinct from a previous flare survey of Kepler data. We were able to detect this unique population of flares because the time resolution of the GALEX data allowed us to construct light curves with a 10 second cadence and thus detect shorter duration flares than could be detected within Kepler data. We applied algorithmic flare detection to a sample of 37,000 stars, and identified a final count of 2,065 flares on 1,121 stars. We discuss the implication of these events for the flare frequency distributions of solar-like stars.

E2.2-0016-18 PARTICLE ACCELERATION IN SOLAR FLARES AT DIFFERENT FREQUENCIES

Douglas Silva, douglas93f@gmail.com

Universidade Presbiteriana Mackenzie/CRAAM, São Paulo, Brazil Adriana Valio, adrivalio@gmail.com

Universidade Presbiteriana Mackenzie/CRAAM, Sao Paulo, Brazil

The multifrequency analysis of solar flares is necessary due to the great complexity it presents. We present the investigation of thirteen solar flares that occurred between 2011 and 2013, studied in radio from 5 to 212 GHz (RSTN, POEMAS, SST), and in X-rays up to 800 keV (FERMI and RHESSI). The goal of this work is to determine the population of accelerated electrons by studing the spectral index in radio and hard X-rays (HXR). Previous works have shown that the temporal profiles at both wavelengths are very similar which is indicative of a common accelerated electron population. In this work, the radio spectral index was calculated by fitting the radio spectra by gyrosynchrotron emission, whereas the hard X-ray spectra were fit by thermal emission plus non-thermal emission from accelerated electron with a power-law distribution, yielding the HXR spectral index. Finally, we compare the results of both spectral indices and discuss the results in light of the models of particle acceleration.

E2.2-0017-18 THE UV NEUPERT EFFECT: HEATING AND COOLING OF SOLAR FLARE PLASMAS

Jiong Qiu, qiu@montana.edu

Shanghai Astronomical Observatory, Chinese Academy of Sciences, Shanghai, China

Explosive energy release in solar flares is believed to be governed by magnetic reconnection usually occuring in the corona. Yet at the onset of a flare, the immediate and more significant response to reconnection energy release is often observed in the lower atmosphere. The chromosphere being the lower boundary of the corona, its radiation signatures in UV or optical wavelengths provide clues to understanding corona heating. The lower atmosphere is also the only place where reliable measurements of magnetic field are currently available. Therefore, reconnection events in the Sun's corona can be mapped, tracked, and measured with observations of the lower atmosphere during the flare.

In the past decades, high-resolution observations reveal that flare heating takes place in "quantas", or a cluster of flare loops and their foot-points. We have recently developed a method to construct the history of heating of numerous flare loops from the UV emission signatures at their foot-points, which can be used in hydrodynamic models to study flare plasma evolution and compare with coronal observations. The method helps improve the estimate of the amount of energy used in heating these loops, and explore the nature of heating. Our recent analysis and multi-loop modeling suggest that heating of a flare loop likely proceeds in two phases, an intense impulsive heating followed by a low-rate gradual heating. We discuss properties of the different phases of heating, and the distribution of heating events in a flare with their relation to magnetic properties in the active region.

E2.2-0018-18 RECONNECTION MEDIATED BY MAGNETIC FRACTURES AND THE SOLAR FLARE

Gerhard Haerendel, hae@mpe.mpg.de

Max-Planck-Institut fuer extraterrestrische Physik, Garching, Germany

Reconnection of sheared magnetic fields is commonly treated by regarding the component perpendicular to the anti-parallel components as a largely inert guide field. In this paper an alternative is proposed in which the free energy residing in the shear field is being converted prior to reconnection. This happens in high-density, dissipative current sheets bordering the reconnection site. A global scenario is presented in which low-intensity currents out of the photosphere are converging into the narrow, high-intensity currents at high altitude. This is enabled by the obliqueness of the latter. The very short time-scale of the energy conversion causes a lateral propagation of the current sheets. In a quasi-stationary situation, it balances the reconnection rate, which turns out to be much lower than in guide-field approaches. Another important consequence of the obliqueness is the field-parallel emission of runaway electrons. Accelerated up to tens of keV, they are possibly important contributors to the production of hard X-rays during the impulsive phase of a flare, however only in areas of upward directed currents. Quantitative evaluation of the model predicts various potentially observable properties, such as width and propagation speed of the generated flare ribbons, spatial dependences of the electron spectrum, size of the area of energy deposition, and successive decrease of the shear angle between conjugate foot points. The presented theoretical model can account for the observed brightness asymmetry of flare ribbons with respect to the direction of the vertical currents.

E2.2-0019-18 MAGNETIC RECONNECTION FLUXES IN SOLAR FLARES AND THEIR IMPLICATIONS FOR SOLAR AND STELLAR SUPERFLARES

Astrid Veronig, astrid.veronig@uni-graz.at University of Graz, Graz, Austria

Johannes Tschernitz, johannes.tschernitz@edu.uni-graz.at University of Graz, Graz, Austria

Julia K. Thalmann, julia.thalmann@uni-graz.at University of Graz, Graz, Austria

Jürgen Hinterreiter, juergen.hinterreiter@uni-graz.at University of Graz, Graz, Austria

Werner Pötzi, werner.poetzi@uni-graz.at University of Graz, Graz, Austria

We study the energy release process of a set of 51 solar flares which span almost four orders of magnitude in flare energy, from GOES class B3 to X17. 19 events of our sample are eruptive, i.e. have a CME associated, and 32 are confined (no CME associated). We use Hα filtergrams from Kanzelhöhe Observatory together with SDO HMI and SOHO MDI magnetograms to derive magnetic reconnection fluxes and reconnection rates. We find that the flare reconnection flux is strongly correlated with the peak of the GOES 1-8 Å soft X-ray flux (r=0.9, in log-log space), both for confined and eruptive flares. In the largest events, up to 50% of the total magnetic flux of the host active region (AR) is involved in the flare magnetic reconnection. Based on these findings, we extrapolate the properties of the largest flares that may be launched from our present day's Sun. A complex solar AR that hosts a magnetic flux of 2 1023 Mx, which is supported by the largest active-region magnetic fluxes directly measured, is capable of producing an X80 flare (corresponding to a bolometric energy of about 7 1032 ergs). Using a magnetic flux estimate of 6 1023 Mx for the largest solar AR observed, we find that flares of GOES class X500 could be produced (Ebol 3 1033 ergs). Our results lie on the lower end of the energies of superflares on solar-type stars recently detected in Kepler data. Furthermore, they suggest that the present day's Sun is capable of producing flares and related space weather events more than an order of magnitude stronger than observed in the past.

E2.2-0020-18 HIGHLY IONIZED CA X-RAY SPECTRA FROM FLARES SEEN WITH THE DIOGENESS SPECTROMETER

Janusz Sylwester, js@cbk.pan.wroc.pl

X-ray lines of helium-like calcium (Ca XIX) and nearby Ca XVIII dielectronic satellites have been observed in solar flares with a number of high-resolution spectrometers. The DIOGENESS instrument on the CORONAS-F spacecraft, a scanning crystal spectrometer which operated in 2001, observed these lines but in addition satellites of lower ionization stages of Ca as well as ionized Ar lines in the spectral range 3.05–3.35 Angstroms. In this work, spectra from flares including the X5 flare on 2001 August 25 are analyzed and compared with synthetic spectra. The latter were generated with a specially written code based on various theoretical data including results from the Cowan Hartree–Fock pseudo-relativistic code run for satellite lines. Solar flare spectra taken with the P78-1 SOLFLEX instrument in 1980–1981 are also analyzed. There is close agreement between the solar flare and synthetic spectra for the Ca XIX lines and Ca XVIII satellites (3.17–3.21 Angstroms) and also the Ca XVII satellites at 3.215–3.235 Angstroms clearly seen in DIOGENESS and some SOLFLEX spectra. In addition, fainter line emission at longer wavelengths (Λ> 3.24 Angstroms) in DIOGENESS spectra is identified with Ca XVI satellites and with the Ca XVIII "o" and "p" satellites as well as a feature due to Ar XVI. These identifications are confirmed by recent analysis of X-ray Ar and Ca spectra from the Alcator-C Mod tokamak high-temperature plasmas. The synthetic code developed for this work will be used for analysis of X-ray spectra, recently characterized with new calibration data, from the Solar Maximum Mission Bent

Crystal Spectrometer, and spectra expected from the Polish high-resolution ChemiX spectrometer/dopplerometer, due to fly on the [two] Russian Interhelioprobe spacecraft in 2025/2026.

E2.2-0021-18 KELVIN-HELMHOLTZ INSTABILITIES: A NOVEL INGREDIENT TO THE STANDARD FLARE MODEL

Rony Keppens, rony.keppens@kuleuven.be KU Leuven, Leuven, Belgium

Chun Xia, chun.xia@ynu.edu.cn Yunnan University, Kunming, China

Wenzhi Ruan, wenzhi.ruan@kuleuven.be KU Leuven, Leuven, Belgium

In the standard flare model, energy deposition near the chromosphere from downwards accelerated particles leads to evaporation flows that invade the flaring loop. We modeled this process in isolation of the overarching reconnection site, and found that one can frequently encounter situations where these upflows from both loop legs meet up in a loop-top localized, turbulent fashion. At the loop apex, Kelvin-Helmholtz instability (KHI) of the interacting flows sets in and thermal soft X-ray photons are abound in the interaction zone. This, together with the intrinsically fragmented magnetic field topology due to the vortical disruption can explain hard X-ray sources in loop apexes: electrons trapped and accelerated in the turbulent region can upscatter soft X-ray photons. A parametric survey in a magnetohydrodynamic setting finds that the trigger of KHI and the generation of turbulence are determined by the amount of energy deposited in the chromospheric foot-points and the time scale of energy deposition.

E2.2-0022-18 DIAGNOSING FLARE DYNAMICS THROUGH THE FE XXI 1354.08Å LINE

Hui Tian, huitian@pku.edu.cn Peking University, Beijing, China

The Fe XXI 1354.08 line is the only strong emission line formed above 10 MK in the spectral range of IRIS. It has been demonstrated to be very useful in diagnosing flare dynamics. For instance, the complete evolution of chromospheric evaporation has been well observed and it appears to correlate with the energy deposition rate in many flares, which provides critical constraint to models of chromospheric evaporation. With the Fe XXI line we have even observed multi-episode chromospheric evaporations in a flare. The Fe XXI line has also been successful in observing reconnection outflows, revealing important insight into the flare reconnection process. Moreover, global MHD oscillations have been detected in flare loops, both in the intensity and Doppler shift of the Fe XXI line, allowing more accurate mode identification that is crucial for coronal seismology.

E2.2-0023-18 HIGH-ENERGY ASPECTS OF SOLAR FLARES: RECENT ADVANCES IN OBSERVATIONS AND MODELS

Solar flares are one of the most spectacular manifestations of solar activity with significant space-weather impacts. They also serve as a unique laboratory for probing the underlying physics of wide-ranging processes, including magnetic reconnection, generation of plasma turbulence and shocks, particle acceleration, and plasma heating. Solar flares thus bear important implications for physically similar phenomena elsewhere in the universe, such as laboratory plasmas, planetary magnetospheres, and flares on other stars or near compact objects. In this presentation, we review recent observational and modeling advances in solar flare research, with a focus on high-energy aspects. Special attention will be paid to imaging and spectroscopic observations, e.g., of long-duration and behind-the-limb gamma-ray flares detected by Fermi, of coronal reconnection sites seen by RHESSI, SDO, Hinode, and IRIS, and of the flaring lower atmosphere (chromosphere and transition region) seen by IRIS. We will discuss broad physical connections of flares to other phenomena on the Sun (to a much greater extent than conventionally thought), such as the correlation between quasi-periodic flare pulsations (seen from radio to hard X-rays) and various MHD waves (some are directly imaged). We will also review relevant modeling efforts to explain these observations, focusing on a hybrid model of stochastic (by turbulence) plus shock acceleration of particles, as well as combined kinetic and radiative hydrodynamic simulations.

E2.2-0024-18 SUPERFLARES ON SOLAR TYPE STARS

Daisaku Nogami, nogami@kusastro.kyoto-u.ac.jp Kyoto University, Kyoto, Japan

Superflares are defined as flares which are over 10 times more energetic (1033 erg) than largest flares ever observed on the Sun, and many superflares have been found on many solar-type stars, i.e. G-type main sequence stars in the Kepler-spacecraft data. Statistical analyses indicate that the frequency distribution to the flare energy of the superflare is almost consistent with that of the Sun. Many of superflare stars show quasi-periodic variations with timescales of about 1 to 30 days. Spectroscopic measurements of the projected rotation velocity suggest that these variations are due to rotation of superflare stars with large starspots. The size distribution of starspots shows the power-law distribution which is on the same line of the size distribution of relatively large sunspots. The frequency-energy distributions for flares originating from spots with various sizes are the same for solar-type stars with superflares and the Sun. These results suggest that the magnetic activity on solar-type stars with superflares and that on the Sun is caused by the same physical processes. Long term monitoring of the chromospheric activity and research on possible coronal mass ejections accompanying with superflares will give us an insight on the effects of superflares on the planetary environment, and possible extreme space weather events on the Earth.

Recently, many superflares on solar-type stars have been discovered as white-light flares. Our statistical study found a correlation between their energies (E) and durations (t): t E0.39

(Maehara et al. 2015, EP&S), similar to those of solar hard/soft X-ray flares: t E0.2−0.33.

This indicates a universal mechanism of energy release on solar and stellar flares, i.e., magnetic reconnection. We here carried out a statistical research on 50 solar white-light flares with SDO/HMI and examined the correlation between the energies and durations, aiming to universally explain solar and stellar white-light flares. As a result, the t-E relation on solar white-light flares (t ∝ E0.38) is similar to that on stellar superflares (t ∝ E0.39). However, the durations of stellar superflares are one order of magnitude shorter than those expected from solar white-light flares. We proposed that the discrepancy can be understood by applying a scaling law (t E1/3B−5/3) which is derived from the magnetic reconnection theory (Namekata et al. 2017, ApJ, 851, 91). In this case, the observed superflares are expected to have 2-4 times stronger magnetic field than solar flares. Although there might be another effect like the cooling time of white-light flares, the scaling law has a potential to estimate coronal magnetic field strength of spatially unresolved stellar flares.

E2.2-0026-18 COLLISIONAL AND NON-COLLISIONAL KINETIC MODELING OF FLARING REGIONS WITH STOCHASTIC DIFFERENTIAL EQUATION METHODS

Frederic Effenberger, feffen@gfz-potsdam.de

German Research Centre for Geosciences, Potsdam, Germany Natasha Jeffrey, natasha.jeffrey@glasgow.ac.uk

University of Glasgow, Glasgow, United Kingdom

The rapid energy release in solar flares and the formation of non-thermal electron distributions is widely believed to be caused by magnetic reconnection near the looptop region. Depending on the background plasma properties, an interplay of collisional and non-collisional processes can shape the energetic coronal population that may emit, for example, hard X-ray bremsstrahlung radiation. Both the finite background plasma temperature, as opposed to a simple cold target approach, and the turbulence properties in the flaring region, are crucial in shaping the emerging energy distribution of particles. Here, we present results of a newly developed kinetic simulation approach that models these processes in conjunction. It is based on a stochastic formulation of the underlying Fokker-Planck kinetic equation that is fully pitch-angle and time-dependent, to allow also detailed studies of the time evolution during acceleration, the relaxation to stationary solutions, and the escape from the acceleration region. In particular, we will discuss the relaxation to non-thermal kappa distributions in velocity. We present the results together with synthetic X-ray emission profiles that can be compared to observations of looptop and above-the-looptop signatures. Future extensions of the model to cross-field transport effects and the relation to solar energetic particle release are also addressed.

E2.2-0028-18 OBSERVING TURBULENCE EARLY IN A SOLAR FLARE WITH THE HIGH TIME RESOLUTION OF IRIS

Natasha Jeffrey, natasha.jeffrey@glasgow.ac.uk University of Glasgow, Glasgow, United Kingdom Lyndsay Fletcher, lyndsay.fletcher@glasgow.ac.uk University of Glasgow, Glasgow, United Kingdom Nicolas Labrosse, nicolas.labrosse@glasgow.ac.uk University of Glasgow, Glasgow, United Kingdom Paulo Simões, paulo.simoes@glasgow.ac.uk

SUPA - School of Physics and Astronomy, U. Glasgow, Glasgow, United Kingdom

Wave and turbulent dissipation play a key role in the transfer of energy in magnetized plasmas. Here we report the first high time-resolution, <2 s, spectroscopic study of flare turbulence in the lower solar atmosphere, using the Interface Region Imaging Spectrograph (IRIS). We observe the line Si IV 1402.77 Å, formed at a transition region temperature of 80000 K, at the eastern flare footpoint, over a region of <0.3" during the flare duration. The non-thermal broadening indicates turbulent motions with velocities of 60-70 km/s. The line broadening rises sharply, and precedes the flare onset as indicated by its impulsive radiation signatures in Si IV intensity, extreme ultraviolet (EUV) and X-rays. The <2 s cadence shows that the line broadening oscillates with a period of 10 s before its decay, coinciding with motions in the Si IV line centroid position. The results are consistent with the dissipation of turbulent energy in the lower atmosphere, early in the solar flare, and before the flare brightening.

E2.2-0030-18 SOLAR FLARE OBSERVATIONS WITH INTEGRAL FIELD SPECTROSCOPY IN H-ALPHA SPECTRA AND SDO/AIA

Yoshinori Suematsu, suematsu@solar.mtk.nao.ac.jp

National Astronomical Observatory of Japan, Mitaka, Japan

Integral field spectroscopy is a two dimensional spectroscopic technique, providing spectra simultaneously for each spatial direction of an extended two-dimensional field. Using the field integral spectroscopy made of microlenslet-array (30x30 lenslets) in H-alpha spectrum, GOES Cand M-class flares on 3 Nov 2011 were successfully observed with the 60 cm aperture Domeless Solar Telescope at Hida Observatory, Kyoto University. The data spatially sampled with 0.5 arcsec over 10x10 arcsec FOV and 1 nm wavelength band centered H-alpha line demonstrated that simultaneous 2D spectroscopic observations over extended solar structures, at a high spatial resolution and temporal cadence, are important to track and understand the physics of transient phenomena happening in impulsive flare bright kernels. We made monochromatic images at given wavelengths in the H-alpha line and nearby continuum to co-align the data with X-ray, UV images and magnetograms from SDO/AIA and HMI. To reveal dynamical properties of the flare kernels, we carried out line profile analysis and derived 2-D distribution of parameters such as line-of-sight velocity and line width. The results clearly show the rapid development of red asymmetry at the flare kernels, giving a large downward Doppler shifts of up to 50 km/sec. The accompanied formation of coronal dynamic flaring loop structures seen in SDO X-ray images are consistent with a scenario of downward motion of compressed chromospheric flare kernels due do impulsive heat flow from the corona to the chromosphere and simultaneous evaporation of the chromospheric material into the corona.

E2.2-0031-18 THE ACTIVE REGION 12673 X9 FLARE OBSERVED FROM THE SUBMILLIMETER TO MID-IR

Universidade Presbiteriana Mackenzie, Sao Paulo, Brazil Adriana Valio, adrivalio@gmail.com

Universidade Presbiteriana Mackenzie/CRAAM, Sao Paulo, Brazil

Active Region 12673 produced the most intense event of the solar cycle 24: in a few days of early September 2017, four X-class and eight M-class flares occurred. SOL2017-09-06T12:00, a GOES X9.3 flare, that also produced a two-ribbon white-light emission across the sunspot detected by SDO/HMI, was observed at 212 and 405 GHz with the arcminute-size beams of the Solar Submillimeter Telescope focal array while making a solar map, and at 30 THz, with a 17 arcsec difraction-limited IR camera. SST was observing far from the source when the maximum of the impulsive phase occurred and did not detect a significant flux excess. When the antenna was pointing close enough to the source, we derived the excess brightness temperatures by comparing with the quiet Sun and obtained 5900 and 1800 K at 212 and 405 GHz respectively. Images at 30 THz revealed that the sunspot gradually increased in brightness while the event proceeded, reaching a temperature similar to quiet Sun values. From the images we derive a 180 K flare peak excess brightness temperature assuming 5000 K for the quiet Sun. The peak occurred tens of seconds before the Soft-X Rays peak observed by GOES, afterwards the 30 THz source cooled and returned to the preflare level only almost 2 hours after the flare started.

E2.2-0032-18 X4.9 CLASS SOLAR FLARE ASSOCIATED WITH FILAMENT ERUPTION AND SOLAR ENERGETIC PARTICLES ON 2014 FEBRUARY 25

Mirabbos Mirkamalov, abbos.astrin@gmail.com Samarkand State University, Samarkand, Uzbekistan Zavkiddin Mirtoshev, zmirtoshev@gmail.com Samarkand State University, Samarkand, Uzbekistan Bakhrom Makhmudov, bmakhmudov.samsu@gmail.com Samarkand State University, Samarkand, Uzbekistan

We perform a detailed multi-wavelength study of an eruptive X4.9 flare and its associated halo CME-driven shock. On 2014 January 25, AR NOAA 11990 was situated close to the eastern limb at heliographic coordinates of S12E82. A major flare occurred in the time interval between 00:39 and 01:03 UT with maximum emission at 00:49 UT as recorded the GOES and RHESSI flux data. The flare light curves exhibit an abrupt rise of non-thermal emission with very high HXR bursts up to 300 keV evidencing an intense energy release in the form of non-thermal particles. The HXR time profiles displayed multiple peaks. Around the HXR impulsive peak (at 00:46 UT) temperature was about 30 MK which corresponds to the maximum temperature during the flare. This fact and SDO/AIA observations in the different (E)UV bands point that the observed plasma is multi-thermal. The non-thermal HXR emission was not very significant after 00:55 UT. The combined multi-wavelength (E)UV view of the flare exhibits a set of coronal magnetic loop structures with different orientations underwent a series of morphological evolutions at the AR. With the beginning of impulsive phase we can clearly recognize two localized structures as low-lying loops which are not associated with significant X-ray emission but show distinct bright (E)UV emission above the core region. These structures consist of rapidly expanding bright helically twisted loops associated with the erupting prominence and can be attributed to the portions of the heated prominence within the flux rope. Expanding bright loops displayed ejection in the form of Ω-like kinked eruption structure. The prominence along with its supporting flux rope had a successful escape through the overlying loops. The complete eruption of the filament proceeded symmetrically from the AR with a strong halo CME-driven shock but thereafter, the eruption evolved into an asymmetrically propagated fast huge structure which is one of the sources responsible for SEPs as recorded the in situ observations of the inner heliosphere from WIND spacecraft.

Key words: solar flare, CME and SEP; X-ray and (E)UV emissions.

E2.2-0033-18 INITIATION PROCESSES FOR THE 2013 MAY 13 X1.7 LIMB FLARE

Jinhua Shen, shenjh@xao.ac.cn

Chinese Academy of Sciences, Urumqi, China Haisheng Ji, jihs@pmo.ac.cn

Purple Mountain Observatory, Chinese Academy of Sciences, Nanjing, China

For the X 1.7 class limb flare on May 13, 2013 (SOL2013-05-13T01:53), its initiation processes were well observed and it incorporates following phenomena: an X-ray precursor that peaked sim 7 minutes before the onset of the flare, two J-shaped magnetic loops forming a Sigmoid magnetic structure, an expanding magnetic flux rope, and a contracting flare loop. We report that the two J-shaped magnetic loops were activated by the X-ray precursor. After the activation, magnetic reconnection occurred inside the Sigmoid structure, which produced the expanding magnetic flux rope and the contracting flare loop. For this flare, the real initiation time can be regarded as from the starting time of the precursor and its impulsive phase started when the magnetic flux rope began its fast expansion. In addition, we confirm that the phenomenon of contracting flare loop, which proceeds expanding post-flare loops, can be regarded as the signature of magnetic reconnection between sheared magnetic fields that produces magnetic flux rope.

E2.2-0035-18 HALPHA BRIGHTENING ON THE PROPAGATION OF EXCITOR OF CORONAL TYPE V SOLAR RADIO BURST

Ebenezer Chellasamy Edwin, eben@iiap.res.in IIA, Kodaikanal, India

This paper presents multiwavelength observations of a type V radio burst in the absence of solar flare in X-ray band. The kinematics of the speed derived from the type V closely match with a fast drifting radio emission seen in the dynamic spectra recorded in Kodaikanal Solar Observatory(KSO). It was initially observed in the KSO dynamic spectra after a delay in WINDS/ WAVES ultra low frequency radio spectrum recorded from space. The uniform and usual coronal density topology was revealed at the flare site studied using polarised brightness pB (LASCO). A small, confined filament eruption (sunspot area 300m) was also observed. We suggest that fast transport of energetic particles through open field lines responsible for the absence of flare or coronal mass ejection or Coronal shock.

E2.2-0036-18 THE FIRST STEPS OF A NEW SPACE SUN-TERAHERTZ PROJECT

Development of a new space SUN-TERAHERTZ project started at the Lebedev Physical Institute of the Russian Academy of Sciences in 2017, in the scope of the Russian Space Agency Program. The SUN-TERAHETZ' device is planned to fly on board Russian segment of the International Space Station in 2021-2022. This paper reports on the details of the first stage of the SUN-TERAHERTZ space project. We discuss scientific goals of the future experiment and present specification of the proposed THz experimental device.

E2.2-0037-18 SCIENCE OBJECTIVES OF THE SOLAR-C_EUVST

Shinsuke Imada, shinimada@gmail.com Nagoya University, Aichi, Japan

Solar-C WG

Shimizu T., Kawate T. et al.

Solar-C EUVST (EUV High-Throughput Spectroscopic Telescope) is designed to comprehensively understand the energy and mass transfer from the solar surface to the solar corona and interplanetary space, and to investigate the elementary processes that take place universally in cosmic plasmas. The proposed mission is a fundamental step for answering how the plasma universe is created and evolves, and how the Sun influences the Earth and other planets in our solar system. The two primary science objectives for Solar-C EUVST are: I) Understand how fundamental processes lead to the formation of the solar atmosphere and the solar wind, II) Understand how the solar atmosphere becomes unstable, releasing the energy that drives solar flares and eruptions. Solar-C EUVST will, A) seamlessly observe all the temperature regimes of the solar atmosphere from the chromosphere to the corona at the same time, B) resolve elemental structures of the solar atmosphere with high spatial resolution and cadence to track their evolution, and C) obtain spectroscopic information on the dynamics of elementary processes taking place in the solar atmosphere. In this talk, we will first discuss the science target of the Solar-C EUVST, and discuss the science topic associated flare in detail. Photospheric motions lead to the accumulation of free magnetic energy in the corona. This system eventually becomes unstable, releasing the energy through magnetic reconnection. This process of energy conversion heats the plasma to high temperatures and drives coronal mass ejections (CMEs). By measuring the properties of multi-temperature flaring plasma, Solar-C EUVST will investigate why the reconnection is fast despite the high magnetic Reynolds number. It will also monitor the temporal evolution of solar active regions and identify the triggering mechanism for the flare and eruption. Therefore two important science objectives are defined for the flare physics. The first objective is “Understand the Fast Magnetic Reconnection Process”. Magnetic reconnection is one of the fundamental processes for converting magnetic energy into the thermal and kinetic energy of the plasma. This process occurs much faster than is predicted by classical theory. Solar-C EUVST will observe the dynamics of magnetic structures to understand the mechanisms that lead to fast magnetic reconnection in partially or fully ionized plasmas. The second objective is “Identify the Signatures of Global Energy Buildup and the Local Triggering of the Flare and Eruption”. Understanding the accumulation and release of free magnetic energy in the corona is a fundamental problem. Solar-C EUVST will perform long-term monitoring of active regions to identify the signatures of energy buildup and high-resolution observations to understand the triggers of energy release.

E2.2-0038-18 DEFINING A SUN QUAKE: A STEP TOWARDS AUTOMATED DETECTION

Sergei Zharkov, s.zharkov@hull.ac.uk University of Hull, Hull, United Kingdom Connor Macrae, c.macrae(at)hull.ac.uk University of Hull, Hull, United Kingdom

Using acoustic holography, we study the acoustic emission from near-surface layers in the photosphere: quiet Sun, flaring and non-flaring active regions and place the results in the context of known and newly discovered sunquakes. We demonstrate the existence of unique set of parameters allowing us to detect a sun quake based on the analysis of photospheric data only without a priori knowledge of the flare.

E2.2-0039-18 MODERNISED FLARE DETECTION ROUTINES FOR MULTI-WAVELENGTH TIMESERIES DATASETS

Alex Hamilton, a.hamilton@2016.hull.ac.uk University of Hull, Hull, United Kingdom Sergei Zharkov, s.zharkov@hull.ac.uk University of Hull, Hull, United Kingdom

We present a new method for the detection of solar flares in low cadence timeseries, based on modern peak-recognition signal processing techniques. Using both simulated and observational data we evaluate this method's performance against other techniques for detection qualitatively and quantitatively.

Applied to GOES XRS X-ray lightcurves, we show that this algorithm makes compelling improvements to detections as reported in the Heliophysics Events Knowledgebase (HEK), with specific breakdowns given on the resulting population of flares detected with variation of the input parameters and signal pre-processing. We extract flare parameters including peak, duration and estimated energy, establishing their dependence or independence on the input parameters for the method. The resulting distributions are compared with available observations and models.

Furthermore, we adapt the method to work on multi-spectral data, including solar white-light intensity data, presenting initial results of detection and analysis with Kepler datasets, with the latter cross-references and compared with GOES output.

E2.2-0041-18 MULTIWAVELENGTH STUDY OF 24 EQUATORIAL CORONAL-HOLE JETS

Pankaj Kumar, pankaj.kumar@nasa.gov

C. Richard DeVore, c.richard.devore@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States Craig DeForest, deforest@boulder.swri.edu

Southwest Research Institute, Boulder, Colorado, United States

We studied 24 equatorial coronal-hole (ECH) jets using SDO/AIA and HMI observations on 27-28 June 2013 and 8-10 January 2014. Out of 24 jets (i) 16 jets (67%) are associated with mini-filament eruptions; (ii) 8 jets (34%) are triggered without mini-filament eruptions but with mini-flare arcades and other CME-like signatures; (iii) 5 jets (21%) are apparently associated with tiny flux-cancellation events at the polarity inversion line; (iv) 3 events are associated with sympathetic eruptions of filaments from neighboring jet source regions. The potential field extrapolations of the source regions reveal that almost all jets occurred in the fan-spine topology, and most of the events are in agreement with the breakout model of solar jets. We will present selected examples of each type, and discuss the implications for the jet energy-buildup and initiation mechanisms.

E2.2-0043-18 SOLAR SOFT X-RAY OBSERVATION BY CHANG'E-2 SOLAR X-RAY MONITOR

Institute of High Energy Physics, CAS, China, Beijing, China

Solar X-ray monitor (SXM) was a part of X-ray spectrometer onboard CHANG'E-2 mission. It measured solar X-ray spectra in the energy band of 1keV 10keV, which could be helpful for the elemental quantitative analysis of lunar X-ray fluorescence. Meanwhile SXM also act as a scientific payload for solar flare studies. From October 2010 to May 2011, SXM was operated for more than 200 days in a 100km lunar orbit. During that time, more than 100 solar X-ray bursts (GOES level from B to X) were observed. In this paper, a summary of in-orbit operation and dataset status of SXM were present. Besides, several flare spectra were analyzed to achieve the fundamental parameters (e.g. electron temperature, EM) which could describe the evolution of solar coronal plasma in these flares.

Spectrometer for Temperature and Composition (STC) will monitor solar X-ray flux between 0.8 keV and 15 with 0.2 keV emergency resolution. The instrument provide fast solar X-ray spectroscopy in the entire flux intensity range, variable seven order in intensity form quiet solar conditions to strongest flares. The exceptionally wide dynamic range of this instrument as well as its high spectral and temporal resolution and wide plasma temperature coverage will result in unprecedented measurements, crucial for energy release processes and space weather monitoring. In addition the data collected by STC will complement the main FOXSI instrument measurements and allow temperature, composition and emission measure analysis for structures seen in the solar corona.

E2.2-0045-18 ANALYTICAL STUDY OF X-CLASS FLARES RELEASED DURING THE DECLINE PHASE OF SC24

Ahmed AbdelHady, aahady@yahoo.com Cairo University, Cairo, Egypt Scientific Commission E

Eruptive X-class flares occurring during the decline phase of the solar cycle 24 are stronger than those of solar cycle 23. We notice that the solar cycle 24 is the weakest in last 100 Years. The last two cycles are very weak compared to other cycles, except for the Dalton Minimum cycles 4, 5, 6 and 7; which means the appearance of a new Dalton minimum during 23, 24, 25 and 26. During the last 5 solar cycles, a new peak has appeared releasing high energetic particles and X-class solar flares which are called the secondary peak or the double peak of the solar cycle. The aim of this analytical study is to follow the X-class flares released during the decline phase of SC24, to predict, applying data analysis, when they would be released, and to compare it with other solar cycles. The causes of the release of such eruptive storms, through the year 2014, during the double peak of the solar cycle 24 were also discussed.

E2.2-0046-18 SOLAR FLARE NEUTRINO SIGNALS AND FLAVORS BY HYPER KAMIOKANDE IN JAPAN AND COREA: A NEW NEUTRINO ASTRONOMY

Daniele Fargion, daniele.fargion@roma1.infn.it

Physics Department, Rome University 1, INFN Rome 1,, Rome, Italy

The project and the near future building of a twin Megaton neutrino detector as HyperKamiokande both in Japan and possibly, in South Corea will provide in a near future the most advanced (in few MeV up to several GeVs energy windows) telescope of galactic and nearby (Andromeda, LMC.) Supernova (SN) thermal neutrino events by their SN neutrino burst. These rare SN must be located within one or a few Mpc. The underground HK may also better trace the atmospheric neutrinos signals testing their precise flavor mixing and their matter-anti matter component (or eventual asymmetry). In this flavor test the same elusive tau neutrino appearence (by atmospheric muon neutrino oscillation at several GeV) may be also be finally well probed. In addition to astrophysical and (atmospheric and fundamental) physics, the HK may also discover the first multiwave detection of X-gamma photons and their correlated tens MeV (up to GeV) neutrino signals during largest solar flare. Such a physics may combine the solar flare plasma physics with its inner proton proton scattering and with consequent, also via Delta resonances, pion and Kaon production. This expected discover, after SN1987A and Solar neutrino astronomy, will open a third independent solar Neutrino windows. The neutrino flavor mixing, might test better the neutral lepton parameters. The prompt and timed detection of solar flare may offer the most advances alarm system for satellite (and astronauts) survival. In particular when the solar flare occurs in the hidden solar side. Foreseen solar neutrino spectra, signature and rate in HK for each neutrino flavor will be shown in details. E2.3-0001-18 SOLAR POLARIMETRY - FROM TURBULENT MAGNETIC FIELDS TO SUNSPOTS

Lucia Kleint, lucia.kleint@fhnw.ch FHNW, Windisch, Switzerland

Polarimetric measurements are essential to investigate the solar magnetic field. Scattering polarization and the Hanle effect allow us to probe the turbulent magnetic field and the still open questions of its strength and variability. Directed magnetic fields can be detected via the Zeeman effect. To derive their orientation and strength, so-called inversion codes are used, which iteratively modify a model atmosphere and calculate the resulting polarization profiles that are then compared to the observations. While photospheric polarimetry is well-established, chromospheric polarimetry is still in its infancy, especially because it requires a treatment in non-LTE, making it a complex non-linear problem. But some of the most important open questions concern the strength and geometry of the chromospheric magnetic field. In this talk, I will review different polarimetric analysis techniques and recent advances in magnetic field measurements going from the small scales of turbulent magnetic fields to changes of magnetic fields in an active region during flares.

E2.3-0002-18 EMERGENCE OF INTERNETWORK MAGNETIC FIELDS THROUGH THE SOLAR ATMOSPHERE

Milan Gosic, mgosic@lmsal.com

Lockheed Martin Solar and Astrophysics Laboratory, Palo Alto, California, United States Bart De Pontieu, bdp@lmsal.com

Lockheed Martin Solar and Astrophysics Laboratory, Palo Alto, California, United States

L. R. Bellot Rubio, lbellot@iaa.es

Instituto de Astrofisica de Andalucia CSIC, Spain

Internetwork (IN) magnetic fields are highly dynamic, short-lived magnetic structures that populate the interior of supergranular cells. Since they emerge all over the Sun, these smallscale fields bring a substantial amount of flux, and therefore energy, to the solar surface. Because of this, IN fields are crucial for understanding the quiet Sun magnetism. However, they are weak and produce very small polarization signals, which is the reason why their properties and impact on the energetics and dynamics of the solar atmosphere are largely unknown. Here we use coordinated IRIS and SST observations of IN regions at high spatial and temporal resolution. They give us the opportunity to follow the evolution of IN magnetic loops as they emerge into the photosphere. For the first time, our polarimetric measurements provide a direct observational evidence of IN fields reaching the chromosphere. Moreover, we show that IN magnetic loops contribute to the chromospheric and transition region heating through interaction with preexisting ambient fields.

E2.3-0003-18 SPECTRAL LINE POLARIZATION IN THE SUN, THE LANGUAGE OF THE CHROMOSPHERIC MAGNETIC FIELDS

Tanausú Del Pino Alemán, tanausu.tdpa@gmail.com Instituto de Astrofisica de Canarias (IAC), La Laguna, Spain

The solid understanding of the solar chromosphere and its magnetic connection with the photosphere and the corona is, nowadays, one of the big challenges in solar astrophysics. Within the chromosphere, an extended region of about nine pressure scale heights, the temperature rises from few thousand kelvin to the million degrees of the low corona. Moreover, the dominant physics in this region changes with height from a medium dominated by hydrodynamics to a plasma dominated by the magnetic field. While the observed intensity spectrum mostly contains information about the thermodynamics of the emitting plasma, at least under quiet Sun conditions, the polarized spectrum of atomic lines contains key information to determine the strength and topology of the magnetic fields. In this presentation I will talk about our current capabilities and recent advancements on the theory and modeling of spectral line polarization in optically thick plasmas such as the solar atmosphere, in particular, for strong permitted chromospheric lines.

Actual limitations in understanding physical processes occurring in the solar atmosphere are related with our poor capabilities in measuring magnetic fields in its layers. The knowledge of magnetic fields in the solar corona is crucial to understand the origin of solar flares and Coronal Mass Ejections, waves, coronal heating and solar wind acceleration. For these reasons many different techniques have been proposed to provide these measurements by analysing the emission related with many different physical phenomena (e.g.: radio observations of gyrosynchrotron and free-free emission, infrared observations of Zeeman effect, visible and infrared obervations of the Hanle effect, UV-EUV observations of CME-driven shock waves, etc.). In order to provide a continuous monitoring of coronal fields, new groundand space-based instrumentations are currently under development, as well as new techniques to infer the real fields from the line-of-sight integrated coronal emission. At the same time, the forward modelling of the expected emission starting from different possible coronal field configurations is being developed, allowing the definition of the required properties for future instrumentation and the verification of the data analysis results.

E2.3-0005-18 LINEAR LINE-POLARIMETRY: PROBING THE MAGNETIC FIELD MECHANISMS OF ENERGY DEPOSITION IN CORONA.

Silvano Fineschi, fineschi@oato.inaf.it INAF, Pino Torinese, Torino, Italy Roberto Susino, sur@oact.inaf.it

INAF - Osservatorio Astronomico di Torino, Pino Torinese, Italy Sarah Gibson, sgibson@ucar.edu

Purple Mountain Observatory, Chinese Academy of Sciences, Nanjing, China

Optically-thin, UV spectral lines in corona are linearly polarized by resonance scattering of chromospheric line-emissions off coronal ions. In the presence of coronal magnetic fields, the resontantly-scattered line-polarization is modified by the Hanle effect. Spectro-polarimetric UV observations from space of these line-emissions, interpreted in terms of the Hanle effects, are a powerful tool for the diagnostics of magnetic fields in the solar chromosphere/corona. Through the anisotropic Doppler-dimmng effect, the linear polarization of optically thin spectral lines is sensitive to anisotropic ion-velocity distributions that can be induced by the ion-cyclotron resonance between plasmas and MHD waves in corona. This effect is believed to influence some heavy ions in the solar corona. Thus, coronal polarimetry of resonantly scattered UV spectral lines can also serve as a powerful tool for probing the magnetic field mechanism(s) of energy deposition in corona.

This presentation reports the parameter study carried out by forward modeling of the linear polarization of the coronal UV spectral lines HI Lyman-α, 121.6 nm, and OVI, 103.2 nm. The study was based on the FORWARD numerical code developed by the High Altitude Observatory. The study used FORWARD to reproduce synthetic linear line-polarization maps for different MHD models of the corona.

The results from the parameters study indicate that the Hanle effect diagnostics is most effective within a few tens of solar radii from the solar limb in closed-field, active regions where the strength the coronal magnetic field is within the Hanle effect sensitivity for the HI Lyman-α and OVI lines (i.e., 2-60 gauss). On the other hand, the effect of anisotropic velocity field distributions of scattering ions on the line-polarization emitted by resonance scattering is most effective in open-filed regions of non-radial solar wind, such as the interface coronal holesstreamers.

To obtain quantitative information on the magnetic field in low beta regions (i.e., upper chromosphere and above) has been increasingly important to understand the energetic phenomena of the outer solar atmosphere such as flare, coronal heating, and the solar wind acceleration.

In the UV range, there are abundant spectral lines that originate in the upper chromosphere and transition region. However, the Zeeman effect in these spectral lines does not give rise to easily measurable polarization signals because of the weak magnetic field strength and the larger Doppler broadening compared with the Zeeman effect. Instead, the Hanle effect in UV lines is expected to be a suitable diagnostic tool of the magnetic field in the upper atmospheric layers.

To investigate the validity of UV spectro-polarimetry and the Hanle effect, the Chromospheric Lyman-Alpha Spectro-Polarimeter (CLASP), which is a NASA soundingrocket experiment, was launched at White Sands in US on September 3, 2015. During its 5 minutes ballistic flight, it successfully performed spectro-polarimetric observations of the hydrogen Lyman-alpha line (121.57 nm) with an unprecedentedly high polarization sensitivity of 0.1% in this wavelength range. CLASP observed the linear polarization produced by scattering process in VUV lines for the first time and detected the polarization signals which indicate the operation of the Hanle effect.

Following the success of CLASP, we are confident that UV spectro-polarimetry is the way to proceed, and we are planning the second flight of CLASP (CLASP2: Chromospheric LAyer SpectroPolarimeter 2). For this second flight we will carry out spectro-polarimetry in the Mg II h and k lines around 280 nm, with minimum modifications of the CLASP1 instrument. The linear polarization in the Mg II k line is induced by scattering processes and the Hanle effect, being sensitive to magnetic field strengths of 5 to 50 G. In addition, the circular polarizations in the Mg II h and k lines induced by the Zeeman effect can be measurable in at least plage and active regions. The combination of the Hanle and Zeeman effects could help us to more reliably infer the magnetic fields of the upper solar chromosphere. CLASP2 was selected for flight and is being developed for launch in the spring of 2019.

Based on these sounding rocket experiments (CLASP1 and 2), we aim at establishing the strategy and refining the instrument concept for future space missions to explore the enigmatic atmospheric layers via UV spectro-polarimetry.

E2.3-0007-18 CONSTRAINING THE MAGNETIZATION AND GEOMETRICAL COMPLEXITY OF THE CHROMOSPHERE-CORONA TRANSITION REGION VIA RADIATIVE TRANSFER MODELING OF THE CLASP OBSERVATIONS

Javier Trujillo Bueno, jtb@iac.es

Instituto de Astrofisica de Canarias, La Laguna, Spain

On 3 September 2015 an international team of scientists from Japan, USA and Europe carried out succesfully a challenging measurement using a vacuum ultraviolet telescope and a spectropolarimeter called CLASP, launched by a NASA suborbital rocket (see the talk by R. Ishikawa et al.). For the first time, CLASP measured the linear polarization profiles of the hydrogen Lyman-alpha and Si III 120.6 nm lines produced by the scattering of anisotropic radiation in the enigmatic chromosphere-corona transition region of the Sun. Here we report about the radiative transfer investigations we have carried out for interpreting the Stokes Q/I and U/I profiles observed by CLASP in such ultraviolet resonance lines. We explain why the observed Lyman-alpha polarization does not show a clear center to limb variation. We show also that the observed Stokes profiles encode a rich information on the magnetization and geometrical complexity of the plasma of the upper solar chromosphere.

Though they are now understood to be the drivers of all solar activity and the reservoir of energy for coronal heating, coronal magnetic fields remain notoriously hard to measure. The low radio frequency (< 300 MHz) solar emissions originate at coronal heights of beyond 0.1R0 above the photosphere, and are intrinsically sensitive to the magnetic fields in this region due to a range of different phenomena. The type III solar burst emission, for instance, is believed to come from beams of accelerated electrons streaming along the magnetic fields; accordingly their imaging can potentially provide direct determination of coronal magnetic field structures, geometries, and magnetic reconnection. In a handful of instances, it has been possible to directly image the synchrotron emission from the semi-relativistic plasma in the Coronal Mass Ejections and constraints on their magnetic fields have been successfully obtained. The birefringent nature of the coronal plasma implies that even the unpolarized thermal free-free emission picks up a small amount of circular polarization, the measurement of which can provide a measure of the average coronal magnetic field. In spite of their unique and informative diagnostic capabilities, applications of radio observations have remained rather limited. This is primarily because of the limited capacity of the radio instrumentation available till recently to capture this information in sufficient detail. This is now rapidly changing with the new generation radio interferometers like the Murchison Widefield Array (MWA), the LOw Frequency Array (LOFAR) and the Long Wavelength Array (LWA). The high dynamic

range snapshot spectroscopic imaging capabilities of the MWA are much better matched to the needs of solar radio science. We have been working on systematically developing the tools needed to enable the scientific exploration of these high-SNR fine-grained data and pursue science opportunities with them. Our efforts have spanned the range from developing techniques for flux calibration and an imaging pipeline; to quantifying the strength and prevalence of weak impulsive nonthermal emissions; and detailed multi-wavelength analyses to elucidate the relationship between the magnetic structures and geometries seen in SDO UV-EUV bands and the type III bursts imaged by the MWA. Here we will briefly discuss the opportunity presented by the new generation low radio frequency arrays, present the current status of our efforts with some examples and touch upon the challenges ahead.

E2.3-0009-18 INTERPRETATION OF HANLE EFFECT MEASUREMENTS IN THE SOLAR CORONA: PROMISES AND DIFFICULTIES

Veronique Bommier, v.bommier@obspm.fr LESIA, Observatoire de Paris, Meudon, France

After having recalled the main features of the Hanle effect, and of its application to coronal lines, the promises and difficulties of the measurement interpretation in terms of magnetic field vector diagnostics, will be investigated, based on Bommier, V., Leroy, J.L., and Sahal-Bréchot, S., 1981, A&A, 100, 231, and in the light of the new instrumentation presently available or in project, as well as data-driven modeling present possibilities. The feasibility of measuring the Coronal magnetic field by interpretation of the Zeeman effect observed in the infrared, will also be investigated.

E2.3-0010-18 SELF-CONSISTENT MULTI-DIMENSIONAL INVERSION PROBLEM

Jiri Stepan, jiri.stepan@asu.cas.cz

Astronomical Institute AS CR, Ondrejov, Czech Republic

The main goal of solar spectropolarimetry is to infer reliable physical information about the plasma structures from the observed Stokes profiles of spectral lines. In order to solve the general multi-D inversion problem of optically thick spectral lines, one can take advantage of sparsity of the observed data. Additional regularization of the problem imposed by the need to satisfy the requirement of the NLTE self-consistent solution leads to a robust inference method. Coupling of the massivelly parallel forward solver taking into account the scattering polarization, Hanle, and Zeeman effects with a suitable inversion algorithm allows us to develop efficient inversion procedures for thermal and magnetic properties of the solar plasma. Here we show the first results of our numerical experiments.

E2.3-0011-18 THE MAGNETIC NEEDS FOR UNDERSTANDING (AND PREDICTING) SOLAR ENERGETIC EVENTS

K D Leka, leka(at)nwra.com

NWRA, Boulder, Colorado, United States

Energetic Solar Events – solar flares, coronal mass ejections, and the acceleration of high-energy particles – are all believed to be triggered at some level by the sudden reconfiguration of solar magnetic field lines, and powered at some level by stored magnetic energy. So, to understand and ultimately predict these events, we need to measure the magnetic fields on the Sun at all times, in all of space (with no uncertainty, of course). Is that even possible? No. So, what information is really accessible about this all-important magnetic field, how do we acquire it, and how can we best use what we've got? In this talk I will touch upon the diversity (and limitations) of our present resources and the wide range of questions they are being used to answer regarding solar energetic events. I will also review some outstanding questions and what these imply for future magnetic field observational requirements in the quest to further extend our understanding (and ultimately, the prediction) of these phenomena.

E2.3-0012-18 DATA-INSPIRED, DATA-CONSTRAINED AND DATA-DRIVEN MODELING OF SOLAR ACTIVE REGIONS

Mark Cheung, cheung@lmsal.com

Lockheed Martin Solar and Astrophysics Laboratory, Palo Alto, California, United States

Recent advances in numerical modeling have provided important lessons on the physics that cause solar active regions to erupt and flare. While the majority of past work has been datainspired (and based on somewhat idealized scenarios), improvements in observational coverage is beginning to facilitate data-constrained and data-driven modeling. Data-constrained models are those that use observational constraints in one instance in time, while data-driven models are evolved in response to changing boundary conditions (e.g. at the solar photosphere) consistent with observations. In this talk, we review some recent results from these three classes of models. The implications of the models for desired future instrumentation will also be discussed.

E2.3-0013-18 "BUILDING A MAGNETIC SKELETON OF THE SOLAR CORONA: TOWARDS BETTER 3-D CONSTRAINTS ON THE CORONAL MAGNETIC FIELD

Anna Malanushenko, anny@ucar.edu

High Altitude Observatory, NCAR, Broomfield, Colorado, United States Sarah Gibson, sgibson@ucar.edu

NCAR, Boulder, Colorado, United States Therese Kucera, therese.a.kucera@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, United States David McKenzie, david.e.mckenzie@nasa.gov

NASA Marshall Space Flight Center, Huntsville, United States

The energy stored in the solar magnetic field is what is powering many violent explosive events in the solar atmosphere, or the corona. Some of these events result in the coronal mass ejections (CME's) released into the interplanetary space. The magnetic field in the solar corona is therefore very important to know, yet it is very difficult to measure. Most of the time it is modeled with the magnetic maps at the solar surface used as boundary conditions. The magnetic maps on the surface are therefore also important to know, yet the full vector of the field on the surface is also difficult to measure. Once such measurements are made, constructing a model capable of predicting eruptive potential of a given region is on its own a complicated task. One of the problems arising is that that the equations for low-beta equilibria, which are often used to describe the coronal field, do not, strictly speaking, work for the solar surface. In short, we need better inputs to model the solar corona. The use of non-magnetic and nonsurface constraints on the magnetic field becomes increasingly popular. For example, the paths of filaments can be used to guide flux rope trajectories; the loops of active regions, seen in extreme ultraviolet (EUV) can be used to obtain 3-D trajectories of magnetic field lines and estimate electric currents flowing along them. We are currently exploring ways to use other sources of data, such as flows in prominences and coronal spectropolarimetric data, in a similar fashion. I will talk about this work, and about our project of aggregating many different sources of non-magnetic 3-D constraints on the magnetic field. The resulting 'skeleton' can be used to constraint global field models, or to validate models obtained in traditional ways. We intend to develop a pipeline and assemble several skeletons for several instances in time of the Sun, which we will then release to community.

E2.3-0014-18 DIAGNOSING THE MAGNETIC FIELD STRUCTURE OF A CORONAL CAVITY OBSERVED DURING THE 2017 TOTAL SOLAR ECLIPSE

Yajie Chen, chenyajie@pku.edu.cn Peking University, Beijing, China Hui Tian, huitian@pku.edu.cn Peking University, Beijing, China Yingna Su, ynsu

Harvard-Smithsonian Center for Astrophysics, Cambridge, Massachusetts, United States Linhua Deng, lhdeng@ynao.ac.cn

China

Patricia Jibben, pjibben@cfa.harvard.edu

Harvard-Smithsonian Center for Astrophysics, Cambridge, Massachusetts (USA), Cambridge, Massachusetts, United States

Zhongquan Qu, zqqu@ynao.ac.cn China

We present an investigation of a coronal cavity observed above the western limb in the coronal red line Fe X 637.4 nm using a telescope of Peking University and in the green line Fe XIV 530.3 nm using a telescope of Yunnan Observatories, Chinese Academy of Sciences during the total solar eclipse on 2017 August 21. A series of magnetic field models are constructed based on the magnetograms taken by the Helioseismic and Magnetic Imager onboard the Solar Dynamics Observatory (SDO) one week before the eclipse. The model field lines are then compared with coronal structures seen in images taken by the Atmospheric Imaging Assembly on board SDO and in our coronal red line images. The best-fit model consists of a flux rope with a twist angle of 3.1pi, which is consistent with the most probable value of the total twist angle of interplanetary flux ropes observed at 1 AU. Linear polarization of the Fe XIII 1074.7 nm line calculated from this model shows a “lagomorphic” signature that is also observed by the Coronal Multichannel Polarimeter of the High Altitude Observatory. We also find a ring-shaped structure in the lineof-sight velocity of Fe XIII 1074.7 nm, which implies hot plasma flows along a helical magnetic field structure, in the cavity. These results suggest that the magnetic structure of the cavity is a highly twisted flux rope, which may erupt eventually. The temperature structure of the cavity has also been investigated using the intensity ratio of Fe XIII 1074.7 nm and Fe X 637.4 nm.

E2.3-0015-18 PREDICTING SUNSPOT CYCLE 25 BASED ON CENTURY-SCALE CALIBRATED SOLAR ACTIVITY SIMULATIONS

Dibyendu Nandi, dnandi@iiserkol.ac.in

Center of Excellence in Space Sciences India, IISER Kolkata, Mohanpur, India Prantika Bhowmik, pb13rs014@iiserkol.ac.in

India

The cycle of sunspots modulates the electromagnetic and particulate environment of near-Earth space creating hazardous space weather. Space weather impacts satellite operations, telecommunications, polar air-traffic and electric power-grids. Predicting the sunspot cycle, however, has remained an outstanding challenge. No consensus was achieved among early forecasts for cycle 24 and the cycle strength was much lower than expected. Based on understanding gleaned in recent years, and utilizing a coupled solar surface flux transport model and a dynamo model, we perform the first ever century-scale calibrated, data driven simulations of solar activity to predict the strength and timing of the upcoming cycle – sunspot cycle 25. We present our results here.

E2.3-0016-18 SOLAR CORONAL MAGNETIC FIELD STUDIES WITH ADITYA-L1 MISSION

Sankarasubramanian Kasiviswanathan, sankark@isac.gov.in Indian Space Research Organization, Bengaluru, India

Aditya-L1 is a first dedicated and approved solar mission from India. The main scientific objective of this mission is to study the solar coronal dynamics. The satellite will be placed at the Sun-Earth Lagrangian – L1 in order to observe the Sun uninterruptly. This mission carries seven payloads with four remonte sensing and three in-situ instruments. While the remote sensing payloads observe the chrmospheric and coronal dynamics, the in-situ payloads measures the particles and magnetic fields at L1 point which are modified by the activities originating from the Sun. One of the payload, called Visible Emission Line Coronagraph (VELC) is a coronagraphic instrument with four channels operating simultaneously. While one channel observe the coronal mass ejections closer to the solar disk (from 1.05Rsun to 3.0Rsun), the other three channels are spectroscopic channels carrying out the spectral diagnostics of the multi-temperature plasma. The spectral lines formed by the highly ionized Fe is used to diagnose the coronal plasma. Magnetically sensitive Fe XIII line at 1074.7nm is used along with a polarimetry for coronal magnetic field diagnostics. Spectro polarimetry is carried out to obtain all the Stokes parameters in order to estimate the coronal magnetic field. In this presentation, the VELC configuration for the coronal plasma diagnostics particularly the magnetic field diagnostics will be discussed. The design and measurement principle of the polarimetric mode of operation of VELC will be detailed. Ground based support along with the VELC coronal observations will also be carried out in order to understand the magnetic field connectivity from photosphere to corona. The plan for ground based observations will also be discussed along with the data handling methods for both groundas well as space-observations.

E2.3-0017-18 PROSPECTS FOR CORONAL MAGNETIC FIELD MEASUREMENTS FROM SPACE

Frederic Auchere, frederic.auchere@ias.u-psud.fr IAS, CNRS / Univ. Paris Sud XI, Orsay, France

Despite its fundamental importance as a driver for the physics of the Sun and of the heliosphere, the magnetic field of our star's outer atmosphere remains poorly understood. This is due in large part to the fact that the magnetic field is a very dfficult quantity to measure. Our knowledge of its strength and orientation is largely based on extrapolations from photospheric observations, not from direct measurements. These extrapolations require strong assumptions on critical but unobserved quantities and thus fail to accurately reproduce the complex topologies inferred from remote-sensing observations of coronal structures in white light, EUV, and X-rays. Direct measurements of the coronal magnetic field are clearly identified by the international heliophysics community as a key element in the understanding of our star.

In the past ten years, reliable ground based coronal magnetic field measurements have emerged. However, these measurements wil always be limited by the difficulty to observe the corona from the ground. Much like routine coronagraphic observations from space by SOHO/LASCO have revolutionized our knowledge of the solar corona, space based polarimetric observations are expected to lead to major breakthroughs. In this perspective, we will review the past and future projects of space missions designed to measure the coronal magnetic field from space.

E2.3-0018-18 ASO-S: FOCUSING ON SOLAR MAGNETIC FIELD AND ITS RELATIONSHIP TO SOLAR ERUPTIONS

Weiqun Gan, wqgan@pmo.ac.cn

Purple Mountain Observatory, Nanjing, China

ASO-S (Advanced Space-based Solar Observatory) is a mission proposed for the 25th solar cycle by the Chinese solar community. The scientific objectives are to study the relationships among solar magnetic field, solar flares, and coronal mass ejections. In the beginning of 2018, ASO-S has been officially set up and the approved time table is 4 years for the design and manufacture. This talk will extend the scientific objectives and introduce in brief the latest progress of Phase -B study.

E2.3-0019-18 THE ERUPTION OF A PROMINENCE CARRYING CORONAL FLUX ROPE: FORWARD SYNTHESIS OF THE MAGNETIC FIELD STRENGTH MEASUREMENT BY THE CORONAL SOLAR MAGNETISM OBSERVATORY LARGE CORONAGRAPH

Yuhong Fan, yfan@ucar.edu

National Center for Atmospheric Research, Boulder, Colorado, United States Sarah Gibson, sgibson@ucar.edu

NCAR, Boulder, Colorado, United States Steven Tomczyk, tomczyk@ucar.edu

High Altitude Observatory, NCAR, Boulder, United States

From a magnetohydrodynamic (MHD) simulation of the eruption of prominence hosting coronal flux rope, we carry out forward synthesis of the circular polarization signal V/I produced by the MHD model as measured by the proposed COronal Solar Magnetism Observatory (COSMO) Large Coronagraph (LC) and infer the line-of-sight magnetic field BLOS above the limb. With an aperture of 150 cm, integration time of 300 sec, and an observation pixel of 12 arcsec, the LC can measure a significant BLOS with sufficient signal to noise level, from the simulated flux rope with a peak azimuthal field strength of about 10 G. The measured BLOS is found to relate well with the axial field strength of the flux rope within the height range of the prominence, and can discern the increase with height of the magnetic field strength along the prominence that is a definitive signature of the concave upturning dipped field supporting the prominence. The measurement can also detect above the noise the outward rise of the BLOS due to the slow rise of the flux rope as it develops the kink instability, during the phase when its rise speed is still below 15 km/s and up to a height of about 1.25 solar radius. These results suggest that the COSMO LC has great potential in providing quantitative information about the magnetic field structure of CME precursors (such as prominences) and their early evolution for the onset of eruption.

E2.3-0020-18 THE PROBA-3 MISSION AND ITS CONTRIBUTION TO THE STUDIES OF THE MAGNETIC FIELD IN THE SOLAR CORONA

Andrei Zhukov, andrei.zhukov@sidc.be

Royal Observatory of Belgium, Brussels, Belgium the PROBA-3/ASPIICS team

D. Berghmans, B. Bourgoignie, L. Dolla, C. Jean, B. Nicula, S. Shestov, S. Fineschi, S. Gunar,

B. Inhester, P. Lamy, M. Mierla, E. M. Popescu, P. Rudawy, M. Steslicki, K. Tsinganos, C. Aime, A.Bemporad, W. Curdt, J. Davila, M. Druckmuller, P. Gallagher, S. Gibson, P. Heinzel,

R. Howard, A. Katsiyannis, S. Koutchmy, F. Landini, A. Paschalis, H. Peter, L. Rachmeler, P. Rochus, L. Rodriguez, M. Romoli, W. Schmutz, D. Seaton, S. Solanki, J. Zender, M. West, D. Galano, R. Rougeot, C. Thizy, C. Galy

PROBA-3 is the next ESA mission in the PROBA line of small technology demonstration satellites. PROBA-3, to be launched in 2020, is a mission dedicated to the in-flight demonstration of precise formation flying techniques and technologies. The PROBA-3 mission will place two small satellites in a highly elliptical orbit around the Earth. The two satellites will fly in a precise formation, producing a very long baseline solar coronagraph called ASPIICS (Association of Spacecraft for Polarimetric and Imaging Investigation of the Corona of the Sun). One spacecraft will carry the optical telescope, and the second spacecraft will carry the external occulter of the coronagraph. The inter-satellite distance of around 150 m will allow observing the inner corona close to the solar limb with very low straylight. The scientific objectives of PROBA-3 will be discussed. A particular emphasis will be put on the transition between the two physical regimes in the corona. The dynamics of the low corona is dominated by the magnetic field, and the dynamics of the high corona is dominated by the solar wind outflow. These two physically different regimes are typically observed respectively by soft X-ray/EUV imagers (Hinode/XRT, PROBA2/SWAP, SDO/AIA) and white-light externally occulted coronagraphs (SOHO/LASCO, STEREO/COR2). The transition between these two regimes is currently not well observed due to the gap between the observations of the low and high corona. It will be demonstrated that, due to its unique field of view and low straylight, PROBA-3/ASPIICS will provide a crucial information on the coronal magnetic field configuration. ASPIICS will allow tracking the connectivity of coronal structures to the solar surface and, in combination with state-of-the-art MHD models, allow us to determine reliably the large-scale coronal magnetic field configuration.

E2.3-0022-18 THE EFFECT OF MAGNETIC TONGUES IN THE DETERMINATION OF JOY'S LAW

Mariano Poisson, mpoisson@iafe.uba.ar IAFE, Buenos Aires, Argentina

Marcelo Lopez Fuentes, lopezf@iafe.uba.ar IAFE, Buenos Aires, Argentina

Cristina H. Mandrini, mandrini@iafe.uba.ar

Instituto de Astronomía y Física del Espacio, Buenos Aires, Argentina Pascal Demoulin, pascal.demoulin@obspm.fr

Observatoire de Paris, Meudon, France

We study the emergence of 186 bipolar active regions (ARs) to determine the relation between the tilt angle formed with respect to the E-W direction and the latitude of emergence. This relation, known as Joy's law, plays a fundamental role to test the ability of dynamo models to explain, among other things, the equatorial flux cancelation and the inversion of the poloidal magnetic field between solar cycles. The methods used in recent works to determine this law are based on the automatic computation of the tilt angle from line-of-sight (LOS) magnetograms (Stenflo Kosovichev 2012; Wang et al. 2015). However, since those results show a large dispersion, the precise latitudinal depedence on the tilt is still a topic of discussion. We consider that an important part of this dispersion can be due to the effect of the so called magnetic tongues. These are produced by the line of sight projection of the azimuthal magnetic field of the twisted emerging flux-tubes that form ARs. The tongues are observed in LOS magnetograms as an elongation of the magnetic polarities. In Poisson et al. (2016, Solar Phys., 291, 1625-1646) we showed that the magnetic tongues affect the photospheric field distribution observed in LOS magnetograms and, consequently, impact on the determination of the tilt angle. In this work we test a novel method to remove the effect of the tongues on the tilt angle determination and we quantify the effect of this correction on Joy's law. Furthermore, we study the relation of the latitudinal dependence of the corrected tilt with other AR properties such as the magnetic helicity sign, the hemisphere of emergence, and the sense of rotation of the bipoles.

E2.3-0023-18 SCALING LAWS OF TOMOGRAPHICALLY RECONSTRUCTED PHYSICAL PARAMETERS OF QUIET-SUN CORONAL LOOPS

Cecilia Mac Cormack, cmaccormack@iafe.uba.ar

Instituto de Astronomía y Física del Espacio (IAFE), Buenos Aires, Argentina Marcelo Lopez Fuentes, lopezf@iafe.uba.ar

IAFE, Buenos Aires, Argentina

Cristina H. Mandrini, mandrini@iafe.uba.ar

Instituto de Astronomía y Física del Espacio, Buenos Aires, Argentina Alberto Vásquez, albert@iafe.uba.ar

Instituto de Astronomía y Física del Espacio (IAFE), Buenos Aires, Argentina

The knowledge of the relation among different physical parameters of coronal magnetic loops allows us obtaining observational scaling laws to compare to those derived from theoretical coronal heating models. In previous works, theoretical scaling laws have been compared with observations of magnetic loops belonging to active regions (AR) (see Mandrini, Demoulin and Klimchuk 2000, ApJ, 530, 999). Since in the quiet-Sun corona loops are not directly observable the task is more difficult. In recent works, a technique called differential emission measure tomography (DEMT) was developed. This technique provides the three-dimensional distribution of the average temperature and density in the coronal volume from a series of observations from EUV telescopes throughout a solar rotation (see the review of Vasquez 2016, AdSpR, 57, 1286). The tomographic results are combined with magnetic field extrapolations to obtain average temperature and density of the plasma along the field lines. In this work, we study the scaling laws obtained from the analysis of parameters reconstructed tomographically for Carrington rotation 2081 (see Mac Cormack et al 2017, ApJ, 843, 70). We compare these scaling laws with the expected relations according to the most known models of coronal heating.

E2.3-0024-18 THREE-DIMENSIONAL STRUCTURE OF CORONAL STREAMERS OBSERVED BY SOHO/ LASCO AND STEREO/COR2

Bieke Decraemer, bieke.decraemer@oma.be

Royal Observatory of Belgium, Heverlee, Belgium Andrei Zhukov, andrei.zhukov@sidc.be

Royal Observatory of Belgium, Brussels, Belgium

Tom Van Doorsselaere, tom.vandoorsselaere@wis.kuleuven.be KU Leuven, Leuven, Belgium

Helmet streamers are a prominent manifestation of magnetic structures with current sheets in the Solar corona. These large-scale structures are regions with high plasma density, overlying coronal active regions. We investigate the 3D structure of coronal streamers, observed by white-light coronagraphs (SOHO/LASCO and STEREO/COR2). 3D reconstruction of coronal structures is often ambiguous. Inverse reconstructions are difficult, so we design a forward model based on plausible assumptions about the 3D streamer structure taken from previous physical models (a plasma sheet centered around a current sheet). The streamer stalk is approximated by a plasma sheet, with electron density that is characterized by three functions describing the radial, transverse and face-on profiles respectively. We simultaneously fit the observational data from SOHO and STEREO vantage points using a multivariate minimization algorithm. We demonstrate that our model can reasonably describe the observations.

E2.3-0025-18 RECONSTRUCTING NONLINEAR FORCE-FREE MAGNETIC FIELDS IN THE SOLAR CORONA

Sadollah Nasiri Gheydari, nasiri@iasbs.ac.ir Shahid Beheshti University, Tehran, Iran

It seems that the potential and linear force-free magnetic fields are inadequate to represent the observed magnetic events occurring in different regions of the solar corona. To reconstruct the nonlinear force-free fields from the solar surface magnetograms, various analytical and numerical methods have already been examined by different authors. Here, using the Lagrange multiplier technique, a new approach for reconstructing force-free magnetic fields is proposed. In the minimization procedure the solenoidal property is considered as a constraint on the initial nonforce-free field. It is shown that the Wheatland, Sturrock and Roumeliotis (2000) optimization method emerges as a special case of our approach. Other solutions are obtained and tested by the Low and Lou (1990) semi-analytic solution. During the iteration, the deviation of magnetic field from the solenoidal condition, caused by discretizing effect of the numerical solutions, is compensated by applying a divergence cleaning method to the updated magnetic field.

E2.3-0026-18 OPTIMUM MODULATION FOR CORONAL VECTOR FIELD MEASUREMENTS ON A SPACE BASED OBSERVATORY

Mohanakrishna Ranganath, mohankrishna@iisc.ac.in IISc, Bangalore, India

Sankarasubramanian Kasiviswanathan, sankark@isac.gov.in Indian Space Research Organization, Bengaluru, India

A vector magneto-graph of the coronal magnetic field provides insight into the orientation and strength of the field lines which in-turn helps in understanding the dynamics during events like CMEs and flares. There are several theoretical models on coronal field strength and their variation with solar activity and there have been indirect ways of measuring coronal field strength through models of non-linear force free field extrapolation to estimate upper chromosphere and coronal field strength from photospheric field. These results form the basis for expected field strength and estimates of 3-40 G from solar minima to maxima. Though statistical estimates of magnetic field using Stokes vector-V have been performed, the vector magnetic field measurements of the corona are yet to be done. As the corona is faint with weak fields, such measurements become extremely difficult for a ground based observatory while a higher SNR can be achieved using a space based observatory. Unlike a ground based instrument, a space based instrument has several constraints including mass, number of moving parts and shelf life of the components used in it. So for a typical vector magnetograph which consists of a spectrograph and a polarimeter, we chose a single crystal continuously rotating retarder as modulator and a pair of polarizing beam displacers as dual beam analyzer for the polarimeter unit.

We present a modulation scheme for the solar corona to measure the vector magnetic field of coronal loops. The design takes into account the crosstalk due to satellite jitter and minimizes the crosstalk from linear into weak circular polarization. A laboratory setup is made to verify the capabilities of the modulation scheme. Typical jitter of a low earth orbit satellite is recreated and linear to circular polarization crosstalk is measured. The results obtained from the experiments are comparable to the simulated crosstalk levels.

E2.3-0027-18 GALILEO SOLAR SPACE TELESCOPE MISSION: A CONCEPT FEASIBILITY STUDY

Luis Eduardo Antunes Vieira, luis.vieira@inpe.br

INPE - National Institute for Space Research, São José Dos Campos - SP, Brazil INPE/GSST

Alisson Dal Lago, Ana Paula Rabello, Antônio Lopes, Arcelio Louro, Braulio Albuquerque, Douglas Silva, Edson Miranda, Fabiano Sousa, Fátima Mattiello-Francisco, Felipe Tavares, Fernando Luis Guarnieri, Flavia Reis Cardoso Rojas, Franciele Carlesso, Gino Genaro, Graziela da Silva Savonov, Jenny Marcela Rodriguez, João Paulo Estevam de Souza, Joaquim Costa, Jognes Panasiewicz, José Cecatto, Ligia Alves da Silva, Livia Ribeiro Alves, Lucas Costa, Luis Eduardo Antunes Vieira, Luiz Angêlo Berni, Marcelo Sampaio,Maria José Barbosa,Mario Eugênio Saturno, Marlos Rochenbach, Mateus Aguiar, Miguel Carretero, Odim Mendes Jr.,Paulo Jauer, Renato H. F. Branco, Renato Dallaqua, Ricardo Toshiyuki Irita, Ronan Chagas,Sebastião Varotto, Sergio Andrade, Tardelli Stekel, Valentino Lau, Vitor M. Souza, Waldeir Amaral Vilela, Willer Gomes

Here we present the concept feasibility study of the Galileo Solar Space Telescope Mission (GSST Mission) proposed by the Space Geophysics Division (DIDGE) of the Brazilian's National Institute for Space Research (INPE). The study was conducted at the Space Missions Integrated Design Center (CPRIME - Centro de Projeto Integrado de Missões Espaciais) of INPE's Space System Division (DIDSE). The GSST shall contribute to the understanding of the evolution of the magnetic structure in the outer layers of the Sun and its influence on the Earth's space environment. The scientific observations requirements proposed for the mission include high spatial and temporal resolution observations. Those measurements involve observations of the magnetic structure of the photosphere and outer layers of the solar atmosphere through the solar cycle, observations of the variability of the total solar irradiance, and in situ observations of magnetic field and high energy particle fluxes within the Earth's magnetosphere. The concept feasibility study, which was carried out during the second half of 2017, included:

(a) the definition of the scientific objectives, requirements and restrictions of the mission; (b) the identification of the system drivers; (c) the definition of the candidate solutions for the system; (d) the conceptual design of the mission's architecture components, including the optical payloads; (e) the pointing accuracy analysis of the designed attitude control subsystem; (f) the simulation and verification of the mission operational concept; (g) the assessment of the ground segment required to fulfill the mission; (h) estimate of the schedule for the development of the mission; and (i) the risk analysis. The optical payload architecture, orbit and ground segment were identified as the main system drivers. The concept of two full disk telescopes and one high-resolution telescope for visible and ultraviolet spectropolarimetric observations have been the bases for the solution of the optical payload architecture selected for the scientific purposes. For optimizing the solar visibility and the data downlink, the study has considered two orbits as possible: a sun-synchronous Low Earth Orbit (LEO), and a Geosynchronous Orbit (GEO). Each solution implies an exclusive spacecraft layout development. We point out that the cost analysis is still preliminary due to the lack of a similar mission in INPE's portfolio. Finally, the limitations of the concept and future strategies to implement such mission in a challenging funding environment as the current Brazilian scenario shall be addressed.

E2.3-0028-18 A MAGNETOHYDRODYNAMIC RELAXATION METHOD FOR NON-FORCEFREE MAGNETIC FIELDS IN MAGNETOHYDROSTATIC EQUILIBRIA

Takahiro Miyoshi, miyoshi@sci.hiroshima-u.ac.jp Hiroshima University, Higashi-Hiroshima, Japan Kanya Kusano, kusano@nagoya-u.jp

Institute for Space-Earth Environmental Research, Nagoya University, Nagoya, Japan Satoshi Inoue, inosato@nagoya-u.jp

Nagoya University, Nagoya, Japan

Various activities in the solar atmosphere are caused by the Sun's magnetic field. In order to predict those activities, information on the three-dimensional magnetic field distribution is indispensable. The magnetic field, however, cannot be directly observed with high accuracy except for the vector magnetic field on the photosphere at present. Therefore, various methods reconstructing the magnetic field in the solar atmosphere from the two-dimensional magnetic field on the photosphere have been proposed so far.

In particular, using a nonlinear force-free (NLFF) magnetic field model, the coronal magnetic fields have been reconstructed well. However, since the plasma beta on the photosphere is larger than unity, the vector magnetic field on the photosphere is not force-free. The magnetic field in the chromosphere whose plasma beta is not small also deviates from NLFF in general. Therefore, in this paper, we propose a new magnetohydrodynamic (MHD) relaxation method to reconstruct non-force-free (NFF) magnetic fields in the solar atmosphere including both the chromosphere and the corona. The method solves an additional time evolution equation for a scalar field, pseudo-pressure, and converges the magnetic field to a magnetohydrostatic equilibrium field. Theoretical studies and numerical experiments show noteworthy properties of the present method.

E2.3-0029-18 MAGNETIC FLUX EMERGENCE TRIGGERED LIGHT BRIDGE BRIGHTENING AND RECONNECTION JETS

Xu Yang, xy88@njit.edu

New Jersey Institute of Technology, Big Bear City, California, United States Vasyl Yurchyshyn, vayur@bbso.njit.edu

Light bridges (LBs) are elongated, bright, granular structures that divide the umbra of a large and complex sunspot into two or more umbral regions with the same magnetic polarity. Surgelike activities are common phenomenon appear above the LBs which always accompanied by the magnetic flux emergence process. Former works tried to interpret the triggering mechanism for them, however they often lacked the support of high spatial and temporal resolution vector magnetic measurement. Our recent Observation shows a strong magnetic flux emergence happened at the edge of a filamentary Light Bridge (LB) and accompanied by brightness enhancement of photospheric granulations at the endpoints of the emerged magnetic structure. We study the origin and dynamics of this magnetic flux emergence event with high resolution Fe I 1.56 μm polarimetry magnetogram, TiO photosphere image and Hα chromosphere image from the Goode Solar Telescope. The emerged magnetic structure was 1.5 Mm 0.3 Mm in size at its peak time and lasted for 17 minutes. Doppler map detected upflows before its formation and downflows during the destruction. The magnetic orientation change was obtained by calculating the shear angle and plotting the magnetic field vectors. The result indicates that the new emerged more transverse magnetic field reconnected with the pre-existing more vertical field, which triggered the fan-shaped jets. The expanding fields at the endpoints due to the flux emergence pushed and compressed the existing granulations and led to their enhanced brightness.

E2.3-0030-18 ELLERMAN BOMBS VS. UV BURSTS

Cheng Fang, fangc@nju.edu.cn Nanjing University, Nanjing, China Jie Hong, hshongjie@126.com

School of Astronomy and Space Science, Nanjing University, Nanjing, China Mingde Ding, dmd@nju.edu.cn

Nanjing University of Information Science & Technology, Nanjing, China Zhen Li, lizhen@nju.edu.cn

Nanjing University, China

Ellerman bombs (EBs) are small brightening events in the solar lower atmosphere. Most authors found that the temperature increase of EBs around the temperature minimum region is in the range of 600K-3000K. With recent IRIS observations, people found UV brightening events called UV bursts or IRIS bombs. Some authors proposed that the temperature increase of EBs could be more than 10000K, and the UV bursts could, in some cases, related to EBs. Using non-LTE semi-empirical modeling, we investigate the line profiles, continuum emission and the radiative losses for the EBs, and compare them with observations. Our result indicates that if the EB maximum temperature attains more than 10000K around the temperature minimum region, then the resulted Hα and CaII 8542 Å line profiles and the continuum emission would be much stronger than that of EB observations. Moreover, due to the high radiative losses, the high temperature EB would have a very short lifetime, which is not comparable with the observations. Thus, our study does not support the proposal that the EB temperatures are higher than 10000K. Our non-LTE calculation also indicates that the UV bursts are not the same as the EBs. The former are probably at the higher layer of the solar atmosphere, while the latter are at the lower atmosphere with lower temperature.

E2.3-0031-18 SIMULATING THE SOLAR MINIMUM CORONA IN UV AND VISIBLE/IR WAVELENGTHS WITH FORWARD MODELING

Jie Zhao, zhaojie.pmo@gmail.com

Purple Mountain Observatory, Chinese Academy of Sciences, Nanjing, China Sarah Gibson, sgibson@ucar.edu

NCAR, Boulder, Colorado, United States Silvano Fineschi, fineschi@oato.inaf.it INAF, Pino Torinese, Torino, Italy Roberto Susino, sur@oact.inaf.it

INAF - Osservatorio Astronomico di Torino, Pino Torinese, Italy

The magnetic field in the corona is important for understanding solar activity, but is difficult to measure due to the tenuous plasma. Therefore many alternative methods have been adopted to get the 3D magnetic field in the corona, such as extrapolation methods relying on the photospheric magnetograms. Such extrapolations make problematic assumptions about the force-free nature of the photosphere, and are highly sensitive to uncertainties in the photosphere magnetic measurements. Measuring the coronal magnetic field directly is thus to be desired, and linear polarization measurements in the visible/IR are already obtained by the CoMP telescope providing information about coronal magnetic direction and topology. However other observations such as circlar polarization in the visible/IR and UV unsaturated Hanle measurements are needed to better observe the 3D coronal field. Until such observations are available, we turn to the FORWARD model (Gibson et al. 2016) which simulates all of these polarization data. As a physical state to input into FORWARD, the analytic magnetic model in this work is adopted from Gibson et al.(1996), which gives a potential field with an exception at the boundary of the helmet streamer where current sheets are added between the open and closed fields. This analytic model has the benifit of matching white light and also photospheric magnetic flux observations at solar minimum. Given this model input of a 3D distribution of magnetic field and plasma, we obtain simulated polarization results in UV and visible/IR wavelengths. This allows us to consider how such observations might be used together in future to diagnose the coronal magnetic field.

E2.3-0032-18 PROJECT OF A NEW 2.5M SOLAR TELESCOPE

Nanjing Institute of Astronomical Optics & Technology, Nanjing, China

A project of a 2.5m Solar Telescope has been worked out in China. It is the first facility in the world with a special innovation design and can conduct both high-resolution solar observations and the large-field of view (FOV) night survey. Its scientific objectives cover solar physics and time-domain astronomy, all of which are recent hot topics in astronomy. As a large onaxis solar telescope in the world with a larger FOV (7′) than all the large solar telescopes operating at present, it can provide unprecedented high-resolution solar imaging and magnetic field data, which can help us obtain breakthrough achievements on the study of solar active regions and solar eruptions. The data are also very useful for the study of space weather. As a large telescope in China, the telescope is very unique in continuously monitoring shorttime transient events by filling the gap in the specific time-zone. Moreover, the telescope can make essential contribution to training the graduate and undergraduate students majoring in observational astronomy.

E2.3-0033-18 PSEUDOSTREAMER TOPOLOGY REVEALED BY COMP OBSERVATIONS

IRAP - Institute of Research in Astrophysics and Planetology, Toulouse, France

Pseudostreamers represent sources of the solar wind whose properties are a subject of active investigation. Their magnetic structure, and particularly the expansion of magnetic flux tubes associated with them, is a matter of current debate. Pseudostreamers are associated with magnetic nulls, which are known to be locations prone to magnetic reconnection that potentially facilitate eruptions. A recent study demonstrated the novel constraints on pseudostreamer topology provided by coronal spectropolarimetry, in particular linear polarization measured by the Coronal Muiltichannel Polarimeter (CoMP) telescope at the Mauna Loa Solar Observatory. That study for the first time provided a method for determining magnetic expansion in the corona independent from any extrapolation or global MHD model representation of the coronal field. It found that this expansion factor was larger and the magnetic null was higher for a pseudostreamer observed by CoMP than expected from a potential field calculation. In this work we extend our analysis to additional observations of pseudostreamers made by CoMP, for which we identify the magnetic nulls and quantify expansion factor. Our goal is to understand if there are systematic differences between these observations and predictions of a potential field model.

E2.3-0034-18 SOLAR MAGNETIC FIELD OSCILLATIONS AND ACTIVITY ON A MILLENNIUM TIMESCALE DERIVED WITH PRINCIPAL COMPONENT ANALYSIS

Valentina Zharkova, valentina.zharkova@northumbria.ac.uk University of Northumbria, Newcastle Upon Tyne, United Kingdom Simon Shepherd, s.j.shepherd@bradford.ac.uk

University of Bradford, Bradford, United Kingdom Helen Popova, popovaelp@mail.ru

The Schmidt Institute of Physics of the Earth of the Russian Academy of Sciences (IPE RAS), Moscow, Russia

Sergei Zharkov, s.zharkov@hull.ac.uk University of Hull, Hull, United Kingdom

Applying Principal Components Analysis (PCA) to the full-disk synoptic maps of solar magnetic field variations obtained by Wilcox Solar Observatory in solar cycles 21-24 we derive 4 pairs of eigen values and eigen vectors (Zharkova et al, 2015) and analytical expressions as the sums of periodic sin and cosine functions for the first pair of eigen vectors (principal components). The analytical expression for the summary curve of the pair is applied for prediction of solar magnetic field variations in the two layers of the solar interior in the past three millennia. Extrapolation of the summary curve of PCs in the past 3000 years confirms the eight grand cycles of 350-400-years superimposed on 22 year-cycles caused by beating effect of the two dynamo waves generated by dipole magnetic sources in the two (deep and shallow) layers of the solar interior. The grand cycles in different periods comprise a different number of individual 22-year cycles. Furthermore, the summary curve reproduces a remarkable resemblance to the sunspot and terrestrial activity reported in the past: known grand minimaMaunder Minimum, Wolf minimum, Homer minimum and many other grand minima occurring every 350-400 years, a medieval warmth period and Roman warmth Period. Temporal variations of the dynamo waves are modelled for dipole sources with the two-layer mean dynamo model with meridional circulation. The addition of quadruple magnetic waves in the inner layer allowed us to recover Dalton minimum and the other minima of Gleissberg's centennial cycle (Popova et al, 2017). The modelled dynamo waves reveal a remarkable resemblance of the temporal variations and butterfly diagrams to those derived with PCA and predict the upcoming modern grand minimum in 2020-2055 (Zharkova et al, 2017). We expand our summary curve back to 100000 years to discover further periods of activity of 11000 years confirmed by the terrestrial data.

E2.3-0035-18 DATA-DRIVEN MODELING OF SOLAR CORONA/INNER HELIOSPHERE BY A 3D MHD MODEL

Xueshang Feng, fengx@spaceweather.ac.cn

National Space Science Center, Chinese Academy of Sciences, Beijing, China Fang Shen, fshen@spaceweather.ac.cn

State Key Laboratory of Space Weather,NSSC,CAS, Beijing, China

In this talk, the evolution of solar wind from the solar surface to the Earth's orbit during Year 2008 is simulated by a new three-dimensional (3D) magnetohydrodynamic (MHD) solar wind model. The time-dependent projected characteristic equations are used to updates the inner boundary conditions with high-cadence observed photospheric magnetic field data as input. The simulation results are analyzed and quantitatively evaluated by comparing model output with remote-sensing observation of the corona and in-situ observation at the Sun-Earth L1 point. The analysis demonstrates that our model reproduces the main pattern and the evolutionary feature of large scale coronal structures, including the shapes and distributions of the coronal holes, and the positions and shapes of helmet streamer and pseudostreamers. From the simulation result, we find that the height of the pseudostreamer X point is positively correlated with the distance of the coronal holes connected by the pseudostreamer. During Year 2008, the helmet streamer belt is found to have a net southward displacement from the equator while the pseudostreamer belts are biased to the northern hemisphere. Both helmet streamer belt and pseudostreamer belts exhibit a general trend of flattening towards the equator during most time of the year. The evaluation of the modeled results at L1 point shows that the general structures can be generated by the model, and the speed is the best among the solar wind parameters reproduced. However, the temperature of the fast solar wind and the magnitude of interplanetary magnetic field are underestimated. The success rate of prediction and arrival time error are also calculated for magnetic field polarity reversals and stream interaction regions.

E2.3-0036-18 DATA-OPTIMIZED CORONAL FIELD MODEL (DOC-FM): APPLICATION TO MAGNETIC FLUX ROPES

Solar flares and coronal mass ejections (CMEs) are driven by the 3D evolution of the magnetic field in the solar atmosphere. Knowing the 3D magnetic field prior to the trigger of these flaring events is a key feature for predicting their onset. Multiple data-constrained techniques have been developed to reconstruct the pre-eruptive, 3D coronal magnetic field from remotesensing measurements. One that exploits line-of-sight photospheric magnetograms and X-ray and EUV observations of coronal loops is the flux rope insertion method. In this poster, we use the flux rope from a 3D MHD simulation, forward modeling from the SolarSoft package FORWARD, and a recently developed optimization method, to show that coronal polarimetric measurements of forbidden infrared lines can be used to further constrain the parameters of the flux rope insertion method when reconstructing the pre-eruptive magnetic field of CMEs. This synthetic test bed is performed in the context of the Fe XIII 10747 A line observed by the Coronal Multichannel Polarimeter (CoMP) and installed at the Mauna Loa Solar Observatory. We discuss the perspectives offered by coronal polarimetric measurements of the Daniel K. Inouye Solar Telescope (DKIST) and the COronal Solar Magnetism Observatory (COSMO) project.

E2.3-0037-18 3D MODELLING OF MAGNETIC FIELD AND PLASMA STRUCTURE OF ENTIRE PROMINENCES

Stanislav Gunár, stanislav.gunar@asu.cas.cz

Astronomical Institute, Academy of Sciences of the Czech Republic, Ondrejov, Czech Republic Duncan Mackay, dhm@st-and.ac.uk

University of St Andrews, 8HB, United Kingdom Petr Heinzel, pheinzel@asu.cas.cz

Astronomical Institute, Academy of Sciences, Ondrejov, Czech Republic Ulrich Anzer, ula@mpa-garching.mpg.de

Max Planck Institute for Astrophysics, Garching, Germany

The 3D Whole-Prominence Fine Structure (WPFS) model allows us for the first time to simulate entire prominences/filaments including their numerous fine structures. This model combines a 3D magnetic field configuration of an entire prominence obtained from non-linear force-free field simulations, with a detailed description of the prominence plasma. The plasma is located in magnetic dips in hydrostatic equilibrium and is distributed along hundreds of fine structures within the 3D magnetic model. The prominence plasma has realistic density and temperature distributions including the prominence-corona transition region. This allows us to produce synthetic H-alpha images of simulated prominences both in emission on the solar limb and in absorption against the solar disk (viewed as filaments) using a single model.

Such 3D WPFS model provides us with consistent information about the prominence magnetic field configuration, prominence fine structure plasma and its radiative output. Moreover, we are able to follow the evolution of modeled prominences caused by changes of the underlying photospheric magnetic flux distribution. Thanks to these capabilities we can study links between the photospheric flux distribution, prominence magnetic field configuration, distribution and composition of the prominence plasma and its observable signatures. These relationships are important for interpretation of the observed imaging and spectral/spectropolarimetric data and for inference of the properties of the prominence magnetic field.

Direct measurement of the polarized spectra of forbidden coronal emission lines (CELs) is the most powerful tool for the study of the solar coronal magnetic fields. Due to its low optical density, simultaneous multi-sight-lines observations of the corona from space are needed for tomographic inversion to disentangle the 3D structure of the solar corona. This presentation will describe the mission concept and instrument design of a future space coronal magnetometry mission, consists of many clusters of small spacecraft in near-sun heliocentric orbits to observe the sun to enable tomographic determination of the 3D magnetic and thermodynamic structures of the corona. The spacecraft will be equipped with a wide field, super achromatic lens coronagraph equipped with two 100-slit, 4-channel spectropolarimeters optimized for measurement of the polarized CEL spectra from space. This instrument is tentatively named 'mxCSM'- the massively-multiplexed Coronal SpectroMagnetometer. A prototype mxCSM is currently under construction with funding from a 2017 National Science Foundation Major Research Instrument program grant. This space coronal space magnetometry mission will advance our knowledge of the corona and the physics of energetic coronal eruptions, and ultimately enable accurate space weather forecast.

E2.3-0039-18 OBSERVATION ON CURRENT AND HELICITY FROM PHOTOSPHERIC VECTOR MAGNETOGRAM IN SOLAR ACTIVE REGIONS

Yu Gao, gy@bao.ac.cn

National Astronomical Observatories, Chinese Academy of Sciences, Beijing, China

A review of observation on electric current and current helicity in solar active regions by applying the photospheric vector magnetograms will be presented. A part is concerned with the statistical observation of net electric current in the region of isolated polarity. Another part is about the evolution of the variation of electric current, with some comparison with the corresponding time series of GOES X-ray flux.

E2.3-0040-18 MAGNETICALLY INDUCED CURRENT PISTON FOR GENERATING EXTREMEULTRAVIOLET FRONTS IN THE SOLAR CORONA

California Institute of Technology, Pasadena, California, United States

EUV waves, also called EIT waves, were first observed in 1995 by the Extreme-ultraviolet Imaging Telescope (EIT). These ‘waves’ are single-pulse, globally-propagating coronal fronts and their physical mechanism has been a subject for debate for two decades. Two distinct types of theories have been used to describe EUV waves, depending on the presumed driving mechanism: wave or pseudo-wave. We propose a hybrid model where EUV waves are compressional fronts driven by a reverse electric current layer induced from the coronal mass ejections (CMEs). The CMEs are considered as erupting flux ropes that induce the layer of electrical current. The reverse electric current layer, flowing in the opposite direction with respect to the current in the driving CME, is an eddy current layer that is necessary to maintain magnetic flux conservation in the coronal regions above the layer. The opposing CME and reverse currents mutually repel via magnetic forces with the result that the moving induced reverse current layer acts as a piston that drives a compressional perturbation in the coronal regions above the layer. Given a sufficiently fast initial speed of the driving layer, the compressional perturbation becomes a shock that separates from the driving layer when the driving layer later slows down. Since the model relates the motion of the EUV front to CME properties, the model can provide a bound on the internal current of the erupting flux rope. This model is supported and motivated by detailed results from 3D ideal magnetohydrodynamics (MHD) simulations and from laboratory experiments.

E2.3-0042-18 MULTIFRACTAL DETRENDED FLUCTUATION ANALYSIS OF SOLAR WIND PARAMETERS DURING SOLAR CYCLE 23

Satish Kumar Kasde, sbskasde@gmail.com Barkatullah University, Bhopal, India

Deepak Kumar Sondhiya, deepsondhiya@gmail.com

Lakshmi Narain College of Technology and Science, Bhopal, India, Bhopal, India Ashok Kumar Gwal, ashok.gwal@gmail.com

Rabindranath Tagore University, Raisen, India

Multifractal analysis based approaches have been recently developed as an alternative framework to study the complex dynamical fluctuations in solar wind plasma. To reveal the multifractal characteristics of solar wind plasma parameters (i.e. temperature, density and speed) from January 1996 to December 2006 (Solar Cycle 23) are analyzed using wavelet based Multifractal Detrended Fluctuation Analysis (MFDFA) technique. MFDFA allows a reliable characterization of multifractal characterization of solar wind plasma parameters. Multifractality in solar wind plasma generate turbulence, which govern various anomalous processes in magnetosphere and interior of Sun. MFDFA analysis provide direct supporting evidence that the solar wind plasma parameters have multifractal structure. Keywords: Solar Wind Plasma Parameters, Magnetic field, Multifractal analysis and wavelet Transform Technique.

E4.1-0001-18 EARLY RESULTS FROM THE TRANSITING EXOPLANET SURVEY SATELLITE (TESS)

George Ricker, grr@space.mit.edu

Massachusetts Institute of Technology, Cambridge, Massachusetts, United States

TESS Science Team

The Transiting Exoplanet Survey Satellite (TESS) will discover thousands of exoplanets in orbit around the brightest stars in the sky. In a two-year survey, TESS will monitor 200,000 pre-selected bright stars for planetary transits in the solar neighborhood at a 2-minute cadence. The survey will identify planets ranging from Earth-sized to gas giants, around a wide range of stellar types and orbital distances. TESS will also provide full frame images (FFI) at a cadence of 30 minutes or less. These FFI will provide precise photometric information for every object within the 2300 square degree instantaneous field of view of the TESS cameras. In total, more than 30 million stars and galaxies brighter than magnitude I=16 will be precisely photometered during the two-year prime mission. In principle, the lunar-resonant TESS orbit will provide opportunities for an extended mission lasting more than a decade, with data rates of 100 Mbits/s.

An extended survey by TESS of regions surrounding the North and South Ecliptic Poles will provide prime exoplanet targets for characterization with the James Webb Space Telescope, as well as other large ground-based and space-based telescopes of the future. The TESS legacy will be a catalog of the nearest and brightest main-sequence stars hosting transiting exoplanets, which should long endure as the most favorable targets for detailed future investigations.

The launch as a NASA Astrophysics Explorer is to take place in April 2018 from Cape Canaveral on a SpaceX Falcon 9 rocket. First light results from the TESS mission will be presented.

E4.1-0002-18 EXOPLANET SCIENCE WITH A NANOSAT: DEVELOPMENT, OPERATION, AND FIRST RESULTS OF THE PICSAT FIBERED PHOTOMETER

Mathias Nowak, mathias.nowak@obspm.fr Observatoire de Paris, Meudon, France Sylvestre Lacour, sylvestre.lacour@obspm.fr Observatoire de Paris, Meudon, France Vincent Lapeyrere, vincent.lapeyrere@obspm.fr Observatoire de Paris, Meudon, France Antoine Crouzier, antoine.crouzier@obspm.fr Observatoire de Paris, Meudon, France

Lester David, lester.david@obspm.fr Observatoire de Paris, Meudon, France

PicSat is a nanosatellite developed to observe the transit of the giant planet β Pictoris b, expected in 2018. The science objectives of the mission are: the observation of the transit of the giant planet's Hill sphere, the detection of exocomets in the system, and the fine monitoring of the circumstellar disk inhomogeneities.

Developping a payload to address these ambitious objectives with the specific constraints imposed by a nanosatellite platform is a challenge. The PicSat payload is based on a single mode optical fiber, which is used as spatial filter. This alleviates the need for a bulky baffle to protect the detector from contamination by scattered light. In this unique concept, the starlight is collected by a small aperture telescope, directly injected into the single-mode fiber, and brought to a temperature-regulated single-pixel avalanche photodiode. The stability of the light injection into the optical fiber is ensured by a fine pointing system based on a two-axis piezoelectric actuation system, driven by a taylor-made tracking alorithm. Overall, the system weights about 2 kg, and fits in a single CubeSat unit.

The PicSat nanosatellite is a 3 unit CubeSat platform, design to carry this ambitious payload. It was launched on the Indian PSLV-C40, in January 2018. The payload is currently (Feb. 2018) being commissionned.

This presentation will be focused on the ambitious opto-mechanical payload of the PicSat mission, and its science case. We will present the general concept of the fibered photometer, and show how a science instrument can be designed to fit on a small Cubesat platform, without sacrificing its science case. We will also present the results of the first months of flight of this instrument. Operating an astrophysical payload in the frame of a small Cubesat project comes with its own challenges, and we will give our return of experience on this.

E4.1-0003-18 PLANET IMAGING CORONAGRAPH TELESCOPE USING A REUSABLE EXPERIMENT FOR JUPITER (PICTURE-J): A HIGH ALTITUDE BALLOON EXPERIMENT TO DIRECTLY IMAGE EXO-JUPITERS

Supriya Chakrabarti, supriya_chakrabarti@uml.edu

University of Massachusetts Lowell, Lowell, Massachusetts, United States PICTURE-J

Supriya Chakrabarti Christopher Mendillo Jason Martel Garreth Ruane Dimitri Mawet Nikole Lewis Chris Stark Marc Kuchner Karl Stapefeldt Marrk Swain Eugene Serabyn David Stuchlik Ronal Polidan Gerry Rafanelli

We describe a research program consisting of two high-altitude balloon flights that will culminate in the first direct image of an exo-Jupiter in the visible band and at a distance of 1 AU from the parent star. In addition, it will also obtain a moderate resolution spectra of the observed planetary systems. The Planet Imaging Coronagraph Telescope Using a Reusable Experiment for Jupiter (PICTURE-J) will accomplish these tasks with a telescope that uses a non-circular primary mirror and a state-of-the-art coronagraph aboard the the Wallops Arc Second Pointer (WASP) platform. PICTURE-J takes the next logical step to the ultimate goals of exoplanetary studies - characterizing Earth-like exoplanets in solar system like systems and will serve as a pathfinder for these upcoming flagship missions.

E4.1-0004-18 ASTERIA: A CUBESAT ENABLING HIGH PRECISION PHOTOMETRY IN A SMALL PACKAGE

Mary Knapp, mknapp@mit.edu

Massachusetts Institute of Technology, Cambridge, Massachusetts, United States Sara Seager, seager@mit.edu

Massachusetts Institute of Technology, Cambridge, Massachusetts, United States ASTERIA Team

Matthew W. Smith Christopher Pong Amanda Donner Brian Campuzano Peter DiPasquale Colin Smith Joel Krajewski Mary White

ASTERIA (Arcsecond Space Telescope Enabling Research In Astrophysics) is a 6U CubeSat that advances the state of the art in nanosatellite capabilities for astrophysical measurements. The 6U CubeSat (approximately 10 x 20 x 30 cm, 10 kg) was deployed from the International Space Station (ISS) in November 2017 and has completed its nominal 90-day mission. ASTERIA's objective was to demonstrate enabling technologies for high precision photometry in a CubeSat form factor. Specifically, ASTERIA demonstrated arcsecond-level line-of-sight pointing stability and repeatability and highly stable milliKelvin-level focal plane thermal control.

Light spot motion over detector pixels can cause variations in measured stellar flux since both the between-pixel (interpixel) and within-pixel (intrapixel) responses vary across the detector. ASTERIA's pointing control is achieved through a two-stage approach. A set of reaction wheels provides coarse three-axis control of the spacecraft body, holding an inertial attitude that points the payload to a target star. Within the payload, a two-axis piezoelectric stage provides an additional level of fine control by making small, rapid adjustments to the detector position to keep the target star stationary.

The second technology demonstrated by ASTERIA is milliKelvin-level temperature stability of the imaging detector. The gain of each pixel is temperature sensitive, so tight thermal control reduces instrumental photometric variation that could otherwise be mistaken as an astrophysical signal. Precision thermal control is achieved by isolating the payload from the spacecraft bus and passively cooling the detector using a space-facing radiative surface. Thermal sensors and trim heaters located on the detector then act in closed loop to perform small temperature corrections over the course of an observation, maintaining stability to the required precision.

ASTERIA's design, operations, and technology demonstration results from the 90-day nominal mission will be described in this talk. I will also describe the photometric precision ASTERIA achieved for stars with known exoplanets. Finally, I will compare the photometric precision obtained with and without ASTERIA's fine pointing and thermal control systems active to highlight the value of these technologies for future small space telescopes.

E4.1-0005-18 THE CHEOPS MISSION - RATIONALE AND STATUS

Christopher Broeg, broeg@space.unibe.ch University of Bern, Bern, Switzerland Willy Benz, wbenz@space.unibe.ch University of Bern, Berne, Switzerland

Andrea Fortier, andrea.fortier@space.unibe.ch University of Bern, Bern, Switzerland CHEOPS

Alibert Yann, Alonso Roi, Barczy Tamas, Barrado y Navascues David, Barros Susana, Baumjohann Wolfgang, Beck Mathias, Benz Willy, Bonfils Xavier, Brandeker Alexis, Broeg Christopher, Cabrera Juan, Cameron Andrew Collier, Charnoz Sébastien, Davies Melvyn, Deleuil Magali, Demangeon Olivier, Demory Brice-Olivier, Ehrenreich David, Enric, Pallé, Erikson Anders, Fortier Andrea, Fossati Luca, Fridlund Malcolm, Gandolfi Davide, Gillon Michaël, Güdel Manuel, Gutierrez Antonio, Heng Kevin, Ignasi Ribas, Kiss Laszlo, Laskar Jacques, Lecavelier des Etangs Alain, Lendl Monika, Lovis Christophe, Maxted Pierre, Muñoz Antonio García, Nascimenti Valerio, Nicholas Walton, Olofsson Göran, Pagano Isabella, Piotto Giampaolo, Pollacco Don, Queloz Didier, Ragazzoni Roberto, Rauer Heike, Renotte Etienne, Ribas Ignasi, Santos Nuno C., Scandariato Gaetano, Ségransan Damien, Simon Attila, Smith Alexis M. S., Sousa Sérgio, Steller Manfred, Szabó Gyula, Thomas Nicolas, Udry Stéphane, Van Grootel Valérie

The CHaracterising ExOPlanet Satellite (CHEOPS) is a mission jointly led by Switzerland and ESA which was selected in October 2012 as the first small-class mission in the ESA Science Programme. CHEOPS will be the first space observatory dedicated to search for transits of exoplanets by means of ultrahigh precision photometry on bright stars already known to host planets. The CHEOPS telescope will have access to more than 70% of the sky, which will provide the unique capability of determining accurate radii for planets for which the mass has already been estimated from ground-based spectroscopic surveys. This, in turn, will allow a first order characterisation of the planets' internal structure (i.e. the determination of the mean density, which provides direct insights into its composition). CHEOPS will also provide precise radii for new planets discovered by the next generation of groundor space-based transits surveys. To reach its goals, CHEOPS is designed to measure photometric signals with a precision of 20 ppm in 6 hours of integration time for a 9th magnitude star and 85 ppm in 3 hours of integration for a 12th magnitude star. The CHEOPS payload consists in a single instrument, a space telescope of 30 cm clear aperture, which has a single CCD focal plane detector. The optical configuration consists of a Ritchey-Chrétien telescope, which provides a defocussed image of the target star on the focal plane. The main design drivers are related to the compactness of the optical system and to the capability to reject the stray light. The nominal CHEOPS operational orbit is a polar Sun-synchronous orbit (SSO) with an altitude of 700 km and a local time of the ascending node (LTAN) of 6 am; the orbit inclination is about 98° and the orbital period is 100 min. The nominal mission lifetime is 3.5 years, with a possible extension to a total of 5 years enabled by appropriate sizing of the consumables budget. The target launch date is end of 2018. With the launch coming up in less than a year, the instrument is already fully assembled and tested and the final steps for its delivery to the spacecraft premises are ongoing. This paper will review the scientific goals of the mission in combination with the expected performance of the instrument, the latter derived from the latest measurements taken during the calibration campaign.

E4.1-0006-18 CHEOPS SCIENTIFIC OPERATIONS - INSIGHT INTO TIME-CRITICAL OBSERVATIONS SCHEDULING

Nicolas Billot, nicolas.billot@unige.ch University of Geneva, Versoix, Switzerland CHEOPS SOC Team

M. Beck, R. Rohlfs, A. Bekkelien, D. Futyan, H. Machin, M. Meharga, M. Deleuil, S. Hoyer, P. Guterman, S. Sousa, J.-C. Meunier, G. Kovacs, F. George, G. Olofsson, H.-G. Floren, F. Verrecchia, A. Brandeker, P. Loeschl, A. Gutierrez, K. Isaak, C. Broeg, A. Fortier, D. Ehrenreich,

D. Queloz, W. Benz.

A partnership between Switzerland and the Science Programme of the European Space Agency (ESA), the CHaracterising ExOplanet Satellite (CHEOPS) is ESA's first mission of the recently created S-Class type. CHEOPS will be launch-ready by the end of 2018, and it will be launched from Kourou's spaceport as co-passenger on-board a Soyuz rocket.

With its effective mirror size of 30 cm and its remarkable photometric precision of 20 ppm (over 6 hours), CHEOPS will be able to measure the bulk density of exoplanets known to transit bright host stars (Vmag = 6-12), thus providing suitable targets for spectroscopic follow-ups with spaceor ground-based observatories like e.g. the JWST or the E-ELT.

The CHEOPS Mission Consortium, under the leadership of the University of Bern, holds 80% of the observing time, with the remaining 20% being opened to the international community through ESA yearly Announcements of Opportunities (AO). The ESA AO is foreseen for summer 2018, and, by the time of the COSPAR meeting, the Guaranteed Time observing program will have been consolidated already.

Unlike other larger ESA missions, the development and operation of the CHEOPS Mission Operations Centre (MOC) and the Science Operations Centre (SOC) are under the responsibility of the Mission Consortium. The University of Geneva is hosting the SOC, where we will run science operations, including the phase-2 submission proposal handling, the mission planning, and the data processing, archiving and dissemination activities. The SOC will deliver scienceready data products through the CHEOPS archive, and all proprietary data will become public one year after their observation for the wider community to access.

In this contribution, we will present the CHEOPS Science Operations concept and its implementation at the Geneva Observatory. We will present all SOC activities, and in particular the challenging task of optimising the schedule of hundreds of time-critical observations making use of genetic algorithms.

E4.1-0007-18 THE COLORADO ULTRAVIOLET TRANSIT EXPERIMENT (CUTE): A NASA CUBESAT MISSION TO STUDY ATMOSPHERIC MASS-LOSS AND MAGNETIC FIELDS IN EXTREME EXOPLANETARY SYSTEMS

Kevin France, kevin.france@colorado.edu

University of Colorado Boulder, Boulder, Colorado, United States CUTE

Kevin France, Luca Fossati, Brian Fleming, Arika Egan

The Colorado Ultraviolet Transit Experiment (CUTE) is NASA-supported 6U CubeSat mission designed to characterize the interaction between exoplanetary atmospheres and their host stars. CUTE will search for: 1) enhanced transit absorption in atomic, molecular, and continuum tracers at NUV wavelengths (255 - 330 nm) and 2) evidence of transit asymmetries due to bow shocks ahead of the planet's orbital motion or trailing "tails". This dataset will provide an unprecedented look at the mass-loss mass-loss, which is key to our understanding of planetary evolution, and, potentially, magnetic properties of the most extreme exoplanetary systems. CUTE will observe 6 - 10 transits of 12 primary targets during a nominal seven-month science mission. The CUTE science mission is enabled by the dedicated mission architecture, an optical system employing a novel rectangular primary Cassegrain telescope, and a compact spectrograph. The system obtains a projected effective area of > 25cm^2 over the entire science band pass and a peak resolving power of R 3000. This talk will provide a summary of the CUTE science motivation, an overview of the instrument and spacecraft design, and a status update ahead of our planned 2020 launch date.

E4.1-0008-18 GLUV - A HIGH-CADENCE HIGH-ALTITUDE UV SURVEY

Brad Tucker, brad@mso.anu.edu.au

Australian National University, Weston Creek, ACT, Australia GLUV

Brad Tucker, Rob Sharp, Jamie Gilbert, Ryan Ridden-Harper

GLUV is a 30cm ultraviolet survey telescope under development at ANU (Sharp et al. 2016) for a high altitude balloon platform. It will feature a 7 deg2 field of view and a limiting magnitude in near-UV of 22. The system is expected to fly in 2019 and build towards a constellation of telescopes flying in observation campaigns. GLUV will fly in campaigns with some campaigns being dedicated to provide high-cadence transients of exoplanets discovered by other sources (Kepler, TESS, etc) but in the UV.

E4.1-0009-18 FINDING AND CHARACTERIZING EXOPLANETS WITH THE JAMES WEBB SPACE TELESCOPE (JWST)

Charles Beichman, chas@ipac.caltech.edu

California Institute of Technology, Pasadena, California, United States

Charles Beichman (IPAC/NASA Exoplanet Science Institute), Natalie Batalha (NASA Ames Research Center), Elodie Choquet (Jet Propulsion Laboratory), Camilla Danielski (Observatoire de Meudon), Andras Gaspar (University of Arizona), Tom Greene (NASA Ames Research Center), Sasha Hinkley (University of Exeter), Klaus Hodapp (University of Hawaii), David Lafrenière (Université de Montreal), Pierre-Olivier Lagage (CEA, Saclay), Jarron Leisenring (University of Arizona), Laurent Pueyo (Space Telescope Institute), Everett Schlawin (University of Arizona), Josh Schlieder (NASA Goddard Research Center), Gene Serabyn (Jet Propulsion Laboratory) and Marie Ygouf (IPAC/NASA Exoplanet Science Institute)

The large diameter, low thermal background and broad suite of instruments will make the James Webb Space Telescope (JWST) the premier observatory for the characterization of exoplanets and, in some cases, for their discovery. Transit spectroscopy covering the 0.6 to 28 um range at resolutions varying from a few to few thousand will revolutionize the study of the atmospheric composition and physical properties of planets ranging from Hot Jupiters to temperate Super Earths like those discovered orbiting the nearby M dwarf Trappist-1. Coronagraphic and spectroscopic observations will target young Jupiter-mass planets to characterize their properties as well as to search for new planets with masses as low as that of Saturn or even Uranus. Coronagraphic observations will also study the debris disks associated with planets, studying their morphology and composition as well as looking for planets which might be responsible for structures such as rings, gaps and spiral arms. In addition to highlighting the Cycle 1 programs from the Guaranteed Time Observers and Early Release Science investigations, we will discuss some of the dramatic discoveries JWST might make as it achieves its full potential in the years after launch.

E4.1-0010-18 TWINKLE - A LOW-EARTH ORBIT VISIBLE AND INFRARED EXOPLANET SPECTROSCOPY OBSERVATORY

Max Joshua, max@blueskiesspace.co.uk

Blue Skies Space Ltd., London, United Kingdom Giovanna Tinetti, g.tinetti@ucl.ac.uk

University College London, London, United Kingdom Marcell Tessenyi, m.tessenyi@ucl.ac.uk

University College London, London, United Kingdom Giorgio Savini, g.savini@ucl.ac.uk

University College London, London, United Kingdom Jonathan Tennyson, j.tennyson@ucl.ac.uk

University College London, London, United Kingdom

Twinkle is a small, dedicated satellite that has been conceived to measure the atmospheric composition of exoplanets. This cost-effective spacecraft is being constructed on a short timescale in the UK and is planned for launch in early 2021. The satellite uses an existing platform designed by Surrey Satellite Technology Ltd. and instrumentation built by a consortium of UK institutes. Twinkle will carry a 45cm telescope with two instruments (visible and near-IR spectrographs - between 0.4 and 4.5μm with resolving power up to R=300) and will follow a Sun-synchronous low-Earth polar orbit. The mission implementation is based upon a commercial delivery approach that has been successfully applied in other demanding space disciplines by the satellite platform supplier.

Twinkle's science cases include observations of transiting exoplanets and of solar system objects. Twinkle will use visible and infrared spectroscopy to analyse the chemical composition and weather of at least 100 exoplanets in the Milky Way, including super-Earths (rocky planets 1-10 times the mass of Earth), Neptunes, sub-Neptunes and gas giants like Jupiter. It will also be capable of follow-up photometric observations of 1000+ exoplanets. The exoplanet targets observed by Twinkle will be composed of known exoplanets discovered by existing and upcoming groundand space-based surveys (e.g. K2, GAIA, Cheops, TESS). Solar system objects ideally suited for spectroscopic and photometric observations with Twinkle include asteroids and comet comae - Twinkle's broad wavelength range will allow the observation of key hydration, organic and volatile features in their spectra.

E4.1-0011-18 COMPLETING AN EXOPLANET CENSUS WITH THE WFIRST EXOPLANET MICROLENSING SURVEY

David Bennett, david.bennett@nasa.gov NASA/GSFC/CRESST/ UMCP, Greenbelt, Maryland, United States WFIRST Microlensing Science Investigation Team

Scott Gaudi, David Bennett, Jay Anderson, Chas Beichman, Andrea Bellini, Aparna Bhattacharya, Valerio Bozza, Geoffrey Bryden, Sebastiano Calchi Novati, Sean Carey, Andrew Gould, Cheongho Han, Calen Henderson, Davy Kirkpatrick, David Nataf, Matthew Penny, Radek Poleski, Kailash Sahu, Yossi Shvartzvald, Keivan Stassun, Rachel Street, Takahiro Sumi, Daisuke Suzuki, and Jennifer Yee

The process of planet formation is far too complicated to calculate from first principles, which implies that our understanding of planet formation is largely dependent on observations that reveal the details of exoplanet systems and proto-planetary disks. Kepler has made the first step toward obtaining a statistical census of exoplanets of all sizes with its study of planets in short period orbits (1 year or less). WFIRST's exoplanet microlensing survey will complete this statistical census with sensitivity to planets in orbits down to the mass of Mars with orbital periods of 1 year more more, as well as unbound planets that have been ejected from the planetary systems of their birth. We expect that this planetary census will reveal important insights into planet formation scenarios that can produce habitable planets. We also briefly summarize some of the challenges to planet formation theory posed by recent ground-based microlensing results.

E4.1-0012-18 WFIRST CORONAGRAPH INSTRUMENT FOR EXOPLANET IMAGING AND CHARACTERIZATION

Margaret Frerking, margaret.a.frerking@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

The Wide-Field Infrared Survey Telescope (WFIRST) is a NASA observatory designed to perform wide-field imaging, slitless spectroscopic surveys of galaxies and supernovae for dark energy, and microlensing surveys to look for distant exoplanets in our galaxy. The use of an existing 2.4 m telescope enables the addition of the Coronagraph Instrument (CGI) for direct imaging and spectroscopy of nearby giant exoplanets and imaging of circumstellar debris disks. The CGI serves as a technology pathfinder for future exoplanet missions capable of detecting bio-signatures in Earth-like exoplanet atmospheres.

For more than 20 years, NASA has been studying coronagraph missions that could detect and characterize exoplanets. In addition, NASA's technology programs have resulted in the steady progress of coronagraph technology development in the laboratory. Direct imaging of exoplanets in reflected light requires 100 million to billions of times suppression of starlight because exoplanets are much fainter than their host stars and lie at small angular separations (typically much less than 1 arc second). The WFIRST CGI baseline design contains two types of coronagraphs, the Hybrid Lyot Coronagraph (HLC) and the Shaped Pupil Coronagraph (SPC), to suppress diffracted starlight. Nearly noiseless, photon-counting EMCCD detectors measure the faint signal from the planets. The angular resolution is determined by the diameter of the telescope.

Two of the largest challenges in coronagraphy are diffraction from the instrument aperture and wavefront errors in the optical beam train. The CGI employs active optics - actuated, highdensity deformable mirrors, a focus control mechanism, and a fast steering mechanism - to attain and maintain extremely high starlight suppression, allowing imaging and spectroscopy of exoplanets in visible light. These mechanisms, along with their control algorithms, correct both static and dynamic wavefront errors.

Most previous coronagraph design and technology development were based on unobscured monolithic telescopes; WFIRST's contributed 2.4 m aperture, however, is obscured aperture by a secondary mirror supported with 6 struts. The CGI's coronagraphs have been designed to accommodate the contributed, obscured aperture. Integrated modeling simulations of the CGI have been validated on a vacuum testbed to within a factor of 2. These validated models allow further optimization of the coronagraph designs.

The CGI consists of a stable structure supporting the optical bench, the electronics, and thermal control elements. It incorporates mechanisms to select a set of masks and filters to configure either a HLC or a SPC, optimized for direct imaging in two photometric bands or for spectroscopy with the integral field spectrograph. High order wavefront sensing with the imaging sensor is used to achieve the initial starlight suppression with the deformable mirrors. A low order wavefront sensor is used to sustain the starlight suppression in the presence of jitter and thermal drift via control of the deformable mirrors, focus correction mirror, and fast steering mirror.

In this presentation we give a detailed overview of the CGI design. Requirements and expected performance will be presented.

E4.1-0013-18 THE PLATO SPACE MISSION: REVEALING HABITABLE WORLDS

Ana M. Heras, ana.heras@esa.int ESA/ESTEC, Noordwijk, Netherlands Heike Rauer, heike.rauer@dlr.de

Institut für Planetenforschung, Berlin, Germany Don Pollacco, d.pollacco@warwick.ac.uk University of Warwick, Coventry, United Kingdom

PLATO is the third medium-class mission in ESA's Cosmic Vision programme. PLATO will combine the detection and characterisation of exoplanets with the study of their host stars, focusing on terrestrial planets orbiting in the habitable zone of solar-like stars. Thanks to the brightness of its core targets ($V < 11$), PLATO will allow us to determine the planetary bulk properties (mass, radius, mean density) and age with unprecedented precision. To achieve this, the satellite will carry out long-duration photometric observations to detect planetary transits and perform asteroseismology analysis of the host stars. The planets masses will be determined through radial velocities measurements at ground-based observatories, which, for the core targets, will be organised through an ESA coordinated programme. Moreover, the precision of PLATO will allow us to address a variety of additional exoplanet topics, like circumbinary planets, exo-moons, rings, misaligned planets or planets around young and evolved stars. For statistical studies, the PLATO stellar samples will extend to fainter targets ($V < 13$). To benefit from PLATO's photometric capabilities in other areas of astronomy, a guest observers programme will be set up in which the general community will be invited to submit proposals on complementary science topics. The PLATO payload consists of four groups of six cameras each, pointing at different directions of the sky with overlapping regions, and covering a total field of about 2230 deg2. Two additional cameras equipped with frame transfer CCD detectors will observe the brightest stars and act as fine guidance sensor. The satellite is planned to be launched in 2026 and operate in an orbit around the L2 Lagrangian point.

E4.1-0014-18 EFFORTS OF INDIAN CENTRE FOR SPACE PHYSICS FOR SEARCHING EXOPLANETS

Sandip Kumar Chakrabarti, chakraba@bose.res.in

Indian Centre for Space Physics, Kolkata, India

The Ionospheric and Earthquake Research Centre and Optical Observatories (IERCOO; 22.51N, 87.786E) under Indian Centre for Space Physics has two dedicated telescopes: A CDK24, a 24inch reflector from Planewave instruments, is named Vashista (Sanskrit name of Mizar) and an SN 10, a 10inch reflector from Meade, is named Arundhati (Sanskrit name of Alcor). These are on Ascension 200 and MyT mounts respectively. The field of views we scan for transit is about 12′ x 8′ and 30′ x 20′ minutes We use Transit method to detect exoplanets and have scanned several fields in our galaxy close to Gemini constellation and. We have revisited some known candidates and have isolated some candidates for further tests.

E4.1-0015-18 CHARACTERIZING THE ATMOSPHERE OF PROXIMA B WITH A SPACEBASED MID-INFRARED NULLING INTERFEROMETER

Denis Defrère, ddefrere@uliege.be University of Liège, Liège, Belgium

As potentially our nearest rocky exoplanet, Proxima b represents a formidable opportunity for exoplanet science and possibly astrobiology. With an angular separation of only 35 mas (or 0.05 AU) from its hosts star, Proxima b is however hardly observable with current imaging telescopes and future space-based coronagraphs. To separate the photons of the planet from those of its hosts star, a solution is to use an interferometer that can easily resolve such spatial scales. In addition, its proximity to Earth and its favorable contrast with its host M dwarf (10E-5 at 10 microns) makes it an ideal target for a space-based nulling interferometer with relatively small apertures. In this talk, we present the main observational challenges to overcome in order to study the atmospheric composition of this planet and review what will be possible with current and/or planned facilities. Then, we describe the concept of a space-based infrared (5-20 microns) interferometer with relatively small apertures that can measure key details of Proxima b, such as its size, temperature, climate structure, as well as the presence of important atmospheric molecules such as H_2O, CO_2, O_3, NH_3, and CH_4. Finally, we illustrate the concept by showing realistic observations using synthetic spectra of Proxima b computed with coupled climate chemistry models.

E4.1-0016-18 A SPACE INTERFEROMETER ON A 6U CUBESAT: FIRST-S

Vincent Lapeyrere, vincent.lapeyrere@obspm.fr Observatoire de Paris, Meudon, France Sylvestre Lacour, sylvestre.lacour@obspm.fr Observatoire de Paris, Meudon, France Mathurin Grenot, mathurin.grenot@obspm.fr Observatoire de Paris, Meudon, France Mathias Nowak, mathias.nowak@obspm.fr Observatoire de Paris, Meudon, France Antoine Crouzier, antoine.crouzier@obspm.fr Observatoire de Paris, Meudon, France

Pierre-Cecil Konig, pierre-cecil.konig@obspm.fr Observatoire de Paris, Meudon, France

The FIRST-S project is an astronomical project in the context of exoplanet detection. The scientific objective of this mission would be to study the visible emission of exozodiacal light in the habitable zone around the closest stars. It requires high dynamic range (10e3) at moderate resolution (arcsec).

The proposed instrument is 60 cm baseline stellar interferometer with nulling capabilities based on single-mode fibers and $LiNbO_3$ (Lithium niobate) photonic ship on a 6U CubeSat. This nulling technique is currently developed in the context of FIRST project (Fibered Imager foR a Single Telescope), and is suitable for a nanosatellite application.

The first part of this challenge - controlling the injection of the star light in a single-mode fiber with a accuracy of 1 arcsecond - is addressed by the PicSat mission. PicSat is using a 2 stages pointing system: the Attitude Determination and Control System (ADCS) of the platform, and the control of a 2 axis piezo stage.

The design is based on two 9cm aperture telescope, inspired by the PicSat payload. The light collected by these two telescopes is guided with the single mode fibers to the integrated active optics. The active part of this ship controls the optical phase difference to a nanometer accuracy over few microns and allow to scan the null fringe. The interferometer itself is used as an OPD sensor and interacts with the ADCS of the platform to maintain this OPD lower to few microns.

In this presentation I will present the performances of PicSat on which be can base this design. The satellite design will then be described including the telescopes and injection into fibers and the recombination system. Finally the first results on a lab demonstrator with these parts will be shown.

E4.1-0017-18 THE ARIEL SPACE MISSION: EXPLORING THE COMPOSITIONAL FINGERPRINTS OF EXOPLANETS

Diego Turrini, diego.turrini@iaps.inaf.it INAF - IAPS Rome, Rome, Italy the Ariel Team the Ariel Team

The Atmospheric Remote-Sensing Infrared Exoplanet Large-survey (ARIEL) has been selected by the European Space Agency (ESA) as the fourth medium-class science mission of its Cosmic Vision programme (http://sci.esa.int/ariel/). The first mission dedicated to investigating the atmospheres of planets orbiting distant stars, ARIEL's goal is to measure the chemical composition and thermal structures of about one thousand transiting exoplanets in order to address the fundamental questions on how planetary systems form and evolve.

Due for launch in 2028, during its four-year mission ARIEL will observe hundreds of exoplanets ranging from Jupiterand Neptune-size down to super-Earth and Earth-size in the visible and the infrared with its meter-class telescope. The main focus of the mission will be on hot planets orbiting very close to their star, as they represent a natural laboratory in which to study the chemistry and formation of exoplanets. In cooler planets, different gases separate out through condensation and sinking into distinct cloud layers. The scorching heat experienced by hot exoplanets overrides these processes and keeps all molecular species circulating throughout the atmosphere.

The ARIEL mission concept has been developed by a consortium of more than 50 institutes from 12 countries, which include UK, France, Italy, Germany, the Netherlands, Poland, Spain, Belgium, Austria, Denmark, Ireland and Portugal. The analysis of ARIEL spectra and photometric data will allow to extract the chemical fingerprints of gases and condensates in the planets' atmospheres, including the elemental composition for the most favorable targets. It will also enable the study of thermal and scattering properties of the atmosphere as the planet orbits around the star.

E4.1-0018-18 EXOPLANET SCIENCE WITH THE ORIGINS SPACE TELESCOPE

Tiffany Kataria, tiffany.kataria@jpl.nasa.gov

NASA Jet Propulsion Lab / California Institute of Technology, Los Angeles, California, United States

For the first time in human history, our generation will have the technology needed to answer one of the longest-standing questions: "Are we alone?" Only recently have planet-hunting programs (such as TRAPPIST, MEarth, and Kepler) confirmed the first Earth analogues orbiting M dwarfs. However, it is unknown whether planets orbiting the most ubiquitous stars in our galaxy can support life. The Origins Space Telescope (OST), one of the four large mission concepts currently being studied by NASA in preparation for the Astrophysics 2020 Decadal Survey, will seek to answer that question. OST is extraordinarily sensitive in midto far-IR wavelengths, and will include an instrument designed to obtain spectra of both transiting and directly imaged exoplanets. In this talk I will discuss the challenges and opportunities of looking for biosignatures in transiting exoplanet atmospheres at mid-infrared wavelengths and argue that the only way to ascertain the truth is to make a measurement. I will also present how a survey of nearby mid-to-late M dwarfs could empirically determine the fraction of habitablezone planets that develop life. Additionally, I will highlight other exoplanet science discovery space to be opened up by OST, including the measurement of full-orbit thermal phase curves of potentially habitable planets, as well as the direct imaging of true Jupiter and Saturn analogs over a range of stellar ages.

E4.1-0019-18 EXOPLANETARY CANDIDATES TO OBSERVATIONS WITH MILLIMETRON

Vladimir Strokov, vnstrokov@gmail.com

Lebedev Physical Institute of Russian Academy of Sciences, Moscow, Russia Pavel B. Ivanov, pbi20@cam.ac.uk

Lebedev Physical Institute of Russian Academy of Sciences, Moscow, Russia

Millimetron observatory, under development at the Lebedev Physical Institute, includes a spacebased 10-meter telescope operating at millimeter and infrared wavelengths from 0.02 to 17 mm (millimetron.ru). In the single-dish mode, it can detect exoplanets in the lowest spectral band. We provide the list of exoplanets that would be available to Millimetron according to its planned sensitivity. We take into account different sources of the candidates' radiation: reradiation of the energy of the host star and the proper flux, contribution of which is important for young and hot exoplanets. Also, we consider transits and the respective decrease in flux.

E4.1-0020-18 THE HABITABLE EXOPLANET IMAGING MISSION (HABEX): SCIENCE GOALS AND PROJECTED CAPABILITIES

Scott Gaudi, gaudi.1@osu.edu

Ohio State University, Columbus, Ohio, United States

The Habitable-Exoplanet Imaging Mission (HabEx) is a candidate flagship mission being studied by NASA and the astrophysics community in preparation of the 2020 Decadal Survey. The HabEx mission concept is a large (4 to 6.5m) diffraction-limited optical space telescope, providing unprecedented resolution and contrast in the optical, with likely extensions into the near UV and near infrared domains.

The primary goal of HabEx is to answer fundamental questions in exoplanet science, searching for and characterizing potentially habitable worlds, providing the first complete "family portraits" of planets around our nearest Sun-like neighbors and placing the solar system in the context of a diverse set of exoplanets.

At the same time, HabEx will enable a broad range of Galactic, extragalactic, and solar system astrophysics, from resolved stellar population studies that inform the stellar formation history of nearby galaxies, to characterizing the life cycle of baryons as they flow in and out of galaxies, to detailed studies of bodies in our own solar system.

We report here on our team's efforts in defining a scientifically compelling HabEx mission that is technologically executable, affordable within NASA's expected budgetary envelope, and timely for the next decade. In particular, we present architectures trade study results, quantify technical requirements and predict scientific outcome for a small number of design reference missions, all with broad capabilities in both exoplanet science and cosmic origins science.

This research was carried out at the Jet Propulsion Laboratory, California Institute of Technology, under a contract with the National Aeronautics and Space Administration.

E4.1-0021-18 EXOPLANET AND SOLAR SYSTEM SCIENCE WITH THE LUVOIR MISSION

Avi Mandell, avi.mandell@nasa.gov

NASA Goddard Institute for Space Studies, Greenbelt, Maryland, United States

This presentation will give an overview of the exoplanetary and planetary observing capabilities of the Large UV-Optical-Infrared (LUVOIR) Surveyor. LUVOIR is one of four large mission concepts for which the NASA Astrophysics Division has commissioned studies by Science and Technology Definition Teams (STDTs) drawn from the astronomical community, in advance of the next Astrophysics Decadal Survey. LUVOIR is a general-purpose space-based observatory with a wavelength range spanning from the far-UV to the near-infrared, and will support a broad range of astrophysics, exoplanet and Solar System studies. LUVOIR will operate at the Sun-Earth L2 point, and will be designed for extreme stability to support unprecedented spatial resolution and coronagraphy. It is intended to be a long-lifetime facility that is both serviceable, upgradable, and primarily driven by guest observer science programs.

One of the main science objectives for LUVOIR will be to directly image rocky-sized planets in the habitable zones of stars out to 20 pc, measure their spectra, analyze the chemistry of their atmospheres, and obtain top-level information about their surfaces. Such observations will allow us to evaluate the habitability of these worlds, and search for potential signs of life in their spectra. LUVOIR will also be capable of ultra-high spatial resolution imaging of Solar System bodies, and simultaneous spectroscopy between 300 nm and 2 microns. We will review the specific observational strategies needed for astrobiological assessments of both exoplanetary and Solar System environments, including the wavelength range and spectral resolution required for these habitability analyses and biosignature searches, and we will provide an overview of the LUVOIR instrument capabilities and planned survey strategy to achieve these goals. We will also describe the wide range of additional exoplanetary and planetary science that LUVOIR will accomplish, including high-quality spectroscopic analysis of hundreds of directly imaged Neptuneand Jupiter-class objects, transit spectroscopy of M-Earths and other transiting planets across the visible and near-IR, and high-precision time-domain astronomy of every planet in the Solar System.

E4.1-0022-18 PICSAT: A CUBESAT FOR BETA PICTORIS OBSERVATION

Lester David, lester.david@obspm.fr Observatoire de Paris, Meudon, France Sylvestre Lacour, sylvestre.lacour@obspm.fr Observatoire de Paris, Meudon, France Vincent Lapeyrere, vincent.lapeyrere@obspm.fr Observatoire de Paris, Meudon, France Antoine Crouzier, antoine.crouzier@obspm.fr Observatoire de Paris, Meudon, France Mathias Nowak, mathias.nowak@obspm.fr Observatoire de Paris, Meudon, France

PicSat is a nanosatellite that was integrated and operated by the Paris Observatory to observe the transit of the giant planet Beta Pictoris b, expected to happen in 2018. The satellite has been successfully put into a 505 km Sun synchronous orbit in January (PSLV C-40). The mission is based on a 3U CubeSat architecture, with a 2 kg opto-mechanical payload specifically designed for high precision photometry. While the platform has been provided "off-the-shelf" by ISIS (Innovative Solutions In Space), the payload (hardware and software), the flight software and the ground segment/station have been mostly developed in-house at the Observatory. The main scientific objective of the mission is the nearly continuous monitoring of the brightness of Beta Pic at a precision of up to 200 ppm per hour, with interruptions of at most 30 minutes, caused by the eclipse of BetaPic by the Earth in some fraction of the satellite orbit. This setup will allow Picsat to finely characterize the debris disk, the transiting exoplanet, its gravitational surroundings (the Hill sphere) and to detect exocomets in the Pictoris system. The payload is a telescope with a 3.5 cm effective aperture which injects the light in a single-mode fiber linked to an avalanche photodiode, operating in the visible spectrum. A two-axis piezoelectric actuator system, driven by a feedback loop control algorithm based on a Kalman filter, is used to lock the fiber on the center of the star in the focal plane. These actuators complement the attitude determination and control system of the satellite to maintain the sub-arcsecond pointing accuracy required to reach the excellent level of photometric precision. Overall, the mission raises multiple technical challenges: high temperature stability of the avalanche detector (achieved with a thermoelectric cooling device), high pointing accuracy and stability, and short timeframe for the development. The mission is also a technological demonstrator. By showing that we can inject light into a single mode fiber, using only a small (1U) payload, we pave the way for a more ambitious cubesat: FIRST-S, an interferometer based on two injecting telescopes and a beam combiner using integrated optics.

E4.1-0023-18 A NEW NUMERICAL INVERSION SCHEME OF M SIN I EXO-PLANET MASS DISTRIBUTION: ITS DOUBLE PEAK REMAINS AFTER INVERSION.

Jean-Loup Bertaux, jean-loup.bertaux@latmos.ipsl.fr LATMOS / UVSQ - IPSL - CNRS, Guyancourt, France Karim Gizatullin, karimgizatullin@gmail.com

Space Research Institute of RAS (IKI), Moscow, Russia Alexander Tavrov, tavrov@iki.rssi.ru

Space Research Institute (IKI), Russian Academy of Sciences, Moscow, Russia

The use of radial velocity (RV) measurements of stars has proven very successful at the indirect detection of planets orbiting other stars, since both the planet (unseen) and the star are orbiting around their common center of mass. Unfortunately the mass m of the exo-planet cannot be retrieved: only the product m sin i is derived from the amplitude of the RV wobble, where i is the inclination of the polar axis of the orbit on the line of sight (LOS) from the observer to the star. However, when a reasonable number of exo-planets are detected, giving an observed distribution of m sin i it is possible to retrieve the distribution function of planetary masses f(m) that will give the observed distribution fO(m sin i). One has to make the assumption that the orientations of orbital polar axis are isotropically distributed in space, and independent of the distribution f(m). We have developed a new representation of exo-planets in a 3D space, and established a formally exact solution to the inversion problem, based on spheres and cylinders. We have applied this method to the more than 700 known exo-planets masses. The observed distribution of m sin i shows two peaks, one around 0.025 Mjup (Jupiter mass) and one around 2 Mjup. After inversion, the true distribution of masses still present a double peak, showing that this double peak is not an artefact or shortcoming of the RV method. Our new inversion scheme will be presented and the double peak discussed. Coauthors from IKI acknowledge support from the Russian Government Grant 14.W03.31.0017.

E4.1-0024-18 POSTER SHORT PRESENTATION SESSION

Francesca Altieri, francesca.altieri@iaps.inaf.it INAF - IAPS Rome, Rome, Italy

This slot is reserved to short presentations from poster presenters.

E4.1-0025-18 EARTHFINDER: A PROBE MISSION CONCEPT STUDY FOR THE PRECISE RADIAL VELOCITY DETECTION OF EARTH-MASS EXOPLANETS

Peter Plavchan, pplavcha@gmu.edu

George Mason University, Fairfax, Virginia, United States EarthFinder Team

Bryson Cale, Patrick Newman, Bahaa Hamze, Natasha Latouf (George Mason); Chas Beichman, David Ciardi (NExScI); Bill Purcell, Paul Lightsey (Ball); Heather Cegla, Xavier Dumusque (Geneva); Courtney Dressing, Peter Gao (UC Berkeley); Gautam Vasisht, Stephanie Leifer (JPL); Sharon Wang, Jonathan Gagne (Carnegie DTM); Fabienne Bastien, Thomas Beatty, Jason Wright (Penn St); Cullen Blake, Sam Halverson (Penn); Jonathan Crass, Justin Crepp, Andrew Bechter, Eric Bechter (Notre Dame); Scott Papp, Scott Diddams (NIST); Jason Eastman, Sam Quinn (Harvard); Debra Fischer, Sarbani Basu, Sophia Sanchez-Maes (Yale); Dimitri Mawet, Andrew Howard, Ji Wang, Kerry Vahala (Caltech); Angelle Tanner (Miss St); Samantha Thompson (Cambridge); Alex Wise (U Del); Andrew Mayo (Technical University of Denmark); Ben Pope (NYU); Simon Murphy (Sydney); Emily Martin (UCLA)

We are investigating the science case for a 1.0-1.4 meter space telescope to survey the closest, brightest FGKM main sequence stars to search for Habitable Zone (HZ) Earth analogs using the precise radial velocity (PRV) technique at a precision of 1-10 cm/s. Our baseline instrument concept uses two diffraction-limited spectrographs operating in the 0.4-1.0 microns and 1.02.4 microns spectral regions each with a spectral resolution of R=150,000 200,000, with the possibility of a third UV arm. Because the instrument utilizes a diffraction-limited input beam, the spectrograph would be extremely compact, less than 60 cm on a side, and illumination can be stabilized with the coupling of starlight into single mode fibers. With two octaves of wavelength coverage and a cadence unimpeded by any diurnal, seasonal, and atmospheric effects, EarthFinder will offer a unique platform for recovering stellar activity signals from starspots, plages, granulation, etc. to detect exoplanets at velocity semi-amplitudes currently not obtainable from the ground. Variable telluric absorption and emission lines may potentially preclude achieving PRV measurements at or below 10 cm/s in the visible and <50 cm/s in the near-infrared from the ground. Placed in an Earth-trailing (e.g. Spitzer, Kepler) or Lagrange orbit, the space-based cadence of observations of a star can be year-round at the ecliptic poles, with two 100-day "seasons" every 6 months in the ecliptic plane. This will provide a distinct advantage compared to an annual 3-6 month observing season from the ground for mitigating stellar activity and detecting the orbital periods of HZ Earth-mass analogs (e.g. 6-months to 2 years). Finally, we are compiling a list of ancillary science cases for the observatory, ranging from asteroseismology to the direct measurement of the expansion of the Universe.

E4.1-0026-18 LEARNING ABOUT EXOPLANETS' EXOSPHERES FROM THE LYMAN-ALPHA LIGHT CURVE.

Ana Gomez De Castro, aig@mat.ucm.es Universidad Complutense de Madrid, Madrid, Spain Leire Beitia-ANtero, lbeitia@ucm.es

Universidad Complutense de Madrid, Madrid, Spain

Earth's exosphere extends further than 38 Earth radii. The most abundant element in the exosphere is Hydrogen which is very sensitive to Lyman α (Lyα) radiation; a gas column of

NH < 1017 cm−2 suffices to block the stellar radiation. As a result Earth analogues orbiting around nearby M-type stars could be detectable by monitoring Lyα variability. In spite of the interstellar, heliospheric and astrospheric absorption, the transit signature would be detectable in M5 V type stars with a dedicated Lyα flux monitor implemented in a 4-8 m class space telescope. In this work, we present simulations of the Lyα profile for various models of planetary outflows and show how the contrast between the core and the wings of the line could be used to derive the properties of exoplanets' exospheres.

E4.1-0027-18 OBSERVING WITH CHEOPS: THE CHEOPS GUEST OBSERVERS PROGRAMME

Kate Isaak, kate.isaak@esa.int ESA/ESTEC, AZ, Netherlands

CHEOPS (CHaracterising ExOPlanet Satellite) is the first exoplanet mission dedicated to the search for transits of exoplanets by means of ultrahigh precision photometry of bright stars already known to host planets. It is the first S-class mission in ESA's Cosmic Vision 2015- 2025. The mission is a partnership between Switzerland and ESA's science programme, with important contributions from 10 other member states.

Foreseen to be ready to launch at the very end of this year, CHEOPS will provide the unique capability of determining radii of planets in the super-Earth to Neptune mass range to 10% precision. It will also provide accurate radii for new planets discovered by the next generation of ground-based or space transit surveys (from super-Earth to Neptune-size). The high photometric precision of CHEOPS will be achieved using a photometer covering the 0.33 - 1.1um waveband, designed around a single frame-transfer CCD which is mounted in the focal plane of a 30 cm equivalent aperture diameter, f/5 on-axis Ritchey-Chretien telescope.

20% of the observing time in the 3.5 year nominal mission will be available to the Community through the Guest Observers Programme that will be run by ESA. The call for proposals for the first year of observing will come out in Summer 2018.

In this poster I give an overview of observing with CHEOPS, with a particular focus on the ESA CHEOPS Guest Observers Programme.

E4.1-0028-18 DETECTION OF EXOPLANETS IN MULTISYSTEM STARS

Abd El Fady Morcos, fadymorcos@hotmail.com

National Research Institute of Astronomy and Geophysics (NRIAG), Cairo, Egypt

Detection of the exoplanets in multisystem stars represents one of the important tasks in the coming interval of time. Thousands of multisystem in particular triple systems have been observed. The detection of the nature of the third body as a planet represents a hard question to be answered in triple systems. In a previous theoretical trial, Morcos in 2013, derived a simple relation, in the framework of scale relativity (Nottale (1997)), to find the orbital period of solar system plants by using a quantized form. That formula has been adapted to calculate the quantum orbital number of some exoplanets (Morcos, et al (2016)). In this work, the previously mentioned relation has been reformed using Hill radius of Margot (2015) to detect exoplanets in multisystem stars. The results may through a light on detection of the third body as an exoplanet by using the quantization of the body's orbit.

E4.1-0029-18 THE CHEOPS GROUND SEGMENT AND OVERALL MISSION OPERATIONS CONCEPT - AN ESA MISSION OPERATED BY THE MISSION CONSORTIUM

Mathias Beck, mathias.beck@unige.ch University of Geneva, Versoix, Switzerland CHEOPS Ground Segment Team

ASI Science Data Centre (IT), ASE (ES), AstroCast (CH), CAUP (PT), DEIMOS Engenharia (PT), ESA/ESOC, ESA/ESTEC, eSpace @ EPFL (CH), GMV (ES), INTA (ES), Laboratoire d'Astrophysique de Marseille (FR), University of Bern (CH), University of Cambridge (UK), University of Geneva (CH), University of Stockholm (SE), University of Vienna (AT).

A partnership between Switzerland and the Science Programme of the European Space Agency (ESA), the CHaracterising ExOPlanet Satellite (CHEOPS) is ESA's first mission of the recently created S-Class type. By the end of 2018 CHEOPS is planned to be ready for launch from Kourou's spaceport as co-passenger on-board a Soyuz rocket. The nominal mission lifetime is 3.5 years.

With its effective mirror size of 30 cm and its remarkable photometric precision of 20 ppm (over 6 hours), CHEOPS will be able to measure the radii of exoplanets known to transit bright host stars (Vmag = 6-12). CHEOPS will reveal very valuable as a high-performance follow-up of explanatory transits detected by, for example, NASA's TESS mission. Together with the mass measurements from other instruments like ESPRESSO at ESO's Paranal site, CHEOPS will provide well suitable targets for spectroscopic follow-ups with spaceor groundbased observatories like the JWST or the E-ELT.

The CHEOPS Mission Operations Centre (MOC) and the Science Operations Centre (SOC) are developed and operated by the Mission Consortium, which is lead by the University of Bern. The MOC development is under the responsibility of GMV, a world leader for satellite ground segments. Critical subsystems like the Mission Control System are provided as part of a turnkey system by ASE, the spacecraft prime contractor. The MOC is operated by INTA. As the leader of a team from 9 institutes and companies located in 6 ESA member states, the University of Geneva hosts the SOC. The SOC will deliver science-ready data products through the CHEOPS archive. All proprietary data will become publicly accessible to the scientific community at large one year after their observation.

20% of the CHEOPS observing time are open to the international community through Announcements of Opportunities (AO) operated by ESA. The fist AO is foreseen in summer 2018.

In this contribution, we will present the CHEOPS Ground Segment and the Mission Operations concept. Focus will be given to the challenges and benefits of CHEOPS' small mission character.

E4.1-0031-18 A COSPAR ROADMAP ON EXOPLANETS FOR THE NEXT DECADES

Giuseppina Micela, giusi@astropa.inaf.it INAF-OAPa, Palermo, Italy

Mark R. Swain, mark.r.swain@jpl.nasa.gov

Jet Propulsion Laboratory, California, United States

The COSPAR Bureau has approved to initiate a new roadmap study on exoplanets, "as a multidisciplinary domain in full development, involving astronomy, planetary sciences, and ultimately life sciences, not to mention more philosophical questions". The roadmap will include several aspects related to exoplanets, including the planned missions for next decade and foreseen discoveries, the synergy with the large project from ground, the technological developments for future more challenging experiments, the status and foreseen development of models, the role of the host star and of the environment, the habitability definition, conditions and life, and the support of the laboratory activity to models and interpretation of observations. We are building the team covering a large range of competences and countries, with a good balance of senior - junior participants and gender. The time scale planned to deliver the roadmap is approximately one year and will be prepared by a working group in the context of the SubCommission E4: Exoplanets Detection, Characterization and Modelling https://cosparhq.cnes.fr/scientific-structure/scientific-commissions-e

E4.1-0032-18 IMPORTANCE OF POLARIZATION OBSERVATIONS TO SUPPORT WFIRST EXOPLANET SEARCHES WITH GRAVITATIONAL MICROLENSING

Alexander Zakharov, zakharov@itep.ru

Institute of Theoretical and Experimental Physics, Moscow, Russia

As it was predicted by Mao and Paczynski (1991) gravitational microlensing is among the most efficient technique. Several dozens exoplanets have been discovered with this technique (some of them are located near the snow line) with relatively modest ground based facilities. However, there are degeneracies in theoretical modeling such binary planetary systems and some of these degeneracies can be resolved with polarization measurements. One of the primary goal of WFIRST mission is searches of exoplanets with gravitational microlensing. Therefore, it is important to design early warning system for microlensing event candidates observing with WFIRST and to build a world-wide ground network for follow-up polarization observations. It will allow to increase an efficiency of WFIRST observations for exoplanet searches.

E4.1-0033-18 EXOTRANS FOR THE ADVANCED DETECTION OF TRANSITING PLANETS IN STELLAR LIGHT CURVES

Sascha Grziwa, grziwas@uni-koeln.de

Rhenish Institute for Environmental Research at the University of Cologne, Cologne, Germany

The software package EXOTRANS was developed by the Rheinisches Institut für Umweltforschung (RIU-PF) to detect transits of exoplanets in stellar light curves monitored by space telescopes. EXOTRANS was first applied to the stellar light curves from the CoRoT space mission (2006-2013), on KEPLER light curves and it is currently used to detect candidates in K2 light curves as part of the KESPRINT collaboration.

The detection pipeline was improved with wavelet-based filter routines: the VARLET filter separates faint transit signals from stellar variation, orbital disturbances and instrumental effects without using a-priori information about the target star considering variations by frequency, amplitude and shape simultaneously; the PHALET filter separates periodic features with wellknown periods independent of their shape. PHALET is implemented in the "Advanced-BLS" detection algorithm to remove detected transits from light curves to search for additional faint transiting planets. EXOTRANS lowers the detection limit, reduces false alarms and simplifies the detection of faint transits in variable stellar light curves.

EXOTRANS works fully automatically (including candidate vetting), is fully scalable on several computer systems and is ready to process the large data volumes of future space missions like TESS and PLATO. Examples of candidates detected in K2 light curves as part of the KESPRINT collaboration shall be presented. The KESPRINT collaboration published 24 papers of confirmed K2 planets with determined radius and mass since 2016.

E4.2-0001-18 THE PHYSICS OF PLANET FORMATION

Christoph Mordasini, christoph.mordasini@space.unibe.ch
University of Bern, Bern, Switzerland

This talk provides a broad overview on the physical processes governing planet formation and evolution. In the first part of the talk, current key observational constraints for theoretical models will be discussed coming from both ground and space-based observatories. Then, the most important physical mechanisms controlling planet formation will be presented, namely the accretion of solids and gas, orbital migration, and planet-planet interactions. Global planet formation models that include these effects and their statistical predictions for the planetary mass function, the radius distribution, the planetary luminosities at young ages, and the dependencies of system architectures on protoplanetary disk properties will be presented. In the end, I will address key open questions that need to be addressed in order to advance our understanding of how planets form. Here, a focus will be made on the opportunities arising from observing planet formation as it happens.

(solicited talk)

E4.2-0002-18 STARLIGHT RESHAPES PROTOSTELLAR DISKS

Neal Turner, neal.turner@jpl.nasa.gov

NASA Jet Propulsion Lab / California Institute of Technology, Pasadena, California, United States

Andrea Isella, isella@rice.edu

Rice University, Houston, Texas, United States Mario Flock, mail@mario-flock.de

Max Planck Institute für Astronomie, Heidelberg, Germany

Many protostellar disks show central cavities, rings, or spiral arms likely caused by low-mass stellar or planetary companions, yet few such features are conclusively tied to bodies embedded in the disks. Even small features on the disk's surface cast shadows, because the starlight grazes the surface. We therefore focus on accurately computing the disk's thickness, which depends on its temperature. We present models with temperatures set by the balance between starlight heating and radiative cooling, and that are in vertical hydrostatic equilibrium. The planet has 20, 100, or 1000 Earth masses, ranging from barely enough to perturb the disk significantly, to clearing a deep tidal gap. The hydrostatic balance strikingly alters the model disk's appearance. The planet-carved gap's outer wall puffs up under starlight heating, throwing a shadow across the disk beyond. The shadow appears in scattered light as a dark ring that could be mistaken for a gap opened by another planet. The surface brightness contrast between outer wall and shadow for the 1000-Earth-mass planet is almost an order of magnitude greater than a model neglecting the temperature disturbances. The shadow is so deep it largely hides the planet-launched spiral wave's outer arm. Temperature gradients are such that outer lowmass planets undergoing orbital migration will converge within the shadow. Furthermore, the temperature perturbations affect the shape, size, and contrast of features at millimeter and centimeter wavelengths. Thus, starlight heating and radiative cooling are key factors in the appearance of protostellar disks with embedded planets.

E4.2-0003-18 HEAVY ELEMENTS IN EXOPLANETS: PLANETESIMAL ACCRETION VS PEBBLE ACCRETION

Yasuhiro Hasegawa, yasuhiro.hasegawa@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, Wyoming, United States

Better measurements of the mass and radius of exoplanets enable determination of the composition of planets, which provides invaluable insights about how planets form. The recent studies combine such a good quality of the data with the thermal and structure evolution model of planets and reveal a relationship between the total mass and the total heavy element mass of observed exoplanets. While the relationship is regarded as good evidence that the core accretion scenario is the dominant mechanism of forming these planets, it is still unclear how heavy elements are accreted onto planets. Here, we present a new analysis of the relationship in which core formation and accretion of solids such as pebbles and planetesimals are examined. We combine the semi-analytical formula of planetesimal accretion with the gas accretion recipe, and find that the relationship is regulated by the final stage of planet formation, where planets accrete solids from gapped planetesimal disks and the supply of gas onto the planets is limited by disk evolution. Our analysis also shows that the critical core mass for initiating gas accretion is about 4 Earth-masses that are much smaller than the canonical value of 10 Earth-masses often used in the literature. This in turn enables us to propose that exoplanets with the mass of 4 Earth-masses would be rocky super-Earths. The subsequent solid accretion onto planetary cores would be important to postpone the onset of efficient gas accretion for planets with the mass of 4 Earth-masses < Mp < 100 Earth-masses. These planets can be classified as gas-poor, sub-giant planets like Neptune in the solar system. The current understanding of pebble accretion is still premature, and a more detailed study of how simultaneous accretion of gas and pebbles proceeds is required for performing the same level of the analysis. We finally propose the classification of observed exoplanets based on our analysis to obtain better understanding of planet formation.

E4.2-0004-18 CATCHING PLANET FORMATION IN THE ACT: SIGNATURES OF PLANETS IN DISKS

Hannah Jang-Condell, hjangcon@uwyo.edu

University of Wyoming, Laramie, Wyoming, United States

Interactions between forming planets and the young circumstellar disks from which they develop can result in large-scale structural changes to disks that are potentially observable. The observation of these signatures promises to be a direct probe of the planet formation process, provided that those signatures can be properly interpreted. As new observatories develop, we have begun to observe some of these features. In this talk, I will discuss theoretical predictions of planet formation signatures as well as some possible false positives. I will discuss how these predictions can be used to interpret observations, both from our current latest and greatest observatories as well as upcoming missions.

E4.2-0005-18 ASTROCHEMICAL OUTCOMES OF THE FORMATION OF GIANT PLANETS IN CIRCUMSTELLAR DISCS: THE CASE STUDY OF HD163296

Diego Turrini, diego.turrini@iaps.inaf.it INAF - IAPS Rome, Rome, Italy

Francesco Marzari, francesco.marzari@pd.infn.it Department of Physics, University of Padova, Padova, Italy Danae Polychroni, danae.polychroni@iaps.inaf.it Universidad de Atacama, Copiapo, Chile

Leonardo Testi, ltesti@eso.org

INAF/Osservatorio Astrofisico di Arcetri, Firenze, Italy

The observational capabilities of ALMA are providing an unprecedented view of circumstellar discs, revealing the signatures left in their gas and dust by the formation of giant planets. At the time giant planets form, planetesimals should still contain a significant fraction of the initial solid mass of the discs and their dynamical excitation by the planetary perturbations should lead to a significant collisional dust production. We investigate the dynamical and collisional evolution of the planetesimals in HD163296's circumstellar disc across the formation of its three giant planets to assess whether the second-generation dust produced by planetesimal collisions could refill the disc with dust, formerly depleted by the planetary formation process, and produce potentially observable features. We use N-body simulations and statistical methods developed for the study of the asteroid belt in the Solar System to estimate the dynamical and collisional response of the planetesimal population to the formation of the three giant planets. We took advantage of impact experiments and scaling laws to assess the outcome of the collisions among the planetesimals. Our results show that the formation of HD163296's giant planets should be followed by a global phase of dynamical excitation of the planetesimals, producing a violent collisional environment that should still be active today. The associated high impact velocities would cause a tenfold-to-hundredfold increase in the dust production by impacts, with a predicted peak in the region interior to the inner planet in agreement with observational data. The excited velocities of the planetesimals could result in the release of transient, non-equilibrium gas species like H2O due to ice sublimation during impacts and, being supersonic with respect to the gas, could produce bow shocks in the gas, possibly causing a broadening of its emission lines.

E4.2-0006-18 HIGH-CONTRAST IMAGING OF A NEW CIRCUMBINARY DISK AROUND A YOUNG SPECTROSCOPIC BINARY

Marie Ygouf, mygouf@ipac.caltech.edu

IPAC Infrared Processing and Analysis Center, Pasadena, California, United States Disk team

R. Patel, J. Debes., C. Beichman, G. Duchene, A. Weinberger, L. Pueyo, M. Perrin, S. Lubow,

E. Choquet, T. Meskhat, J. Sahlmann, D. Mawet

Since the Kepler mission discovered extrasolar planets orbiting binary stars, we know that these circumbinary planets are relatively common. The scenario for their formation is however still unclear. Did they form in the perturbed environment close to their host stars or did they form further out and then migrate inwards? Solving this mystery requires detailed study of the morphology, composition, and dynamics of young binary-disk systems where planets may still be forming. We report the most detailed high-resolution images in scattered light of a new disk around a spectroscopic binary, embedded in a multi-stellar system. With a ring, a cavity, at least two spiral arms, and hints for temporal variability, the disk's structure indicates possible interactions with close stellar companions. The spatial constraints provided by these multispectral images, used in the context of radiative transfer modeling, give a more precise picture of this system. They also raise additional questions that may be addressed with JWST and ALMA follow-up.

E4.2-0007-18 IMAGING PROTOPLANETS

Steph Sallum, ssallum@ucsc.edu

UC SANTA CRUZ, Santa Cruz, California, United States

Understanding the details of the planet formation process requires direct observations of protoplanets themselves. The distances to nearby young stars make these detections extremely difficult, pushing the limits of current facilities. However, instrumentation improvements have enabled the detection of some protoplanet candidates. I will discuss the candidates discovered so far, as well as the techniques that led to their detection. I will also discuss the expected advances in protoplanet detection and characterization from next-generation facilities.

E4.2-0008-18 DETECTING FORMING EXOPLANETS WITH A NEW VLTI HIGH-CONTRAST INSTRUMENT

Thibault Boulet, thibault.boulet@student.ulg.ac.be Universite de Liege, Liège, Belgium

Denis Defrère, ddefrere@uliege.be University of Liège, Liège, Belgium Olivier Absil, oabsil(at)uliege.be Universite de Liege, Liège, Belgium

Jean-Philippe Berger, bergejea@univ-grenoble-alpes.fr

Institut de Planétologie et Astrophysique de Grenoble, Grenoble, France Michael Ireland, michael.ireland@anu.edu.au

Australian National University, Weston Creek, Australia Maddalena Reggiani, mreggiani@ulg.ac.be

Universite de Liege, Liège, Belgium Stefan Kraus, s.kraus@exeter.ac.uk

University of Exeter, Exeter, United Kingdom

The scarcity of giant exoplanets discovered by ongoing single-aperture direct imaging surveys challenges our understanding and theories of planet formation. For the nearest population of young stars, these surveys are typically sensitive to planets further than 15-20 AUs from their host stars due to the limited angular resolution. Deep observations at higher angular resolution are therefore required to fully explore the range of possible orbits and bridge the gap with radial velocity surveys. In this presentation, we present the scientific motivations and expected science yield of a high-angular resolution and high-contrast thermal near-infrared (3-5 microns) VLTI instrument. The thermal near-infrared is ideal to provide deep mass sensitivity for intermediate age (several hundred Myr-old) systems as well as to image very young and still embedded (proto-)planets. We discuss the prospects for known giant planets and predict the number of possible new detections in young moving groups based on Monte-Carlo simulations. Synergies and scientific preparation for the Planet Formation Imager are also briefly discussed. This project is dubbed Hi-5, for High-contrast Interferometry up to 5 microns.

E4.2-0009-18 LINKING ASTROCHEMISTRY IN PROTOPLANETARY DISKS WITH THE ATMOSPHERIC COMPOSITION OF EXOPLANETS

Ilsedore Cleeves, ilse.cleeves@cfa.harvard.edu

Harvard-Smithsonian Center for Astrophysics, Cambridge, Massachusetts (USA), Cambridge, Massachusetts, United States

Recent advances in sensitivity have allowed us to begin to measure and even map the compositions of gas-rich protoplanetary disks. How these compositions are imparted into newly forming planets is still an open question that draws from topics of gas motions, dust dynamics, and, of course, chemistry. I will discuss how ALMA is shedding light on each of these topics, and how these parts fit into a newly emerging (and potentially dynamic) picture of chemistry during planet formation. I will finally discuss how what we've learned from the outer disk (> 10 AU) from ALMA may influence the compositional properties of the inner terrestrial planet formation region, and how we might test such ideas with future facilities such as JWST.

E4.2-0010-18 FUTURE MISSIONS AND SYNERGIES FROM GROUND AND SPACE MISSIONS

Michael Ireland, michael.ireland@anu.edu.au

Australian National University, Weston Creek, Australia

The study of planetary formation and evolution is challenging from an observational perspective because of the very high angular resolutions and contrasts required. In the medium to long term, only formation flying long-baseline high contrast interferometry has the capability to image the full range of exoplanets needed to observationally understand planet formation from the terrestrial to giant planet range. However, there are many exciting intermediate steps, both from the ground and space. I will begin by outlining the scientific requirements for studying the key stages of planetary formation and young planetary system evolution, including accretion of the first planetary cores, runaway gas accretion, and dynamical planetary system evolution. The fundamental requirement for high spatial resolution drives even the study of wide giant planets beyond the spatial resolution of JWST to the ground-based extremely large telescopes and ground-based long baseline infrared interferometry. ESO's VLTI, using for example the VIKiNG beam combiner under the Hi-5 framework, offers the best opportunity over the next 5- 10 years to detect a wide range of giant exoplanets. Beyond that, the Planet Formation Imager (PFI) concept aims to resolve structures as small as giant planet Hill-spheres. Moving beyond this requires formation flying of a cooled beam combiner. I will discuss pathways for microsatellite formation-flying demonstrators that could enable unique planet formation science, and point the way towards km-scale space interferometry.

Despite recent advancements, many fundamental questions still surround the processes that are involved in planetary birth: Where in the protoplanetary disk do the planets form and how do they grow? What factors determine the final architecture of planetary systems? How are water and other volatiles delivered to the protoplanets and how does this affect the potential habitability of these worlds?

As part of the "Planet Formation Imager" (PFI) project we develop the roadmap for a future infrared high-angular resolution imaging facility that aims to answer these questions by witnessing the planetary formation processes on the natural scales where the material is assembled, which is the Hill sphere of the forming planets. PFI will detect giant protoplanets on all stellocentric radii, image their interaction with the ambient disk material, and trace their dynamical evolution during the first 100 million years, thereby reveal the processes that determine the architecture of planetary systems.

In this contribution we give an overview about the work of the PFI science and technical working group and present radiation-hydrodynamics simulations from which we derive preliminary specifications that guide the design of the facility. We will present a baseline PFI architecture that can achieve these goals, point at remaining technical challenges, and suggest activities today that will help make the Planet Formation Imager facility a reality.

We present the current status of the Millimetron Space Observatory (MSO) -international space mission led by Russia. The unprecedented sensitivity and angular resolution of the cryogenically cooled 10-m telescope, placed in a L2 orbit, will provide unique capabilities for millimeter, submillimeter and FIR astronomy and astrophysics. There will be no cryogenic liquids on board, which will reduce the mass of the observatory. Instead the mission will be cooled passively by heat shields and actively by mechanical coolers. That combination will enable achieve on the observatory mirrors temperature less than 10K. One of the exciting opportunities is the possibility of MSO working in two different modes - as a single dish observatory and as an element of Earth-space VLBI system. The MSO payload equipment includes two direct detection instruments complemented by several heterodyne instruments. All of them are based on the state-of-the-art components. The current status of the MSO will be presented.

Centro de Investigaciones Biológicas (CSIC), Madrid, Spain

Light and gravity play a substantial role in plant orientation and directed growth movements (tropisms). However, very little is currently known about the interaction between light (phototropic) and gravity (gravitropic) mediated growth responses. Utilizing the European Modular Cultivation System (EMCS) on board the International Space Station (ISS), we investigated the interaction between phototropic and gravitropic responses in three Arabidopsis thaliana genotypes, Landsberg wild type as well as mutants of phytochrome A and phytochrome B. Onboard centrifuges were used to create a fractional gravity gradient ranging from microgravity to reduced gravity to 1g. Two types of data resulted from these space experiments: (1) downlinked images of seedlings showing growth and tropistic curvature; (2) molecular analyses of seedlings which were frozen at the end of the experiment.

In terms of the tropism experiments resulting from imaging of the seedlings, a novel positive blue-light phototropic response of roots was observed during conditions of microgravity, and this response was attenuated at 0.1g. In addition, a red-light pretreatment of plants enhanced the magnitude of positive phototropic curvature of roots in response to blue illumination. Additionally, a positive phototropic response of roots was observed when exposed to red light, and a decrease in response was gradual and correlated with the increase in gravity. The positive redlight phototropic curvature of hypocotyls when exposed to red light was also confirmed. Both red-light and blue-light phototropic responses were also shown to be a product of directional light intensity.

In terms of the molecular analyses, seedlings were grown in µg or 1g and subsequently frozen at -80C. RNA-Seq analysis was conducted to identify genes differentially expressed between the µg and 1g growth conditions. This analysis (utilizing the HISAT2-Stringtie-Ballgown suite of bioinformatics tools) identified 11 highly-significant genes associated with growth in microgravity.

Two particularly interesting genes include AT3G12830 (SAUR-like auxin-responsive protein family) and AT4G02440 (F-box protein that functions as a negative regulator in phytochrome A). Phytochrome is an important photoreceptor molecule that plays a role in phototropism, and auxin plays an important role in the differential growth in gravitropism and phototropism.

These studies will be considered in the broader context of understanding gene expression of plants grown in the microgravity environment. In the long term, the results of our spaceflight experiments will help us to understand plant growth as part of bioregenerative life support, which is important for missions to Mars and other planets.

F1.1-0002-18 PLANT GRAVITY RESPONSES UNDER FRACTIONAL GRAVITY

Chris Wolverton, scwolver@owu.edu

Ohio Wesleyan University, Delaware, Ohio, United States

Plant growth shows a high degree of plasticity, with input from environmental conditions like temperature, light, and gravity playing a dominant role in determining plant form. These inputs result in directional growth responses in young seedlings that contribute to seedling establishment, water uptake, mineral acquisition, and the transition to fully autotrophic growth. Gravity is a principal cue influencing the direction of plant growth, but despite its importance, much remains unknown about how plants perceive and regulate their response to this pervasive signal. To further our understanding of gravity perception and response regulation, we have designed a spaceflight experiment for the European Modular Cultivation System (EMCS) the central aim of which was to determine the gravity perception threshold in roots. The EMCS, housed on the International Space Station, is a growth chamber capable of controlling all necessary conditions to support plant growth while supplying artificial gravity through the rotation of 2 independent centrifuge rotors, allowing the application of 0.003 - 2.0 g. Here we report the growth responses of roots of Arabidopsis thaliana wild type (Col-0) and starchless mutants (pgm-1) to a range of fractional g treatments. Starchless mutants lack functional statoliths, causing them to respond more slowly to gravity on Earth. Here we report on the differences in the threshold acceleration force required to activate gravity responses in the mutant relative to wild type roots, as well as differences in gravitropic response rates under varying g treatments. Finally, we report on the response of both types of roots to unilateral blue light treatments in microgravity. Our results will inform planning for plant growth facilities on future spaceflight missions as well as contribute to our overall understanding of plant gravity sensing, an important input governing plant form and productivity on Earth.

F1.1-0003-18 PROTEOMICS AND TRANSCRIPTOMIC ANALYSIS OF ARABIDOPSIS SEEDLINGS IN MICROGRAVITY REVEAL NOVEL REGULATORY PATHWAYS.

Low earth orbit provides a wholly unique opportunity to study plant gravity response at the molecular level. Indeed, several studies over the past decade have assessed gene expression and protein abundance under microgravity conditions. However, RNA sequencing technologies have advanced substantially in recent years, and few if any studies have comprehensively examined gene expression with the resolution provided by next generation sequencing. Additionally, pairing RNAseq data with the assessment of individual protein abundances provides a far more complete picture of the molecular environment within plants subjected to microgravity. Here, etiolated seedling were grown for 3 days aboard ISS in BRIC hardware. Seedlings were fixed with RNAlater, frozen at -80 °C, and returned to Earth for analysis. A series of ground controls were conducted to correct for the effects of preservative and hardware. RNA and proteins were extracted and subjected to paired-end RNA sequencing and protein mass spec analysis, respectively, and protein data were further analyzed for post-translational modifications. In total, 1,974 genes, 94 soluble and 79 membrane proteins and were found to be differentially expressed between the space flown samples and ground controls. Further analysis revealed a general incongruity between the RNA and protein datasets, highlighting the value in using multiple molecular approaches to delineate the effects of microgravity environments. Considering all data collected, novel microgravity-induced molecular dysregulation was uncovered in post transcription regulation, light signaling, and growth-related pathways.

F1.1-0004-18 COMPARISON OF THE REGULATORY MECHANISMS FOR GRAVITROPISM AND HYDROTROPISM IN SEEDLING ROOTS

Hideyuki Takahashi, hideyuki@ige.tohoku.ac.jp Tohoku University, Sendai, Japan

Roots of land plants show gravitropism and hydrotropism due to gravity and moisture gradients, respectively, for controlling their growth orientation. It has been shown that gravitropism interferes with hydrotropism. We differentiated hydrotropism from gravitropism in cucumber roots by clinorotation and spaceflight experiments. Clinorotated or microgravity-grown cucumber seedling roots hydrotropically bent toward wet substrate in the presence of moisture gradients, but they grew straight along the direction of stationary 1G on the ground or centrifuge-generated 1G in space. The expressions of auxin-inducible genes were much higher in the high-humidity (concave) side than the low-humidity (convex) side of hydrotropically responding cucumber roots. Auxin transport inhibitors significantly reduced the hydrotropic response. The auxin efflux protein CsPIN5 was differentially expressed by reducing its expression in the convex side of cucumber roots following hydrostimulation. These results suggested that hydrotropic and gravitropic responses in cucumber roots were competitive one another, being mediated via auxin dynamics to be independently regulated in response to moisture gradients and gravity. However, the root cap was indispensable for gravitropism and dispensable for hydrotropism, suggesting a novel mechanism that induced asymmetrical transport and distribution of auxin in the elongation zone without the root cap in hydrotropically responding cucumber roots. Arabidopsis roots also displayed hydrotropism after laser-ablation of the rootcap cells. In Arabidopsis roots, MIZ1 and ABA functioned in cortex of the elongation zone, but auxin was not essential, for the induction of hydrotropism. Thus, our results revealed the regulatory mechanism unique to hydrotropism in roots, which could differ between plant species.

F1.1-0005-18 SPACE EFFECTS IN BRASSICA SEEDLINGS - GENE TRANSCRIPTION BY TISSUE TYPE

Karl H. Hasenstein, hasenstein@louisiana.edu

University of Louisiana, Lafayette, Louisiana, United States

An experiment that validated the role of amyloplast displacement as curvature-inducing process was used to examine the gene expression in space-grown and control seedlings. Brassica roots responded to High Gradient Magnetic Fields (HGMF) by curving in space and on a clinostat. Q-PCR data from root tip, root proper, root-shoot junction and cotyledons of 42 h old seedlings that were fixed in space in RNA-later was investigated for transcription of genes related to growth, auxin transport, cell wall biosynthesis and starch metabolism. Sixteen genes were analyzed for their variability in the different tissues and as to their sensitivity to physical stimulation such as high-gradient magnetic fields in space, clinorotation, and controls. Transcription studies showed greater differences between HGMF-exposed roots and space controls than between space and ground controls. Space grown roots showed stronger transcription of common reference genes such as actin and ubiquitin in HGMF than in non-magnetic space controls. In contrast, -amylase, glucokinase and PIN encoding genes were transcribed stronger under non-magnetic conditions than under HGMF. The available large number of comparisons between space, ground, and HGMF prompted the assessment of transcription differences between root segments, root-shoot junction, and seeds. Because presumed transcription of reference genes varied more than genes of interest, changes in transcription cannot be based on reference genes. Nonetheless, the different tissues show consistent variability in transcription. The highest variability was found in roots, the lowest variability occurred in the seed/cotyledon material. The data provide insight in gene regulation as function of physiological state rather than experimental treatment.

Mechanical resistance to the gravitational force, termed gravity resistance, is a principal graviresponse in plants, comparable to gravitropism, and has sustained the evolution of land plants.

We have shown, with ground-based experiments using centrifugal hypergravity conditions, that cortical microtubules play an

important role in signal transduction and the cell wall in the final response to hypergravity. However, it is uncertain whether this hypothesis is as applicable to resistance to 1 g gravity as to the resistance to hypergravity. To confirm this point by using true microgravity conditions in space as the control, we conducted the Resist Tubule space experiment, consisting of three runs, on the Kibo Module of the International Space Station. The modifications by microgravity of the formation and orientation of cortical microtubules were analyzed with wild-type Arabidopsis seedlings, cultivated in the Cell Biology Experiment Facility (CBEF) onboard the Kibo and recovered to earth after chemical fixation, and by observing on-site seedlings of GFP-expressing Arabidopsis lines. In the epidermis of the growing region of hypocotyls, cells with transverse cortical microtubules were predominant, and their reorientation from transverse to longitudinal directions occurred in the region where elongation growth has almost ceased at 1 g. Under microgravity conditions, the percentage of cells with transverse microtubules increased, whereas that with longitudinal microtubules decreased in the transition region, as compared with on-orbit 1 g conditions. Such a modification of reorientation of cortical microtubules may contribute to maintain the capacity of cell elongation under microgravity conditions. On the other hand, we cultivated Arabidopsis alpha-tubulin mutants, it tua4 and it tua6 with different degrees of defects, in the CBEF, and analyzed growth and cell wall properties of inflorescence stems. Growth of both mutants was stimulated and their cell wall rigidity was lower under microgravity conditions, as compared with on-orbit 1 g controls. The decrease in levels of cell wall polysaccharides, as well as the modification of expression of cell wall-related genes, responsible for the decrease in cell wall rigidity, also occurred under microgravity conditions. These results support the hypothesis that both cortical microtubules and the cell wall play an essential role in resistance of plants to gravity in the range from 1 g to hypergravity.

In the context of the space conquest, plants will constitute a life support system for long-term space missions which will provide oxygen and food. In this perspective, the spatial environment's effect, and more particularly the microgravity effect on plants, must be studied. This work concerns the action of microgravity on the development on Arabidopsis thaliana plant model at the level of its main roots. This study was carried out in three parts: (i) measur- ing the root length of plants grown in simulated microgravity, (ii) characterizing the action of microgravity on the cell cycle and (iii) observing the action of microgravity on the elongation of differentiated cells. The length of the roots subjected to microgravity, measured by DIC filter microscope, was shorter than the control 1g. The action of microgravity on the cell cycle was analyzed by flow citometry, expression of marker genes encoding the proteins of cell-cycle regulation by PCR quantitative and transgenic plant lines by histoenzymological test of glucuronidase. The results showed a dysfunction in the cell cycle and more particularly in the G1

/ S phase in microgravity. Cellular elongation and ploidy, measured by flow citometry, showed a decrease in the index of endoreplication of differentiated cells from plant in microgravity. Based on these results, we can conclude that microgravity disrupts the cell cycle, in particular by slowing down the G1 phase, decreasing the meristematic cell rate of proliferation and decreasing the endocycle index. These processes contribute to a decrease of the plant root growth subjected to microgravity.

F1.1-0008-18 EFFECTS OF LONG-TERM 3 G-HYPERGRAVITY ON THE FORMATION OF TISSUES IN THE PEDUNCLE OF ARABIDOPSIS

Ichirou Karahara, karahara@sci.u-toyama.ac.jp University of Toyama, Toyama, Japan

Kimitaka Sasaki, m1741309@ems.u-toyama.ac.jp University of Toyama, Toyama, Japan

Masaki Muramoto, hytcp422@ybb.ne.jp University of Toyama, Toyama, Japan Daisuke Tamaoki, tamaoki@sci.u-toyama.ac.jp University of Toyama, Toyama, Japan

To explore how gravity is involved in the formation of tissues in the plant stem including the ones having supporting functions, we have performed long-term microgravity experiments and obtained results indicating a possibility of an involvement of gravity in the formation of pith cavity and fibers. To verify the results of space experiment, we have developed a long term-hypergravity experimental system and performed a 3 G-hypergravity experiment for 30 days. In the present study, we have examined effects of this 3 G-hypergravity environment on the formation of tissues in the peduncle of Arabidopsis (Arabidopsis thaliana (L.) Heynh.). Though still preliminary, an anatomical observation showed that cross sectional areas of tissues generally increased under 3 G in the basal part and these areas tended to increase generally also in the apical part. Interestingly, however, that of pith cavity tended to decrease under 3 G, indicating a possibility that gravity suppress its formation. The formation of fibers also tended to be suppressed under 3 G in the apical part, indicating a relationship of between the formation of pith cavity and of fibers.

F1.1-0009-18 SPATIOTEMPORAL CONTROL OF FLOWERING GENE EXPRESSION USING A HEAT-SHOCK-ACTIVATED GENE SWITCH UNDER MICROGRAVITY ONBOARD SJ-10 RECOVERABLE SATELLITE

Lihua Wang, lhwang@sibs.ac.cn

Chinese Academy of Sciences, Shanghai, China Huiqiong Zheng, hqzheng@sippe.ac.cn

CAS, Shanghai, China

The reproductive success of plants is often dependent on their flowering time being adapted to the territorial environment, in which gravity remain constant. Whether plants can follow the same rule to determine their flowering time under microgravity in space is unknown. Flowering time in Arabidopsis is controlled by the day-length specific expression of FLOWERINGLOCUS (FT) gene in leaves. In the present experiment, we developed transgenic Arabidopsis containing the heat shock (HSP 17.4)-inducible gene promoter to the green fluorescent protein (GFP) reporter gene (HSPpro:: GFP) and the FT gene (HSPpro::FT), respectively, to assess whether function of FT in regulating flowering time was similar to that on the terrestrial condition. The expression of HSPpro:: GFP and HSPpro::FT in Arabidopsis leaves at 37C under shortday conditions, were monitor by a plant GFP imager. In the same time, time-lapse images also documented the effect of microgravity on the flowering induction of Arabidopsis and rice plants under a long-day (16h light::8h dark) and a short-day (8h light::16h dark) conditions, respectively. 37C heating for 30 min induced strong expression of GFP and FT in the leaves of Arabidopsis plants in microgravity but flowering time apparently delayed. For the first time, the importance of gravity in expression of FT gene and its induction flowering in microgravity was unequivocally demonstrated. The network of transcriptional regulation of flowering gene expression are also analyzed.

F1.1-0010-18 REGULATION OF CORTICAL MICROTUBULE ORGANIZATION BY ASSOCIATED PROTEINS IN PLANT CELLS IN SIMULATED MICROGRAVITY

Galina Shevchenko, galina-shevchenko@ya.ru Institute of Botany of NAS of Ukraine, Kiev, Ukraine

Kostya Krutovsky, konstantin.krutovsky@forst.uni-goettingen.de Germany

Cortical microtubules (cMTs) are highly dynamic plasma membrane bound arrays that can undergo reorganization affected by internal or external stimuli, including gravity and mechanical stress. It still remains unclear how parallel orientation of MTs in cortical arrays is controlled, and what determines whether an array will be oriented transverse or longitudinal relative to the cell axis. CMTs are known to be stabilized by numerous MT associated proteins, among which are MAP65-1, CLASP and Phospholipase D delta (PLD delta) that can bundle antiparallel MTs, regulate MT plus-end dynamics and stabilize cell wall-plasma membrane-cytoskeleton continuum. Experiments with Arabidopsis thaliana seedlings grown on the 2D slow rotating clinostats have revealed a decreased expression of MAP65-1, CLASP and PLD delta under clinorotation. Pharmacological studies with oryzalin (inhibitor of tubulin polymerization) provided evidence that activity of MAP65-1, CLASP and PLD delta depends on the state of MTs and the decrease in their expression happened due to MT depolymerization. Contrary, under clinorotation, expression of the MAP65-1, CLASP and PLD delta was increased, and supposedly aimed at stabilization of cMT arrays, which could be disordered by stress stimuli. Each of these proteins stabilizes cMT in a special way referring to its functional activity and participates either in MT bundling and plus-end stabilization or promotes connection of MTs with plasma membrane. Our study contributes into understanding of plant cell growth regulation and cytoskeleton involvement in the mechanism of gravity signaling in plants.

F1.1-0011-18 PLANT ROOTS CHANGE THEIR GRAVITROPIC REACTION IN STATIC MAGNETIC FIELD OF DIFFERENT ORIENTATION COMBINED WITH ALTERNATIVE ELECTRIC FIELD OF DIFFERENT ORIENTATION

Nadiia Sheykina, sheykina@ukr.net

National University of Pharmacy, Kharkov, Ukraine Nina Bogatina, n_bogatina@rambler.ru

Institute for low temperature physics &Engineering of National Academy of science of Ukraine, Kharkov, Ukraine

Alexandr Linnik, biologyneuph@gmail.com

Institute for low temperature physics &Engineering of National Academy of science of Ukraine, Kharkiv, Ukraine

It was shown before that the effect of the combined magnetic field on the plants' roots gravitropic reaction depended essentially on the initial orientation of roots and combined magnetic field and gravity vectors. Aim of the work was to summary the experimental results obtained in our previous works and to understand the common mechanism of these differences. So the experiments of simultaneous action of static magnetic field and alternative electric field of different orientations relatively each other were observed. The gravitropic reaction of cress roots was investigated in static both vertical and horizontal magnetic fields and alternative electric field of different directions. The alternative electric field was tuned to cyclotron frequency of Ca2+ ions in magnetic fields. It was shown that the direction of roots relatively both static magnetic field and alternative electric field is very important. The effect may be explained by membrane breathing caused by alternative electric field. The alternative electric field created the alternative magnetic field. The results in combined magnetic field coincided very well with the results obtained in static magnetic field combined with alternative electric field.

F1.1-0012-18 CELL CYCLE EVENTS IN PLANTS BY THE CONDITIONS OF ALTERED GRAVITY

Olga Artemenko, oartemenko66@gmail.com

Institute of Botany of NAS of Ukraine, Kyiv, Ukraine

The leading areas of modern biology space are cell biology under conditions of altered gravity and definition the cellular and molecular mechanisms plants gravisensitive. The most investigations aimed at solving the fundamental problems of cell biology and are in the knowledge of basic metabolic processes in the cell, growth, development and reproduction of plant organisms in microgravity. One of them is research in the field of space biology contribute to a clarification of the fundamental problems of space biology and create the controlled human life-support systems in manned space flight including the biotechnology development. But the create of reliability of forecasting systems in living space flights possible by the base of deep and comprehensive study of the impact factors of space flight on living organisms and their adaptation responses. The obtained literature data of cell cycle events and duration by microgravity are contradictory and diverse, that is does not allow to understand the integrity of the process. We show known data of the processes of beginning plant cell cycle events by conditions of altered gravity (real or simulated) and our own results for understanding real state of plant cell in the same conditions and for identify future study areas.The conflicting data about the increase or decrease of proliferative activity caused by the different timing of cell cycle research. During the first cell cycle is an increase the transcription of certain cell cycle genes and delay of transition from G1- phase to phase of DNA synthesis, which leads to a decrease of the proliferative pool. In all experiments we can see that in microgravity conditions and under clinorotation the duration of first cell cycle more than in control. We suppose that this is due to prolongation of G1- phases (pre-synthetic) in the cycle. However, in the later stages of growth the increase of proliferative activity might indicate the work of recovery and adaptation mechanisms of cell's life support.

F1.1-0013-18 LIPID BILAYER OF THE PLASMALEMMA IN PEA SEEDLING EPICOTYL CELLS IS SENSITIVE TO SIMULATED MICROGRAVITY

Olena Nedukha, o.nedukha@hotmail.com

Institute of Botany of Nat Acad Sci Ukraine, Kiev, Ukraine

Lipid bilayer of the plasmalemma in pea seedling epicotyl cells is sensitive to simulated microgravity Olena Nedukha, Elizabeth Kordyum and Tamara Vorobiova Institute of Botany of NASU, Kiev, Ukraine. Tereschenkivska str., 2, 01601, Kiev, Ukraine. E-mail: o.nedukha@hotmail.com

Biological membranes, especially plasmalemma, and their properties and functions can be considered as the most sensitive indicators of the effect of gravitation or altered gravity on the cell. We studied the composition and content of lipids (glycolipids, phospholipids, triglycerides, sterols) and fatty acids in the plasmalemma isolated from epicotyls of pea 6-day old seedlings grown under slow horizontal clinorotation (2 rpm). The plasmalemma was isolated from epicotyl cells, using the two-phase water-polymer system with an ultracentrifuge Optima L-90K, and was studied with transmission electron microscopy. Lipids and saturated and unsaturated fatty acids were determined by liquid chromatography using a chromatograph Angilent 1100. A length of epicotyls of seedlings grown under clinorotation was less than in control seedlings. Under clinorotation, the content of glycolipids decreased nearly 2.5 times in comparison with control ones, while the content of sterols, increased twice. The common content and composition of phospholipids, saturated and unsaturated fatty acids did not almost change under clinorotation. However, there were some changes in the content of certain fatty acids, namely: the content of myristoleic (14:1), linolic (18:2), and oleic (18:1) acids decreased, the content of linolenic (18:3), dihomolinolenic (20:3), and palmitic (16:0) acids increased. An unsaturation index of fatty acids in the plasmalemma under clinotation was similar to that in the control. This event may be explained with a new balance which is settled between increasing and decreasing certain unsaturated and saturated fatty acids in the new conditions and it maintains the membrane fluidity at the normal level. As well known, the membrane fluidity is a decisive factor for cell functioning and integrity, in particular for activity of membrane-bound proteins, protein transport and other molecules across membrane in the signaling process and cell division, A balance between unsaturated and saturated fatty acids is a fundamental biophysical determinant of membrane fluidity. The obtained data show the sensitivity of the plasmalemma lipid bilayer to simulated microgravity on the one hand, on the other hand - its ability to maintain the fluidity at the normal level and thus to make contribution in plant adaptation to microgravity. .

F1.1-0014-18 HSP90 DEPENDENCE OF PLASTICITY RESPONSES TO CLINOROTATION AND LIGHT/DARKNESS IN ARABIDOPSIS SEEDLINGS

Liudmyla Kozeko, liudmyla.kozeko@gmail.com Institute of Botany of NAS of Ukraine, Kyiv, Ukraine

Two main regulators of plant growth activity and orientation in space are gravity and light. Alterations of these factors affect significantly the growth pattern. Light-grown Arabidopsis thaliana seedlings have short hypocotyls and long roots, but dark-grown ones have elongated hypocotyls and shorter roots. Altered gravity, in particular, clinorotation disorients the growth. However, interaction of these effects is not well understood. It has been shown that a role in the networking different signal pathways and plasticity responses may play HSP90. This chaperone family is involved in many cellular processes through regulation of a diverse set of substrate proteins. In particular, it takes part in hormonal signaling, cell cycle control, dark and gravity responses, photomorphogenesis etc. In addition, there are evidences for its participation in restriction of stochastic development. In this study, involvement of two cytosolic HSP90s in plastic responses of A. thaliana seedlings to white light/darkness under horizontal clinorotation (2 rpm) has been tested. Athsp90-1 and Athsp90-4 loss-of-function mutants (NASC) were compared with Col-0 ecotype. Seedlings were grown for 6 d under the following conditions: 1) 1 g + light; 2) clinorotation + light; 3) 1 g + darkness; and 4) clinorotation + darkness, at 23±1°C. Measurement of hypocotyl, root and total length in 6-d-old seedlings demonstrated opposite effects of clinorotation in light and darkness in both the mutants and wild type. At lighting, clinorotation resulted in a decrease in the seedling length mainly due to lower root growth activity, when compared to the seedlings grown motionlessly. In contrast, in the dark, seedlings grown under clinorotation were longer than at 1 g due to more active growth of both the hypocotyls and roots. Thus, clinorotation seems to interact with the light and dark responses in different ways. At that, Athsp90-1 and Athsp90-4 showed some specific alterations in the plasticity traits. In Athsp90-1, the mean seedling length did not significantly differ from the wild type, but in the dark the hypocotyl/root ratio was lower. In Athsp90-4, a moderate reduction in growth activity at 1 g both in light and in the dark was determined, but this effect was absent under clinorotation. In addition, both mutants were characterized with higher variation of all the traits in all the variants that indicates increased development instability. Taken together, these results may suggest specific roles of AtHSP90-1 and AtHSP90-4 in the plasticity responses and, at the same time, their importance for stabilization of the growth at all the conditions.

F1.1-0015-18 DEPENDENCE OF THE GRAVITROPIC REACTION'S THRESHOLD ON THE DIRECTION OF MAGNETIC INDUCTION OF THE STATIC MAGNETIC FIELD RELATIVELY CRESS ROOTS

Nadiia Sheykina, sheykina@ukr.net

National University of Pharmacy, Kharkov, Ukraine Nina Bogatina, n_bogatina@rambler.ru

Institute for low temperature physics &Engineering of National Academy of science of Ukraine, Kharkov, Ukraine

It was revealed that the gravitropic reaction's threshold value (value of magnetic induction) of cress roots depended essentially on the relative location of roots and static magnetic field. Although in all cases the gravitropic reaction had the threshold character, the magnitude of the threshold essentially differed (by two orders) for different directions of roots relatively the static magnetic field. The explanation of the effects observed was proposed. It was based on the quantitative difference between the interactions of static magnetic field with ions and ion's magnetic moments. It was shown that both effects were possible. The difference was caused by ions downstream. All experiments were fulfilled under well reproducible magnetic conditions i.e. in μ-metal shield or superconductive shield with warm volume. The magnetic field of needed direction was created artificially.

F1.1-0016-18 ADAPTATION OF PEA PLANTS TO LOW LIGHT CONDITIONS UNDER THE INFLUENCE OF SIMULATED MICROGRAVITY

Vasyl Brykov, brykov_vo@nas.gov.ua

Institute of Botany of NAS of Ukraine, Kyiv, Ukraine

It is well known that it is possible to obtain plant biomass and seeds in conditions of real microgravity while maintaining optimal parameters in the growth chamber. Providing optimal conditions for plant cultivation during long-range space missions can be disturbed. Providing optimal (high) light level in future space greenhouses of large size may be an excessive load on power supply systems. Therefore, it is important to know the adaptive rearrangements of plants under suboptimal and/or stressful conditions, which are likely to arise during long-term extraterrestrial missions. In addition, it is important to know the minimal sufficient quantitative parameters that are necessary for plants development, namely lighting, watering, mineral nutrition, and gas composition for designing feather onboard greenhouses. The aim of our work was to determine the respiration and photosynthesis response of peas plants on the vegetative growth phase under the influence of simulated microgravity (clinorotation 2 rpm/min) under sufficient light (180 mol m−2 s−1 PAR) and low light (20 mol m−2 s−1 PAR) conditions. The duration of clinorotation was 12 and 18 days. The ultrastructure of mitochondria and plastids, chlorophyll fluorescence parameters, tissue respiration, soluble sugar content and in vivo CO2 exchange under light/dark conditions were determine. Adaptive changes of plants under reduction of light level, namely, decrease of fresh and dry weight of plants, significant reduction of leaf thickness, change of the ultrastructure of chloroplasts and chlorophyll fluorescence parameters are observed in the conditions of simulated microgravity. At the same time independently of light conditions clinorotation caused to slightly increase of respiration and photosynthesis according CO2 exchange data and tissue respiration of mitochondria. It is suppose that an increase in the level of respiration can affected of the accumulation of nutrients in the seed of plants in the condition of microgravity.

F1.1-0017-18 STARCH CHARACTERISTICS OF POTATO MINITUBERS CHANGE UNDER SIMULATED MICROGRAVITY

Olena Nedukha, o.nedukha@hotmail.com

Institute of Botany of Nat Acad Sci Ukraine, Kiev, Ukraine

Starch characteristics of potato minitubers change under simulated microgravity Olena Nedukha and Elizabeth Kordyum

Institute of Botany of NASU, Kiev, Ukraine. Tereschenkivska str., 2, 01601, Kiev, Ukraine E-mail: o.nedukha@hotmail.com

Further understanding the gravisensitivity of basic cell processes and mechanisms of plant adaptation to microgravity is necessary for working out the technologies of the autotrophic chain in the Bioregenerative Life Support Systems and its reliability, since plants are considered as sources of oxygen and food for astronauts. We studied the behavior of starch in minitubers formed on potato mini plants grown during 45 days under slow horizontal clinorotation (2rpm). The content and composition of starch and soluble sugars were determined using Gilbert's method in the modification by Bolotova et al. (2001) with a spectrophotometer (SP-2000). Taking into account that potato taste properties depend on starch solubility in hot water and its boiling power, we studied these parameters with the method of Richter et al. (1975). Minitubers formed under clinorotation were larger in comparison with control ones owing to an increase in both the number of storage parenchyma layers and a size of its cells. Under clinorotation, the starch total content increased 1.4 times, while the content of monoand disaccharides decreased 1.5 times. The content of amylose in clinorotation tubers decreased 4 times, thereafter a ratio of amylose/amylopectin was 1:16, it was 1:3 in control samples. The swelling strength of starch decreased 4.6 times and its solubility in hot water - 4.5 times in comparison with those of starch in the control minitubers. These changes reflect the starch physical properties, in particular on the density and its swelling power. It is assumed, that starch becomes amorphous and loses its typical molecular structure owing to such changes. The obtained results indicate the possibility of plant vegetative reproduction and the formation of storage organs in simulated microgravity on one hand, on the other hand - the sensitivity of this process to altered gravity. As potato plants are defined the food components of Bioregenerative Life Support Systems for long-term space flights, the investigations of tuber formation and especially their quality (storage starch) by the methods of biochemistry, cellular and molecular biology require the further continuation. Dosimetry and radiation monitoring are key factors for the planning of future human exploration on deep-space missions outside of Low-Earth Orbit (LEO), as radiation exposure poses one of the major health risks for astronauts in deep space. The amount of radiation dose astronauts would accumulate during typical mission scenarios and durations can potentially exceed currently allowable exposure limits within months.

In space radiation monitoring the three main areas of concern are: 1) high-energy and deeplypenetrating Galactic Cosmic Rays (GCRs); 2) impulsive Solar Energetic Particle (SEP) events with high flux intensities up to a few hundred MeVs; and 3) secondary neutrons created by interactions of primary radiation with spacecraft material or planetary atmospheres and soils. Furthermore, in-situ radiation measurements provide invaluable input for radiation transport models that are used to calculate

expected radiation exposures and shielding effectiveness, and subsequently potential health risks for future deep-space mission scenarios.

Here, we present an overview of dosimetry in LEO, lunar orbit, and in deep space, and place the findings from years of measurements in context of what our current state of knowledge of space radiation implies for future exploration missions. Because the planet Mars is a prime goal for future exploration, we will focus in more detail on measurements conducted on the Martian surface with the Radiation Assessment Detector (RAD) as part of the Mars Science Laboratory (MSL) mission. Since Mars lacks a global magnetic field and its atmosphere is very thin, the surface is only weakly protected from impacts of GCRs and SEPs. This makes understanding and assessing the Martian surface radiation environment a key goal for future exploration. MSL/RAD has been characterizing in detail the charged and neutral particle environment induced by GCRs, as well as during short-term radiation enhancements from SEP events arriving at Mars.

We will discuss the capabilities of the existing space dosimetry instrumentation, as well as highlight areas outside the current scope where we need to improve our understanding of the space radiation environment.

F2.1-0002-18 HIGHLIGHTS OF RECENT FINDINGS ON BIOLOGICAL CONSEQUENCES OF EXPOSURES TO CHARGED PARTICLE RADIATION

Gregory Nelson, grnelson@llu.edu

Loma Linda University, Loma Linda, California, United States

COSPAR session F2.5 focuses on cross discipline aspects of space radiation and consequences for human health and long-term spaceflight mission success. In this presentation I will highlight findings in the last few years from ground-based accelerator research and spaceflight experiments that address the biological consequences of exposure to charged particle radiation typical of galactic cosmic rays and solar particle events. This is a broad topic that includes molecular damage and repair, cell signaling, systems biology, tissue and organ responses, and late pathological consequences to animal models and humans. It also includes the impact of radiation on microorganisms in the spaceflight environment, including microbiota of the body, which interact with host organisms, their life support systems and inform issues important to astrobiology. Health consequences range from acute radiation syndrome to cancer, cataracts, and impaired behavior and performance. Charged particle exposure regimens are evolving from single particle, moderate dose, acute exposures to multi-ion, low dose and dose rate schedules that represent the spaceflight environment with ever higher fidelity and are revealing complex dose effect relationships. Spaceflight in situ measurements have also evolved in their sophistication and address biological reactions to radiation in the context of other spaceflight stressors. The presentation will illustrate how the space radiation research community continues to refine its understanding of the biological processes underlying human health and safety in the context of spaceflight.

F2.1-0003-18 SPACE RADIATION INDUCED BIOLOGICAL EFFECTS AND THEIR MECHANISMS IN DIFFERENT ORGANISMS

Yeqing Sun, yqsun@hit.edu.cn

Dalian Maritime University, Dalian, China

Space radiation biology is one of important parts of space biology, mainly focusing on space radiation induced biological effects and their mechanisms of the genetic variations in organisms. As well known, space radiation environment is extremely complex, including multiple primary radiation particles with different initial energies and various secondary particles in the spacecraft. Despite the low dose and dose rate of space radiation, there are strong evidences that space flight can induce a series of DNA damage and other stress responses in organisms.

There are more than 50 varieties of seeds of Oryza sativa on board recoverable satellites ("JB-1", "20th, 21th and Shijian 10 recoverable satellites") and spacecrafts ("Shenzhou-3", "Shenzhou4", "Shenzhou-6" and Shenzhou-8) since 1996. After landing from spaceflights, the phenotype variations, cytological effects, the characteristics of genomic mutations, and the changes of protein profiling and genomic methylation level were further studied, which indicating that space radiation could induce wide variations in different levels of organisms. In addition, the inheritable effects could also be observed in these results. In order to study on dose and different LETs dependent biological effects, we had also investigated the effects in the 24 japonica and indica varieties of O. sativa with different maturation periods induced by space radiation and γ-rays, which were the same radiation dose as spaceflight (2 mGy) but different LETs HZE ions by Heavy Ion Medical Accelerator In Chiba (HIMAC), respectively. In the levels of plant height and ripening rate, the results showed that the biological effects caused by space radiation in different varieties were equivalent to the mutagenic effects induced by 10 50Gy γ-rays. The phenotypic mutations, chromosomal aberrations and mitotic indexes of root tip meristem in 9 varieties of O. sativa showed that the mutagenic effects caused by space radiation were significantly higher than those of the same doses of the iron ions radiations (500keV/μm), neon ions radiations (31 keV/μm) and carbon ions radiations (13.3 keV/μm). The analysises of the genomic methylations showed that space flight and heavy ion simulated radiations could cause the changes of genetic methylations in genomic DNA, and the changes of methylations were more pronounced in the phenotypic variants.

To study the synergistic effect of space radiation and microgravity on organisms, dauer larvae of Caenorhabditis elegans, including dys-1 mutant, ced-1 mutant, and wild-type, were exposed to spaceflight and spaceflight control (in a 1×g centrifugal device). Functional genomics results indicated that, microgravity, depending on gravity sensor of organisms, enhanced the DNA damage response in the presence of space radiation, and probably play a vital role on DDR during short-duration spaceflight. These results indicated that space radiation biological effects were significantly different from those of ground-based irradiations. In addition, it can be seen that the space radiation biological effects cannot be described by a simple dose-effects relationship due to the complexity of the space radiation environment, and should be considered from the perspective of multi-dimensional and systematic views of point. Therefore, the further in-depth studies will focus on the systems biology approaches, which will be used to mine the biomarkers sensitive to the space radiation and the key factors or main mechanisms of the biological effects induced by space radiation.

F2.1-0004-18 INTERPLAY OF SPACE RADIATION AND MICROGRAVITY IN DNA DAMAGE AND DNA DAMAGE RESPONSE

Honglu Wu, honglu.wu-1@nasa.gov

NASA/Johnson Space Center, Houston, Texas, United States

Maria Moreno-Villanueva, maria.moreno-villanueva@uni-konstanz.de NASA-Johnson Space Center, Konstanz, Germany

Ye Zhang, ye.zhang-1@nasa.gov

NASA/Kennedy Space Center, Kennedy Space Center, Florida, United States

In space, multiple unique environmental factors, particularly microgravity and space radiation, pose constant threat to the DNA integrity of living organisms. Specifically, space radiation can cause damage to DNA directly, through the interaction of charged particles with the DNA molecules themselves, or indirectly through the production of free radicals. Although organisms have evolved strategies on Earth to confront such damage, space environmental conditions, especially microgravity, can impact DNA repair resulting in accumulation of severe DNA lesions. Ultimately these lesions, namely double strand breaks, chromosome aberrations, micronucleus formation, or mutations, can increase the risk for adverse health effects such as cancer. How spaceflight factors affect DNA damage and the DNA damage response has been investigated since the early days of the human space program. Over the years, these experiments have been conducted either in space or using ground-based analogs. We will review the evidence for DNA damage induction by space radiation and/or microgravity as well as spaceflight related impacts on the DNA damage response. We will also discuss the conflicting results from studies aimed at addressing the question of potential synergies between microgravity and radiation with regard to DNA damage and cellular repair processes. We conclude that further experiments need to be performed in the true space environment in order to address this critical question.

Although charged particles in space have been detected with radiation detectors on board spacecraft since the discovery of the Van Allen Belts, reports on the effects of direct exposure to space radiation in biological systems have been limited. Measurement of biological effects of space radiation is challenging due to the low dose and low dose rate nature of the radiation environment, and due to the difficulty in distinguishing the radiation effects from microgravity and other space environmental factors. In astronauts, only a few changes, such as increased chromosome aberrations in their lymphocytes and early onset of cataracts, are attributed primarily to their exposure to space radiation. In this study, cultured human fibroblasts were flown on the International Space Station (ISS). Cells were kept at 37 °C in space for 14 days before being fixed for analysis of DNA damage with the -H2AX assay. The 3-dimensional -H2AX foci were captured with a laser confocal microscope. Quantitative analysis revealed several foci that were larger and displayed a track pattern only in the Day 14

flight samples. To confirm that the foci data from the flight study was actually induced from space radiation exposure, cultured human fibroblasts were exposed to low dose rate rays at 37 °C. Cells exposed to chronic rays showed similar foci size distribution in comparison to the non-exposed controls. The cells were also exposed to lowand high-LET protons, and high-LET Fe ions on the ground. Our results suggest that in G1 human fibroblasts under the normal culture condition, only a small fraction of large size foci can be attributed to high-LET radiation in space.

F2.1-0006-18 DNA DAMAGE RESPONSE OF EX-VIVO PORCINE EYE LENSES IN ORGANCULTURE AND IN-VITRO CULTURED LENS EPITHELIAL CELLS TO IONIZING RADIATION

Christa Baumstark-Khan, christa.baumstark-khan@dlr.de DLR - Inst. of Aerospace Medicine, Koeln, Germany Bikash Konda, bikash.konda@dlr.de

Deutsches Zentrum fuer Luft-und Raumfahrt (DLR), Köln, Germany Luis Spitta, luis.spitta@dlr.de

DLR - Inst. of Aerospace Medicine, Koeln, Germany Christine Hellweg, christine.hellweg@dlr.de

DLR - Inst. of Aerospace Medicine, Koeln, Germany

Astronauts on space missions, especially on long-term missions to Moon or Mars have a higher risk for the expression of radiation late effects such as cancer or sub-capsular cortical eye lens opacities. This is due to higher dose and different patterns of cellular energy deposition from high-linear-energy-transfer (LET) components of galactic cosmic radiation in space than that of terrestrial low-LET radiation on Earth. The eye lens is considered to be a radiation sensitive organ with radiation induced cataract to occur with a threshold absorbed dose of 0.5 Gy of sparsely ionizing radiation. For terrestrial occupational radiation lens exposure limit is set to yearly 20 mSv by the International Commission on Radiological Protection (ICRP, Statement on tissue reactions, Ottawa, Canada, 2011). Doses perceived by astronauts are much higher: in average 150 mSv per year on the International Space Station (ISS) and 1.2 to 1.4 mSv per day on Apollo and Skylab missions (Cucinotta FA, Manuel FK, Jones J, Iszard G, Murrey J, Djojonegro B, Wear M. Space radiation and cataracts in astronauts. Radiat Res. 156:460-466, 2001).

Radiation-induced lens opacification is assumed to initiate from post irradiation proliferative activity of genetically damaged lens epithelial cells with alterations in cell cycle control, apoptosis, differentiation, and cellular disorganization, or other pathways controlling lens fiber cells' differentiation. As the porcine eye lens is similar to the human lens in size and anatomy DNA damage response was investigated in ex-vivo porcine lenses in organ culture, in in-vitro cultivated lens epithelial slabs (ES) and in porcine lens epithelial cells (pLEC). Cell survival of proliferative cells was calculated from colony forming ability (CFA) assay. The phosphorylated form of H2AX, known as γH2AX, was used as a molecular marker to visualize DNA double strand breaks (DSB) and their repair. The modified thymidine analogue EdU was efficiently incorporated into newly synthesized DNA and visualized by a photo-stable Alexa Fluor dye in a fast, highly-specific click reaction. Propidium iodide based DNA staining for cellular DNA content marked radiation-induced cell cycle disturbances.

Results for in-vitro cultivated pLEC are compared to in-vitro cultivated epithelial slabs and to ex-vivo porcine lenses in organ culture. The fraction of cells positive for DNA synthesis as documented microscopically for a 2 h EdU pulse was highest in pLEC, followed by ES > whole lenses. In pLEC the cell survival curve of immediate plated cells and after a recovery period of 24 h follow the equation S=1.40xD+ln 1.47 and S=1.59xD+ln 1.79, respectively. DNA DSB are induced in a dose-dependent manner (18 DSB/cell/Gy) and repaired during successive recovery (5 DSB/cell/Gy residual damage after 24 h). For doses >2 Gy a cell cycle arrest in G2 phase occurred 24 h after X-irradiation and persisted up to 72 h post-irradiation. DNA DSB induction and repair could as well be documented for ES and whole lenses after Xirradiation. In whole lenses, the amount of residual damage (after 24 h and 48 h) was highest in the equatorial zone while in the central epithelial zone DSB repair seemed to proceed with time in a manner comparable to in-vitro cultivated pLEC.

Summary: Lens organ culture allows cellular metabolism and DNA synthesis in whole lenses. Repair of DNA DSB takes place in the central epithelial layer and is reduced in the equatorial region of cultivated lenses.

F2.1-0007-18 PROTON AND FE ION-INDUCED EARLY AND LATE CHROMOSOME ABERRATIONS IN DIFFERENT CELL TYPES

Rosalin Goss, rosalinflood@gmail.com

Texas Southern University, Houston, Texas, United States Honglu Wu, honglu.wu-1@nasa.gov

NASA/Johnson Space Center, Houston, Texas, United States

An early stage of cancer development from radiation exposure is believed to be genomic instability (GI), which accelerates the mutation rate in the descendants of the cells surviving the initial damage. To investigate GI induced by charged particles, we exposed human lymphocytes ex vivo, human fibroblasts, and human mammary epithelial cells to high energy protons and Fe ions, and collected chromosomes at different cell divisions after exposure. Chromosome aberrations were analyzed with fluorescence in situ hybridization (FISH) with whole chromosome specific probes. Comparison of chromosome damages immediately after irradiation to late damages after multiple cell divisions indicated that, after proton irradiation, the frequency of late aberrations was about half of the initial value for both the lymphocytes and epithelial cells. In contrast, after Fe ion irradiation, the late chromosome aberration frequency was about half of the initial value for human epithelial cells, but was significantly lower for human lymphocytes, suggesting different relative biological effectiveness (RBE) values between early and late chromosome aberrations and between different cell types. In addition to human cells, we isolated bone marrow cells from CBA/CaH and C57BL/6 mice, and irradiated the cells to charged particles for analysis of cell survival and chromosome aberrations after multiple cell divisions. After Fe ion irradiation, the late chromosome aberration frequency was similar to the early damages for CBA cells, but different for C57 cells. Our results suggest that RBE values can be different for different cell types, and for the same cell type of different mouse strains.

F2.1-0008-18 CHARGED PARTICLES AND MITOCHONDRIAL SIGNALING

Tom K. Hei, tkh1@cumc.columbia.edu

Columbia University Medical Center, New York, New York, United States Jinhua Wu, jw3185@cumc.columbia.edu

Columbia Univeristy Medical Center, New York, New York, United States

High energy and high charged particles are the major components of the natural radiation environment in space and their biological characteristics are of major concerns to space agencies for the purpose of radiation protection to the astronauts. The scientific basis for the biological effectiveness of these (HZE) radiation has been accumulated over several decades using a variety of cellular and molecular endpoints and with a range of laboratory model systems. Charged particles altered the dynamic equilibrium of mitochondrial fusion and fission and reduced oxidative metabolic function of cells. In contrast, human small airway epithelial (SAE) cells with depleted mitochondrial DNA (0) and, therefore, no oxidative metabolic functions, exhibited a significantly lower response. Mitochondrial dysfunction induced by targeted cytoplasmic irradiation led to activation of autophagy, which degraded dysfunctional mitochondria in order to maintain cellular energy homeostasis. The activation of autophagy was cytoplasmic irradiation specific and was not detected in nuclear irradiated cells. The autophagy was oxyradical-dependent and required the activity of the mitochondrial fission protein dynamin related protein 1 (DRP1). The resultant mitochondrial fission induced phosphorylation of AMP activated protein kinase (AMPK) leads to further activation of the extracellular signal-related kinase (ERK) 1/2 with concomitant inhibition of the mammalian target of rapamycin (mTOR) to initiate autophagy. Inhibition of autophagy resulted in delayed DNA damage repair and decreased cell viability, which support the cytoprotective function of autophagy. Our results reveal a novel mechanism by which dysfunctional mitochondria are degraded by autophagy to protect cells from toxicity induced by charged particle irradiation.

F2.1-0009-18 NF-KB ACTIVATION AFTER HEAVY ION EXPOSURE: INCREASING THE SENSITIVITY OF THE REPORTER SYSTEM

Biological effects of ionizing radiation are strongly influenced by the radiation quality. The biological effectiveness of accelerated heavy ions (which constitute the biologically most important radiation type in space) with medium to high linear energy transfer (LET), for affecting DNA damage response pathways as a gateway to cell death or survival, is of major concern for space missions. The transcription factor Nuclear Factor κB (NF-κB) can be activated during the DNA damage response. In order to determine NF-κB activation after exposure to different radiation qualities, a reporter system was constructed, in which the destabilized variant of a reporter gene (DD-tdTomato) is controlled by a synthetic promoter containing four κB binding sites for NF-κB. The current study aims to analyze NF-κB activation after exposure to space-relevant radiation qualities including 16O (95 MeV/n, LET 51 keV/mum), 48Ti (1000 MeV/n, LET 108 keV/mum), 36Ar (95 MeV/n, LET 272 keV/mum) and 12C (95 MeV/n, LET 73 keV/mum) ions by means of the HEK-pNFκB-DD-tdTomato-C8 reporter cell line. The fluorescent protein DD-tdTomato encompasses the ProteoTuner system: DD-tdTomato is rapidly degraded in human cells, but in the presence of the synthetic molecule Shield-1, the fluorescent protein is stabilized and a stronger fluorescent signal is achieved. The fluence and dose of heavy ions and the number of hits per cell nucleus that double the NF-κB-dependent DD-tdTomato expression were investigated in absence and presence of Shield-1. In absence of Shield-1, 44 hits of 16O ions and 12 hits of 48Ti per cell nucleus were required to double the NF-κB dependent DD-tdTomato expression whereas only 3 hits of 36Ar were sufficient. In presence of Shield-1, even single particle hit of 36Ar with LET 272 keV/mum doubled the NF-κB-dependent DDtdTomato expression. In the presence of Shield-1, the fluorescent protein DD-tdTomato was accumulated inside the cell and the detection limit for activation of NF-κB-binding site containing promoter activity after 36Ar ion exposure was lowered. In conclusion, stabilization of the reporter protein can increase the sensitivity for NF-κB activation

detection by a factor of three and the effect of single particle hits was detected. With this sensitive HEK-pNFκB-DDtdTomato-C8 reporter system, agents counteracting heavy ion induced NF-κB activation can be screened at low cost.

F2.1-0010-18 BIOLOGICAL EFFECTS OF RAPID SEQUENTIAL EXPOSURE TO MULTIPLE ION BEAMS IN MAMMALIAN MODEL SYSTEMS: CANCER-RELEVANT AND NON-CANCER ENDPOINTS

The biological consequences of exposure to space relevant radiations have generally been examined with acute exposure to accelerated ion beams with one or at most two ion species employed in ground-based studies. However, the radiation environment in deep space includes ions from protons to uranium across a wide energy range. Recently, it has become possible to deliver high energy protons, He ions, and heavy ions in rapid succession at the NASA Space Radiation Laboratory. A standardized GCR simulator model is still under development, however it has been suggested by others that the best field to simulate a GCR environment would be derived from a local tissue model that takes into account shielding and fragmentation of the free GCR spectrum as it is transported through relevant materials. To this end, feasibility studies have been designed using high energy protons, which represent a majority of the ions in a model local tissue field, together with two other high energy ions delivered in rapid succession. In murine tissues and cells, cancer-relevant endpoints have been examined with cytotoxicity and autosomal mutations as indicators of genotoxic effects, and non-cancer endpoints have focused on cognitive and behavioral changes. Additional studies have examined the impact of rapid, sequential exposure to three ion species (a majority of high energy protons and lesser contributions from two heavier ions) on endpoints

that are indications of cardiac risk in rats. This presentation will compare and contrast the effects of exposure to single ions with the effects of combined exposure to three particle beams using the relevant model systems.

F2.1-0011-18 EFFECTS OF MODELED MICROGRAVITY ON NON-TARGETED RADIATION EFFECTS IN ARABIDOPSIS THALIANA

Po Bian, bianpo@ipp.ac.cn

Particle radiation and microgravity are two important space environmental factors which have inevitable impacts on organisms during space missions. A remarkable characteristic of space radiation is chronic exposure at a low dose and fluence, which gives rise to two critical nontargeted radiation effects: radiation-induced bystander effects (RIBEs) and radio-adaptive responses (RARs). To date, almost all experiments of RIBEs and RARs, however, have been demonstrated under the earth-based conditions. This brings forward the need for evidence regarding the effect of microgravity on RIBE and RAR. For this purpose, a two-dimensional rotation clinostat was used to model the microgravity, in which the RIBEs and RARs in Arabidopsis thaliana (A. thaliana) was investigated. It was shown that the modeled microgravity affected the RIBE in intra-plants, exhibiting the repressive effects on the expressions of the genes in HR repair pathway, ROS level, and alleviation of transcriptional gene silencing (TGS) in the bystander tissues. Similarly, the alleviation of TGS could not be effectively induced by irradiated neighboring plants in modeled microgravity, suggesting a repressive effect of microgravity on RIBE in inter-plants. The low-dose priming irradiation can attenuate the repression of following high-dose irradiation to root growth of A. thaliana. However, in the modeled microgravity, the attenuation was not initiated by the priming radiation, indicating a modulation of modeled microgravity on the RAR in plants. These results indicate that the non-targeted radiation effects experimented on the earth cannot completely reflect their real manifestations in space environments.

F2.1-0012-18 CREMIR914 REGULATED UVB ADAPTATION IN CHLAMYDOMONAS REINHARDTII

Institute of Hydrobiology, CAS, Wuhan, China

UV radiation is one of the factors that may harm earth organisms in space exploration, and algae have developed highly efficient adaptations to UV radiation through the course of evolution. To date, studies investigating the mechanisms of UV adaptation in algae have focused on physiological regulation and associated protein coding genes, with no reports on associated protein non-coding genes. In a previous study, we found that Cre-miR914 was significantly down-regulated in Chlamydomonas reinhardtii in response to heat shock. Additionally, bioinformatics analysis and degradom sequencing indicated that the target gene of Cre-miR914 is RPL18 (ribosomal protein L18). In the present study, we want to know whether Cre-miR914 and RPL18 play roles in response to UV-B radiation. We measured the expression of CremiR914 and RPL18 in response to UV-B radiation through Q-PCR analysis. Then, we constructed cell lines overexpressing Cre-miR914 or RPL18, and performed survival experiments under UV-B stress. The results showed that Cre-miR914 overexpression depressed resistance while RPL18 overexpression enhanced tolerance to UV-B radiation. These results indicate that Cre-miR914 and its target gene RPL18 are involved in the adaptation to UV-B in C. reinhardtii, which represents a new regulatory pathway for UV-B adaptation in algae.

F2.1-0013-18 CHANGES IN NEURONAL FUNCTION AND COGNITIVE PERFORMANCE FOLLOWING EXPOSURE TO VERY LOW DOSES OF HELIUM PARTICLES

Helium (4He) particles will form a significant portion of the radiation environment on exploratory class missions, such as a mission to Mars. Because the linear energy transfer (LET) of 4He particles is low (0.9 keV/µm), they might be expected to produce less damage to neuronal tissue as they pass through the brain. As such, they might be expected to have little effect on cognitive performance.

Sprague-Dawley rats weighing between 200-225 g were given either head-only or whole-body exposures to 4He particles (1000 MeV/n) at doses ranging from 0.01 to 0.5 cGy. Following exposure, the brains were removed from a subset of the rats for analysis of oxidative stress by measuring NADPH oxidase (NOX2) expression. Measurements were also made of phosphorylated-cyclic AMP (cAMP)-responsive element-binding protein (CREB) and nuclear factor E2-related factor 2 (Nrf2). The remaining rats (n = 10/dose) were shipped to UMBC for behavioral testing, including elevated plus maze (baseline anxiety); novel object and novel spatial recognition (learning and memory); and operant responding on an ascending fixed-ratio schedule (motivation to work for reward).

The results indicated that changes in behavioral endpoints could be observed following exposures to 4He particles at doses as low as 0.01 to 0.025 cGy. Differences in neurochemical endpoints were observed following exposure to doses as low as 0.05 cGy (the lowest dose tested). There were no significant differences between head-only and whole-body exposures on behavioral performance. Analyses of the neurochemical data suggest that whole body exposures may not have been as effective in producing changes in neuronal functioning as were head-only exposures.

Because 4He particles will constitute a significant fraction of the radiation dose to which astronauts will be exposed, the present results suggest the possibility that astronauts on exploratory class missions may be at a greater risk for HZE-induced cognitive deficits than anticipated.

ACKNOWLEDGMENTS This research was supported by NASA Grants: NNX13AB73G and NNX16AE06G.

F2.1-0014-18 NEUROCHEMICAL CHANGES IN SPECIFIC REGIONS OF RAT BRAIN FOLLOWING PARTIAL OR WHOLE BODY EXPOSURES TO 56FE PARTICLES

Barbara Shukitt-Hale, barbara.hale@tufts.edu USDA-ARS, Boston, Massachusetts, United States Shibu Poulose, shibu.poulose@tufts.edu Massachusetts, United States

Donna Bielinski, donna.bielinski@tufts.edu

USDA-ARS, Boston, Massachusetts, United States Marshall Miller, mease19@gmail.com

University of Maryland, Baltimore County, Baltimore, Maryland, United States

Exposing young rats to particles of high energy and charge (HZE particles), a ground-based model for exposure to cosmic rays, disrupts cognitive performance, possibly via production of oxidative stress and inflammation and disruption of the functioning of neuronal communication in critical regions of the brain. Furthermore, these changes in neuronal function are similar to those seen in aging. Although it is known that radiation exposure can cause long-term damage to the brain, it is unknown if this exposure needs to occur directly to the brain or if hits restricted to the body will also cause residual damage. The present experiments were designed to evaluate the neuromodulation of oxidative stress and inflammation following head-only, body-only, and whole-body exposures to 56Fe particles in two areas of the brain critical for cognitive function, the hippocampus and the frontal cortex.

Male, Sprague-Dawley rats were given either head-only, body-only or whole-body exposures to 56Fe (600 MeV/n; 50cGy) particles at the NASA Space Radiation Laboratory at Brookhaven National Laboratory. Tungsten bricks were used to shield either the head or the body, as required; the bricks were removed for whole body exposures. The non-irradiated control rats (0 cGy) were taken to the NSRL, but not exposed. Rats were euthanized 60 days following irradiation.

Results indicated a significant ($p<0.05$) increase in NF-B, a pro-inflammatory transcription factor, in the hippocampus of rats exposed to 56Fe irradiation, regardless of the target of exposure. An indication of dysfunctional autophagy (i.e., accumulation of ubiquitinated p62)

was also increased in hippocampus and frontal cortex, regardless of target of exposure. Two endogenous antioxidant enzymes, GST and SOD, showed increased activation in head-only exposure, but decreased activation with body-only and further significant decrease with wholebody exposure. Nuclear factor E2-related factor 2 (Nrf2) expression, a transcription factor for antioxidant enzymes, and a possible link between oxidative stress, neuroinflammation and autophagy mechanisms, showed differential effects depending on the area of the brain and the target of exposure.

These results show that exposures restricted to the body can still disrupt neuronal function, as some measures were directly affected by body-only radiation, while other measures showed greater change following whole-body exposures. Oxidative stress and inflammation caused by radiation seem to be critical factors in these neuromodulatory changes, as well as in the behavioral disruptions seen following irradiation with cosmic rays.

ACKNOWLEDGMENTS This research was supported by NASA Grants: NNX13AB73G and NNX16AE06G.

F2.1-0015-18 NEUROBIOLOGICAL EFFECTS OF HIGH ENERGY PROTONS AND CARBON IONS 12C IMPACT ON MONKEY'S BRAIN

Andrey Shtemberg, shtemberg@imbp.ru IMBP, Moscow, Russia

Alexandra Belyaeva, yasya@mail.ru IMBP, Moscow, Russia

The greatest danger for astronauts in interplanetary spaceflights is the galactic space rays (high energy protons and heavy ions), that may cause to the significant disorders of central nervous system functions and, in accordance, to disorders of astronauts performance capability and operator performance. These disorders determine risk of astronaut's death immediately during spaceflight as contrasted with delayed stochastic effects. Consequently the neurobiological effects of two components of galactic space rays - high energy protons and carbon ions 12C in model ground experiment with rhesus monkeys (Macaca mulatta) upon indicators of cognitive functions, that modeling of basic elements of operator performance, and monoamines and their metabolites in peripheral blood were investigated. The monkey's head irradiation by protons in dose 3 Gy did not caused significant changes of cognitive functions and monoamines and their metabolites in peripheral blood. But the carbon ions impact in dose 1 Gy were provoked the significant decreasing of cognitive functions and dopamine metabolites concentration in blood of monkeys with excitable unbalanced type of higher nervous activity. It is expected that the decreasing of monoamines concentration in the blood plasma may be indirectly speak for corresponded decreasing of neurotransmitters concentration in the key brain structures that may be provoke of deficit of dopamine-depend behavior and cognitive functions disorders. The study was funded by the RFBR, research project № 17-29-01002.

F2.1-0016-18 SENSORY ILLUSIONS PRODUCED BY PROTON IRRADIATION

Livio Narici, narici@roma2.infn.it

INFN and University of Rome Tor Vergata, Rome, Italy Gregory Nelson, grnelson@llu.edu

Loma Linda University, Loma Linda, California, United States Andre Obenaus, aobenaus@dominion.llumc.edu

Loma Linda University Medical Center, Loma Linda, United States Elena Titova, elenatitovakrsk@gmail.com

Loma Linda University, Loma Linda, California, United States

Deep space human exploration is associated with health risks also due to the presence galactic cosmic rays (GCR: protons and higher Z ions, with spectra peaking in the high energy region) and solar particle events (SPE) mostly protons, with lower energies than GCR. Protons are used throughout the world in radiotherapy centers for cancer therapy, providing distinctive capabilities for treatment of difficult brain and head and neck tumors.

A number of anecdotal reports have suggested the exposure of the brain to irradiation either during therapy or during space travel can elicit anomalous visual responses. Astronauts have reported light flashes (phosphenes) of different colors, shape and movement, in absence of light, and correlations with particle fluxes suggested that these visual effects derive from single particle traversals, probably of the retina or optic nerve (Sannita et al 2006, Narici 2008 and references therein). Recently observations from heavy ion or proton therapy patients have reported visual illusions for which time structure has been noted associated with the pulsed nature of the radiation sources (Narici 2008, Khan et al. 2010, Schardt et al. 2013, Chuard et al. 2016). The current interpretations of mechanisms underlying these sensory illusions include the possibility of neural stimulation through the action of radiation-induced free radicals (Narici et al. 2009).

Mechanisms to describe radiation interactions with sensory and non-sensory neurons or cortex that gives rise to acute visual and other sensory illusions, especially at low doses, are not well understood and investigations into these topics have largely lapsed since the early work undertaken in the 1970's.

To approach this issue, we explored the occurrence of reported sensory events during the treatment of central nervous system tumors using the large patient database available at the Loma Linda University's Medical Center, proton treatment center.

A retrospective review of 300 proton radiotherapy patient records identified 29 reports from 19

patients who spontaneously reported visual, olfactory, auditory and gustatory illusions during treatment. Our results suggest that small numbers of protons can evoke neuronal responses on a 0.1 sec time scale sufficient to elicit conscious illusionary experiences analogous to those from normal sensory inputs. The regions of the brain receiving the highest doses corresponded with the anatomical structures associated with the type of illusion.

University of Petroleum & Energy Studies, Dehradun, India

The study deals with the spacecraft reentry. In this we come across design problems faced during reentry of space and recent researches along with some of the solutions proposed by us. Along with completion of the mission, spacecraft must also be able to return its human passengers safely to the earth's surface. In the earliest crewed spacecraft, this problem was solved simply by allowing the vehicle to travel along a ballistic path back to the earth's atmosphere. Later spacecrafts were modified to allow pilots some control over their reentry path. Perhaps the most serious problem encountered during reentry is the heat that develops as the spacecraft returns to the earth's atmosphere. Friction between vehicle and air produces temperatures that exceed 3,000°F (1,700°C). Most metals and alloys would melt or fail at these temperatures. To deal with this problem, spacecraft designers have developed a class of materials known as ablators that absorb and then radiate large amounts of heat in brief periods of time which are made out of a variety of materials, including phenolic resins, epoxy compounds, bio material and silicone rubbers. The force of deceleration and the heat generated during re-entry increase with the steepness of the angle relative to the atmosphere. If the angle is too steep, the spacecraft burns up, and anyone unlucky enough to be inside is crushed. If the angle is too shallow, on the other hand, the spacecraft skims off the edge of the atmosphere. The ideal reentry trajectory is a narrow band between these two extremes which is the Re-entry Corridor. When the object enters the upper extremities of the atmosphere, the frictional interaction with air molecules begins to slow it down, and the lost momentum gets converted into heat. Temperatures can reach 1,650 degrees Celsius (3,000 degrees Fahrenheit), and the force of deceleration can be seven or more times greater than the force of gravity. Deceleration for atmospheric reentry, especially for higher-speed Mars-return missions, benefits from maximizing the drag area of the entry system. An inflatable aeroshell provides one alternative for enlarging the drag area with a low-mass design. This could also be achieved by using high temperature tolerant parachute for atmospheric air braking. Next big problem is that of Cosmic rays. Without sufficient protection, galactic cosmic rays would penetrate spacecraft and astronaut's bodies, damaging their DNA, mutations of cells ,cancer ,disrupting nerve cells in their brains over the long-term. Shielding is necessary, but it is always a trade-off between human protection and spacecraft weight, so aluminum is used for making space crafts which is 25 percent effective at blocking heavy ion radiations particles. But the need of the hour is to look for compounds like antioxidants because they can soak up certain harmful molecules caused by this radiation. In the nutshell, this can be concluded that the reentry of space is the most dangerous part of any space derbis but it could be handled safely if proper emphasis is given. Our approach to solve this problem is by using shielding property of natural biomass against gamma rays. On a density basis, it has been observed that the cyanobacteria absorbs more of the incoming energy than Lead. In this research paper we have done a trade study and analysis on the biomass material versus different available shielding materials. Cyanobacteria is capable of living in extreme conditions, By analyzing and comparing the radiation shielding properties of existing materials and cyanobacteria, we'll test the effectiveness and efficiency of this process.

F2.1-0018-18 GROUND SIMULATION EVALUATION ON MUTATION EFFECTS INDUCED BY HEAVY IONS IN SWEET SORGHUM

Xicun Dong, dongxicun@impcas.ac.cn

Institute of Modern physics, Chinese Academy of Sciences, Lanzhou, China Wenjian Li, wjli@impcas.ac.cn

China

With the development of space research, plant becomes an excellent model to investigate the biological effects of ionizing radiation for assessing the damage of the space environment. Sweet sorghum is a C4 plant, making it an attractive model plant for functional genomics because of its small genome (730 Mb). In our research, the dry seeds of sweet sorghum were irradiated by carbon ions with different doses, generated by the Heavy Ion Research Facility in Lanzhou (HIRFL) facility, Institute of Modern Physics, Chinese Academy of Sciences. The results showed that the survival fraction presented "saddle like model" that the survival rate decreased, then increased and decreased again with irradiation doses increased. Although the differences between doses were small at 10, 20 and 30 Gy for the phenotypic variations, the carbon ions had a marked stimulatory effect on the survival rate at low doses, with the value at 30 Gy being 86%, higher than that of non-irradiated seeds. After carbon ion irradiation, some abnormal mutants, such as growing point vanishing, tip curling, plant withering and etiolation, were obtained at the seedling stage. At the same time, an early-maturity mutant, KFJT-1, was isolated at 80 Gy, which the growth period was shortened by about 20 days compared to the wild type KFJTCK. Physiological analysis showed that the proline content of KFJT-1 was increased by 11.05% while the malondialdehyde content was significantly lower than that of KFJT-CK. Regarding to the characteristic of KFJT-1, the expression of the circadian rhythm genes was investigated by RNA-seq analysis, which indicated that a critical photoreceptor PHYA gene was significantly up-regulated in leaf and root of KFJT-1, suggesting the mutation could occur on the genomic upstream of PHYA. In conclusion, our work will provide helpful insights to further understand the mutation effects of heavy ions and assess the damage of the space environment in the future.

F2.1-0019-18 BIOLOGICAL EFFECTS ON PLANT MATERIALS BY HEAVY ION BEAM ON GROUND

Wenjian Li, wjli@impcas.ac.cn China

Wenjian Li, wjli@impcas.ac.cn China

Xicun Dong, dongxicun@impcas.ac.cn

Institute of Modern physics, Chinese Academy of Sciences, Lanzhou, China

Heavy ions irradiation, predominantly present in space, is known to have stronger biological effects than low-LET radiations, such as Xor rays, resulting in lethality, mutation, chromosomal aberrations and other biological endpoints. Therefore, heavy-ion radiation is the most dangerous radiation for astronaut in space environment. Generally speaking, ionizing radiation is known to have several effects on plant growth and development, ranging from stimulatory effects at very low doses, harmful consequences at intermediate levels and pronounced detrimental outcomes at high doses. Firstly, the biological effects of wheat seeds irradiated by 48 MeV/ and 20 MeV/ 14N7+ beams were studied, respectively in our research. The results revealed that heavy ion irradiation could induce a lot of free radicals and inhibit seedling growth of wheat seeds, leading to a great variety of chromosomal aberrations in root tip cells of irradiated seeds and high aberration frequencies compared to the corresponding control. Secondly, wheat dry seeds were exposed to various doses of 12C6+ beams and the biological endpoints reflecting plants growth and root apical meristem activities were investigated in order to analyze the relationship between plant growth and cytological effects. The results showed that the plant survival rate descended at higher doses and various types of chromosome aberrations were observed in the mitotic cells. The frequencies of mitotic cells with lagging chromosomes and these with anaphase bridges reached the peak around 60 Gy, while the frequencies of fragments increased as the irradiation doses increased up to 200 Gy. Thus, the total frequencies of mitotic cells with chromosome aberrations induced by irradiation increased significantly with the increasing doses. Thirdly, Liu et al. comparatively studied the differences of pollen viability and pollen mother cells meiosis between KFJT-1 and KFJT-CK in sweet sorghum, which KFJT-1 was isolated from KFJT-CK after carbon ion beam irradiation, aiming at investigating the mutagenic mechanism. The results showed that the total number of pollens and pollen viability of KFJT-1 were more than that of KFJT-CK. Triad, unequal separation of chromosome and asychronization of chromosomes segregation were found in KFJT-1 meiosis, but the most of chromosomal aberrations induced by carbon ions were repaired, the aberration rate of KFJT-1 being only 4.5In conclusion, our research will provide basic data for assessing potential damage by space radiation.

F2.1-0020-18 EVALUATION OF THE TOXICITY OF IRON-ION IRRADIATION IN MURINE BONE MARROW DENDRITIC CELLS VIA INCREASING THE EXPRESSION OF INDOLEAMINE 2,3-DIOXYGENASE 1

Hong Zhang, zhangh@impcas.ac.cn

Institute of Modern Physics, Chinese Academy of Sciences,, Lanzhou, China Yi Xie, xieyi@impcas.ac.cn

Institute of Modern physics, Chinese Academy of Sciences, China

High linear energy transfer radiation is known to deposit higher energy in tissues and cause greater toxicity compared to low-LET irradiation. Local immunosuppression is frequently observed after irradiation (IR). Dendritic cells (DCs) play important roles in the initiation and maintenance of the immune response. The dysfunction of DCs contributes to tumor eva- sion and growth. However, molecular mechanisms underlying the establishment of immune tolerance induced by heavy ion IR through this DC population are poorly understood. Therefore, here we report our findings on the dysfunction of bone marrow-derived dendritic cells (BMDCs) induced by 1 Gy iron ion radiation and promotions of expressions of JNK1/2/3, indoleamine 2,3-dioxygenase 1 (IDO1), p-ERK1/2 and p38/MAPK; and decrease of IDO2, MHC class II, CD40, CD80 expressions and IFNand TNFsecretion after totalbody IR in mice. JNK+IDO1+ BMDCs showed up-expression of p-ERK1/2 and p-p38/MAPK, reduced expression of MHC class II and CD80, and were not able to effectively stimulate allogeneic spleen T cells. The inhibition of IDO1 expressions could partly restore the function of BMDCs. In all, our study shows that elevated JNK and IDO1 expression induced by Fe ion IR could result in dysfunction of BMDCs via p-p38/MAPK and p-ERK1/2 signal pathway, and it may represent a new mechanism in radiation-induced immune tolerance.

F2.1-0021-18 INVESTIGATION OF PLANT GENOME STABILITY IN RADIOACTIVE ENVIRONMENT OF SPACE FLIGHT

Galina Shevchenko, galina-shevchenko@ya.ru Institute of Botany of NAS of Ukraine, Kiev, Ukraine

Planning of interplanetary missions makes it necessary to investigate impact of radiation on plants since radiation is known to break genomic DNA and distort plant development. Due to sessile nature plants should evolve robust system allowing DNA-protection against damage, which is a challenge for science. The aim of our research is to investigate pathway of plant genome protection in microgravity. We perform experiments under clinorotation (2rpm) and treat Arabidopsis thaliana with heavy metal Cd^{2+} known to cause oxidative stress similar to impact of low doses of radiation. Our aim is to find out to what extent DNA is damaged in simulated microgravity. For estimation of DNA damage we applied method of single cell gel electrophoresis (comet assay). Our preliminary experiments have shown decrease of DNA damage by Cd^{2+} under clinorotation suggesting activation of the protective mechanisms. Part of the experiments is devoted to investigation of cytoskeleton involvement in pathways promoting plant genome protection. For this purpose, A. thaliana seedling were treated with actin disrupting drug cytochalasin D (CD) and then grown on Cd^{2+} containing medium. Estimation of DNA damage has shown its enhancement in plants treated with CD in microgravity which means actin participation in signaling pathways regulating genome protection. Besides, impact of radiation and clinorotation cause retardation of plant root growth meaning affection of cell elongation, the process in which actin is also actively involved. To reveal the mechanism of plant genome protection we are investigating expression of genes, involved in DNA damage repair pathways (BRCA, Lig4, Rad51) and actin regulation (formins). Our investigations provide unique information for researchers working on plant growth in space and data obtained will be a good contribution into biotechnology of stress tolerant plants capable to grow in harmful environment.

Université Paul Sabatier Toulouse III, Toulouse Cedex, France

The space flights carried out so far have shown that living organisms are able, under certain relatively well-controlled conditions, to live for several months in space vehicles in low orbit. In the context of the space conquest to Mars, the duration of space flights will be extending between 2 and 3 years. In this frame, it is essential to design and set up a life support where plants have a crucial role as a source of food, in air renewal and in the recycling of waste. The two major challenges associated with space flight are radiation and microgravity effects on living organisms and, as the duration of space flights become longer, radiation doses and time of exposure to microgravity will become higher. It is therefore important to study the action of these factors on plant development. One of the characteristics of space radiation is the chronic exposure at low doses. The primary effect of low doses of radiation is a free radical formation and damage to DNA. Then, cells stop the cell cycle and initiate the mechanisms of DNA repairs. If the repair is incomplete, it can lead to mutations or cell death. Plants have an important post-embryonic development. Indeed, the growing apices of plants contain meristematic cells that continually produce tissues. These cells remain active throughout the plant's life and are particularly exposed to environmental factors that cause DNA damage and mutations. The impact of radiation exposure on plants may be described in terms of short-term effects and long-term risks. Here, we studied the short-term adaptation of plants to radiation during its early vegetative development. Plants of Arabidopsis thaliana have been exposed to low dose of chronic radiation (0.4 mGy/day) and to simulated microgravity (10-4g) using a Random Positioning Machine (RPM). A morphometric analyze, a study of oxidative stress and a characterization of cell cycle have been carried out on root apices of seedlings exposed during 6 days to radiation and / or simulated microgravity. Space is a complex and new environment to which plants must adapt. This study contributes to a better understanding of the effects of the short-term space environment on vegetative development of plants, as well as the interplay between radiation and microgravity on the adaptation of plants to this new environment.

F2.2-0001-18 LEASONS LEARNED FROM THE RADIATION MEASUREMENTS OF THE MARS SCIENCE LAB RADIATION ASSESSMENT DETECTOR (MSL-RAD)

Guenther Reitz, guenther.reitz@dlr.de

German Aerospace Center (DLR), Koeln, Germany

The Radiation Assessment Detector (RAD) was designed to characterize the radiation environment on the Mars surface and to contribute to an improved assessment of radiation risk for a future human mission to Mars. The flight was chosen to cover a period of solar maximum activity to allow besides the measurement of the galactic cosmic rays an intense study of exposures by solar particle events. The Mars Science Laboratory spacecraft (MSL), containing the Curiosity rover, in which RAD was integrated, was launched to Mars on November 26, 2011. Although not part of the mission planning, RAD was operated already during the 253 day and 560 million km cruise to Mars and made the first time detailed measurements of a radiation environment comparable to that inside a future spacecraft carrying humans to Mars and in other deep space missions. Exactly 100 years after the discovery of cosmic rays on August 7, 1912 RAD makes the first observation of the radiation environment on the surface of another planet and is still gathering data until today. Meanwhile the maximum activity of the current solar cycle has been passed and the solar activity is decreasing. Unfortunately the present solar cycle was an unexpected weak cycle. As a matter of fact only very small solar particle events could be observed during the still ongoing RAD measurements. The paper highlights the achievements of RAD by presenting selected data measured during the cruise and on the Mars surface and describes its impact on predictive models for health risks of astronauts during space missions.

F2.2-0002-18 ISS4MARS, INTEGRATED SIMULATIONS OF MARS FLIGHTS ON THE ISS: THE RADIATION ISSUES

Livio Narici, narici@roma2.infn.it

INFN and University of Rome Tor Vergata, Rome, Italy Guenther Reitz, guenther.reitz@dlr.de

German Aerospace Center (DLR), Koeln, Germany

The human quest towards the exploration of the solar system and beyond will likely begin with the exploration of the planet Mars in the next few decades. Many scientific and technological challenges are still to be approached and solved to enable long deep space human exploration. Once solutions to these challenges are ready, these will be integrated in the flight plans as ad hoc operational strategies.

The International Space Station (ISS) can be considered the only available integrated analogue, where the impact of microgravity, radiation, living and psychological conditions that astronauts will face during a deep space cruise, can be mimicked at the same time, in part or in full. It is conceivable to use the deep space analogue features of the ISS to perform integrated tests of those operational strategies needed to allow for deep space voyages, toward a possible final integrated space test of the entire voyage to Mars, with a fidelity as high as achievable. This utilization strategy for the ISS (ISS4Mars) would help in focusing research and technology on enabling issues for deep space exploration, pushing them to provide a clear deadline for a final test of their solutions. It will also provide the ISS the rank of springboard towards deep space also for the general public, increasing the awareness for human space exploration. Among the many topics to face, obtaining the due mitigation of the radiation risk is certainly a major issue.

In this talk the strategy to fulfill these needs, including, for example monitoring and mitigation of the effects due to Galactic Cosmic Rays (GCR) and Solar Particle Events (SPE) using on vessel solar events now-casting monitors, re-arrangement of the items in the vessel, reorientation of the vessel, shelter modeling, pharmacological countermeasures and the ability to tailor duties and countermeasures to each crew member will be discussed. The need to move the radiation related decisional process from ground (Mission Control) to space is going to be addressed, as well as the the strong benefit in validating all the foreseeable solutions of these issues in synergy during a full dry run of the Mars voyage in the ISS.

The related needs in hardware development (detectors, habitat, shielding, etc), simulation capability and intelligent systems will be discussed, with the goal to assess how far we are to be able to conduct the ISS4Mars dry run from the radiation standpoint.

F2.2-0003-18 INDIVIDUAL RADIOSENSITIVITY: BIG CHALLENGE FOR THE FUTURE OF MANNED SPACE FLIGHTS

Laure Sabatier, laure.sabatier@cea.fr CEA, Fontenay-aux-Roses, France

Radiation exposure is a major limiting facto for long duration manned space flights. Radiation protection standards are based on the assumption that all members of the population are equally sensitive to ionizing radiation. However when people are confronted with exposures to IR, they have been asking questions not only about how much the general population but also how much individually, each person, has been adequately protected against IR related health risks. Indeed, the studies of secondary effects post-radiotherapy have shown a great variability among individuals. However, there is insufficient information on the influence of individual radiation sensitivity on health risk estimates, in particular, data at different dose levels, dose rates and with radiation of different qualities are scarce. The gold standard of biodosimetry, ie scoring of dicentrics, have described large discrepancies among cosmonauts after the same flight (Testard et al, IJRB, 1996). Variations into individual exposure or radiosensitivity, the questions are open. Our recent results on the effect of radiation quality have shown that individual radiosensitivity exists among healthy individuals following irradiation with carbon ions and -rays, and individuals may not be equally sensitive to different types of IR (Shim et al, Frontier in Oncology 2016). Thus, a bottleneck is to identify useful biomarkers for the detection of highly sensitive individuals in human polulations (Hall et al, Mut Res, 2017). Biomarkers will be discussed as regards as individual radiation sensitivity versus long term susceptibility (Shim et al, Mut Res 2014).

F2.2-0004-18 ADVANCED DEPTH-DOSE CURVES FOR FAST SPACE RADIATION DOSE CALCULATION IN A SPACECRAFT WITH COMPLEX GEOMETRY

Mikhail Dobynde, mikhail.dobynde@skolkovotech.ru

Skolkovo Institute of Science and Technology, Skolkovo, Russia Alexander Drozdov, adrozdov@ucla.edu

Institute for Biomedical Problems RAS, Moscow, Russia

Space radiation is one of the main concerns in planning human space missions. Radiation environment isn't fixed and varies in time. That's why it is very important to predict radiation dose rate according to current the state of radiation environment. Complicated geometry of a spacecraft and variety of astronaut position inside it make impossible fast and detailed calculations with Monte-Carlo codes. More perspective are methods that apply shield distribution function for spacecraft description and dose-depth curves for dose calculations. We report on improved depth-dose curves method for fast calculations of the radiation dose during the space flight.

Radiation dose calculations using depth-dose curves consist of two parts. In the first part real spacecraft geometry is processed into shielding distribution function. This function is calculated for each point of interest using ray-tracing method. In the second part shielding distribution function is convoluted with the depth-dose curves. Depth-dose curve is a dependence of the radiation dose in a very small tissue volume on the shield thickness and composition.

We take into account backscattering from the shield behind the point of interest and assuming the front and behind shields as a double layer aluminum/water structures. Because, we take into account shield composition, shielding distribution function is replaced with shielding and composition distribution function. Aluminum-water shield is a good simplification of the real geometry, as water is good equivalent for biological tissues and aluminum is the major material for a spacecraft wall. We demonstrate that this ratio has influence on the depth-dose curves in the thickness rage over 10 g/cm^2.

Depth-dose curves were calculated using GEANT4 Monte-Carlo code in one-dimensional slab geometry. We calculated contribution of primary, secondary and albedo radiation. Secondary and albedo radiation was additionally separated according to particle type (gammas, protons, neutrons, nucleus, leptons, mesons and baryons).

To validate the results we apply this method to calculate dose distribution in a spherical water phantom placed in an aluminum spherical spacecraft shell. We compare the results with direct Monte-Carlo simulations for the same geometry.

F2.2-0005-18 EXPOSURE DOSE CALCULATION INSIDE JEM USING PHITS AND 3D ISS GEOMETRY

Aki Goto, goto.aki@jaxa.jp

Japan Aerospace Exploration Agency (JAXA), Ibaraki, Japan Kazunori Shimazaki, shimazaki.kazunori@jaxa.jp

Japan Aerospace Exploration Agency (JAXA), Ibaraki, Japan

The International Space Exploration Coordination Group (ISECG), a forum set up by 14 space agencies including Japan Aerospace Exploration Agency (JAXA), is planning future human space missions following the International Space Station (ISS) mission, such as long-term stay onboard the lunar orbital station called "Deep Space Gateway" and exploration on the Moon and Mars. One of the problems to solve for realizing such missions is space radiation effects on human health. In space, high liner-energy-transfer (LET) radiation that causes significant biological damage flows from outside of the solar system and the sun. Especially, outside of the geomagnetic field where the future missions will be undertaken, the radiation flows at high dose rates. Establishment of radiation protection technology is required for conducting the future missions while ensuring astronauts safety. The radiation protection technology includes accurate estimation of exposure dose and optimization of shielding design. We expect computer simulation using a radiation transport code as a method to estimate exposure dose for the future missions. In order to perform the simulation for actual missions, it is needed to evaluate the accuracy of the transport code (including nuclear reaction models and nuclear data libraries) and the radiation environment models, and the appropriate setting of calculation geometry. This time, we calculated the exposure doses inside the ISS Japan Experiment Module (JEM, called "Kibo") using PHITS (Particle and Heavy Ion Transport Code System) code and the ISS 3D-CAD model. The ISS 3D-CAD model, that includes JEM 3D-CAD model, was created for these calculations. The ISS CAD model (except the JEM model) describes simplified geometry of the ISS. And, the JEM CAD model consists of the geometry of the Pressurized Module (PM), the Experiment Logistics Module Pressurized Section (ELM-PS), and the Exposed Facility (EF) model. The PM and the ELM-PS models reproduce the approximate geometry of the outer shell structure, the debris bumpers, the racks, and so on. This ISS 3D-CAD model was converted to PHITS input format by using SuperMC (Super Monte Carlo simulation program for nuclear and radiation process) software system. The radiation environment model developed by Mattiä et al was employed for calculating the galactic cosmic ray (GCR) fluxes, while AP8 and AP9 model was used for calculating the trapped proton fluxes in the geomagnetic field.

The calculated doses were absorbed dose and dose equivalent of the virtual dosimeters placed inside JEM geometry. In this presentation, we show the calculation results of the exposure doses inside the JEM, and discuss the method to estimate dose based on the comparison between the calculated data and the flight data.

F2.2-0006-18 NEW DEVELOPMENTS IN THE LIèGE INTRANUCLEAR MODEL (INCL4) FOR HIGH ENERGY NUCLEAR COLLISIONS.

Joseph Cugnon, j.cugnon@uliege.be University of Liège, Liege, Belgium

Jean-Christophe David, jean-christophe.david@cea.fr CEA Saclay, France

Davide Mancusi, davide.mancusi@cea.fr France

Alain Boudard, alain.boudard@cea.fr CEA Saclay, France

Sylvie Leray, sylvie.leray@cea.fr CEA Saclay, France

The new developments of the Liège Intranuclear (INCL4) cascade model for nuclear collisions will be presented. The INCL4 model has originally been proposed for modeling of nucleoninduced spallation reactions in the incident energy range spanning from a few MeV to 2 GeV, with special emphasis for applications in transmutation of nuclear waste. The performances of this nuclear model are remarkable. They are testified by the intercomparison of cascade+evaporation codes carried by IAEA a few years ago [1], which showed that INCL4 is generally the best one for describing an exhaustive set of (particle and residue) cross-sections. A general view of the physical aspects of the model are contained in Ref. [2], where it is explained also that INCL4 is well suited to study radiation effects (particle production, gamma production, energy deposits, etc) when included in nuclear transport codes such as MCNPX, Geant4 and PHITS. The purpose of this presentation is to report on the developments which have taken place since the work of Ref.[2]. They pertain to the extension of the model to light to medium-heavy nuclei as incident projectiles, to the inclusion of many inelastic nucleon-nucleon and pion-nucleon reactions, including strange particles production and interactions, allowing a realistic description of nuclear collisions up to 20-30 GeV incident energy, improvements of the nuclear density distributions (allowing in particular a strong improvement of single-nucleon removal cross sections), etc). These new developments make the INCL code quite suitable for the study of radiation effects produced by cosmic rays in the atmosphere and/or space mission vehicles. Particular attention will be brought to the validation of the mode first on individual cross sections in nucleus-nucleus collisions, but also to the description of test experiments relevant for light ion induced reactions in medical and space applications. 1.IAEA-intercomparison:

University of Nevada Las Vegas, Las Vegas, Nevada, United States Premkumar Saganti, pbsaganti@pvamu.edu

Prairie View A&M University, Prairie View, Texas, United States

The Galactic Cosmic Ray Event-based Risk Model code (GERMcode) is a fast Monte-Carlo based stochastic simulation of the passage of hydrogen, helium, and heavy ions through shielding and tissues. Stochastic models that go beyond deterministic descriptions of average fluence and absorbed doses are needed to support new approaches to risk assessment and to understand uncertainties. The GERMcode uses a 190 particle isotopic grid to describe energy dependent interactions of GCR particles. We review recent developments in the theoretical description of helium and heavy ion cross sections used in the GERMcode. A second-order optical model of absorption cross sections, which considers two-body correlations, has been extended to include the mass and charge number dependence of nuclear one and two-particle densities. The model has been extended to low energies (<100 MeV/u) by addition of improved descriptions of Coulomb scattering and two-body medium effects. We consider the impact of these corrections on helium and heavy ion fragmentation cross sections, which are constrained by the total absorption cross sections. Comparisons to experiments for thin and thick target measurements are described for a large number of projectiles and target materials.

F2.2-0008-18 NEW HUMAN ANATOMICAL MODEL FOR CREW RADIATION ANALYSIS

Hesham Hussein, hesham.hussein@lmco.com Lockheed Martin, Houston, Texas, United States Razvan Gaza, razvan.gaza@lmco.com

Lockheed Martin, Houston, Texas, United States Chirag Patel, chirag.patel@lmco.com

Lockheed Martin, Houston, Texas, United States Tad Shelfer, tad.d.shelfer@lmco.com

The ionizing radiation environment in space pretenses substantial risks to human exploration. It consists primarily of 3 components, Solar Particles Events (SPE), Galactic Cosmic Rays (GCR), and Van Allen Belts (trapped protons) that differ in elemental compositions, energy spectra, and intensities. The extravehicular environment is then modulated by interaction with the shielding provided by the spacecraft design, and the body self-shielding provided differentially to internal organs and tissues. The Orion Multi-Purpose Crew Vehicle (MPCV) is NASA's deep space exploration spacecraft developed for exploration of the solar system. Orion is designed by an industry team lead by Lockheed Martin as the prime contractor. Spacecraft shielding is quantified analytically using Computer Aided Design (CAD) tools to great details. However, NASA is using the Computerized Anatomical Male (CAM) model to quantify the body self-shielding to internal organs and tissues, which is dated back to the 70s and cannot be verified by the modern CAD tools. For this reason, a highly detailed, radiationspecific model, representing the most anatomically correct geometric of the human body, has been developed by Lockheed Martin Space to be used in analyzing radiation dose distribution for human. The model was derived from the BodyParts3D database. BodyParts3D is a threedimensional anatomical structure database for body segments representing the whole-body model for an adult human. The model contains 2234 unique geometric surfaces with no solid regions. A program was developed to convert surface models to solid representation with no loss in geometric quality. The models were then divided into 25 assemblies by organ levels, and organ points were uniformly distributed inside each organ. Multiple analyses were performed with the model. Analyses included tracing rays in CAD through the body geometry, converting results from ray-tracing information to areal density distributions, and creating cross-sectional views. This presentation will discuss the radiation exposure to trapped protons, solar particle events (SPE), and galactic cosmic rays (GCR) at each organ dose point in the body by combining space radiation transport models with the detailed body-shielding mass of BodyParts3D and CAM, respectively, and calculating the dose equivalent to organs and the effective dose per NCRP-132 weighting factors.

F2.2-0009-18 IMPACT OF NANOAND MICROMETER SCALES ON RELATIVE BIOLOGICAL EFFECTIVENESS OF ION RADIATION: COMPUTER MODELLING OF DNA DAMAGE AND DICENTRIC INDUCTION

Werner Friedland, friedland@helmholtz-muenchen.de

Institute of Radiation Protection, Helmholtz Zentrum München, Neuherberg, Germany Pavel Kundrat, pavel.kundrat@helmholtz-muenchen.de

Institute of Radiation Protection, Helmholtz Zentrum München, Neuherberg, Germany Janine Becker, janine.becker@helmholtz-muenchen.de

Institute of Radiation Protection, Helmholtz Zentrum München, Neuherberg, Germany

Detailed understanding of the enhanced relative biological effectiveness (RBE) of ions, in particular at high linear energy transfer (LET) values, is needed to reduce the uncertainty in radiation risk estimations of manned space missions. Track structure based models of radiation effects, such as PARTRAC [1], are suited tools to address this issue. It is generally accepted that the enhanced RBE of high-LET particles results from the spatial clustering of energy depositions around their trajectories. This clustering affects biological material both on nanometer and on micrometer scales. On nanometer scale it leads to multifaceted DNA lesion patterns, in particular DNA double-strand breaks (DSB) of various complexity. Recently, a comprehensive evaluation of DNA damage by light ions over a wide range of LET-values has been undertaken [2]. With increasing LET the damage pattern changes from individual strand breaks towards DSB induction, with highest yields around 100 - 200 keV/µm, and above 300 keV/µm to more complex DSB clusters. On micrometer scale, the energy deposition patterns of high-LET ions are characterized by rather high local doses along the trajectories, decreasing rapidly in radial direction. The preferred localization of DNA lesions along straight lines leads to non-random DNA fragmentation patterns observed experimentally and in computer simulations. However, the role of µm-scale clustering of energy deposition events on biological effects has been largely unclear so far; in conventional radiobiological experiments it could not be frankly separated from local nm-scale effects since both scales are inherently interlinked when radiation quality is changed. To address this issue in an innovative way, experiments at the ion microbeam SNAKE and corresponding track-structure based model calculations of DSB induction and subsequent repair with the biophysical code PARTRAC have been performed [3]. In the experiments, hybrid human-hamster AL cells were irradiated with 55 MeV C ions (LET: 310 keV/µm), 45 MeV (60 keV/µm) Li ions or 20 MeV (2.6 keV/µm) protons; the induction of dicentrics was measured. The particles were either quasi-homogeneously distributed or focused to 0.5 x 1 µm^2

spots on regular matrix patterns of 5.4 µm, 7.6 µm and 10.6 µm grid size, with pre-defined particle numbers per spot so as to deposit a mean dose of about 1.7 Gy for all irradiation patterns. The induction of dicentrics increased with LET after homogeneous irradiation: Li and C ions induced about twoand four-fold higher yields of dicentrics than protons. The induction of dicentrics is, however, affected by µm-scale, too: focusing 20 Li ions or 451 protons per spot on a 10.6 µm grid induced two or three times more dicentrics, respectively, than a quasi-homogenous irradiation [3]. These experimental data provide a unique benchmark for corresponding model calculations. Indeed, first PARTRAC simulations of dicentrics induction with model assumptions and parameters used so far failed to properly match the focusing effect for protons and Li ions as well as the dependence on ion type (or LET) in single-ion irradiation modes [3]. This discrepancy has initiated model and parameter refinements, in particular on DNA end mobility, that enabled the simulations to largely reproduce both the LET-dependence and the focusing effect as well as the usual biphasic rejoining kinetics. The predictive power of the refined model has been successfully benchmarked against measurements of dicentrics after photon irradiation. Ongoing work aims at verifying the model assumptions on the mobility of DNA ends and their processing.

Acknowledgement. This work was partially supported by the German Federal Ministry of Education and Research (Funding no. 02NUK031C).

Albeit its frequent use to quantify radiation-induced DNA insult, the induction of DNA damage foci (e.g. γ-H2AX) is not trivially correlated to the real number of lesions within the nucleus. Moreover, the overall amount of damage and its distribution in space are strongly dependent on the pattern of energy depositions inside the biological matter. This motivated the development of a novel approach to simulate the onset of foci arising from the exposure to different radiation qualities, starting from the initial damage imparted to cells. In the presented study, lowand high-LET radiations adopted in cancer therapy have been used, namely X-rays and Carbon ions. Furthermore, the biological consequences due to neutrons have been investigated exploiting a radiation field mimicking the Hiroshima neutron spectrum at 1.5 km from the device explosion, as reproduced at the RARAF irradiation facility (Columbia University, NY). The proposed strategy consists of different calculation steps, from the characterization of the particle fields involved in the damage induction, to the estimation of initial DNA insult in cells, and finally to the simulation of γ-H2AX foci by applying an ad-hoc clustering algorithm of single damages. Results from calculations have been compared to experimental foci yields scored by a conventional immunocytochemistry protocol: this highlighted the limitations of such detection technique, and a dedicated software optimization has been

carried out to reproduce the artifacts caused by experimental resolution. Preliminary data from confocal microscopy will be shown to offer a better insight on radiation track-structure and on the realistic DNA damage content, and these will be correlated with 3-dimensional simulations. Finally, we address as a pilot study the extension of our modeling approach to radiation fields of interest for space applications, with a particular focus on deep-space travels, also including neutron fields as produced by GCR interactions in the Martian atmosphere or with the walls of an interplanetary spacecraft.

Recently, we developed a radiation detector system to characterize heavy ion particle trajectory at micron resolution (utilizing a 1.67 microns per pixel sensor). The CMOS (Complementary Metal Oxide Semiconductor) sensor used to develop the detector system has an active array of 3664 x 2748 pixels in about 6.1 mm x 4.6 mm dimensions. We also incorporated a holder for chamber slides to be positioned and placed on top of the CMOS sensor. The chamber slide with appropriate biological cell structure, once positioned precisely on the pixel array sensor and exposed to the radiation, the particle trajectory from the sensor data at 1.67 micron resolution can be correlated for the observed particle induced damage at the cell level. Our preliminary studies with heavy ions as part of the NASA Space Radiation Laboratory (NSRL) experiments at Brookhaven National Laboratory (BNL) are very promising with H, He, C, O, Si, and Fe ions. Our preliminary assessment of radiation particle trajectory from the sensor data has been correlated with several biological samples including mCherry 53BP1 mouse hippocampal neuronal cells. We present our preliminary approach in the development of our pixel array radiation detector system and correlate radiation particle induced damage at the cell level. Also, we present our observed radiation track image data of heavy ions at cell dimensions.

F2.2-0012-18 CHALLENGES OF SPACE WEATHER AND SPACE RADIATION PREDICTIONS FOR HUMAN EXPLORATIONS IN DEEP SPACE

Jingnan Guo, guo@physik.uni-kiel.de University of Kiel, Kiel, Germany

Robert Wimmer-Schweingruber, wimmer@physik.uni-kiel.de Christian-Albrechts-Universität zu Kiel, Kiel, Germany Donald M. Hassler, hassler@boulder.swri.edu

Southwest Research Institute, Boulder, Colorado, United States

Space agencies such as ESA, NASA, the Chinese space agency and even private sectors have already launched human deep space exploration programs to the Moon and Mars. It requires a very timely and thorough study to better understand the space weather conditions and effects for such human deep space activities in order to further develop mitigation strategies against the associated radiation risks.

In the long-term, there is the omnipresent radiation induced by Galactic Cosmic Rays (GCRs) which are modulated by solar activities. Continuous exposure to the background GCRs may increases the chance of long term health consequences, such as onset of cancer, cardiovascular diseases, skin atrophy, eye cataract, leukemia, anemia, leucopenia and malfunctions of the central nervous system.

In the short-term, intense solar energetic particles (SEPs) can be considered as mightily related to deterministic radiation effects which are of great concern for space exploration. Acute radiation syndrome (ARS) or sickness or poisoning or toxicity is induced after a whole body exposure to high doses of radiation between at the Gy [J/kg] level. Such events, despite of being rather infrequent, could result in severe damage to humans and equipment and lead to failure of the entire mission and therefore should be detected and mitigated as immediately as possible.

Under different shielding environment, the intensity and composition of the GCRs/SEPs may vary due to the interactions of primary particles (of different energies and charges) with the surrounding material (such as the spacecraft and the planetary atmosphere) and the generation of secondaries. Habitable shelters on the Moon and Mars with regolith shielding could provide sufficient protection against such radiations. However the situation of a transit spacecraft in deep space or an astronaut carrying out extra-vehicle or planetary surface activities may be much more severe, especially during the onset of a solar particle event (SPE). This is because an SPE generally have a sudden and sporadic nature and can be very intense, dynamic and vary drastically in time and location. Therefore radiation and particle enhancement measured near Earth (such as the onset time and intensity) may be completely different from of that detected elsewhere in the heliosphere such as on the surface Mars.

Three major factors should be taken into account for evaluating the solar energetic particle radiation environment at different locations in the heliosphere (where the deep space exploration activities may take place): (1) the acceleration process at the Sun which are often related to the flare eruptions and associated shocks, (2) the properties of the accelerated particles injected into the open magnetic field which are connected to the missions (that can be very differently connected compared to Earth), and (3) the atomic and nuclear interaction of particles with the local shielding environment (such as the spacecraft or the Martian atmosphere). Taking into consideration of these 3 factors, we will show our recent study of the September 2017 event which is seen on the surface of both Earth and Mars as well as at STEREO-A (a spacecraft surrounding the Sun at 1 AU). These three locations have a heliospheric longitudinal separation of more than 240 degrees apart and they all saw the SPE with different time profiles, intensities and particle spectra. We highlight the utmost importance of utilizing multi-spacecraft in- situ and remote sensing observations of the Sun and the heliosphere to better understand such dynamic events and their dynamic effects across the heliosphere in particular at locations where human explorations may take place.

F2.2-0013-18 ACTIVE DOSIMETER-BASED ESTIMATE OF ASTRONAUT ACUTE RADIATION RISK FOR REAL-TIME SOLAR ENERGETIC PARTICLE EVENTS

Christopher Mertens, christopher.j.mertens@nasa.gov

NASA Langley Research Center, Hampton, Virginia, United States
Tony Slaba, tony.c.slaba@nasa.gov

NASA Langley Research Center, Hampton, Virginia, United States

Universities Space Research Association, Houtson, United States

Radiation exposure from solar energetic particle (SEP) events becomes a much greater concern as human exploration extends beyond low Earth orbit (LEO) and the protective environment of Earth's magnetic field. Free space SEP events have an increased impact on mission planning and operations, as countermeasures may be necessary to avoid exceeding astronaut permissible exposure limits (PELs) and acute radiation syndrome (ARS). Operational analysis tools are needed to assess acute radiation effects during SEP events in order to determine courses of action during the mission. A methodology has been developed to meet this need, which utilizes onboard vehicle dosimeter measurements to estimate dose quantities at astronaut crew locations. The estimated dose quantities provide the necessary inputs to acute biological response models that predict radiation induced performance decrement (RIPD) and other acute radiation effects. The active dosimeter-based crew dose estimate methodology is specifically applied to predicting astronaut organ doses at the storm shelter locations within the Orion spacecraft, which will be tested on the Exploration Mission 1 (or EM-1). The methodology is evaluated and assessed in this presentation, and a simulation of the acute radiation responses in the storm shelter of the Orion spacecraft are shown for the October 1989 SEP event.

F2.2-0014-18 CURRENT APPROACHES TO EVALUATE SPACE RADIATION HEALTH RISKS AND MITIGATION

Eleanor Blakely, eablakely@lbl.gov

Lawrence Berkeley National Laboratory, Berkeley, California, United States

Estimating health risks from space radiation exposures during interplanetary travel into deep space currently still involves significant uncertainties. Despite major progress by an international cadre of astrophysicists in characterizing the various radiation types, doses and dose-rates during the 11-year solar cycle, the biological and medical consequences of the multiple combined stressors (including microgravity) to be encountered are not yet fully known. Currently, a diverse array of primarily ground-based but also some in-flight (aboard the International Space Station) laboratory approaches using mainly biological surrogates are ongoing to characterize space radiation health risks from exposure to Solar Particle Events (SPE) and Galactic Cosmic Rays (GCR), with a focus on cancer risk, and effects on the Central Nervous System (CNS). Space radiation effects on the Cardiovascular System (CVS) are also being studied. Astrophysicists and biophysicists are working together to define the relevant set of radiation parameters required to identify key genetic, epigenetic, genomic, and physiological features, and the underlying mechanisms of action attributable to unique particle track structure effects with quantitative and qualitative differences compared to gamma rays, leading to the composite human response to space travel. Physical and pharmaceutical countermeasures are also under development. More basic radiation research is required in order to fill fundamental data gaps, and to allow future theoretical modeling and predictions of outcomes. This presentation will provide a brief overview of current approaches and remaining challenges.

F2.2-0015-18 SPACE RADIATION MAGNETIC SHIELDING: AN UPDATED ANALYSIS

Roberto Battiston, roberto.battiston@asi.it ASI - Agenzia Spaziale Italiana, Roma, Italy

Martina Giraudo, martina.giraudo-somministrato@thalesaleniaspace.com Thales Alenia Space Italia S.p.a., Politecnico di Torino, Turin, Italy Riccardo Musenich, riccardo.musenich@ge.infn.it

Valerio Calvelli, valerio.calvelli@ge.infn.it INFN and University of Genoa, Genoa, Italy

Deep-space missions will result in harmful exposure of astronauts to space radiation, eventually leading to late and acute detrimental health effects. Current countermeasures include passive shielding, however, to significantly reduce the effective dose to the crew, large amounts of materials would be necessary and this solution is not compatible with the existing weight restrictions to space missions.

In the last decades, it was commonly believed that the problem of space radiation could be solved by surrounding the spacecraft habitats with large superconducting magnets, even though with considerable technological efforts. At the end of the EU FP7 SR2S Project - Space Radiation Superconducting Shield - we demonstrated however how magnetic shielding is characterized by a number of constraints which restricts its effectiveness, unless properly addressed through an extensive RD.

We present here the results of the project, which attempted for the first time to design an active shielding system, based on superconducting MgB2 magnets. Monte Carlo codes were used throughout all the project to support the multidisciplinary design activities, realistically reproducing the interaction of cosmic rays with the structural materials and with the magnetic field. Comparisons were made between confined and partially confined field configurations and figures of merit were defined, concluding that partially confined field could provide better shielding capability for the same structural mass. The results of this work and the correlated simulations activities are reported, together with a comparison of the performances between active shielding and mass-equivalent passive ones.

In parallel, a description is given of the experimental studies focused on some key technologies, necessary to develop such a shield (superconducting cable, cryogenics, quench protection, heat removal). The results of this study define a new starting point for the technology development and research directions towards active shielding design as a suitable protection tools for deep space exploration.

In November 2017, the first phase of the PERSEO (PErsonal Radiation Shielding for intErplanetary missiOns) project, funded by the Italian Space Agency, has come to a successful conclusion with the test on board the International Space Station (ISS) of the first prototype of a water-filled garment for personal radiation protection of astronauts in case exposure to solar particle events.

During the course of the project, a collaboration including academic partners and companies active in space research and technological development designed and manufactured the garment prototype, in compliance with all requirements for use in a space habitat, completing all necessary ground verification tests. The efficacy of the garment as a countermeasure against short-term non-cancer effects was evaluated based on Monte Carlo simulations of achievable dose reduction to sensitive organs of an anthropomorphic phantom, exposed to different reference solar proton spectra in low-shielding conditions, as it could be the case in an emergency scenario during a deep-space mission.

During the test on the ISS, the garment was filled with 21 liters of on-board water and later drained back into the water recovery system, with no water waste. While worn for about 30 minutes,

the garment was judged as comfortable enough, not significantly hindering the astronaut's movements and not posing major problems as a consequence of increased inertial mass.

In this presentation we will revisit the main steps of the project and discuss its achievements, also addressing strategies currently studied for an experimental benchmark of the garment shielding efficacy, and possible future developments for devices of this kind to be used in interplanetary space journeys.

* This presentation will be given also in behalf of the PERSEO collaboration. PERSEO is funded by the Italian Space Agency (ASI), coordinated by the University of Pavia and involve scientists from Thales Alenia Space - Italia, SMAT, AVIOTEC, ALTEC, University of Roma Tor Vergata, Kayser Italia and ARESCOSMO. Full list of contributors is given in the presentation.

F2.2-0017-18 POTENTIAL DIETARY COUNTERMEASURE AGAINST SPACEFLIGHT-INDUCED BONE LOSS

As humans venture further into space and beyond low Earth orbit, space radiation is one of the main challenges for astronauts health. Radiation-induced bone loss is a potential health problem for long duration habitation in space. We showed that a dietary countermeasure prevents bone loss in mice exposed to total body irradiation (TBI). We used a range of ionizing radiation, gamma (137Cs), proton (1H), iron (56Fe), and a combination of sequential proton and iron beam (1H/56Fe/1H) to evaluate skeletal responses. These TBI cover a range of linear energy transfer (LET), from low-LET such as proton, to high-LET such as 56Fe (HZE: high Zhigh energy) at doses between 1-2 Gy. The countermeasure diet, composed of 25% Dried Plum (DP) was effective at preventing radiation-induced cancellous bone loss in appendicular bone (tibia). Furthermore, exposing mice to HZE radiation, such as 56Fe (1Gy), impaired it ex vivo growth of marrow-derived, bone-forming osteoblasts, which led to reduced mineralization capacity (-77%). In contrast, mice fed the DP diet did not display these deficits, showing the diet's capacity to protect marrow-derived osteoprogenitors. Dietary DP prevented the increase of bone resorbing osteoclast cells, inflammation and oxidative stress, while protecting the osteoprogenitors and mesenchymal stem cells, which few drugs against osteoporosis may achieve. Spaceflight

is a combination of multiple factors including microgravity, in addition to space radiation. Therefore, we conducted additional studies to determine if the DP diet could prevent simulated spaceflight (simulated microgravity and radiation combined) bone loss. Mice were exposed to gamma (TBI, 137Cs, 2 Gy), simulated microgravity (using the hindlimb unloading system, HU) or TBI+HU. While we observed bone loss in mice fed the control diet (CD) due to both treatments (TBI=14%, HU=20%), and a worse effect with combined treatments (TBI+HU=25%), mice fed the DP diet did not sustain significant bone loss relative to untreated controls. The DP diet prevented microarchitectural decrements in both appendicular bone (tibia) and axial bone (vertebrae). In addition, the DP diet mitigated HU-induced deficits in osteoblastogenesis. Interestingly, lower doses of DP diet (5%, 10%) did not appear to prevent cancellous bone loss, which shows the importance of identifying the active component(s) of DP. Finally, we have preliminary data showing the potential of DP to prevent radiationinduced damage at a systematic level. In summary, this novel dietary countermeasure is a promising candidate nutritional countermeasure for spaceflight-induced bone loss and tissue damage. F2.2-0018-18 CHASING GHOSTS IN SPACE RADIOBIOLOGY RESEARCH: THE LOST FOCUS ON NON-TARGETED EFFECTS

Francis Cucinotta, francis.cucinotta@unlv.edu

University of Nevada Las Vegas, Las Vegas, Nevada, United States
Eliedonna Cacao, eliedonna.cacao@unlv.edu

University of Nevada, Las Vegas, Las Vegas, Nevada, United States

The doses and dose-rates of astronaut exposures to galactic cosmic rays (GCR) are accurately known, and lead to particle hits per cell nucleus from high charge and energy (HZE) particles of much less than one hit per cell per month. A large number of experiments have shown that additivity of biological effects is a valid assumption for space radiation exposures, while experiments at higher doses and dose-rates than occur in space continue to be a focus of the majority of space radiobiology research. Furthermore HZE particle exposures with mono-energetic particles manifest themselves as a mixed-radiation field due to the contributions of delta-rays and the random impact parameter of a particles track core to DNA and non-DNA targets in cells and tissues. The mixed-field manifestation of mono-energetic HZE particle exposures is well known from theoretical studies of microdosimetry and track structure. Additional mixed-field effects occur for single species experiments due to nuclear fragmentation in particle accelerator beam-lines and biological samples along with energy straggling. In contrast to these well known aspects of space radiobiology there are many open questions on the contribution of non-targeted effects to low dose and dose-rate exposures. Non-targeted effects (NTEs) include cell signaling, bystander effects, tissue microenvironment changes, and genomic instability, and have been shown to be the most important outstanding question for reducing uncertainties in space radiation cancer risk assessment. The dose-rate and radiation quality dependence of NTE's has not been established, while there is an over-arching need to develop 21st century experimental models of human cancer risk. We review possible mechanisms of NTE's and how new experiments to address these issues could be designed

F2.2-0019-18 DYNAMICAL MODELING APPROACH TO RISK ASSESSMENT FOR RADIOGENIC LEUKEMIA AMONG ASTRONAUTS ENGAGED IN INTERPLANETARY SPACE MISSIONS

Olga Smirnova, olgaandreevnasmirnova@gmail.com

Federal State Unitary Enterprise Research and Technical Center of Radiation-Chemical Safety and Hygiene, Moscow, Russia

Francis Cucinotta, francis.cucinotta@unlv.edu

University of Nevada Las Vegas, Las Vegas, Nevada, United States

A biologically motivated dynamical model, which is capable of predicting the excess relative risk (ERR) for radiogenic leukemia among humans exposed to acute/continuous irradiation in wide ranges of doses and dose rates, is developed (Smirnova, 2017; Smirnova and Cucinotta, 2018). This model is applied to study the dependence of the EER for radiogenic leukemia among astronauts on key parameters of space radiation exposure in interplanetary space missions, namely, the dose equivalent rates of galactic cosmic rays (GCR) and large solar particle events (SPEs), the time interval between SPEs, mission duration, the degree of astronaut's additional shielding, and the total mission dose equivalent. It is necessary to emphasize that the results obtained in the framework of the developed model, practically, coincide with those of the linear model in the range of applicability of the latter. In turn, the developed model is capable of predicting the ERR for radiogenic leukemia among astronauts for the irradiation regimes beyond the applicability range of the linear model, which can occur in some emergency cases. As a supplement to the estimations of cancer incidence and death (REIC and REID), the developed model for the assessment of the ERR for leukemia can be employed in the pre-mission design phase (e.g., for the optimization of the regimes of astronaut's additional shielding in the course of interplanetary space missions), as well as in the phase of the real-time responses during the space mission to make the decisions on the operational application of appropriate countermeasures to minimize the risks of occurrences of leukemia, especially, for emergency cases.

F2.2-0020-18 SERUM MICRORNAS AS EARLY INDICATORS FOR ESTIMATION OF EXPOSURE DEGREE IN RESPONSE TO IONIZING RADIATION

Jufang Wang, jufangwang@impcas.ac.cn

Institute of Modern Physics, Chinese Academy of Sciences,, Lanzhou, China

Highly energized particles delivered by galactic cosmic rays as well as solar particle events are one of the most severe detrimental factors to the health of crews during long-term space missions. Researches related to the assessment of radiation risk have been carried out with ground-based accelerator facilities all around the world. Serum microRNAs (miRNAs) have the advantages of specificity and stability, which could be used as disease biomarkers and potential bio-dosimeters. Based on this backgroud, serum miRNAs were isolated after Kunming mice were whole-body exposed to 0.5-2 Gy of 300MeV/u carbon ion beam which were generated by the Heavy Ion Research Facility in Lanzhou (HIRFL). The expression levels of 374 miRNAs were detected by miRNA PCR array. It was found that more than one hundred of serum miRNAs were responded to carbon ion irradiation. A specific signature with 12 miRNAs was selected for further validation following 0.1-2 Gy of carbon ion and iron ion exposure. miR-183- 5p, miR-9-3p, miR-200b-5p, miR-342-3p and miR-574-5p showed significant doseand timedependent changes, demonstrating that they were potential biomarkers of radiation and could be used as ideal bio-dosimeters in the early stages after exposure. We also developed a universal model using these 5 miRNAs to predict the exposure degree with high sensitivity and specificity. Those findings indicate that with the properties of high sensitivity of radiosensitive miRNAs and time-saving quantification by standard PCR assay, serum miRNAs may become potential indicators to estimate the exposure degree under some unexpected circumstances during space exploration.

F2.2-0021-18 SPACE RADIATION INDUCED CHROMOSOME INSTABILITY ACTIVATES IMMUNE SIGNALING IN HUMAN CELLS

Asaithamby Aroumougame, asaithamby.aroumougame@utsouthwestern.edu University of Texas Southwestern Medical Center, Dallas, United States

Space radiation is known to induce genomic instability and has high potential to cause cancer, however the link between these two events has not been established. Here, we provide a novel evidence that the genomic instability caused by high-charge and -energy (HZE) particles, components of space radiation, triggers immune signaling in response to chromatin fragments in the cytoplasm and that might play a key role in the initiation of cancer. Chromosome missegregation due to defective clustered DNA lesions repair creates a preponderance of LAMINB1 coated micronuclei, genomic instability marker, whose rupture exposes chromatin fragments into the cytosol. This leads to the recruitment of a nuclease MRE11, that process the genomic DNA in the cytosol resulting in the binding of cGAS (cyclic GMP-AMP synthase) and subsequent activation of the STING (stimulator of interferon genes) cytosolic DNA-sensing pathway and downstream interferon signaling. Furthermore, genetic and pharmacological inhibition of nuclease activity of MRE11 markedly blocked the activation immune signaling. Significantly, the extent by which cells trigger immune signaling in response to HZE particle exposure is highly dependent on RAD51, a well-known homologous recombination repair factor. Thus, this study suggests that genomic instability triggered by defective clustered DNA lesions repair provokes cGAS-STING cytosolic DNA sensing pathway mediated immune signaling and that might contribute to the initiation of cancer following space radiation exposure.

F2.2-0022-18 CELLULAR MECHANISMS OF HIGH LET RADIATION EFFECTS

George Iliakis, georg.iliakis@uk-essen.de University of Duisburg-Essen, Essen, Germany

Veronika Mladenova, veronika.mladenova@uk-essen.de University of Duisburg-Essen, Medical School, Essen, Germany Agnes Shipler, agnes.shipler

University of Duisburg-Essen, Medical School, Essen, Germany Emil Mladenov, emil.mladenov@uk-essen.de

University of Duisburg-Essen, Medical School, Essen, Germany

The increased biological efficacy of modalities of ionizing radiation (IR) with high linear energy transfer (LET) has been described nearly fifty years ago and has been solidly incorporated into all aspects of human radiation protection. Yet, the underlying molecular mechanisms remain speculative to this date and are typically explored in mathematical models formulated on the basis of biological assumptions that are rarely tested experimentally. In an effort to address this void, we developed biological model systems to study the efficacy of clusters of DNA doubles strand breaks (DSBs) at different biological endpoints. There is experimental evidence for the induction of DSB-clusters after exposure of cells to high LET radiation and their pronounced contribution to the adverse biological effects has been repeatedly modeled in a wide range of mathematical formalisms. In the biological model we developed, DSB clusters of pre-designed configuration are generated by the I-SceI meganuclease, in genomicallyintegrated constructs present in the genome at different numbers. This allows the generation of defined combinations and numbers of DSB-clusters in the absence of any other form of DNA lesions, such as base damages or single strand breaks also generated after exposure of cells to IR. The results show a high potential for DSB-clusters, as compared to single-DSBs, to kill cells. Increased killing is mediated by a dramatic increase in the formation of chromosomal translocations and is thought to derive from a chromatin destabilization at the DSB-cluster site. Indeed translocations forming from DSB-clusters utilize Parp1 activity, implicating alt-EJ in their formation. Furthermore, immunofluorescence experiments show that both single-DSBs and DSB-clusters provoke the formation of -H2AX and MDC1 foci with similar efficiency. Notably, however, the late DDR protein, 53BP1 shows in live-cell imaging strikingly stronger recruitment to DSB-clusters as compared to single-DSBs. These observations provide the first direct mechanistic explanation for the long-known increased efficacy of high LET radiation and point to DSB clusters as major contributors. We postulate that DSB-clusters represent a level of DNA damage complexity that adds substantial excess-accident-risk to the processing of DSBs and underpins much of the effects generated by high LET IR. Acknowledgments: Work supported by grants from BMBF (02NUK043B -COLLAR) and the DFG (GRK1739). Conflict of Interest: The authors declare no conflict of interest.

F2.2-0023-18 BIOLOGICAL CHANGES AND HEALTH EFFECTS IN RODENTS EXPOSED TO SPACE RADIATION

Edouard Azzam, edouard.azzam@rutgers.edu

Rutgers University, Newark, New Jersey, United States

Human health risks that may originate from exposure to low doses/low fluences of ionizing radiation (IR) during long-term interplanetary missions are uncertain and are a major concern. The IR encountered in space is largely protons and high atomic number, high energy (HZE) particles. The linear energy transfer (LET) of protons is low, whereas HZE particles have intermediate and high LET. We have examined oxidative stresses and inflammatory responses in organs of young-adult and middle-aged mice (CBA/CaJ, C57BL/6J) and rats (SpragueDawley) exposed to protons and/or different HZE particles. The radiations were delivered to the whole body or head only at both high and low dose-rates, and the animals were processed for analyses at times ranging from 2 weeks to 15 months after irradiation. The results are compared with those obtained in animals exposed, in parallel, to cesium-137 γγ rays as a reference radiation.

Exposure of the animals to low mean absorbed doses from HZE particles with LET values ranging from 14 to 150 keV/μm, delivered acutely as single bolus or in a fractionated manner, induced structural changes as detected by in vivo imaging several months after irradiation. Moreover, protein oxidation, lipid peroxidation and disruption of redox-modulated physiological functions, such as mitochondrial protein import, were detected in various tissues within days after irradiation and persisted for months thereafter. The changes were observed following wholeand partial body exposures and were associated with effects on antioxidant enzyme activity. Analyses in blood plasma revealed persistent increases in the levels of inflammatory cytokines (e.g., interleukin-6 and interferon-γ). Histological analyses revealed interstitial injury.

At 2 weeks, and 3, 6 and 14 months after irradiation, peripheral blood and bone marrow were also drawn to examine alterations in cell subsets using multicolor flow cytometry. Relative percent change in specific cell populations and absolute cell counts were determined. Increases, up to 10-fold, in circulating neutrophils were detected at two weeks in middle-aged CBA/CaJ mice exposed to 20, 30 or 40 cGy of either of 1 GeV/u Ca, O or Si ions delivered in a fractionated manner ($p<0.001$). The groups also showed an increase in circulating monocytes ($p<0.01$). The mice exposed to a single bolus of 40 cGy of Ca ions did not show significant increases at 2 weeks; however, by 3 months, increases in neutrophils were detected ($p<0.001$). These increases in neutrophils and monocytes in circulating blood were associated with decreases in these cell subsets in bone marrow ($p<0.05$), suggesting mobilization out of this compartment. Common myeloid, as well as granulocyte/macrophage and megakaryocyte-erythroid progenitors were decreased ($p<0.1$) in bone marrow. Notably, decreases ($p<0.01$) in short-term hematopoietic stem cells were detected.

The early response of neutrophils and monocytes in mice exposed to the energetic heavy ions returned to a normal range at 6 months after irradiation, and remained in this normal range at 14 months. However, at the latter time point, the proportion (%) of circulating plasma cells, but not B cells, were increased ($p<0.001$). The effect seems to depend on the radiation dose and delivery manner, and did not occur in rayor proton exposed mice. This indicates the phenotypes may be specific to high LET radiations, and is suggestive of the development of a plasma cell dyscresia.

Analyses of the long-term effects of exposure to isovelocity 1 GeV/u Ca, O or Si ions in a dose range of 20-40 cGy on cancer induction and degenerative conditions in bone and the cardiovascular system are in progress. The effect of a pre-exposure to low LET protons, delivered at low dose rate, on the induced changes is being also evaluated. Together, these ground-based mechanistic studies may contribute to alleviating the uncertainties in predicting health risks to astronauts.

Andrea Ottolenghi, andrea.ottolenghi@unipv.it University of Pavia, Pavia, Italy

In the era of increasingly more affordable "omics" technologies and impressive advancements in artificial intelligence, big datasets can be easily generated and analyzed through novel and sophisticated approaches, allowing to study in greater details more complex experimental designs. Within this framework, systems (radiation) biology approaches could be applied to pave the way towards a correct integration of different multi-scale and temporal dynamics studies of biological systems. Radiation quality investigations at different low doses and/or dose-rates might take the maximum advantages from these advancements and therefore help in unravelling subtler differences among the biological signature of different radiation exposures, of note in space radiation research. During the presentation, the caveat and pitfalls of identifying in advance key questions to be addressed through a complex experimental setup will be discussed through examples of systems biology approaches applied to radiation biology investigations. The described scenario will serve as basis to highlight the potential advantages and limitations of different experimental designs, encouraging a careful planning in order to avoid biases and maximize the potential outcome of different radiation quality comparisons and dose/dose-rate responses.

F2.2-0025-18 LNC CRYBG3-ACTIN AXIS REGULATES CELLULAR RESPONSE TO SPACE ENVIRONMENT

Actin cytoskeleton is one of the main cellular sensors for mechanical changes. Previously, we recognized a long non-coding RNA, LNC CRYBG3, directly binding to G-actin to interfere with the assembly of actin cytoskeleton. Ionizing radiation induces its expression and consequently disrupts the assembly of actin cytoskeleton. We further verified that microgravity-induced dissembly of actin cytoskeleton in turn increases the expression of LNC CRYBG3. Therefore, LNC CRYBG3 and actin form a regulatory axis in cells to sense extrogenous stimuli, including ionizing radiation and microgravity. Our current research progress on this axis opens another window that LNC CRYBG3-actin axis also regulates cell metabolism by interacting with lactate dehydrogenase A (LDHA), a vital enzyme of glycolysis. Once LNC CRYBG3-actin axis is activated, LDHA expression is enhanced and consequently promotes the uptaking of glucose and the production of lactate. However, the knockdown of LNC CRYBG3 inhibits radiationinduced glycolysis. These findings indicate that LNC CRYBG3-actin axis play an important role in regulating cellular response to environmental changes, especially in outer space.

F2.2-0026-18 A COMPUTATIONAL AND MATHEMATICAL MODELING APPROACH FOR THE STUDY OF RADIATION-INDUCED HIPPOCAMPAL NEUROGENESIS IMPAIRMENT AND NEURONAL DENDRITIC DAMAGE

Eliedonna Cacao, eliedonna.cacao@unlv.edu

University of Nevada, Las Vegas, Las Vegas, Nevada, United States
Francis Cucinotta, francis.cucinotta@unlv.edu

University of Nevada Las Vegas, Las Vegas, Nevada, United States

Neurocognitive detriments associated with cranial radiotherapy for cancer treatment and chronic radiation exposure of astronauts for space travel have always been a concern. Neurogenesis impairment and alterations in neuronal morphology are two of the many factors that have been correlated to this cognitive dysfunctions. Computer simulation and mathematical modeling approach provides an effective tool that contributes valuable insights to the role of radiationinduced changes in producing functional deficits in the brain. These computational and mathematical models are also useful for extrapolation to other conditions that are often constrained in experiments. We have developed predictive models to study radiation-induced changes to neurogenesis [1,2] and alterations to dendritic morphology [3]. Using a system of nonlinear ordinary differential equations (ODEs) to represent age, time after exposure and dose-dependent changes to several cell populations participating in neurogenesis as reported in experiments utilizing mouse models, we obtained a description of the age-related dynamics of hippocampal neurogenesis and the effects of a variety of radiation in altering neurogenesis. Predictions of the threshold doses where neurogenesis recovery fails for given radiation types are described in our neurogenesis mathematical model. On the other hand, we investigate radiation-induced changes in neuronal dendritic morphology using a stochastic model that describes time dependent radiation-induced dendritic damage on in silico representations of mouse hippocampal dentate granule cell layer (GCL) and CA1 pyramidal neurons. Our model describes the changes in morphometric parameters, such as total dendritic length, number of branch points and branch number, including the Sholl analysis for single neurons. Our model based predictions for different patterns of morphological changes based on energy deposition in dendritic segments (EDDS) will serve as a useful basis to compare specific patterns of morphological alterations caused by EDDS mechanisms.

Changes in DNA methylation may contribute to the development of cognitive injury after space irradiation. The hippocampus is critical for cognitive function. Hippocampal changes in cytosine methylation, a major epigenetic modification involving the addition of a methyl group to cytosine (5mC), are involved in the regulation of expression of genes required for cognitive performance. A second form of DNA methylation, derived from 5mC by the action of three TET enzymes (TET 1-3), is hydroxymethylcytosine (5hmC). In brain, levels of TET2 are higher than those of TET1 or TET3. Therefore, TET2 is believed most important for brain function. DNA methylation 20 weeks following proton irradiation (150 MeV, 1 Gy) revealed tissue-specific changes in the localizations of 5mC and 5hmC after irradiation when comparing the hippocampus and the left ventricle that reflect perturbations in tissue specific pathways (e.g., vascular development pathways in the ventricle and neuronal specific pathways in the hippocampus), as well as some shared effects (BMC Genomics, 2016, 17:273). As we reported, 56Fe ion (600 MeV/n) (BMC Genomics, 2016, 17:825BMC Genomics) and proton irradiation (150 MeV, 1 Gy) (Scientific Reports, 2017, 7:10227) impaired cognitive function. Impairments in object recognition and spatial memory retention following proton irradiation were observed at the two-week time point and correlated with altered gene expression and 5hmC profiles that mapped to specific gene ontology pathways. Significant overlap was observed between DNA methylation changes at the 2 and 20-week time points demonstrating specificity and retention of changes in response to radiation. Moreover, a novel class of DNA methylation change was observed following an environmental challenge (i.e. space irradiation), characterized by both increased and decreased 5hmC levels along the entire gene body. These changes were mapped to genes encoding neuronal functions including postsynaptic gene ontology categories, indicating that the brain's response to proton irradiation is both specific and prolonged and involves novel remodeling of non-random regions of the epigenome. To determine if different forms of ionizing radiation induce similar types of DNA methylation changes, we compared proton-induced changes in 5mC and 5hmC with those for 56Fe ion-induced changes. Both 0.1 and 0.2 Gy 56Fe gene-associated DHRs (differentially hydroxymethylated regions) and DMRs (differentially methylation regions) showed a highly-significant correlation with proton DHRs and DMRs, demonstrating that many of these changes represent a common response to ionizing radiation exposure regardless of its form, indicating a general space radiation signature. Gene ontology analyses of the overlapping 56Fe and proton DMRs revealed categories linked to cell adhesion, cell junctions, neuronal growth, and synapse function. Following 28Si (600 MeV/n) ion irradiation, mice irradiated with 0.3 Gy were impaired in object recognition, while those at higher doses (0.6 or 0.9 Gy) were not. Consistent with this pattern of the dose-response curve, sham-irradiated mice and those irradiated with 56Fe (600 MeV) at 0.2 Gy showed novel object recognition but mice irradiated with 0.1 Gy were impaired, suggesting that there might be compensatory mechanisms triggered at higher doses that protect against radiation-induced cognitive impairments that might not be present at lower doses. This is especially concerning as the lower doses would be expected to be more pertinent to doses astronauts will be exposed to during space missions than the higher doses. Comparing hippocampal DNA methylation following proton, 56Fe ion, and 28Si ion irradiation revealed a general space radiation synaptic signature with 228 genes that are associated with profound phenotypes, confirming the potential of this approach to identify genes and pathways involved in the CNS radiation response that are critical for CNS function. The most significant category was postsynaptic density. The synapse category was also highly-significant. Thus, the brain's response to space irradiation involves novel postsynaptic remodeling. This study was supported by NASA grant NNJ12ZSA001N.

F2.2-0028-18 STRUCTURE FUNCTION RELATIONSHIPS IN THE IRRADIATED CNS: THE ROLE OF CHARGED PARTICLE LET AND FLUENCE

Exposure to the space radiation environment poses inherent risk to normal tissue functionality, especially when considering the resultant damage to the intricate cellular structures that define the central nervous system (CNS). The complex radiation response of the CNS is underscored by the surprising sensitivity of mature neuronal populations to structural degradation caused by low dose exposures to individual and/or combinations of charged particle species. As a result, multiple irradiation paradigms have been shown to elicit a wide spectrum of persistent cognitive deficits involving diverse and complex molecular mechanisms.

Despite the challenges of pinpointing the cause and effect relationships of radiation-induced cognitive dysfunction, changes in neurotransmitter availability, the assembly of synaptic machinery and structural plasticity that ultimately results in reduced dendritic arborization and spine density have been implicated to play a significant role in eliciting functional deficits. Analyzing the dose-response relationships that might depend on charged particle LET and/or fluence have revealed some clues, and recent efforts in stochastic modeling have highlighted how differences in microdosimetry might account for observed alterations in neuronal structure at various times after exposure.

The foregoing changes are posited to adversely impact a variety of learning and memory processes dependent on specific regions of the brain, where behavioral decrements in spontaneous exploration tasks, attentional-set shifting, fear conditioning and extinction are accompanied by increased anxietyand depression-like behavior. Importantly, these abnormal behaviors are markedly persistent, and likely reflect the differential sensitivities of mature neuronal populations to radiation-induced structural deterioration. Such findings highlight the multifaceted response of the irradiated CNS, and point to previously uncharacterized properties of neurons that dictate their radioresponse.

Understanding the structure function relationships in the irradiated CNS will provide new insights into the long lasting and adverse effects of cosmic radiation exposure that can compromise neurotransmission. Ultimately, such work will help identify strategies for mitigating the risks of manifesting mission critical performance decrements and/or chronic complications with neurocognitive health that may arise from deep space radiation exposure.

F2.2-0029-18 RADIATION EFFECTS ON BRASSICA SEEDS AND SEEDLINGS

Karl H. Hasenstein, hasenstein@louisiana.edu

University of Louisiana, Lafayette, Louisiana, United States Naresh Deoli, nxd0879@louisiana.edu

University of Louisiana at Lafayette, Lafayette, Louisiana, United States

Space radiation consists of high energy charged particles and affects biological systems, but because of its stochastic, non-directional nature is difficult to replicate on Earth. Radiation damages biological systems acutely at high doses or cumulatively at low doses through progressive changes in DNA organization. These damages lead to death or cause of mutations. While radiation biology typically focuses on mammalian or human systems, little is known as to how radiation affects plants. In addition, energetic ion beams are widely used to gener- ate new mutants in plants considering their high-LET (Linear Energy Transfer) compared to gamma rays and X-rays. Understanding the effect of ionizing radiation on plant provides a basis for studying effects of radiation on biological systems and is the first step to mitigate radiation damage in plants. We exposed dry and imbibed Brassica rapa seeds and seedling roots to proton beams of varying qualities and compared the theoretical penetration range of different energy levels with observable growth response. We used 1, 2 and 3 MeV protons in air at the varying fluences to investigate the effect of direct irradiation on the seeds (10121015ions/cm^2) and seedlings (1013ions/cm^2). The range of protons in the tissue was calculated using M o Carlobased SRIM (Stopping and Range of Ions in Matter) software. The simulation and biological resul response curve showed greater sensitivity of imbibed than dry seeds. In addition, germination rate was strongly dependent on ion beam current, at least for 3 MeV protons. Our data show that weak ionizing particles (low MeV protons) are suitable to study radiation effects and that seeds and seedlings are useful biological systems to study (space) radiation effects. Future experiments will assess the number of transcripts as a function of dose received.

F2.2-0030-18 SPACE RESEARCH AS A MULTIDISCIPLINARY ENDEAVOR

Tom K. Hei, tkh1@cumc.columbia.edu

Columbia University Medical Center, New York, New York, United States

The natural radiation environment in space consists of a mixed field of high energy protons, heavy ions, electrons and alpha particles. Future missions to Mars and other destinations in the solar system will require crew members to spend much longer periods in space and in area outside of the radioprotective shielding of the Earth's magnetic field. A better understanding of the biological effects of the space environment, including radiation, and of countermeasures to minimize these effects, are topics of interest to many researchers and space agencies. Life support systems need to be explored in order to help support long term habitability and sustainability in space. A multitude of expertise in different disciplines are necessary to provide the required environmental life support systems with constraints on space and power, and isolated from outside support, in order to advance human exploration to space.

F2.2-0031-18 ROUND TABLE DISCUSSION - PART 1: THE FUTURE OF SPACE RADIATION RESEARCH

Christine Hellweg, christine.hellweg@dlr.de

Dalian Maritime University, Dalian, China

Space radiation is the "Number One Health Risk" (Chancellor et al., 2014) for long-term space missions beyond Low Earth Orbit (LEO). During space missions, astronauts are chronically exposed to galactic cosmic radiation (GCR) consisting of energetic protons, helium and heavier nuclei up to iron. This chronic exposure increases the risk for developing cancer and degenerative diseases (cataract of the eye lens, and possibly also decrements of the central nervous system (CNS) and other organ systems). The extents of these risks and the underlying mechanisms have to be further elucidated. In addition to the baseline exposure to GCR, Solar particle events (SPEs) bear the risk of acute high dose exposure, and might even provoke the acute radiation syndrome. Mitigation of the space radiation risks necessitates a multidisciplinary approach, from understanding the nature of the space radiation environment, the development of relevant radiation dosimeter systems, having the relevant tools to model the radiation environment, understanding the influence of shielding to the biological effects of space radiation, and being able to develop relevant countermeasures. The invited speakers of the cross discipline talks of the session F2.5 will discuss the upcoming challenges in the fields of space radiation physics, dosimetry, and modeling, biology and countermeasure development. References: Chancellor JC, Scott GBI,1, Sutton JP (2014) Space Radiation: The Number One Risk to Astronaut Health beyond Low Earth Orbit. Life (Basel). 2014 Sep; 4(3): 491-510.

F2.2-0033-18 FLIGHT SAFETY IMPLICATIONS OF THE EXTREME SOLAR PROTON EVENT OF 23 FEBRUARY 1956

Kyle Copeland, kyle.copeland@faa.gov

FAA Civil Aerospace Medical Institute, Oklahoma City, Oklahoma, United States William Atwell, william.atwell@boeing.com

The Boeing Company, Houston, Texas, United States

There is considerable speculation about the effects at aircraft altitudes resulting from extreme solar proton events. The ground level event (GLE) of 23 February 1956 (GLE 5), remains the largest solar proton event of the neutron monitor era in terms of its influence on count rates at monitors near sea level. During this event the count rate was increased by over 5100 percent during one 5-minute period and by as much as 4760 percent (15-minute average) at the Leeds monitor relative to the count rate from galactic cosmic radiation (GCR). Two modern models of the event cumulative solar proton spectrum for this event, a 6-parameter fit in energy and a 4-parameter Band fit in rigidity, are compared with 1-hour of GCR at solar minimum. While effective doses calculated with CARI-7A for both models at low geomagnetic cutoff rigidities are indeed high when compared with GCR and can exceed recommended exposure limits, both GLE spectra exhibit a much stronger dependence on cutoff rigidity than GCR, and a larger fraction of the dose from neutrons. At locations with cutoff rigidities above 4.2 and 6.4 GV, respectively, the GLE effective doses are smaller than the GCR hourly dose. At locations with cutoff rigidities above about 4 GV, GCR was the dominant source of exposure in 10 hours or less at all altitudes examined. This suggests that if a similar event occurs in the future, lowand mid-latitude flights at modern jet flight altitudes could be well-protected by Earth's magnetic field.

F2.2-0034-18 MACHINE LEARNING RISKS CLASSIFICATION AND MICROGRAVITY EXPOSURE RISKS MODEL FOR LONG-TERM MANNED SPACE MISSIONS.

Antoni Perez-Poch, antoni.perez-poch@upc.edu Universitat Politecnica de Catalunya, Barcelona, Spain

Astronauts on a long-term mission to Mars or other destinations far from the Earth orbit would be exposed to large amounts of radiation, which is the primary source of morbility and mortality risk. Recent models have added to the fatal cancer risk estimation other risks from circulatory diseases and central nervous system biological effects (1). However, a complete picture of the overall physiological effects and hazards on it from a manned space mission is still not accurate. We report on two additions to these estimations, and the results obtained from adding these models on the existing data on the literature. In the first place, we perform a machine learning classification using Support Vector Machines (SVM) that allows the researcher to classify human subjects depending on their sensitivity to risk of diseases (radiation-induced, cardiovascular, neurological) while exposed to a long-term space mission. Training of the SVM vector machine is based on mordibity and mortality probababilities, coming from available data and simulating different model subjects with a Monte-Carlo method. The method may be useful, for example, to determine likelihood of crew impairement in a given space mission profile of exposure to microgravity and radiation. We correlate some results for a conjunction class and for an opposition class mission to Mars, with existing estimates in the literature, with an average positive 0.93 correlation of disease likelihood (p=0.022). On the other hand, we use results from the implementation of the Numerical Estimation of Long-Term Microgravity Exposure (NELME) developed in our laboratory. This is an electrical-like cardiovascular physiological model that is able to simulate the behaviour and deconditioning of thet human cardiovascular system under altered gravity conditions. The simulator has been validated with parabolic flight experimental data, and is capable to estimate deconditioning of the cardiovascular system for different long-term space missions. Estimations are incorporated to the existing models that take into account other risks such us radiation-induced effects. The results show that the overall risk of exposure induced death (REID) at the upper 95% confidence level of the risk estimate is increased by nearly 1.6% when taking into account deconditioning to the cardiovascular system due to exposure to microgravity; for a typical Mars mission. Results for different mission scenarios, exercise profile countermeasures and thermal stress are also discussed. In conclusion, machine learning and numerical models of the cardiovascular system such as NELME are emerging tools, useful to evaluate the risks to which astronauts are exposed in a long-term manned mission. Space experiments involving biological investigations have generated considerable interest worldwide. Many space experiments have been scheduled for the established experimental area in the International Space Station (ISS), where astronauts and experimental subjects are exposed to both space radiation and microgravity. Both these conditions are difficult to simulate at ground level. Space radiation is comparable to chronic low-dose exposure. It is now well demonstrated that when cells, organs, or entire organisms are exposed to radiation at low doses or at low dose rates, an adaptive response may be observed. We have elaborated an innovative device allowing chronic radiation exposure to be combined with altered gravity. Given the limited access to the

International Space Station, this device could be useful to researchers interested in the field of space biology. The magnitude of the Earth's gravity vector cannot be changed but its effect on biological systems can be modified and microgravity simulators may generate functional near weightlessness of a cell or organism. These kinds of devices are very useful for studying the influence of gravity on biological organisms or to prepare and/or complete a study that has been selected to be performed on the ISS. One of these devices is the "random positioning machine" (RPM), which is characterized by the randomly changing rotational speed and 3D-direction of a platform where biological samples can be placed. Irradiation was provided by thorium nitrate powder, conditioned so as to constitute a sealed source that could be placed in an incubator. Cell plates or plant seedlings could be placed in direct contact with the source or at various distances above it. Moreover, a random positioning machine (RPM) could be positioned on the source to simulate microgravity. Using the RPM placed on the source, we reached a mean absorbed dose of gamma rays of 0.33 ± 0.17 mSv per day.

F2.2-0036-18 SIMULATION OF OPHTHALMIC ALTERATIONS AT THE ARCTIC, ANTARCTICA AND THE INTERNATIONAL SPACE STATION FOR LONG-DURATION SPACEFLIGHT

Antonio De Morais Mendonca Teles, antonioamore@yahoo.com Brazilian Center of Physics Research, Rio De Janeiro, Brazil

C. Gonçalves, cristianecoelhogoncalves@hotmail.com Brazil

Well, we propose a series of long-period medical simulations in scientific bases at the Arctic, at Antarctica and aboard the International Space Station (ISS), involving natural ophthalmic diseases such as radiation and solar retinopathy, induced cataract, etc., and ophthalmic alterations by accidental injuries. These ophthalmic alterations, without a previous diagnosis, are known to appear after 1 month to 1.5 year, in average. Such studies will be valuable for the human deep-space exploration because during long-duration spaceflight, such as staying at the ISS, a Moon base and a manned trip in an astrobiology mission to planet Mars, it requires several months within such environments and during such periods ophthalmic diseases and accidents might eventually occur, which could seriously affect the 'round-the-clock' work schedule of the astronauts and the long-duration spaceight manned program.

Christian-Albrechts-Universität zu Kiel, Kiel, Germany Andrea Ottolenghi, andrea.ottolenghi@unipv.it University of Pavia, Pavia, Italy

The space radiation environment consists of a wide variety of ion species in a continuous range of energies. Nevertheless, most accelerator-based experiments to measure the biological consequences of the exposure to radiation qualities of interest in space radiation protection have been performed with single beams at fixed energies.

Efforts are currently being undertaken to implement simulators of mixed-field for radiobiology experiments. However, the neutral component of space radiation is difficult to reproduce in a ground-based measurement: neutrons are not found free in space in significant amount, but they are produced following nuclear reactions in space vehicle or habitat walls (1), in gas components of the planetary atmosphere (2), and in traversed tissues themselves.

Neutrons might be responsible only for a small contribution to the total dose absorbed by astronauts, but their biological effectiveness varies with the energy, and neutron contribution to dose equivalent (or any biologically weighted dose) can be correspondingly higher (with quality factors as high as 20). Neutron data from radiobiological measurements are much varied among different experiments, often available only in the few MeV regions, while space radiation requires dedicated studies also at hundreds of MeV. In this higher energy range, the question of biological effectiveness of neutrons has still to be addressed experimentally.

In this context, a theoretical effort to predict neutron biological effectiveness for different exposure scenario is highly desirable. This can be achieved with a comprehensive modeling approach, bringing together transport calculations of neutrons through

matter, and the predictive power of track structure approaches for secondary charged particles generated by neutron interactions, up to the evaluation of biological damage induction to a sensitive subcellular target as the nuclear DNA.

In this work we discuss and apply possible models for energy dependent neutron RBE (3) (Relative Biological Effectiveness) to neutron spectra of interest in case of astronauts' exposures in space situations, as neutrons inside a space habitat or on the surface of Mars.

NASA/LaRC, Hampton, Virginia, United States

The current 3DHZETRN-v2 has a detailed 3D treatment of neutron/light-ion transport based on a quasi-elastic/multiple-production assumption allowing improved agreement of the neutron/lightion fluence compared with results of Monte Carlo codes. The current numerical methods are no longer the main limitation to HZETRN code development and further changes in the nuclear model are required. In a prior study we implemented a Serber model leading to an improved quasi-elastic spectrum based on a solution of the transport approximation to nuclear media effects that showed promise but the remaining multiple-production spectrum remained based on a database derived from the Ranft model using Bertini multiplicities. In the present paper, we will implement a complete Serber first step into the 3DHZETRN-v2 code but we retain the Bertini-Ranft branching ratios and evaporation multiplicities. Improved transistion effects are demonstrated for solar particle events near the aluminum/tissue interface. Results are evaluated to the extent possible using modern Monte Carlo codes (Geant4, FLUKA, and PHITS). Extension of the Serber model to HZE interactions of NUCFRG will be discussed.

F2.3-0002-18 GLOBAL NM NETWORK - A USEFULL TOOL TO ASSESS RADIATION HAZARD AT FLIGHT ALTITUDES

Alexander Mishev, alex_mishev@yahoo.com University of Oulu, Oulu, Finland

Ilya Usoskin, ilya.usoskin@oulu.fi University of Oulu, Oulu, Finland

An important topic in the field of space weather is the assessment of radiation exposure at commercial flight altitudes. A specific interest is related to the contribution of solar energetic particles. For this purpose a precise information about solar energetic particle (SEP) characteristics, namely rigidity spectrum and angular distribution is necessary. Direct measurements with space-borne instruments can provide precise information of SEPs. However, they are constrained in some cases, because the specifics of spacecraft orbits. On the other hand ground based detectors, namely the global neutron monitor network provides a continuous operation. SEP characteristics can be derived using neutron monitor (NM) data during a special class of SEP events - the ground level enhancements (GLEs). A precise analysis of SEP spectral and angular characteristics using NM data requires several steps: detailed computation of assymptotic cones and cut-off rigidity of NMs used for the analysis, modeling of global NM network response using NM yield function and optimization procedure in order to derive spectral and angular characteristics of SEPs. Similar procedure with modifications, namely simplification of the model is applied for sub-GLEs analysis. Subsequently on the basis of the derived spectra and angular characteristics and using recent model based on previously computed yield functions we calculate the effective dose during the GLEs and sub-GLEs at typical commercial flight altitude of 35 kft. Several examples are shown. Hence, we demonstrated that the global NM network is a useful tool to assess the radiation exposure of aircrew due to CR of galactic and solar origin. In addition, we created a new database for assessment of radiation doses in the Earth atmosphere, related to GLE events created under VarSiTi/SCOSTEP support and incorporated to the International GLE database. The upgraded database provides, for each GLE event, where possible, information on the estimated SEP energy/rigidity spectra, the corresponding computed effective doses and bibliography. The effective dose rates were computed for altitude of 35 kft in a polar region, where the exposure is maximal.

F2.3-0003-18 CHARACTERISATION OF THE SPACE RADIATION ENVIRONMENT IN THE NEAR-EARTH REGION BASED ON MEASUREMENTS WITH THE TRITEL THREE DIMENSIONAL SILICON DETECTOR TELESCOPE IN DIFFERENT MISSIONS

Balazs Zabori, zabori.balazs@energia.mta.hu

MTA Centre for Energy Research, Budapest, Hungary, Budapest, Hungary Attila Hirn, hirn.attila@energia.mta.hu

MTA Centre for Energy Research, Budapest, Hungary Tamas Pazmandi, pazmandi.tamas@energia.mta.hu MTA Centre for Energy Research, Hungary

Sandor Deme, deme@aeki.kfki.hu Hungary

A three-dimensional silicon detector telescope (TRITEL) was developed in the KFKI Atomic Energy Research Institute (the predecessor of the MTA Centre for Energy Research) in order to determine the average radiation quality factor and to estimate the absorbed dose and the the dose equivalent to the astronauts. Since 2011, TRITEL has been operated on different kind of platforms: on board the BEXUS-12 (September 2011) and the BEXUS-14 (September 2012) stratospheric ballons in the frame of space education projects of ESA; on board the European Columbus module of the International Space Station (ISS) in a collaboration with ESA (November 2012 - May 2013); and on board the ISS Zvezda module in collaboration with the Institute of Biomedical Problems, Russian Academy of Sciences (April - July 2013 and October 2017 -). In the present paper, a comparative analysis of all these measurement results will be given. The result of the analysis will be used to characterise the space radiation environment in the stratosphere and in low Earth-orbit based on experimental data from the TRITEL instrument. The ESEO-TRITEL instrument as the scientific payload on board the European Student Earth Orbiter (ESEO) will be also described. The expected launch of the ESEO microsatellite is due in Q2 2019. The expected measurement results will be also compared to TRITEL experimental data already available from the previous missions.

Short-term increased fluxes in outer radiation belt were widely observed on polar satellites [1,2], as well as in balloon experiments [3]. The authors of these papers connect these features with the precipitation of energetic electrons into the upper atmosphere, or with the relativistic electrons enhancement events at the outer radiation belt boundary. We selected flux increasing of the charged particles and the dose rate in the region of the outer radiation belt in the period from September 1 to September 3, 2016. 01.09 the radiation conditions are moderately normal. The magnitude of the radiation belt maximum is at the value L = 4 less than 0.001 Gy / h. There are no small in duration features, except for one intersection of the belt in 08: 33: 56UT. Next, from 10:12 September 2 to 16:32 on September 3, we noticed 12 intersections of the belt with short-term features. These features are particle flux and dose rate enhancements and at the time scale up to 20 seconds. We show that such short features can contribute up to 25% of the daily dose in outer radiation belt. The amplitude of the increase exceeds that at the maximum of the radiation belt. Such increases occur on L-shells around 5. In this separate case, 11 increases were found on the night side of the magnetosphere (MLT from 18 to 6) and only one on the morning side of the magnetosphere. We analyze the geomagnetic situation with respect to the search for the preconditions for the formation of flows of energetic particles. According to the geomagnetic index SYM / H, at the beginning of the period under review, a geomagnetic disturbance of -75 nT is observed. The particle flux enhancements occur in the second half of the period, 10 hours after the DST minimum (SYM / H). The deviations of the SYM / H index in the presence of increases are no longer so great, up to -50 nT. Since we observe the increases in auroral zones, we use AE index as the criterion for changing the geomagnetic situation. However, the comparison of the detection time of the flux increases does not reveal the correlation of the AE value with the presence and magnitude of the particle flux increases. Instead, the rise times are in good agreement with the abrupt changes in AE in both directions. We also observe a good correspondence between the magnitude of the flow velocity and the time of observed increases.

F2.3-0005-18 RADIATION MEASUREMENTS WITH A PARTICLE PIXEL DETECTOR (PPD): ON SHINEN-2 SPACECRAFT THROUGH RADIATION BELTS

Prairie View A&M University, Prairie View, Texas, United States

Space radiation beyond low-earth orbit is constantly changing due to variations in the radiation particle flux of the Galactic Cosmic Ray (GCR) environment. Prairie View AM University (PVAMU), in collaboration with NASA Johnson Space Center (NASA-JSC), developed a radiation detector system for the Kyushu Institute of Technology (KIT) in Japan and launched the only payload on board their Shinen2 spacecraft in December 2014 as part of the Hayausa2 Mission of JAXA. This newly designed and developed radiation detector (Particle Pixel Detector, PPD) makes use of two CMOS (Complementary Metal Oxide Semiconductor) sensors with custom designed electronic instrumentation capable of identifying radiation particle trajectory and characteristics. Shinen2 spacecraft, designed and built by KIT-Japan, is a hexagonal shaped, 15-kg, 47 x 49 x 49-cm structure built with light-weight and durable Carbon Fiber Reinforced Polymer (CFRP) with dual batteries charged by solar panels on each side of the structure and redundant UHF transmission systems at 437 MHz. Shinen2 proved its success by transmitting radiation data measured by the PPD unit from Moon orbit and up to 30 times distance from Earth to Moon. We present and discuss first data sets received from the Shinen2 spacecraft and assess the measurements with recently obtained calibration data with high energy protons and heavy ions. Our first data through the radiation belts is very promising with additional results from elliptical orbit trajectory around the Sun.

F2.3-0006-18 THE DOSIS 3D PROJECT ONBOARD THE INTERNATIONAL SPACE STATION - STATUS AND SCIENCE OVERVIEW OF 6 YEARS OF MEASUREMENTS (2012 - 2018)

Thomas Berger, thomas.berger@dlr.de

German Aerospace Center (DLR), Cologne, Germany DOSIS 3D - 2018

The radiation environment encountered in space differs in nature from that on Earth, consisting mostly of highly energetic ions from protons up to iron, resulting in radiation levels far exceeding the ones present on Earth for occupational radiation workers. Since the beginning of the space era the radiation exposure during space missions has been monitored with various passive and active radiation instruments. Also on-board the International Space Station (ISS) a number of area monitoring devices provide data related to the spatial and temporal variation of the radiation field in - and outside the ISS. The aim of the DOSIS 3D (2012 - ongoing) experiment is the measurement of the radiation environment within the European Columbus Laboratory of the ISS. These measurements are, on the one hand, performed with passive radiation detectors mounted at eleven locations within Columbus for the determination of the spatial distribution of the radiation field parameters and, on the other hand, with two active radiation detectors (DOSTEL) mounted at a fixed position inside Columbus for the determination of the temporal variation of the radiation field parameters. The talk will give an overview of the current results of the data evaluation performed for the passive and active radiation detectors for DOSIS 3D in the years 2012 to 2018 and further focus on the work in progress for data comparison with other passive and active radiation detector systems measuring on-board the ISS.

Acknowledgments: The participation of the Technische Universität Wien, Atominstitut (ATI), Vienna, Austria in the DOSIS-1 and -2 experiments was supported by the Austrian Space Applications Programme (ASAP) under contract no. 819643. The Polish contribution for the Institute of Nuclear Physics (IFJ), Krakow, Poland was supported by the National Science Center (project No DEC-2012/06/M/ST9/00423). MTA EK greatly acknowledges the possibility to participate in the project to DLR and to the ESA PECS for the financial grant No. PECS4000108464. The participation of the Nuclear Physics Institute of the Czech Academy of Sciences has been supported by the grant of Czech Science Foundation (GACR) No. 15-16622Y. The CAU, University of Kiel was supported by DLR under grants 50WB0826, 50WB1026, 50WB1232 and 50WB1533.

The shielding effect with water-filled tools, called "Protective curtain", for space radiation was experimentally verified in the Russian Segment of International Space Station (ISS). The Protective curtain consists of a stack board made of the hygienic wipes and towels for ISS crews. The passive dosimeters consisted of a combination of luminescence detectors (TLDs: LiF:Mg,Ti, CaSO4:Dy and Al2O3:C and OSLDs: Al2O3:C) and plastic nuclear track detectors (PNTDs: CR-39 HARZLAS/TD-1). Totally 12 passive dosimeter packages were installed in front of/behind the Protective Curtain with 6 g/cm^2 in mass thickness for measuring the dose reduction rate. The experiment was launched in June 2010 and has been continued by March 2016 through 6 sessions. The dose reduction rate which is the dose ratio with/without

Protective Curtain varies from 53 to 93 % in absorbed doses and from 52 to 97 % in equivalent dose, respectively. The observed dose includes secondary radiations such as neutrons and target fragments as we can see in LET spectra. In this presentation, we

will show the recent progress of shielding effect characteristics of Protective Curtain and long term dose variations related to the ISS orbital parameters and solar activity.

F2.3-0008-18 RADIATION DOSE SIMULATIONS FOR SPHERICAL TISSUE-EQUIVALENT PHANTOM USED IN THE MATROSHKA-R SPACE EXPERIMENT ABOARD ISS

We present a numeric method for fast calculation of the radiation dose rate during a space flight. We demonstrate its application for the first and the second sessions of MATROSHKA-R space experiment with the spherical tissue-equivalent phantom.

Radiation dose calculations using depth-dose curves consist of two parts. In the first part, real spacecraft geometry is processed into shielding distribution function. This function is calculated for each point of interest using ray-tracing method. In the second part, shielding distribution function is convoluted with the depth-dose curves. Depth-dose curve is a dependence of the radiation dose in a very small tissue volume on the shield thickness and composition. Depthdose curves for this work were calculated using GEANT4 Monte-Carlo code combined with GCR and AP8/AE8 trapped radiation models. Both absorbed and equivalent doses were calculated. Equivalent dose was calculated using quality factors dependent on LET.

The first main feature of the work is that the depth-dose curves were calculated for a doublelayer aluminum-water shield and shielding distribution function is replaced with shielding and composition distribution function. Aluminum-water shield is a good simplification of the real geometry, as water is good equivalent for biological tissues and aluminum is the major material for a spacecraft wall. We demonstrate that this ratio has influence on the depth-dose curves in the thickness rage over ~10 g/cm^2.

The second main feature is that we calculated contribution of primary and secondary radiation. Secondary radiation was additionally separated according to particle type (gammas, protons, neutrons, nucleus, leptons, mesons and baryons).

After 4 years of intermission, operation of the TRITEL 3D silicon detector dosimeter system, developed in the Centre for Energy Research, Hungarian Academy of Sciences in cooperation with BL-Electronics Ltd., continued on board the Russian Segment of the International Space Station (ISS). The TRITEL instrument has been used aboard the ISS in the framework of the Russian (IBMP and RSC ENERGIA) space experiment MATROSHKA-R to study radiation dose distribution, dynamics, and anisotropy in the space station compartments. The TRITEL instrument, including three silicon detector telescopes with axes mutually orthogonal to each other, thus having almost uniform sensitivity in 4, is capable of determining the energy deposition spectrum in 300-μm-thin silicon detectors and the LET spectrum of the radiation in three mutually orthogonal directions, from which the absorbed dose rate and the dose equivalent rate can be estimated. The scientific objectives, a brief description of the experiment as well as the calibration of the system will be given in the paper. Results of the measurement from the period between April-July 2013 and after October 2017 will be presented, interpreted and compared.

In deep space, personnel and equipment are exposed to the space radiation environment in the form of energetic particles, specifically Galactic Cosmic Rays and sporadic Solar Energetic Particle events. Radiation fields resulting from these particles are modified by shielding, but most radiation measurements in deep space have been made with detectors that were unshielded or very lightly shielded. In contrast, the space radiation environment on the International Space Station is more complicated, with time-dependent modification of the incident flux by the geomagnetic field and complex bulk shielding distributions; measured particle spectra inside the ISS are affected by both types of shielding. Here, our primary aim is to compare charged particle spectra at high linear energy transfer (LET) obtained by the ALTEA detector on ISS during high-latitude portions of the orbit to similar data acquired by the CRaTER and RAD instruments, both in deep space. The CRaTER instrument is on the LRO spacecraft in lunar orbit, and RAD is part of the Curiosity rover science payload. RAD operated for most of its cruise to Mars aboard the MSL spacecraft, during a period in 2012 when ALTEA was in regular operation on the ISS in the USLab. Later in 2012, ALTEA was moved to the Columbus module, while RAD was acquiring data on the surface of Mars. CRaTER operated continuously during both periods. All three instruments report the energy deposition in silicon from charged particles. These energy depositions are used in ground analysis to determine LET spectra in water, which in turn are used to calculate the dosimetric quantities of interest. The results have implications for radiation biology; the ISS radiation environment - at least at high latitudes - may offer a superior platform for radiation biology experiments compared to accelerator laboratories, where even the lowest dose rates are orders of magnitude higher than those in space, though the challenges of performing radiation biology experiments in space would be formidable.

We find that the GCR environments measured by ALTEA when ISS is at high latitudes have many features in common with the environment as measured in shielded environments outside the geomagnetosphere. In the first period studied, ALTEA was in the USLab module of the ISS and under heavy shielding; the LET spectrum it measured is quite similar to that obtained by RAD on Mars in the later period, under similar heliospheric conditions. The spectra obtained by RAD during its cruise to Mars are very similar to the spectrum seen in the most-shielded CRaTER detectors, and the ALTEA spectrum obtained in the second period (while in Columbus) are very similar to these spectra. We conclude that the radiation environment inside the ISS at high geomagnetic latitudes can, in the more-shielded areas, serve as a reasonable proxy for the Martian surface environment, and in less-shielded areas, as a proxy for interplanetary space.

F2.3-0011-18 ESA ACTIVE DOSIMETER A TECHNOLGY DEMONSTRATION FOR ISS AND BEYOND

Ulrich Straube, ulrich.straube@esa.int European Space Agency, Cologne, Germany Thomas Berger, thomas.berger@dlr.de

German Aerospace Center (DLR), Cologne, Germany

Human presence in space has increased significantly over the last decade. Extended space flights supported by various international crews that lasted half a year and longer became a reality. Challenges to human health and well-being proofed to remain significant and increasing with mission-length and workload. Ongoing strong efforts did enable for such mission scenarios and shall do so for the future, the human journey to deep space that is intended. Several of the risks arising seem to have the potential to be mitigated and finally covered sufficiently. Despite health risks from ionizing radiation during extended exploratory deep space missions remain to be of significance and may strongly limit human presence and mission goals beyond Low Earth Orbit. The ESA Active Dosimeter [EAD] hardware enables for advanced personal dosimetry capabilities in real time. The system consists of several small portable Personal Active Dosimeters (MU = Mobile Unit's) as well as a surface attached docking station, called "Personal Storage Device (PSD)". The PSD provides data read-out data and advanced display capabilities as well as data storage and telemetry. The PSD contains a Tissue Equivalent Proportional Counter (TEPC) and an internal MU (iMU) for advanced analysis of the complex radiation environment in the space station and to ensure means of cross calibrations. The MU is applied for personal dosimetry as well as used for area monitoring purposes throughout the station. Verification of the system capabilities have been successfully executed in flight on ISS. Further utilization has been recommend by the ISS partner agencies. System developments and testing, including operations during a future flight of NASA's Orion program, is en-route. This presentation will give an overview of the relevant data from the first year of operations on ISS.

The effects on humans of Solar Particle Events (SPEs) inside a space habitat, are key knowledge for a proper risk assessment. Beside information from the radiobiological standpoint it is important to know how the SPEs will propagate to the habitat, in the habitat and how soon the warning concerning the SPE arrival can be issued. Validation of the related transport models, provision of SPE parameters - as inputs for optimizing the now-casting capabilities - are therefore of paramount importance (now-casting: ability to predict the risk associated to an SPEs from the very first radiation precursors as measured on the vessel itself). Here we focus on two SPEs (August 9th 2011 March 13th 2012) as measured by ALTEA, an active silicon detector system orbiting in Low Earth Orbit (LEO) in the International Space Station (ISS). The SPEs observed by ALTEA are quite different from those detected outside Earth's magnetic field by e.g., GOES, the Geostationary Operational Environmental Satellite, as they are modulated by the geomagnetic shielding The shown measurements provide: i) experimental results of actual SPEs detected within a space habitat; ii) means to extrapolate these results to deep space; iii) information to better understand the interaction between the geomagnetic field and the radiation field from the sun. Results from the the two SPEs will be shown correlating the ALTEA data with data coming from other in-

situ detectors, such as GOES and EPHIN taking into account the geomagnetic field cutoffs. Data from RAD instrument (in transit to Mars) will also be used for the comparison. Other publicly available data from detectors in LEO (such as PAMELA) will be used for the comparisons if available. We will also investigate the reasons of different ALTEA responses to similar SPEs.

F2.3-0013-18 THE DOSIS 3D PROJECT ONBOARD THE INTERNATIONAL SPACE STATION - ANALYSIS OF THE SOLAR PARTICLE EVENT IN SEPTEMBER 2017

Soenke Burmeister, burmeister@physik.uni-kiel.de Christian-Albrechts-Universität zu Kiel, Kiel, Germany Maximilian Bruedern, bruedern@physik.uni-kiel.de Christian-Albrechts-Universität zu Kiel, Kiel, Germany Daniel Matthiä, daniel.matthiae@dlr.de

DLR - Inst. of Aerospace Medicine, Köln, Germany Thomas Berger, thomas.berger@dlr.de

German Aerospace Center (DLR), Cologne, Germany

Besides the effects of the microgravity environment, and the psychological and psychosocial problems encountered in confined spaces, radiation is the main health detriment for long duration human space missions. The radiation environment encountered in space differs in nature from that on earth, consisting mostly of high energetic ions from protons up to iron, resulting in radiation levels far exceeding the ones encountered on earth for occupational radiation workers. Accurate knowledge of the physical characteristics of the space radiation field in dependence on the solar activity, the orbital parameters and the different shielding configurations of the International Space Station ISS is therefore needed. As a follow up to the DOSIS experiment (2009 - 2011) DOSIS 3D measures since May 2012 the spatial and temporal variations of the radiation field in Columbus. The active part the DOSIS MAIN BOX thereby consist of two active radiation detectors (Dosimetry Telescopes = DOSTELs) with a DDPU (DOSTEL Data and Power Unit) is mounted in a Nomex pouch at a fixed location in the bottom area of the European Physiology Module rack (EPM). The temporal variation in dependence of ISS altitude and solar cycle has been measured with the DOSTEL instruments since May 2012 covering thereby already 6 years of continuous measurements in the frame of DOSIS 3D. Of special interest was the first Solar Particle Event (SPE) (GLE 72) measured inside the Space Station within the DOSIS 3D project in September 2017. This was the first event measured since 2012 inside the ISS and in terms of exploration missions extremely important, since it was also measured in Moon orbit and at the surface of Mars. The presentation will focus on the timeline of the event observed inside Columbus and provide data for dose and relevant energy deposition spectra and also show first comparisons with GEANT4 simulations. It will also provide comparison with events observed with DOSTEL like instruments on space station MIR (1997) and on ISS (2001). The CAU contributions to DOSIS and DOSIS 3D are financially supported by BMWi under Grants 50WB0826, 50WB1026, 50WB1232 and 50WB1533.

The Radiation Assessment Detector (RAD) has been continuously monitoring the Martian surface radiation environment in Gale crater as part of NASA's Mars Science Laboratory (MSL) mission since August 2012. On September 11 2017, RAD detected the strongest SEP event on the Martian surface to date. This event lead to the highest radiation levels since the beginning of the RAD operations in Gale crater. The SEPs associated with this solar storm increased the surface radiation dose by a factor of 3 over the course of a few hours, and the peak radiation dose was more than 50% higher than the previous maximum measured in October 2013.

Here, we give an overview of the heliospheric conditions during the September 2017 solar storm, and present measurements of charged particle spectra during and before the event. RAD saw significant increases in the surface proton and helium fluxes, as well as in the neutral particles (neutrons and gamma-rays) created by interactions of the SEPs with the atmosphere and soil.

F2.3-0015-18 A GENERALIZED APPROACH TO MODEL THE SEP/GCR SPECTRA AND RADIATION DOSE RATE ON THE SURFACE OF MARS

Jingnan Guo, guo@physik.uni-kiel.de University of Kiel, Kiel, Germany

Patrick Kühl, kuehl@physik.uni-kiel.de

Christian-Albrechts-Universität zu Kiel, Kiel, Germany

For future human missions to Mars, it is important to study the surface radiation environment during extreme and elevated radiation conditions. In the long term, it is mainly Galactic Cosmic Rays (GCRs) modulated by solar activity that contribute to the radiation on the surface of Mars, but intense solar energetic particle (SEP) events may induce acute health effects due to their high dose rate. Such events may enhance the radiation level significantly and should be detected as immediately as possible to prevent severe damage to humans and equipment. However, the energetic particle environment on the Martian surface is significantly different from that in deep space due to the influence of the Martian atmosphere. Depending on the intensity and shape of the original solar particle spectra as well as particle types, the surface spectra may induce entirely different radiation effects. In order to give immediate and accurate alerts while avoiding unnecessary ones, it is important to model and well understand the atmospheric effect on the incoming SEPs including both protons and helium ions.

In this study, we have developed a generalized approach to quickly model the surface response of any given incoming proton/helium ion spectra and have applied it to a set of historical large solar events thus providing insights into the possible variety of surface radiation environments that may be induced during SEP events. Based on the statistical study of more than 30 significant solar events, we have obtained some empirical correlations for estimating the surface dose rate directly from any given power-law shaped SEP spectra.

We have also found a pivot energy (300 MeV) at which the intensity alone can be used to determine the surface dose rate induced by a power-law SEP event. Such quantified correlations can be used (1) to make instant predictions of the radiation environment on the surface of Mars upon the onset of SEP events and (2) to retrieve the particle spectra properties (intensity and spectral index) at Mars based on the most recent measurements of dose rate by the Radiation Assessment Detector on the Curiosity rover.

F2.3-0016-18 IMPLICATIONS OF THE SEPTEMBER 2017 SOLAR PARTICLE EVENT FOR HUMAN EXPLORATION OF MARS

German Aerospace Center (DLR), Koeln, Germany

Although the Sun is approaching solar minimum, a series of large solar particle events (SPEs) occurred in September 2017 that impacted both Earth and Mars. In particular, the event of 10 September 2017 was the largest event that RAD has seen on the surface of Mars since it landed in 2012. Due to the modulating effect of the Martian atmosphere, the shape and intensity of these SEP spectra will differ significantly between interplanetary space and the Martian surface. Understanding how these SEP events influence the surface radiation field is crucial to assessing associated health risks for potential human missions to Mars. We will discuss in this talk the dosimetric quantities measured by MSL RAD before, during and after the Sept. 10 event, and their implications for potential human missions to Mars.

MSL RAD is supported by NASA (HEOMD) under JPL subcontract 1273039 to SwRI, and by DLR in Germany under contract with Christian-Albrechts-Universitat (CAU).

F2.3-0017-18 MARS NEUTRON RADIATION ENVIRONMENT: SURFACE AND ORBITAL DATA

Space Research Institute (IKI), Moscow, Russia

The charged particles of the Galactic Cosmic Rays (GCR) penetrate through the thin martian atmosphere and collide with the nuclei of basic rock-forming elements in the subsurface layer producing high energy neutrons. This process forms the neutron radiation environment of Mars which present significant problems/hazard for the future robotic and human exploration. Currently some of orbital and surface missions exploring Mars are equipped with neutron spectrometers to monitor martian neutron flux in different energy ranges. In this study we have used neutron spectroscopy data gathered by HEND/Odyssey, DAN/MSL Curiosity and FREND/ExoMars/TGO experiments for the time period starting from 2002 till now. This analysis includes search for long and short-term variations of neutron flux/GCR during quiet and active Sun, comparison between orbital and surface measurements and comparison with dosimetry data.

LIDAL (Light Ion Detector for ALTEA) is a detector based on scintillators for fast time applications, designed to work paired with three ALTEA Silicon Detector Units (SDUs). It performs Time Of Flight (TOF) measurements and allows also to extend the ALTEA (Anomalous Long Term Effects on Astronauts) detection capability for the lower-Z cosmic ions on-board the International Space Station (ISS). Moreover, by merging particle velocity measured by LIDAL with the deposited energy measured by ALTEA, the Particle Identification capability is enhanced. This paper consists of three main parts. The first one is an overview of the different tasks and timing performances required for LIDAL detector: starting from simulations results, we will show how it is possible to fulfill timing requirements using the on-the-edge available technology. The second part is dedicated to the LIDAL prototype-0 developed at University of

Tor Vergata: the different realization steps, like the scintillator assembly, wrapping and light tight procedures, are briefly shown and discussed. The last part is dedicated to the prototype characterization performed at TIFPA proton beam line at Trento (Italy). The results are presented and discussed. Development status, foreseen schedules, flight opportunities and possible collaborations will be also presented.

F2.3-0019-18 HIGH ENERGY PARTICLE ENVIRONMENT IN THE MARTIAN ORBIT: PROPOSED MEASUREMENTS USING ENERGETIC ION SPECTROMETER

Energetic particles of the interplanetary and solar origin are continuously bombarding the Martian ionosphere and plays an important role in the atmospheric loss. These particles can change the state of the Martian ionosphere significantly. In order to quantify and evaluate these changes in the Martian ionosphere due to the arrival of energetic particles generated close to the Sun during flare or due to the passage of interplanetary coronal mass ejection (ICME) and co-rotating interaction region (CIR), it is important to identify the arrival of these energetic particles at the Martian orbit relatively accurately. By measuring the H++ - He++ ratio in the Solar Energetic Particles (SEP), the precise time of arrival of these particles at the Martian orbit can be determined. The measurements of these proton and alpha fluxes at the Martian orbit can also further help to understand the energetic particle environment around the Martian orbit. Keeping these objectives in mind, the Energetic Ion Spectrometer (EIS) is planned for future Indian Mars Orbiter Mission. The prime objective of the EIS is to make the in-situ measurements of the high-energy charged particles (H+ and He++) in the energy range of 20 keV/n to 20 MeV/n from the Martian orbit. EIS uses customized Si-PIN detectors in the E-E configuration mode for the energy measurement and identification of the H+ and He++ particles. It uses a stack of 20 µm thick and 1.5 mm thick Si-PIN detectors to cover the energy range of 20 keV/n to 20 MeV/n. Third detector is placed behind

the 1.5 mm Si-PIN detector to work in the flag mode. This detector and the Anti-Coincidence Shield (ACS) are designed using plastic scintillator and Silicon Photomultiplier (SiPM) readout. Electrons measurements up to the energy of 400 keV are avoided by using the permanent magnetic assembly designed using SmCo magnets and Mu metal shielding. In this talk, overall configuration of the EIS, its salient features will be discussed. Developmental status of the bread-board model with preliminary results will also be presented.

F2.3-0020-18 INTERNATIONAL SCIENCE ABOARD ORION EM-1: THE MATROSHKA ASTRORAD RADIATION EXPERIMENT (MARE) PAYLOAD

The natural ionizing radiation environment present in space poses risks to human exploration that require mitigation. Space ionizing radiation consists primarily of highly energetic charged particles including protons and heavy ions. Solar energetic particles (SEP) originate from the Sun and are emitted during transient events referred to as Solar Particle Events (SPEs). Galactic Cosmic Rays (GCR) originate outside the solar system and form a slowly varying background modulated by the solar cycle. Spacecraft designed for Exploration beyond Earth orbit (BEO) do not benefit from the Earth's magnetosphere protection and are subject to stricter radiation design requirements than their low Earth orbit (LEO) counterparts. Spacecraft flying beyond Earth orbit may also be exposed to the Van Allen (trapped radiation) belts environment depending upon their trajectories. Orion is NASA's next generation crewed spacecraft, developed specifically for Exploration missions. Orion's first test flight Exploration Flight Test 1 (EFT-1) was successfully completed in December 2014, along a trajectory traversing the peak flux region of the Van Allen proton belt. The upcoming Orion mission referred to as Exploration Mission 1 (EM-1) is a test flight scheduled for 2019. The EM-1 trajectory will reach cis-lunar space for a total mission duration of 21-42 days. The Van Allen proton exposure during EM-1 is expected to be lower than EFT-1 primarily due to faster transit through the belts, but significantly higher than that experienced by the International Space Station (ISS) during South Atlantic Anomaly (SAA) passes. Characterization of the space radiation environment and development of mitigation strategies are complex problems. The environmental components (GCR, SPE, Van Allen radiation) differ in elemental compositions, energy spectra, and intensities. The intra-vehicular environment is modified as a result of interaction of the extra-vehicular environment with the spacecraft materials. This occurs due to both the primary particles being slowed down by electronic interactions with the shielding material, and secondary particles being generated by nuclear interactions. Knowledge of exposure specific to organ points of interest is

important for biological effects quantification. Human body self-shielding differs among organs and tissues. The measuring efficiency of detectors varies across the wide range of particle species and energies of interest. Tissue equivalent phantoms have been used to perform space radiation measurements relevant to biomedical effects. The MATROSHKA series of international collaboration experiments using the anthropomorphic Alderson Rando phantom as measurement platform has been conducted starting from 2004, both intraand extravehicular on ISS. Lockheed Martin is the NASA prime contractor responsible for the Orion vehicle. Radiation protection has been incorporated in the Orion spacecraft as a design driving requirement and consistent with the ALARA principle. Feedback invited by Lockheed Martin as part of ongoing efforts to optimize radiation protection of the Orion crew attracted interest in an incremental improvement of previous MATROSHKA experiments. In coordination with Lockheed Martin Advanced Programs, an ionizing radiation science payload referred to as MARE (Matroshka AstroRad Radiation Experiment) was proposed by the German Aerospace Center DLR and the Israel Space Agency ISA. In May 2017, MARE was approved by NASA and manifested aboard the Orion EM-1 flight. MARE consists of two CIRS ATOM® 702 Adult Female radiotherapy phantoms flown inside the Orion cabin at seat positions 3 and 4. The phantoms are fitted with ionizing radiation detectors placed both internal for organ point-, and external for skin exposure measurements. In an improvement over the ISS MATROSHKA, the science objectives are expanded to include characterization of a novel personal protection equipment item deployed on one of the phantoms, the AstroRad individual radiation protection shield. AstroRad is the product of an international collaboration between StemRad Ltd., Israel and Lockheed Martin. AstroRad provides customizable radiation protection for astronauts, focused on radiation-sensitive stem-cell rich organs and tissues. The MARE suite of radiation detectors includes over 5,000 passive detectors for dose depth profile and organ point measurements, consisting of Thermoluminescenceand Optically Stimulated Luminescence dosimeters, and Plastic Nuclear Track Detectors. For purposes of dosimetry intercomparison and detector cross-characterization, assemblies of dosimeters provided by the international research community will be included in MARE, with heritage participation in the DOSIS-3D experiment. MARE also features active detectors - the DLR M-42, the NASA CPAD (Crew Personal Active Dosimeter) and the ESA Active Dosimeter Monitor Unit - Orion (EAD MU-O). Time-resolved measurements provided by the active detectors will allow separate characterization of mission-phase-specific environments. Preliminary environment assessments were performed for the EM-1 mission, including on a family of expected trajectories through the Van Allen belts to confirm sensitivity requirements for the MARE detectors. This presentation will include background on the Orion vehicle, BEO vs. LEO radiation environments, heritage space dosimetry efforts relevant to MARE, and focus on the current MARE status including active radiation detector development, testing and characterization. In conjunction with other radiation detectors aboard the vehicle, the Matroshka AstroRad Radiation Experiment is designed to provide a comprehensive picture of the radiation environment beyond Earth orbit specific to the Orion vehicle and internal to human body analogs. This data set will inform about expected exposures, enable better planning by validating the operational toolsets used to predict crew radiation exposure risk on future Orion missions, and evaluate a potential countermeasure. MARE epitomizes the spirit of international collaboration toward human space exploration. The experiment is co-managed by DLR and ISA, with NASA participation as a co-PI. StemRad and Lockheed Martin contribute to the development of AstroRad science objectives. Numerous research groups on three continents participate as co-Is, including ESA. Lockheed Martin personnel facilitate payload integration in the spacecraft. As one of the first science payloads to fly aboard Orion, MARE demonstrates the research opportunities aboard NASA's next generation space exploration vehicle.

F2.3-0021-18 TIME-DEPENDENT RADIATION DOSE SIMULATIONS DURING INTERPLANETARY SPACE FLIGHTS

Mikhail Dobynde, mikhail.dobynde@skolkovotech.ru

MIT, Cambridge, Cambridge, Massachusetts, United States

Space radiation is one of the main concerns in planning long-term interplanetary human space missions. There are two main types of hazardous radiation - Solar Energetic Particles (SEP) and Galactic Cosmic Rays (GCR). Their intensities and evolution depend on the solar activity. GCR activity is most enhanced during solar minimum, while the most intense SEPs usually occur during the solar maximum. SEPs are better shielded with thick shields, while GCR dose is less behind think shields. The overall dose from SEP and GCR depends on the time of the mission and thickness of the spacecraft shield. In order to minimize the radiation intensity and dose from SEP and GCR it is encourage to the search of the optimal launch date. In this study, we combine state-of-the-art space environment models with GEANT4 simulations to determine the optimal shielding of the spacecraft, and launch time with respect to the phase of the solar cycle. The radiation environment was described by the time-dependent GCR model, and the SEP spectra that were measured during the period from 1990 to 2010. We included gamma rays, electrons, neutrons and 28 fully ionized elements from hydrogen to nickel.

We calculated the astronaut's radiation doses during interplanetary flights using the MonteCarlo code that accounts for the primary, secondary and albedo radiation. Secondary and albedo radiation dose was additionally classified according to particle type (gammas, protons, neutrons, nucleus, leptons, mesons and baryons). We also calculated dose distribution inside the astronaut's phantom, to estimate radiation dose for different organs.

In conclusion, we present the dependences of the radiation dose as a function of launch date from 1990 to 2010, for flight durations of up to 6 years.

F2.3-0022-18 FEASIBILITY OF A USAGE OF SMALL-SIZED P-TERPHENYL SCINTILLATORS WITH ORIENTED CRYSTALLINE AXES IN SPACE MEASUREMENTS OF HIGH ENERGY CHARGE RADIATION

Detector head of the Background Particle Monitor (BPM) is a constituent part of the solar soft X-ray spectrophotometer ChemiX for interplanetary space mission "Interhelioprobe". The BPM measurements of particle fluxes will assist to determine level of X-ray spectra contamination due to high-energy ambient interplanetary particles. BPM's head comprises organic scintillator, which is built on the base of p-terphenyl single crystal, optically coupled with semiconductor multi pixel photon counter - silicon photomultiplier (Si-PM). As far as lightweight organic scintillators typically have moderate technical light yields as compared with "massive" inorganic scintillators such as CsI(Tl), NaI(Tl), we have studied the possibility obtaining highest luminescence intensity from small-sized p-terphenyl single crystals for particle detection.

In this research we present results of laboratory measurements of dependence of technical light yield for small-sized p-terphenyl detectors in relation with the direction of their crystalline axes. The research was performed for a crystal sample with dimensions that are very close to geometric parameters of BPM's anti-coincidence detector. A cubic sample of the scintillator with dimensions 6 x 6 x 6 mm3 has been manufactured with this purpose to match an active area of Si-PM. We have measured its spectrometric characteristics in the energy range from 482 1048 keV along specific crystalline axes using betha-particles from isotopes bismuth-207 and cesium-137.

We demonstrate that scintillation detector made from lightweight organic scintillator and 57,600

pixel' Si-PM photomultiplier is capable to respond to low energy gamma-quanta and electron fluxes in a wide energy range from E = 32 keV up to E = 1048 keV on conditions when the temperature

of photodetector is constant. The greatest technical light yield of such type scintillator is seen when light splashes propagates along axis b of sample crystalline array. Taking into account small values of effective charge and density of this type of organic single crystal scintillator the probability for registration of bremsstrahlung in space is almost negligible, that allow us to detect, to count and even to register energy spectra of primary electrons, protons and other nucleons in magnetosphere and interplanetary space with high efficiency.

F2.3-0023-18 ENERGETIC PARTICLES' FLUXES AND DOSE IN THE RADIATION GENE BOX MEASURED BY SPACE RADIATION DETECTOR ONBOARD SJ-10 SATELLITE

XingZhu Cui, cuixingzhu@ihep.ac.cn China

The space is a total different environment to the surface of the earth, it is essentially without atmosphere, without gravity, without protection form radiation. While radiation in space will hazard the astronauts' health, many experiment about animals and cells abnormal in space have been done to investigate the effect of space radiation on human being. As different types of radiation have different effects on biological tissues, it is important to know exactly fluxes of different radiation particles. The Radiation Gene Box (RGB) was designed to evaluate the effects of space environment on the mESCs and drosophila. While the Space Radiation Detector (SRD) was designed to derive the fluxes of electron, proton, hellion and gamma ray inside the RGB. In this paper, we presented the data obtained during 13 days of instrument operation on low earth orbit. The derived results showed that the total dose of particles inside the RGB would have no obviously biological effect on the mESCs and the fruit fly Drosophila.

F2.3-0024-18 A PROTON IRRADIATION TEST FACILITY FOR SPACE RESEARCH IN ANKARA, TURKEY

Middle East Technical University, Ankara, Turkey

Space radiation often aects the electronic components' performance during the mission duration. In order to ensure reliable performance, the components must be tested to at least the expected dose that will be received in space, before the mission. Accelerator facilities are widely used for such irradiation tests around the world. Turkish Atomic Energy Authority (TAEA) has a 15MeV to 30MeV variable proton cyclotron in Ankara and the facility's main purpose is to produce radioisotopes in three dierent rooms for dierent target systems. There is also an RD room which can be used for research purposes. This paper will detail the design and current state of the construction of a beamline to perform Single Event Eect (SEE) tests in Ankara for the rst time.

ESA ESCC No.25100 Standard Single Event Eect Test Method and Guidelines is being considered for these SEE tests. The proton beam kinetic energy must be between 20MeV and 200MeV according to the standard. While the proton energy is suitable for SEE tests, the beam size must be 15.40cm x 21.55cm and the ux must be between 105p/cm^2/s to at least 108p/cm^2/s according to the standard. The beam size at the entrance of the RD room is mm-sized and the current is variable between 10µA and 1.2mA. Therefore, a defocusing beam line has been designed to enlarge the beam size and reduce the ux value. The beam line has quadrupole magnets to enlarge the beam size and the collimators and scattering foils are used for ux reduction. This facility will provide proton uxes between 107p/cm^2/s and 1010p/cm^2/s for the area dened in the standard when completed. Also for testing solar cells developed for space, the proton beam energy will be lowered below 10MeV. This project has been funded by Ministry of Development in Turkey and the beam line construction will nish in about one year and SEE tests will be performed for the rst time in Turkey.

F2.3-0025-18 SIMULATION OF RADIATION MONITORING TELESCOPES PARAMETERS AND FEATURES OF THEIR OPERATION IN THE DETECTION OF ELECTRONS

This work presents the technique and results of computer simulation of the interaction of cosmic radiation with telescopic detectors. The program code based on Geant4 libraries is designed, to simulate the operation of the detector of ionizing radiation, consisting of several sequentially located semiconductor and scintillation detectors. Using the Geant4 toolkit, we simulate signals from electrons and protons of various energies in the detecting regions of the device, taking into account the generation of secondary particles. Separation of signals from primary particles passing through the entrance window of the telescope and through the walls of the housing is carried out. The obtained data are used to simulate the necessary throughput of the device electronics. The characteristics of the sensitivity and accuracy of the spectrum determination are performed using an original algorithm. This algorithm realizes quantile regression to obtain information on the spectra of cosmic radiation, based on the energy losses of particles in the detectors of the instrument. We can definitely separate signals from electrons and protons but there are some problems with determination of electron energy when using such detectors. The combination of discussed software packages allows optimizing the parameters of the geometry and logic circuits of the device. Application of the results obtained using the presented software codes at the design and production stages of detectors will significantly increase the reliability of received data. The source files of the program codes are available in the public domain.

F2.3-0026-18 AN IMPROVED METHOD TO CORRECT THE THERMAL EFFECTS OF RADFETS FOR SENSITIVE MEASUREMENT OF TOTAL RADIATION DOSE

Binquan Zhang, zhangbinquan@nssc.ac.cn

National Space Science Center, CAS, Beijing, China

"FengYun-4" satellite, which was launch into orbit on December 11, 2016, is the China second generation of geostationary meteorological satellite. The radiation dosimeter on this satellite was designed with the use of 8 radiation sensitive field effect transistors(RADFETs), and it could measurement the total space radiation dose under different shielding thicknesses and directions up to 2000krad(Si) with a sensitivity better than 150rad(Si). RADFETs are specially designed p-MOSFETs to measure the total radiation dose. When the RADFET is irradiated by ionized radiation, electron-hole pairs in the gate oxide of the MOSFET are produced. Then, the holes are trapped in the oxide and the gate threshold voltage is shifted. This shift in the gate threshold voltage is proportional to the total radiation dose. However, the gate threshold voltage could also be shifted as the temperature varies and this is known as the thermal effect. Temperatures inside the "FengYun-4" satellite on the geostationary orbit could varied up to 20C within one day and its effect on the threshold voltages of the p-MOSFETs need to be corrected. An improved method is developed for the correction of the thermal effect. The temperature coefficients are fitted for each RADFET based on the data obtained on-orbit. Then the contributions of temperature fluctuations are subtracted. After thermal effect correction, the total radiation dose of each RADFET is achieved. The results are about 15 35rad(Si)/day with 0.87mm equivalent aluminum shielding thickness and about 0.7rad(Si)/day with 3.87mm shielding thickness. Doses in the Y direction of the satellite are less than those in X and Z directions.

F2.4-0001-18 TRANSCRIPTOME OF ARABIDOPSIS LEAVES UNDER MICROGRAVITY ON BOARD THE CHINESE SPACE LAB TG-2

Huiqiong Zheng, hqzheng@sippe.ac.cn CAS, Shanghai, China

Institute of Plant Physiology and Ecology, Institutes for Biological Sciences, Chinese Academy of Sciences

Plant leaves, which can capture sunlight and fixed CO2, are main sources of food on earth, thus, growth and development of leaves are directly related to the production of crops in agriculture as well as in plant basis space life support system. Leaf development and its physiological activity are regulated by microgravity in space, but how the growth and development of leaves are affected by microgravity at molecular level is still unknown. To delineate the transcriptional response mechanisms, we carried out whole-genome microarray analysis of Arabidopsis leaves of plants grown on board the Chinese space lab Tian gong-2. We identified a novel set of microgravity response genes, recognized mainly by quantitative differences. These included a transcriptome signature of more pronounced proline transport, respiratory burst, protein refolding and jasmonic acid biosynthetic process in developing leaves. This study provides developmental stage specific molecular resolution of different age leaves and demonstrates that a new molecular plasticity in Arabidopsis leaves to adaptation to microgravity by adjusted genome status during development in space.

Key words: Arabidopsis thaliana, leaves, gene expression, microgravity, Chinese space lab

During spaceflight biological samples are exposed to a variety of radiations, including galactic cosmic rays composed of high energy protons and high-energy charged (HZE) nuclei, and solar particle events containing lowto medium-energy protons. On-ground simulated studies have found that HZE exposures can induce early reactive oxygen species (ROS) in seconds which can last for days to months and cause persistent oxidative stresses. In order to investigate the ROS-caused chronic biological effects exposed to actual complex space radiations, Oryza Sativa (Nipponbare) seeds were irradiated by"Shijian-10" (SJ10) spacecraft and the ROS level, antioxidant ability during plant growth and functional protein expression profiles were studied in present research. The results showed that SJ10 space radiations could induce persistent oxidative damage by ROS in rice cells. The H2O2 content and activity of ROS scavenging system were significantly enhanced in 2 or 3-day-old rice seedlings and still existed in 7-day-old plants. Proteome alterations of 21-day-old plants showed that space radiation had significant impacts on the expression of proteins involved in cell redox homeostasis, anti-stress signaling pathway, electron transport chain, removal of superoxide radicals, protein translation and carbohydrate metabolic process. Results indicated that space radiations broke down the homeostasis of rice cells, reduced the synthesis of protein and stored energy metabolism of starch for adapting to oxidative stress induced by chronic ROS. Significant up-regulation of Cytochrome b6f complex proteins involved in photosynthetic electron transport explained that they might be one of the electron sources leading to chronic oxidative stresses in rice.

F2.4-0003-18 GLOBAL RNA-SEQ ANALYSES REVEAL A DRAMATIC LACK OF CONCORDANCE BETWEEN BACILLUS SUBTILIS TRANSCRIPTOMES FROM SPACEFLIGHTVS. CLINOSTAT-GROWN CULTURES

Michael Morrison, mmorrison2015@ufl.edu

University of Florida, Merritt Island, Florida, United States Patricia Fajardo-Cavazos, pfajardo@ufl.edu

University of Florida, Merritt Island, Florida, United States Wayne Nicholson, wln@ufl.edu

University of Florida, Merritt Island, Florida, United States

Performing microbiological experiments in space is constrained by a number factors, including high launch costs, intense competition for limited payload volume and mass, infrequency of rocket launches, and limitations on crew time. These factors nearly preclude opportunities for performing replicate experiments in space, the hallmark of high-quality science. The above constraints have driven experimenters to search for microgravity analogues such as drop towers or parabolic flights. Although cheaper and more convenient, drop towers and parabolic flights provide free-fall conditions for a few seconds at most, which is inadequate for the majority of microbiological experiments that occur over much longer time frames. In an attempt to address this issue, microbiologists have increasingly turned to ground-based clinorotation instruments, which are purported to simulate microgravity by randomizing the gravity vector and minimizing fluid shear within the sample chamber. Clinostats have thus become widely used for testing spaceflight hypotheses prior to spaceflight missions. However, to date few experiments have actually measured the correlation between clinostat and spaceflight results. We recently were afforded a unique opportunity to perform two separate spaceflight experiments (called BRIC21 and BRIC-23), each containing multiple replicates, with matched flight (FL) and ground control (GC) samples using the same medium, hardware, and growth conditions. Comparison of the RNA-seq datasets from the BRIC-21 (n = 3) vs. the BRIC-23 (n = 9) experiments revealed a 32% and 35% concordance in significantly in upand down-regulated transcripts, respectively. These results show that even replicated spaceflight experiments can exhibit substantial experiment-to-experiment variability, highlighting the need for multiple repetitions to increase confidence. Next, to determine whether clinostats are a reliable model for simulating spaceflight effects, we performed RNA-seq analysis on the same B. subtilis strain cultivated in the same medium and temperature as the spaceflight experiments, but in High Aspect Rotating Vessels (HARVs, Synthecon; n = 4), and compared its transcriptome with those from the

BRIC-21 and BRIC-23 spaceflight experiments. Preliminary results of our analysis show essentially no concordance between the transcriptomes from the two spaceflight experiments vs. the samples grown in the HARVs. The results suggest that, at least for B. subtilis, clinostats may not be a reliable analogue for spaceflight missions. Supported by NASA grants NNX14AT38G and NNX17AD51G.

F2.4-0004-18 THE WHOLE GENOME SEQUENCING OF RICE SEEDS SURVIVING 12.5- DAY EXPOSURE TO SPACE ENVIRONMENT

Space radiation was the most important stressor which can induce biological damage and genetic variation in spaceflight. A great deal is known about the kinds of damage produced in the DNA by ultraviolet radiation, to a lesser extent, by ionizing radiation. On the molecular level these effects to the organism are caused mainly by the damage induced by the ionizing radiation to the DNA of the living cell. The SNP, InDel and SV were often found in DNA by radiation after spaceflight. In this study, sequencing research on whole genome of rice seeds surviving 12.5 days exposure to space environment by HiSeqPE150. Taken the genome sequence ofjapanica rice Nipponbare completed the whole genome determination as a control, samtools and breakdancncer and cnvnator were used to study SNP, InDel, SV and CNV of seeds induced by spaceflight and wild-type rice materials. The mapping rate was 82.54%.The analysis showed that the mutagenic effects by space factors evenly distributed and had positive correlation with sizes of each chromosomes. We found 12,775 SNPs, 4,161 InDel, 1,290 SV and 422 CNV. The mutation type occurred in mutant is that SNPs, InDel, SV and CNV, that showed that the space factors changed the single nucleotide of the rice genome was the main factor. This study laid the foundation for exploring the molecular biological mechanism of the real actual spatial environment.

F2.4-0005-18 LONG-TERM SPACE FLIGHT MEDIATED CHANGES IN TRANSCRIPTION INITIATION LANDSCAPE IN ZEBRAFISH (DANIO RERIO) TISSUES

Alexander Cherkasov, cherkasovav@yandex.ru Kazan Federal University, Kazan, Russia Vladimir Sychev, vsychev@imbp.ru

Animal models are important to understanding influence of different factors of long-term space flights on living organisms and can be helpful for forecasting and prevention negative effects of space flights on humans. Teleost fishes, as Japanese medaka (Oryzias latipes) and Zebrafish (Danio rerio), are one of the most popular model organisms in molecular genetics studies, including space biology, primarily by sequenced and well-annotated genome, rapid external development, small size and relatively simple maintenance procedures aboard space-labs. Some previous experiments, which were performed on fish models using simulated microgravity and exposure aboard International Space Station (ISS), showed significant changes in fish behavior, physiology and whole genome gene expression. In this study we focused on several features of transcription initiation landscape and their changes during long-term exposure in space environment in different Zebrafish tissues. To define impact of space flight to tanscriptional activity on promoter level, experiments using cap-analysis gene expression (CAGE) approach were performed. Usage of CAGE, instead more traditional RNA-seq analysis, allows not only perform precise differential expression analysis, but directly map each transcription start site (TSS) with a single nucleotide resolution to access core promoter shape and location. Two groups of Zebrafish individuals were used as experimental and control groups. The individuals from experimental group were launched to international Space Station (ISS). Part of them were fixated in RNA stabilization reagent immediately after arriving, others transfered to Aquatic Habitat (AQH) and fixated after 36 days of staying aboard. Remaining part of experimental group animals were returned alive from ISS to investigate recovery processes. RNA preservation treatment was carried out with this animals in two time-points: 2 and 33 days after return. The animals from control group were maintained in the same Aquatic Habitat system on the Ground with fully identical physical environment conditions and were fixated at the same time-points. First results of CAGE showed the absence of significant changes on promoter shape level. Width of promoter area and dominant TSS position were not demonstrated any differences between pairs of “space” and “ground” samples. However, we have found significant impact of space flight conditions on promoter activity. More than 600

genes changed their expression in eye samples, after arriving aboard ISS. Notably, the number of differentially expressed genes decreased to 154 after 36 days in space, thereby it can be supposed a successful adaptation to space flight conditions after initial stress. Gene Ontology analysis of genes, which were overexpressed after arriving on ISS, showed significant over-representation of functional categories associated with circadian clock system, so it can be supposed an influence of microgravitation to regulation of rhythmic processes in animals. Additionally, from GO categories, enriched in up-regulated genes in all spaceflight time-points, were found several closely related GO terms associated with regulation of transcription. Among genes, characterized by this GO terms, four genes, which are members of Activation protein 1 (AP-1): fosb, fos, jdp2, junbb, showed significant overexpression during spaceflight. The same time analysis of presence of regulatory motifs in promoter surroundings demonstrated over-representation of AP-1-like binding sites in differentially expressed promoters. This facts suggest deeply involvement of AP-1 family members in organismal response to microgravity. The performed transcriptional analysis demonstrated both the considerable gene expression changes in zebrafish eye during long-term spaceflight and the successful adaptation to new environment.

F2.4-0006-18 GUT MICROBES IN CORRELATION WITH MOOD: A STUDY IN "LUNAR PALACE 365"

Zikai Hao, by1510111@buaa.edu.cn Beihang University, Beijing, China Hong Liu, lh64@buaa.edu.cn Beihang University, Beijing, China

Human gut microbiota, sometimes called the second genome or the second brain, may influence our mood through an imaginary microbiota-gut-brain axis. Numerous studies have demonstrated that the gut microbiome and their metabolites are extensively involved in the communication between brain and gut. Understanding the gut-brain correlationship is important for maintenance of mental health and prevention of mental illnesses. However, different from the study on people with mental illnesses, it could be more difficult to study the gut/brain relationship with healthy people whose emotional fluctuation is within a relatively narrow range. Varying physiological, nutritional and environmental conditions would affect the host's gut microbial community, and these factors could also directly affect the mood. Fortunately, the closed experimental bioregenerative life support system (BLSS, Lunar Palace 1) provided an ideal experimental condition under to minimize other possible interferences when we look into the gut/mood correlationship, because it keep the crewmembers living under a relatively stable environment (include environmental microbes), keep a regular dietary and living habit, and maintain a steady activity and health level. In 2014, a 105-day closed experiment with three crewmembers was conducted in the Lunar Palace 1. Previous study by our team has found that 15 genera in the three healthy crewmembers were strongly correlated with mood states. Among which, Faecalibacterium spp. had the highest abundance, and showed a significant negative correlation with mood. Now, a new study on the correlation between gut microbial alternation and mood swings of eight healthy crewmembers was conducted during "Lunar Palace 365" experiment. This study examined the whole metagenome of crewmembers' gut microbes at both speciesand gene-level resolution every week during the 365-day experiment. The mood swings of the crewmembers were investigated by self-rating scale (i.e., POMS, SCL-90), his rating scale (i.e., HAMA, HAMD) and behavioral analysis weekly. The Changes of metabolic, immune, protein were also analyzed. The association analysis between gut microbes and mood were identified with several analytical platforms and various bioinformatics methods (-omics). Our results indicated that the composition of microbial community could play an important role in emotional change in mentally-physically healthy adults. Keywords: Lunar Palace 1,

Microbiota-gut-brain axis, Metagenome, Gut microbes, Mood swing.

F2.4-0007-18 THE SYNERGISTIC EFFECT OF SIMULATED MICROGRAVITY AND CHARGED PARTICLE RADIATION ON GENE EXPRESSION IN HUMAN FIBROBLASTS

Outer space is a unique environment that includes mixed microgravity (μG) and space radiation having a broad range of energy and ions. Currently, there are numerous unclear aspects of various biological responses (ex. gene expression profile change, bystander effect, etc.) induced by exposure to low-fluence heavy-ions under μG for the assessment of human health risks in space. In this study, we focus on comprehensive gene expression analysis for the combined effects using a newly developed 3D clinostat irradiation system with carbon-ion (C-ion) at ground level. Human fibroblasts 1BR-hTERT were maintained in standing or μG condition for 3 h or 24 h after synchronized C-ion irradiation (1 Gy, 290 MeV/nucleon, average linear energy transfer = 50 keV/μm at the center of the 6 cm-spread-out Bragg peak) as part of a total culture time for 2 days. The upor down-regulation change of gene expression profile was listed according to ratios of the expression value using the EDGE (Empirical analysis of Digital Gene Expression) ($p<0.05$, fold change with absolute value>1.5) with CLC Main Workbench software (Qiagen Bioinformatics, CA, USA). After exposure to only C-ions, we found downstream of p53, CDKN1A was enhanced 3 h after irradiation while CCND1 was not significantly changed at either 3 h or 24 h after treatment. On the other hand, in the case of combined treatment,

CDKN1A was suppressed 3 h after treatment and CCND1 was enhanced 24 h after irradiation. Therefore, these results suggest G1 arrest does not occur, and cells may pass through the G1/S check point with DNA damage due to changes in p53 signaling pathway related genes after combined treatment. Further studies are needed to determine whether the changes in gene expressions affect the DNA damage repair of treated cells and could affect bystander cells in simulated space flight environment.

Organisms exposed to the space environment for extended periods of time may evolve in unanticipated ways thereby negatively impacting long duration space missions. We report here, an experimental study of microbial evolution in which the effect of long-term exposure to LSMMG on microbial gene expression and physiology in it Escherichia coli (it E. coli) was examined using functional genomics, and molecular techniques with and with-out simultaneous exposure to broad spectrum antibiotic chloramphenicol. it E. coli MG1655 was grown under simulated microgravity for 1000 generations in High Aspect Ratio Vessels (HARVs) that were either heatsterilized (115 deg C, 15 min) or by using/rinsing the HARVs with a saturated solution of the broad-spectrum antibiotic chloramphenicol. Gene expression patterns and cellular physiology were analyzed in comparison with short-term exposure. In the case of the cells evolved using the antibiotic sterilized HARVs, the expression levels of 357 genes were significantly changed. In particular, fimbriae encoding genes were significantly up-regulated whereas genes encoding the flagellar motor complex were down-regulated. Resequencing of the genome revealed that a number of the flagellar genes were actually deleted. The antibiotic resistance levels of the evolved strains were analyzed using VITEK analyzer. The evolved strain was consistently resistant to the antibiotics used, even after 11 cycles of ‘erasure’ of the ‘adaptation memory’ this ‘erasure’ was accomplished by re-growing the evolved cells under shaker flask conditions and 1 cycle equals 10 generations. In the case of the cells evolved using heat sterilized HARVs, no resistance was observed to any of the antibiotics used, even after 1000 generations of growth under LSMMG. Competition experiments using an isogenic pair revealed that the adaptive advantage of the 1000G strain (in both cases) over an unexposed strain was rapidly eliminated. While this obviously implies that the adaptation was both environmental and genomic, the levels of antibiotic resistance observed to be consistently maintained, raises the concern of persistent resistance conferred to bacterial communities through exposure to antibiotics on space missions.

F2.4-0009-18 EFFECT OF MICROGRAVITY ON THE NUCLEUS

Srujana Neelam, srujana.neelam@nasa.gov

NASA/Johnson Space Center, Houston, Texas, United States

The shape of the nucleus and its position is found to be altered in various pathological conditions, such as cancer, laminopathy and muscular dystrophy. Cells sense the external mechanical cues and these cues alter the cytoskeletal forces, which in turn are sensed by the nucleus due to the mechanical coupling between the nucleus and the cytoskeleton. The shape of the cell and shape of the nucleus are closely related and any changes to the morphology of the cell results in changes in nuclear shape and gene expression. Interestingly, several cell types cultured in microgravity have altered morphology and their cytoskeleton is reorganized. To understand what kind of changes morphology of the nucleus undergoes in cells exposed to microgravity, we analyzed 3-dimensional parameters of the nuclei in human fibroblast cells cultured on International Space Station (ISS) for 3 days and 14 days. The cells were in confluent status before being launched to ISS. Due to contact inhibition, more than 90% of the cells were in G1 phase. The confocal images acquired from the fixed samples were used to reconstruct the 3-D structures of the nucleus, which revealed neither the vertical height of the nucleus and nor the aspect ratio (length/width) changed significantly in cells exposed to microgravity for 3 days or for 14 days compared to the 1 g control cells. Taking together the lack of changes in cell and nuclear morphology and also in gene and miRNA expression levels, it is possible that the exposure to microgravity for longer durations (3 days and 14 days) is giving the cells enough time to adapt to the mechanical effects of microgravity, especially for confluent cell cycle arrested fibroblasts.

Living organisms in space are constantly exposed to radiation, toxic chemicals or reactive oxygen species generated due to increased levels of environmental and psychological stresses. Understanding the impact of spaceflight factors, microgravity in particular, on cellular responses to DNA damage is essential for assessing the radiation risk for astronauts and the mutation rate in microorganisms. In a study conducted on the International Space Station, confluent human fibroblasts in culture were treated with bleomycin for three hours in the true microgravity environment. The degree of DNA damage was quantified by immunofluorescence staining for

-H2AX, which is manifested in three types of staining patterns. Although similar percentages of these types of patters were found between flight and ground cells, there was a slight shift in the distribution of foci counts in the flown cells with countable numbers of -H2AX foci. Comparison of the cells in confluent and in exponential growth conditions indicated that the proliferation rate between flight and the ground may be responsible for such a shift. We also performed a microarray analysis of gene expressions in response to bleomycin treatment. A qualitative comparison of the responsive pathways between the flown and ground cells showed similar responses with the p53 network being the top

upstream regulator. The microarray data was confirmed with a PCR array analysis containing a set of genes involved in DNA damage signaling; with BBC3, CDKN1A, PCNA and PPM1D being significantly upregulated in both flight and ground cells after bleomycin treatment. Our results suggest that whether microgravity affects DNA damage response in space can be dependent on the cell type and cell growth condition.

F2.4-0011-18 THE CANDIDA ALBICANS ADAPTATION RESPONSES TO MICROGRAVITY

Sheila Nielsen, sheila.nielsen@montana.edu

Montana State University, Bozeman, Montana, United States

Candida albicans is an opportunistic fungal pathogen that maintains phenotypic plasticity and is capable of responding to a variety of environmental stimuli. Studies have demonstrated that this normally commensal yeast responds to conditions of low-fluid shear in modeled microgravity studies by displaying phenotypes consistent with pathogenicity. C. albicans responds to low-fluid shear with increased antifungal resistance, increased filamentation, and differential expression of genes in several biosynthetic pathways. We propose that low-fluid shear induces alterations to the chemical environment to which C. albicans is responding. Indeed, C. albicans gene expression studies indicate that there are increased levels of carbon dioxide when the yeast is cultured in conditions of low shear. Extrapolating from our prior findings that low-fluid shear conditions contribute to Amphotericin B resistance in C. albicans, we found that increased carbon dioxide levels result in altered expression of several genes involved in ergosterol biosynthesis. Interestingly, C. albicans cultured in the presence of elevated carbon dioxide plus a sterol sequestering agent assume a highly filamentous cell morphology and hyper irregular wrinkle colony morphology, similar to the response observed following growth in low shear conditions. Taken together, these data indicate that the physiological and morphological responses of C. albicans to low-fluid shear are induced, in part, by increased levels of carbon dioxide.

Microgravity, or an altered gravity environment from the Earth 1g, has been shown to influence global gene expression patterns and protein levels in cultured cells. However, most of the reported studies conducted in space or using simulated microgravity on the ground have focused on the growth or differentiation of these cells. Whether non-proliferating cultured cells will sense the presence of microgravity in space has not been specifically addressed. In an experiment conducted onboard the International Space Station (ISS), confluent human fibroblast cells were fixed after being cultured in space for 3 and 14 days, respectively, for investigations of gene and miRNA expression profile changes in these cells. Results of the experiment showed that on Day 3, both the flown and ground cells were still proliferating slowly, as measured by the percentage of Ki-67 positive cells. Gene and miRNA expression data indicated activation of NFB and other growth related pathways involving HGF and Vegf along with down regulation of the Let-7 miRNA family. On Day 14 when the cells were mostly non-proliferating, the gene and miRNA expression profiles between the flight and ground samples were indistinguishable. Comparison of gene and miRNA expressions in the Day 3 samples with respect to Day 14

revealed that most of the changes observed on Day 3 were related to cell growth for both the flown and ground cells. Analysis of cytoskeletal changes via immunohistochemistry staining of the cells with antibodies for -tubulin and fibronectin showed no difference between flown and ground samples. Taken together, our study suggests that in true non-dividing human fibroblast cells in culture, microgravity experienced in space has little effect on the gene and miRNA expression profiles.

F2.4-0013-18 "OMICS" DATA SYSTEMS FOR SPACEFLIGHT AND SIMULATED SPACEFLIGHT ENVIRONMENT

Sylvain Costes, sylvain.v.costes@nasa.gov

NASA Ames Research Center, Mountain View, California, United States

NASA's GeneLab Data System is a repository that hosts multi-omics datasets generated by biological experiments flown onboard the International Space Station. Strategies regarding how GeneLab envisions the involvement of the scientific community and the public at large will be discussed, and current and future capabilities of the system will be described. Information describing how scientists can participate in analyzing the current datasets on plants, microbes, invertebrates or mammals will be provided, and initial findings from the current datasets will be discussed during this presentation. Anyone interested in genomics, transcriptomics, epigenomics and proteomics, and systems biology, or who is curious to understand how space modifies living organisms should attend.

F2.4-0014-18 A NEW MODEL FOR EVALUATING THE DEPENDENCE OF BIODOSIMETRY ON DOSE-RATES BASED ON GENE EXPRESSION PROFILES

Lei Zhao, zhaol@dlmu.edu.cn

Dalian Maritime University, Dalian, China Xinye He, hexinye0609@163.com

Dalian Maritime University, Dalian, China Yeqing Sun, yqsun@hit.edu.cn

Dalian Maritime University, Dalian, China

Health risks from space radiation are an important barrier for long-term manned spaceflight, in particular towards missions to the Moon and Mars. However, high uncertainties have always existed in estimating space radiation risks for manned interplanetary missions by the conventional method of risk assessment. One of the major uncertainties is related to the dependence of risk on low dose-rates, which can increase or decrease the risk of radiation damage compared to the acute exposures. Several promising approaches to radiation biodosimetry have been proposed in the past few years, while current biodosimetry methods have not yet been developed to distinguish low dose-rate and acute exposures for the risk assessment of potential radiological damage. Because of the diversity of gene expression responses to ionizing radiation, it may be possible to develop a new model of biodosimetry to investigate the dependence of gene expression profiles on dose-rates for providing rapid individual dose estimates and/or space radiation risk assessments. In this study, a combined algorithm, which integrates the feature selection techniques, was used to deal with the microarray datasets of the male C57BL/6 mice irradiated with a range of X-rays doses under low dose-rate (3.09 mGy/min) and acute (1.03 Gy/min) exposures. Compared with controls, a large number of genes were found to be differentially expressed ($p<0.05$) both in low dose-rate and acute exposures. Gene Ontology annotation and functional enrichment analyses showed that distinct patterns of the biological function responses were impacted by low dose-rate and acute exposures. Furthermore, the back propagation algorithm based on artificial neural network was conducted to learn the datasets of the differentially gene expressions and to train the network weights. After training, the estimations of the multi-layer network were agreement with the experimental doses, which indicated that this method could be used to distinguish the low dose-rate and acute exposures and predict the absorbed dose for biodosimetry.

The mechanism of muscle atrophy caused by microgravity has been a key medical issue in the study of space biology. For comparing the muscle movement through life cycle and expression levels of proteins especially participate in regulating muscle contract pathway between N2 wild-type Caenorhabditis elegans (C.elegans) and gravity-sensing defect mutant (dystrophy gene mutation, dys-1)the dauer larva were onboard Chinese SJ-10 satellite for a 303-hour spaceflight. The aim of this study was to in-depth discuss of the mechanisms and regulatory pathways of space microgravity on generation, transmission and regulation of C.elegans locomotion ability. The results showed that space microgravity slowed the rate of decline of C.elegans movement ability as growth. The phenomenon of over-bending in dys-1 mutant disappeared after space flight and returned to the same level as the wild type. Space microgravity significantly affected the locomotion of C.elegans. Proteomic Gene Ontology analysis and differential protein clustering showed that, compared with N2 wild-type, less proteins of dys-1 mutant were significantly changed, especially lacking of proteins involved in muscle contraction-related pathways. Thus, Dystrophy plays a key role in muscle response to microgravity. The effect of the disappearance of gravity signals on dys-1 mutant movement led to the decrease of mechanical signal transduction into the muscle cells, the process of muscle contraction and the structural protein expression level of cytoskeleton. Comparative analysis of differentially expressed proteins of movement pathways revealed that Ca2+ transduction and binding were key pathways for Dystrophy to respond to space microgravity. This finding provides an important basis for revealing the changes in muscle function under space microgravity.

F2.4-0016-18 INVESTIGATION OF CHANGE IN THE GROWTH, MORPHOLOGY, CELL MEMBRANE USING FTIR TECHNIQUE, AND CELL SURFACE HYDROPHOBOCITY OF STAPHYLOCOCCUS AUREUS IN SIMULATED MICROGRAVITY CONDITION.

Micro-organisms have various sensors and receptors which enable them to sense the changes in their environment and adapt to their surroundings. Several studies indicate that microgravity alters the microbial metabolism and physiology, which signifies that microbes sense the change in the mechanical forces that occur in microgravity and it can be speculated that bacterial cells might sense these changes in mechanical forces at their surface. In current project, the effect of simulated microgravity on the growth, morphology, cell surface hydrophobicity using microbial adhesion to solvents (MATS) test, and Fourier transform infrared spectroscopy (FTIR) analysis of the cell membrane extract of S.aureus was investigated. Accelerated growth rate in simulated microgravity was observed in S.aureus, however no significant change in the scanning electron microscope (SEM) imaging of S.aureus bacteria grown in simulated microgravity as compared to normal gravity was observed. FTIR analysis of the cell membrane extract of S.aureus revealed that microgravity could change the conformation of compounds present in the cell membrane of S.aureus. Changes in the cell surface hydrophobicity of S.aureus grown in simulated microgravity conditions compared to normal gravity were also observed. More studies are planned to further scrutinize the mechanisms or processes manoeuvred by the bacterial cells to sense and adapt to the changes in mechanical forces introduced due to microgravity.

F2.4-0017-18 EPIGENETICS RESEARCH ON THE INTERNATIONAL SPACE STATION

John Love, john.e.love@nasa.gov

NASA Johnson Space Center, Houston, Texas, United States

The International Space Station (ISS) is a state-of-the orbiting laboratory focused on advancing science and technology research. Experiments being conducted on the ISS include investigations in the emerging field of Epigenetics. Epigenetics refers to stably heritable changes in gene expression or cellular phenotype (the transcriptional potential of a cell) resulting from changes in a chromosome without alterations to the underlying DNA nucleotide sequence (the genetic code), which are caused by external or environmental factors, such as spaceflight microgravity. Molecular mechanisms associated with epigenetic alterations regulating gene expression patterns include covalent chemical modifications of DNA (e.g., methylation) or histone proteins (e.g., acetylation, phorphorylation, or ubiquitination). For example, Epigenetics ("Epigenetics in Spaceflown C. elegans") is a recent JAXA investigation examining whether adaptations to microgravity transmit from one cell generation to another without changing the basic DNA of the organism. Mouse Epigenetics ("Transcriptome Analysis and Germ-Cell Development Analysis of Mice in Space") investigates molecular alterations in organ-specific gene expression patterns and epigenetic modifications, and analyzes murine germ cell development during long term spaceflight, as well as assessing changes in offspring DNA. NASA's first foray into human Omics research, the Twins Study ("Differential effects of homozygous twin astronauts associated with differences in exposure to spaceflight factors"), includes investigations evaluating differential epigenetic effects via comprehensive whole genome analysis, the landscape of DNA and RNA methylation, and biomolecular changes by means of longitudinal integrated multi-omics research. And the inaugural Genes in Space student challenge experiment (Genes in Space-1) is aimed at understanding how epigenetics plays a role in immune system dysregulation by assaying DNA methylation in immune cells directly in space using miniPCR technology. In addition, NASA's geneLAB campaign covers the epigenome as part of the "expressome", by employing an innovative open source science platform for multi-investigator high throughput utilization of the ISS. Earth benefits of Epigenetics research onboard the ISS range from contributions to the fundamental understanding of epigenetic phenomena with applications in countermeasure development for biomedical conditions, to the generation of integrated strategies for personalized medicine based on unique physiological responses.

F2.4-0018-18 INDUCTION OF GENOTOXICITY BY ACCELERATED HEAVY IRON PARTICLES IN THE HEMATOPOIETIC SYSTEM IN MICE

Bing Wang, wang.bing@qst.go.jp

National Institute of Radiological Sciences, Chiba, Japan

Bing Wang*, Kaoru Tanaka, Takanori Katsube, Yasuharu Ninomiya, Hirokazu Hirakawa, Cuihua Liu, Kouichi Maruyama, Guillaume Vares, Tetsuo Nakajima, Akira Fujimori, Mitsuru Nenoi*

National Institute of Radiological Sciences (NIRS), National Institutes for Quantum and Radiological Science and Technology (QST), Chiba 263-8555, Japan.

*Correspondence to: Bing Wang or Mitsuru Nenoi, NIRS, QST, Chiba 263-8555, Japan. Tel:

+81 43 206 3093, E-mail: wang.bing@qst.go.jp (B. Wang) Tel: +81 43 206 3049, E-mail: nenoi.mitsuru@qst.go.jp (M. Nenoi)

Purpose: The genotoxicity induced by high LET iron particles was studied and compared to that by low LET X-rays in the ground-based experiments carried out at NIRS using total body irradiation (TBI) of mice with the Heavy Ion Medical Accelerator in Chiba (HIMAC) and an Xray generator (Pantak 320S, Shimadzu). Materials and Methods: C57BL/6J Jms strain female mice of 8 weeks old were used. TBI was performed at a dose ranging from 0.1 to 3.0 Gy for iron particles (500 MeV/nucleon, 200 keV/m), or from 0.1 to 5.0 Gy for X-rays (200 kVp, 0.5 mm Al

+ 0.5 mm Cu filter). The RBE of iron particles to X-rays for induction of acute genotoxicity and late residual damage in the hematopoietic system was determined respectively at one and two months after TBI using the frequency of micronuclei in bone marrow erythrocytes as the endpoint. The health condition (body weight gain and the hemogram of the peripheral blood) was also investigated. Animals were treated in accordance with the Guidelines for the Care and Use of Laboratory Animals established by NIRS. Results and Conclusions: Reduction of body weight gain after TBI was in a similar way observed in the groups exposed to high doses from iron particles or X-rays. X-rays caused more efficiently hematological abnormality than iron particles. Iron particles and X-rays reduced the ratio of polychromatic erythrocytes (PCEs) to PCEs plus normochromatic erythrocytes (NCEs), an indicator for bone marrow proliferation, in a similar way, while iron particles resulted in more efficiently micronucleated PCEs and NCEs at low doses than X-rays. The relative effectiveness of iron particles to X-rays for induction of genotoxicity in bone marrow erythrocytes was higher at a low dose (0.5 Gy) than that at a high dose (3.0 Gy).

Microgravity and increased radiation are environmental stresses unique to the spaceflight environment. These stressors can have an impact on the central nervous system (CNS) including brains and eyes, potentially leading to significant risks to astronaut health both acutely, during the course of a mission, or chronically, leading to long-term, post-mission decrements in the quality of life. In an ongoing study, a mouse model was used to simulate these two critical components of the spaceflight environment for 21 days and examine their effects on the brain. To simulate the radiation component, 57Co plates were used to deliver low-dose/low-dose-rate (LD/LDR) whole-body -irradiation of 0.04Gy at 0.01 cGy/h to mature, 6-month old female C57BL/6 mice. A subset of these mice simultaneously underwent anti-orthostatic tail suspension for 21 days to model the unloading, fluid shift, and physiological/psychological stress aspects of the microgravity component. To date, we have characterized tissues from mice on 7 days, 3 and 9 months post-exposure. Brains were isolated for characterization of various oxidative stress markers and vascular topology. Long-term behavioral effects were also evaluated following chronic exposure of radiation + unloading. Our data demonstrated that exposure to simulated microgravity and LD/LDR radiation leads to increased oxidative stress-associated biomarkers and reduced antioxidant defense which may increase the likelihood of brain injury and functional/behavioral changes. In parallel studies, we have focused on the retina in animal models of the space environment. The retina and the retinal vasculature play important roles in vision. Changes in microvascular topology and function are common causes of vision loss in aging individuals and patients with diabetes, as well as after exposure to X-rays. Nonetheless, the retina and the retinal vasculature have not been studied extensively in relation to space travel and space radiation. We have shown that combined exposure to proton radiation of 0.5Gy and hindlimb unloading cause oxidative damage and vascular endothelial cell apoptosis in the retina. Understanding how environmental insults and radiation impact on the neurovasculature will help development toward more effective countermeasures during human spaceflight and planetary exploration. Mechanistic studies may also lead to new efficacious therapies that can prevent, reverse or stop the progression of neurovascular-related diseases and retinal degeneration.

F2.4-0020-18 HUMAN OIGODENDROCYTES IN SIM-0G BUT NOT IN 1G SECRETE NUMEROUS LIPIDS IN JUST THREE DAYS

Araceli Espinosa-Jeffrey, aespinosa@mednet.ucla.edu UCLA, Los Angeles, California, United States

Kevin Nguyen, kevinnguyen4587@gmail.com

Semel Institute for Neuroscience at UCLA, Los Angeles, United States

The primary energy sources of mammalian cells are proteins, fats and sugars that are processed by well-known biochemical mechanisms that have been discovered and studied in 1G (terrestrial gravity). Here we sought to determine how simulated microgravity (sim-0G) impacts in oligodendrocytes (OLs), the myelin forming cells in the central nervous system (CNS). In humans CNS myelination starts perinatally, continues during early postnatal development and it continues into early adulthood (Miller et al., 2012; Young et al., 2013). The myelin membrane has a highly unique protein and lipid composition. Myelin is very rich in lipids (70% of myelin dry weight). Once at the plasma membrane, these myelin elements assemble to form the myelin sheath. Astronauts' health during and after space travel is of vital importance and it has been reported that microgravity induces intracranial hypertension, representing a risk factor and a potential limitation to long-duration space missions.Here we report increased mitochondrial respiration and increased glycolysis 24 hours after of oligodendrocyte progenitors (OLPs) were exposed to sim-0G. Examination OLPs secretome after three days exposure of OLPs to sim-μG revealed a significant increase in the synthesis of fatty acids and complex lipids such as, 1,2-dipalmitoyl-GPC (5.67) and sphingolipids. Longer chain lipids were not observed in this study, it is possible that at longer time points OLs would have continued moving forward toward the synthesis of lipids that constitute myelin. These "surprising findings" indicate that sim-0G preserves, and enhances in just three days, metabolic reactions that are required for membrane synthesis as the first step in myelinogenesis. Because intracranial hypertension does not go away when astronauts come back to earth, we had previously postulated that microgravity associated intracranial hypertension with or without visual impairment and altered ophthalmic anatomy might be at least in part due to increased cell proliferation in the brain based on our data published in our first paper. With the enormous increase of lipids found in the secretome of OLs kept in 0G but not in 1G, we now hypothesize that not only there may be more cells in the CNS of astronauts but perhaps an increased number of molecules secreted by OLs while in space that are contributing to the symptoms mentioned above. A better understanding on how to modulate secretion of lipids in the CNS is very important, in order to maintain a normal intracranial tension in astronauts while in space and upon return to earth. Moreover, for centuries, basic biology research has been the pillar to an array of discoveries that have led to clinical applications for mankind on earth; we believe that studies using microgravity will open new avenues to our understanding of the brain in health and disease, in particular, to the discovery of new molecules and mechanisms impossible to unveil while in 1G.

F2.4-0021-18 EFFECTS OF ACANTHOPANAX SENTICOSUS ON BRAIN INJURY INDUCED BY SIMULATED SPATIAL RADIATION

Sijia Li, 694111255@qq.com

Harbin Institute of Technology, Harbin, China Weihong Lu*, lwh@hit.edu.cn

Harbin Institute of Technology, Haerbin, China Yingyu Zhou, zhouyingyu_work@outlook.com Harbin Institute of Technology, Haerbin, China

Abstract: The active compounds in Acanthopanax senticosus (AS) have different pharmacokinetic characteristics in mouse models. Cmax and AUC of Acanthopanax senticosus polysaccharides (ASPS) were significantly reduced in simulated spatial radiation-injured mice, suggesting that the blood flow of mouse was blocked or slowed, due to the pathological state of ischemia and hypoxia, which are caused by simulated spatial radiation. In contrast, the ability of various metabolizing enzymes to inactivate, capacity of biofilm transport decrease, and lessening of renal blood flow accounts for simulated spatial radiation, resulting in the accumulation of syringin and eleutheroside E in the irradiated mouse. Therefore, there were higher pharmacokinetic parameters-AUC, MRT, and t1/2 of the two compounds in simulated spatial radiation-injured mouse, when compared with normal mouse. In order to investigate the intrinsic mechanism of AS on radiation injury, AS extract's protective effects on brain, the main part of mouse that suffered from simulated spatial radiation, were explored. The function of AS extract in repressing expression changes of radiation response proteins in prefrontal cortex (PFC) of mouse brain included tubulin protein family (α -,β-tubulin subunits), dihydropyrimidinase-related protein 2 (CRMP2),γ-actin, 14-3-3 protein family (14-3-3ζ,ε), heat shock protein 90(HSP90β), and enolase 2.The results demonstrated the AS extract had positive effects on nerve cells' structure, adhesion, locomotion, fission, and phagocytosis, through regulating various action pathways, such as Hippo, phagosome, PI3K/Akt (phosphatidylinositol 3 kinase/ protein kinase B), Neurotrophin, Rap1 (Ras-related protein RAP-1A),gap junction glycolysis/gluconeogenesis,and HIF-1(Hypoxia-inducible factor 1) signaling pathways to maintain normal mouse neurological activity. All of the results indicated that AS may be a promising alternative medicine for the treatment of simulated spatial radiation injury in mouse brain. It would be tested that whether the bioactive ingredients of AS could be effective through the blood-brain barrier in the future.

Purpose: High atomic number and energy (HZE) particles such as iron-56 (Fe) ions are a major contributor to health risks in long-term manned space exploration. To understand radiationinduced differential genotoxic effects between high linear energy transfer (LET) HZE particles and low LET photons, ground-based experiments were carried out at the National Institute of Radiological Sciences (NIRS) using total body irradiation (TBI) of mice with accelerated Fe particles generated by the Heavy Ion Medical Accelerator in Chiba (HIMAC). Materials and Methods: C57BL/6J Jms strain female mice of 8 weeks old were treated in accordance with the Guidelines for the Care and Use of Laboratory Animals established by NIRS. TBI was performed at a dose ranging from 0.1 to 3.0 Gy for Fe particles (500 MeV/nucleon, 200 keV/m), or from 0.1 to 5.0 Gy for X-rays (200 kVp, 0.50 mm Al+0.50 mm Cu filter). At one or two months after TBI, splenocytes were isolated and cultured in the presence of mitogens for 24 h. Colcemid was added to the last 2 h of the culture. Metaphase chromosome spreads prepared from splenocytes were painted with the fluorescence in situ hybridization (FISH) probes for chromosomes 1 (green), 2 (red) and 3 (yellow). Chromosomal aberrations (CAs) visualized by FISH were classified as translocations, insertions, dicentrics, and acentric fragments. Results and Conclusions: The present study is still in progress and observation of CAs is ongoing. Induction of CAs was detected at 0.5 Gy and higher doses of both X-rays and Fe particles. For each mouse, among all types of CAs translocations were around 90%. Fe particles didn't induce CAs as frequently as X-rays. X-rays were 5 times more effective to induce translocations than Fe particles as compared at 3 Gy. The frequencies of unstable-type CAs didn't show dose dependency at high dose and decreased with time. It is probable that DNA double-strand breaks induced by Fe particles are hardly rejoined and cause cell cycle arrest or cell death rather than lead to induction of CAs. Funding:

F2.4-0023-18 SPACEFLIGHT ALTERS THE MUTATION FREQUENCY AND MUTAGENIC SPECTRUM IN BACTERIA

Patricia Fajardo-Cavazos, pfajardo@ufl.edu

University of Florida, Merritt Island, Florida, United States Patricia Fajardo-Cavazos, pfajardo@ufl.edu

University of Florida, Merritt Island, Florida, United States Joshua Leehan, ljeehan(at)ufl.edu

University of Florida, Merritt Island, Florida, United States Wayne Nicholson, wln@ufl.edu

University of Florida, Merritt Island, Florida, United States

In contrast to the classical view that mutations are random, a growing body of evidence indicates that exposure to environmental stresses in microbes can alter both the mutation rate and the mutagenic spectrum, a phenomenon known as Stress-Induced Mutagenesis (SIM). It is thought that SIM supplies an environment-specific variety of mutational outputs for selection to operate on, thus shaping the evolutionary trajectory of organisms. To test whether SIM might be induced in cells exposed to the spaceflight environment, we sent two Gram-positive bacteria to the International Space Station (ISS). On two separate spaceflight experiments (BRIC-18 and BRIC-21), Bacillus subtilis and Staphylococcus epidermidis cells were cultivated in the same medium, temperature, hardware, and duration in matched Flight (FL) and Ground Control (GC) samples. Upon return, we plated the cultures for total viable cells, and selected for mutants that had become resistant to the antibiotic rifampicin (RifR mutants), to calculate the frequency of mutation. We observed that the frequency of mutation to RifR was significantly increased 24-fold in FL samples of S. epidermidis, but was not significantly different between FL and GC samples in B. subtilis.

RifR arises from mutations in the rpoB gene, which encodes the β-subunit of RNA polymerase. To examine mutagenic spectrum in rpoB, we amplified by PCR and sequenced the relevant portions of the rpoB genes from all RifR mutants obtained in FL and GC samples of both S. epidermidis (n = 124) and B. subtilis (n = 181). In both cases we found dramatic differences in the spectrum of mutations between flight (FL) and ground control (GC) samples, including three newly discovered rpoB alleles in FL samples of B. subtilis (Q137R, A478V, and L489S). These results strengthen the idea that exposure to the human spaceflight environment causes unique stresses on bacteria, leading to alterations in their mutagenic potential.

Because RNA polymerase is a single enzyme that interacts with all the promoters in the genome, mutations in its subunits can have far-reaching effects on the global transcriptome, hence the phenotype, of mutants. Future experiments are directed towards understanding how novel rpoB mutations induced by exposure to

spaceflight conditions could alter the evolutionary fitness of the resulting mutants in the spaceflight environment. Supported by NASA grants NNX12AN70G and NNX14AT38G.

F2.4-0024-18 COMBINED EFFECTS OF SIMULATED MICROGRAVITY AND RADIATION EXPOSURE ON OSTEOCLAST CELL FUSION

The loss of bone mass and alteration in bone physiology during space flight are one of the major health risks for astronauts. Although the lack of weight bearing in microgravity is considered a risk factor for bone loss and possible osteoporosis, organisms living in space are also exposed to cosmic radiation and other environmental stress factors. As such, it is still unclear as to whether and by how much radiation exposure contributes to bone loss during space travel, and whether the effects of microgravity and radiation exposure are additive or synergistic. Bone is continuously renewed through the resorption of old bone by osteoclast cells and the formation of new bone by osteoblast cells. In this study, we investigated the combined effects of microgravity and radiation by evaluating the maturation of a hematopoietic cell line to mature osteoclasts. RAW 264.7 monocyte/macrophage cells were cultured in rotating wall vessels that simulate microgravity on the ground. Cells under static 1g or simulated microgravity were exposed to rays of varying doses, and then cultured in receptor activator of nuclear factor-B ligand (RANKL) for the formation of osteoclast giant multinucleated cells (GMCs) and for gene expression analysis. Results of the study showed that radiation alone at doses as low as 0.1 Gy may stimulate osteoclast cell fusion as assessed by GMCs and the expression of signature genes such as tartrate resistant acid phosphatase (Trap) and dendritic cell-specific transmembrane protein (Dcstamp). However, osteoclast cell fusion decreased for doses greater than 0.5 Gy. In comparison to radiation exposure, simulated microgravity induced higher

levels of cell fusion, and the effects of these two environmental factors appeared additive. Interestingly, the microgravity effect on osteoclast stimulatory transmembrane protein (Ocstamp) and Dcstamp expressions was significantly higher than the radiation effect, suggesting that radiation may not increase the synthesis of adhesion molecules as much as microgravity.

F2.4-0025-18 SIMULATED MICROGRAVITY IMPACTS THE LIPID RAFTS IN PLANT CELLS

Elizabeth Kordyum, cellbiol@ukr.net

Institute of Botany of NAS of Ukraine, Kyiv, Ukraine Olena Klymenko, cellbiol@ukr.net

Institute of Botany of NAS of Ukraine, Kyiv, Ukraine Iliya Bulavin, cellbiol@ukr.net

Institute of Botany of NAS of Ukraine, Kyiv, Ukraine

Currently it has been shown the presence of functional microdomains with the specific content of lipids and proteins in the plasmalemma of plant cells, that became known as “lipid rafts”. It is supposed that rafts enriched on cholesterol and sphingolipids modulate the protein interrelation and in this way they include in many vitally important cell processes. Therefore, we studied the composition and content of fatty acids and sterols in lipid rafts isolated from the root plasmalemma of Pisum sativum seedlings grown during 6 days under slow horizontal clinorotation. The raft fraction was controlled by the electron-microscopic method with a transmission electron microscope JEM 1230 (Jeol, Japan). Fatty acids and sterols were determined by the method of gas chromatography with a chromatograph HRGC 5300 (Carlo Erba Instruments, Italy). It was shown that lipid rafts from the root plasmalemma of pea seedlings grown in the stationary conditions and under clinorotation have the appearance of thin tapes of 80-100 nm in length, they were similar to those in other plant species on the structure and size, and also were enriched on cholesterol and saturated fatty acids. Under clinorotation, the percentage of cholesterol in lipid rafts increased 7 times in comparison with control, that may indicate an increase in their density. It is of interest that a significant increase in content of cholesterol and some saturated fatty acids under clinorotation was determined in the plasmalemma microdomains, while the plasmalemma fluidity reached the control level. Based on these firstly obtained data, it is proposed to increase attention to study the impact of microgravity on the behavior of rafts as they contain the protein complexes responsible for perception and transmission of external signals, vesicular transport, protection from stress. Further understanding the gravisensitivity of basic cell processes and mechanisms of plant adaptation to microgravity is necessary for working out the technologies of the autotrophic chain in the Bioregenerative

Life Support Systems and its reliability.

F2.4-0026-18 STUDY ON ANTI-RADIATION MECHANISM OF DIOSMIN

Yuming Yang, viencore@126.com

Harbin Institute of Technology, Harbin, China Mengyao Liu, 1009720661@qq.com

Harbin Institute of Technology, Harbin, China Cuilin Cheng, ccuilin@hit.edu.cn

Harbin Institute of Technology, Harbin, China Weihong* Lu, lwh@hit.edu.cn

Harbin Institute of Technology, Haerbin, China

Diosmin (Diosmetin 7-O-rutinoside) is a natural flavonoid compound extracted from Galium verum L. (Rubiaceae) and has significant effects on the treatment of chronic venous insufficiency, postoperative edema and hemorrhoids. Our research group found that Diosmin also has anti-radiation effect, and the anti-radiation mechanism of Diosmin was studied through in vitro cell experiments, animal experiments and differential protein spots of mouse liver radiation-damaged proteins to obtain the following results: (1) Cell experiment: The splenic lymphocytes of Rattus norvegicus (SD rats) and PC12 cells were cultured in vitro and irradiated by 60Co-γ ray. It has been experimentally demonstrated that the addition of Diosmin to the cells before irradiation to the final concentration of 80μg/ml, can promote cell proliferation and improve cell survival. Meanwhile, at this dose, the activities of superoxide dismutase (SOD) Glutathione peroxidase (GSH-px) increased and the content of intracellular malondialdehyde (MDA) decreased. By measuring the cell cycle and apoptosis in PC12 cells, it was found that Diosmin can promote cell differentiation and reduce the damage brought about by irradiation of cells. (2) Animal experiments: By establishing 60Co-γray irradiation model, the indices of Kunming mice given Diosmin continually for 14 days were measured. It was noted that Diosmin can play a protective role in white blood cells and immune organs such as liver and spleen. The activities of SOD and GSH-px in mouse tissues were improved and the content of MDA, the rate of chromosome aberration and micronuclei in bone marrow decreased. The experimental results above suggested that Diosmin can enhance the antioxidant activity by increasing endogenous antioxidant enzyme activity, decrease DNA damage and protect mice from radiation damage. (3) Through the 2D-PAGE analysis of the liver protein of mice in radiation protection experiment, 10 protein spots with significant difference were selected for MALDI-TOF-MS analysis and proved to be acetylcholinesterase A-acylase 2, peptidyl-proline cis-transisomerase A, 3-hydroxybenzoate 3, 4 double oxidase, three-dimensional structure - myosin-V, heterogeneous nuclear ribonucleoprotein A2 / B1, (TPI), fructose-bisphosphate aldolase B, protein disulfide isomerase, hemoglobin β subunit, and mitochondrial ATP synthase β subunit.

F2.4-0027-18 PROTECTIVE EFFECT OF ULVA PERTUSA POLYSACCHARIDE-FE COMPLEX ON RADIATION

Xin Gao, 1165936772@qq.com

Harbin Institute of Technology, Harbin, China Shan Shan, 1532084928@qq.com

Harbin Institute of Technology, Harbin, China Weihong Lu, lwh@hit.edu.cn

Harbin Institute of Technology, Harbin, China

Radiation protection effect of Ulva pertusa polysaccharide with different molecular weights (100kDa, 30-100kDa and 30kDa) were investigated through mice model. According to the micronucleus, organ index, SOD and MDA contents, the fraction of 30kDa was selected as the best active component. Besides, the effect of radiation protection of active polysaccharide chelating with Fe was also studied. Results indicated that the complex, which nucleus was -FeOOH, has significant anti-radiation effect as well. Proteomics research of spleens from mice treated by active polysaccharide and its Fe complex revealed that 3502, 4705, 5402, 5803 and 6801 were five different protein spots. According to MS, they were 78kD glucose regulatory protein, hydroxylase-5 subunit calcium network protein precursor, tubulin-5 and vimentin respectively, which were all related to immune injury. Therefore, the radiation protection mechanism of polysaccharides and its ion complex may be through repairing these different proteins to improve the immunity and reduce the radiation damage.

F2.4-0028-18 THE DNA DAMAGE REPAIR GENES EXPRESSION OF ARABIDOPSIS THALIANA SEEDS SURVIVING 12.5-DAY EXPOSURE TO SPACE ENVIRONMENT

The microgravity and space radiation were the two important stressors which can induce biological damage and genetic variation in spaceflight. It is emphasized that we must pay high attention to the DNA damage repair pathway. But so far, the molecular biological mechanism of DDR induced by radiation and microgravity were still not clear. In this study, the biological effects of spaceflight were investigated in Arabidopsis thaliana from the levels of phenotypes, cell and molecular. In addition, the expression of Ku70, Rad51, XPD and OGG1 genes, as the important biomarkers, were used to assess the effects of spaceflight on the pathway of DDR. The dry seeds of Arabidopsis of wild type and gravity insensitive mutants (pin2 and pgm-1) were brought to space by SJ10 recoverable satellite for 12.5 days. The results shown that the normal growth of Arabidopsis was influenced after spaceflight for a long time. The genes expressions of DDR pathway was promoted varied by microgravity at different development stages in the wild-type and mutants of Arabidopsis after spaceflight. In summary, this study revealed the combined biological effects and mechanisms induced by space radiation and microgravity in the wild-type and mutants of Arabidopsis after spaceflight. It is of great significance to study the biological effects of the real actual spatial environment.

F2.4-0028-18 EFFECT OF SPACE ENVERIMENT ON ARABIDOPSIS SEED GERMINATION AND GROWTH AFTER A LONG RECOVERY

Ning Gong, cospar06@dlmu.edu.cn

Institute of Environmental Systems Biology, Dalian Maritime University, Dalian, China Ning Gong, cospar06@dlmu.edu.cn

Institute of Environmental Systems Biology, Dalian Maritime University, Dalian, China Meng Zhang, zm_hit@163.com

Dalian Maritime University, Dalian, China Yeqing Sun, yqsun@hit.edu.cn

Dalian Maritime University, Dalian, China

Space flights expose plant seeds to various risks. Space radiation and microgravity are two of the main factors among them. But how long the effects of space envirement will last after flights on seeds germination and plants growth is still uncertain. Arabidopsis (it Arabidopsis thaliana) seeds were tiled on a stacking device with a CR39 radiation detector which were put into the Biological Radiation BOX A and B. The seeds were emplyed in Shijian-10 recoverable satellite (SJ-10) and suffered the space flight of 302.85h at an altitude of 252 km. 420 days after the space flight, the seeds in both of BOX A (group SA) and B (group SB) as well as their controls in ground (group C) were planted. From the detecting results of CR39, the seeds used in this study did not be hit directly by space heavy ions. And there were some differences in radiation dose between BOX A and B. The parameters of growth and early development were determined. There was no significant difference in both of germination potential and germination rate among groups of C, SA and SB. But the root length in 7d of SA group significantly lower than that in other groups. After 4 weeks growth, however, both of space flight groups appeared increase in growth compared to group C. For instance, the averge wet weight of SA and SB were increased 48.95% and 103.22% than that of group C, respectively. The number of leaves (NL) were counted during the nutritional growth period (14-28d). The NL value in SB was prominent higher than that of SA and C groups (it $p < 0.05$). And after 17d growth, the NL value of SA was higher than that in group C although there was no sinificant difference. Besides, the earing rate of SB was higher than that of other groups. The Fv/Fm, which is presented the photosynthetic efficacy of plants, was also affected by space flight. Both SA and SB increased their maximum photosynthetic efficiency significantly (it $p < 0.05$), which maybe one of the reasons of their rapid growth. In summary, after the space flight, the plant seeds presented the stimulatory effect during nutritional growth period although experienced a long term of recovery.

F2.4-0030-18 A NEW MODEL TO STUDY REAL AND SIMULATED MICROGRAVITY INFLUENCE ON PLANT CELL GRAVISENSITIVITY

Iliya Bulavin, iliyavbulavin@ukr.net

Institute of Botany of NAS of Ukraine, Kyiv, Ukraine

A new model "Rhizogenesis in vitro" is proposed to study the biological effects of microgravity. Rhizogenesis from the leaf explant petiole and callus culture of Arabidopsis thaliana wild type, scr mutant and transgenic plants has been investigated. It was shown that roots emerged de novo in two ways: 1) from callus dedifferentiated cells (morphogenic loci) and 2) directly from leaf explant petiole cambium cells. Since roots formed in vitro on callus surface had some structural abnormalities, rhizogenesis in vitro from leaf explants is considered as more convenient. Anatomical and ultrastrucrural analyses demonstrated the absence of significant differences in root cell differentiation in vitro under clinorotation. At the same time, sensitivity to clinorotation was revealed in the cells of the distal elongation zone (DEZ). An increase in the percentage ratio of vacuoles and ER-bodies as well as the presence of numerous smaller mitochondria were found in these cells. Also, cortical microtubules' orientation in DEZ of A. thaliana GFP-MAP4 roots formed de novo was also changed under clinorotation similarly that in embryonic roots. Using A. thaliana DR5rev::GFP transgenic plants allowed to reveal that clinorotation changes auxin distribution in roots formed de novo. We proposed such model for the experiments on board the ISS to study morphogenesis and cell differentiation in vitro in microgravity.

F2.4-0031-18 F2.4-0030-18 RESEARCH OF MICROGRAVITY EFFECTS ON PLANTS ON BOARD THE CHINESE SPACECRAFTS

Weiming Cai, wmcai@sibs.ac.cn

CAS Center for Excellence in Molecular Plant Sciences, Shanghai Institute of Plant Physiology and Ecology, CAS, Shanghai, China

Haiying Chen, hychen@sibs.ac.cn

CAS Center for Excellence in Molecular Plant Sciences, Shanghai Institute of Plant Physiology and Ecology, CAS, Shanghai, China

We focus on the molecular mechanism of the interaction between plants and microgravity environment, try to understand the effects of microgravity environment in the space on plant growth and the molecular mechanisms underlying. The transcriptome of Oryza sativa calli on regular and on hormone free medium was analyzed on board the Chinese spaceship "Shenzhou 8" which was launched at 1 November, 2011 to study the effects of microgravity on plant signal transduction and secondary metabolism. The calli on hormone free medium were precultured for 4 days on ground and fixed by RNAlater after grew 324 h under microgravity and returned to Earth after 17 days. After comparing1 g-inflight controls with 1 g-ground controls, 157 probe sets with different expression levels (fold change 2, $p < 0.05$) were identified. When comparing spaceflight controls to 1 g-ground controls and to 1 g-inflight controls, 678 probe sets with different expression levels (fold change 2, $p < 0.05$) were identified. The fact that the same 678 probe sets were identified in these two comparisons suggests that transcription was affected under microgravity conditions. MapMan analysis was used to classify 627 microgravity responsive (MR) transcripts. The MR transcripts were mainly involved in cell wall structure, the TCA cycle, primary metabolism, transcription, protein modification and degradation, hormone metabolism, calcium regulation, receptor like kinase activity and transport. The calli grown on regular medium under microgravity were also analyzed. The relationship between the cell wall modification and alteration of cell growth under microgravity was discussed. We also carried out epigenetic studies associated with microgravity conditions using Arabidopsis thaliana on board the Chinese recoverable science satellite "SJ-10" which was launched at 6 April, 2016. Interestingly, we found the variation of DNA modification in Arabidopsis seedlings exposed to microgravity. These results are important to understand the mechanism of plant adaptation to the microgravity environment.

F2.4-0032-18 SWATH-BASED PROTEOMICS ANALYSIS OF HIPPOCAMPUS IN MEMORY DEFICIENCY RATS INDUCED BY PROLONGED SIMULATED SPACE ENVIRONMENT

It has been found that spaceflight may lead to impairments in cognitive functions performed by CNS. However, the underlying mechanism of effects of space environment on the learning and memory function in animal nervous system is not elucidated yet. In present study, a simulated spaceflight complex environment rats model (SSCE) was successfully built and assessed. We employed the tail suspension model with noise (65 db), circadian rhythms (1.5 h) and limited space to simulate spaceflight complex environment. Morris water maze test was applied to determine the learning and memory function in SSCE animals. Compared with the control groups, SSCE groups showed significant decrease in memory function. Using SWATH-based proteomics analysis, a total of 4250 proteins were quantified in hippocampus. Of these identified proteins, 425 proteins were found differentially expressed under SSCE. Based on the results of DAVID analysis, we observed transportation of synaptic vesicle and synaptic transmission may play key role in learning and memory function. Moreover, through multiple reaction monitoring(MRM), we found that the concentration of Glu was 154.38 g/mg wet tissue in the rat hippocampus under simulated spaceflight complex environment, compared to 85.68 g/mg in the control, indicating remarkable enhancement, while the concentration of GABA was 15.42 g/mg wet tissue in the rat hippocampus under simulated spaceflight complex environment, compared to 36.44 g/mg in the control, a dramatic drop. These changes all indicated simulated spaceflight complex environment may cause degrading of the learning and memory function and the possible mechanisms might be related with glutamate excitotoxicity and imbalances in specific neurotransmitters.

Tanpopo, a dandelion in Japanese, is a plant species whose seeds with floss are spread by wind. We proposed this mission to examine possible interplanetary migration of microbes, and organic compounds at the Exposure Facility of Japan Experimental Module (JEM: KIBO) of the International Space Station (ISS) [1-4]. The Tanpopo mission consists of six subthemes: Capture of microbes in space (Subtheme 1), exposure of microbes in space (Subtheme 2), analysis of organic compounds in interplanetary dust (Subtheme 3), exposure of organic compounds in space (Subtheme 4), measurement of space debris at the ISS orbit (Subtheme 5), and evaluation of ultra low-density aerogel developed for the Tanpopo mission (Subtheme 6). Exposure Panels for exposure of microbes and organic materials and Capture Panels for aerogel were launched on April 2015. The Panels were placed on the Exposed Experiment Handrail Attachment Mechanism (ExHAM) in the ISS. The ExHAM with Panels were placed on the Exposure

Facility of KIBO (JEM) with the Japanese robotic arms through the airlock of KIBO. The trays and panels were exposed for more than one year. The first set of Capture Panels and a Exposure Panel were retrieved on June 2016, returned to the ground and passed over to Tanpopo team for the analyses in September. Aerogel blocks in Capture Panels are inspected by the automated micro-image detector CLOXS. Tracks and particles identified will be used for organic and inorganic compounds, as well as microscopic analyses [3]. An Exposure Panel consists of 20 Exposure Units. The returned Exposure Panel was disassembled to the units, each was handed over to the researchers for organic compound and microbiological analyses [4]. First year results will be presented. 1) Yamagishi, A. et al.: Tanpopo: Astrobiology exposure and micrometeoroid capture experiments - Proposed experiments at the Exposure Facility of ISS-JEM. In prior to the generation of the first life on the Earth, organic compounds such as amino acids should have been supplied to the primitive Earth. If primitive Earth atmosphere was strongly reducing (e.g., containing large mixing ratios of methane and/or ammonia), production of amino acids and other bioorganic compounds is not difficult by conventional energies such as spark discharges. In these days, however, the primitive Earth atmosphere was regarded as only slightly reducing [1]. In such a case the production of amino acids and other N-containing organics by conventional energies was difficult.

Since a wide variety of organic compounds have been detected in extraterrestrial bodies such as carbonaceous chondrites and comets, it is safe to say that extraterrestrial organic compounds were important sources for the first life on the Earth. Chyba and

Sagan [2] suggested that cosmic dusts delivered much more organics to the primitive Earth than meteorites and comets. It is difficult, however, to detect bioorganics in cosmic dusts if they are collected in the terrestrial biosphere.

We started an astrobiology experiments in Earth orbit named the Tanpopo mission [3] in May 2015. In the mission, cosmic dusts are collected by using aerogel, and amino acid-related compounds are exposed to space environments. The mission is carried out by utilizing an ExHAM (Exposed Experiment Handrail Attachment Mechanism) on the Exposed Facility of Japanese Experimental Module (JEM-EF) in the International Space Station (ISS). We have already recovered the samples exposed for one year in 2016, and those for two years in 2017. The mission will be concluded in 2019. Preliminary results of the organic exposure experiments will be reported.

After the completion of the Tanpopo mission, same spaces for space exposure on the ExHAM facilities would be available. Other facilities for space exposure experiments on JEM-EF, including i-SEEP (IVA-replaceable Small Exposed Experimental Platform), are now available or under discussion. We are also discussing possible astrobiology exposure/capture experiments in the next generation by using Free Flyers. One of possible themes is direct space exposure experiment without optical windows to utilize full spectrum of solar light. Not only organic alteration experiments, but also organic formation experiments are quite interesting. We could examine possible formation of bioorganic compounds in upper planetary atmosphere: Cosmic rays are promising energy sources to synthesize amino acids and other bioorganics in slightly reducing atmosphere [4], but the present flux or cosmic rays is limited. Solar UV flux is quite high, but is singly not a good energy source to synthesize N-containing organics from the slightly reducing gas mixture. We expect, however, that it would enhance amino acid formation by synergistic effect with cosmic rays.

We are also discussing other possible space experiments of the new generation, including an experiment to examine space weathering of meteoritic organics, and that to test abiotic formation of biological molecules in a primordial ocean before the formation of the ozone layer.

The present work was carried out in collaboration with Ms. Saaya Minematsu (Fukuoka Institute of Technology), Ms. Izumi Endo (University of Tokyo), Mr. Tomohito Sato (Yokohama National University), Takuya Yokoo (Yokohama National University) and Dr. Eiichi Imai (Nagaoka University of Technology). This work was partly supported by Grants-in-Aid of MEXT, Japan (17H02991 and 16H04823), and by that of NINS Astrobiology Center Satellite program (AB292002).

We have carried out the space exposure experiment of various kinds of carbonaceous solids using International Space Station (ISS)/KIBO/ExHAM. The major goal of this project is to understand how the carbonaceous dust particles synthesized in the stellar ejecta from evolved stars are chemically and physically altered in nature in the circumstellar environment until it becomes a member of the interstellar medium. In particular, we aim to investigate the properties of 'astronomical' polycyclic aromatic hydrocarbons (PAHs), the carrier of the unidentified infrared (UIR) bands, which have been observed ubiquitously in various astrophysical environments. So far, we have brought three experiment samples to the ISS. Each experiment sample has a 10cm x 10cm exposure surface and has 64 slots for exposure experiment materials. In total, more than 40 kinds of materials including quenched carbonaceous composites (QCCs), deuterated quenched carbonaceous composites (deut-QCCs), nitrogen-included carbonaceous composites (NCCs), anthracite, graphite, and silicates are installed in the experiment samples. Among the three samples, two of them (EE64-I and EE64-II) were attached on ExHAM-1 and were exposed in the space exposure environment for 384 days from 26 May 2015 to 13 June 2016. The final sample (EE64-III) was attached on ExHAM-1 and was exposed for 386 days from 29 June 2016 to 19 July 2017. All the samples are now collected back on earth and the difference in properties of our exposure experiment materials between before and after the experiment is investigated based on infrared micro-spectroscopy. In this presentation, I will present the overview of this space exposure experiment project and introduce some of the initial results.

The Tanpopo mission has been operational onboard the International Space Station JEMExposed Facility since 2015 to expose terrestrial microbes and astronomical organic analogs to space and to intact capture organic-bearing micrometeoroids and Earth-orbiting microparticles including orbital debris and potential terrestrial aerosols which may contain colonies of terrestrial microbes.

As of the writing, more than two dozen of 100x 100x 20 mm sized silica aerogel capture panels were returned from the low Earth orbit to ground laboratories in 2016 and 2017, after being exposed in space for 1 year or so. The first-year samples counted 119 hypervelocity impact signatures larger than 100 microns and the second-year samples are now investigated in the initial sample analysis phase with the CLOXS (Captured particle Locating, Observation and Extraction System) at ISAS.

By calibrating with hypervelocity impact experiments on ground, each impact signatures are estimated their impactor sizes and three-dimensional directionality of impacting trajectories. After identifying and correcting local shielding and secondary impact ejecta effects, the microparticle impact flux onto the ISS orbit is calculated and compared with previous spacecraft data.

In this paper, we summarize the in-orbit operation, initial sample analysis results, flux estimate and other findings from this experiment, in the context of panspermia and chemical evolution hypothesis.

The concept of panspermia hypothesis proposes the interplanetary transfer of life propelled by solar radiation-pressure (Arrhenius, 1903). Japanese space mission named Tanpopo, which means dandelion in Japanese, has performed capture and exposure experiments of microbes using outside of International Space Station (ISS) (Yamagishi et al., 2007; Kawaguchi et al., 2016). Previous exposure experiment of microbes in space revealed that microbes inside shielding (e.g. small fragments of rock, mixture of sugar or clay) with efficient thickness to protect from UV irradiation survive in space for a long period. On the other hand, we proposed the possible interplanetary transfer of cell-aggregate in sub-millimeter to survive in harsh space environment (Kawaguchi et al., 2013). We named the hypothesis massapanspermia. For the investigation of microbial survival and DNA damage induced in space, dried cells of radioresistant bacteria, Deinococcus radiodurans, Deinococcus aerius and Deinococcus aetherius, as well as D. radiodurans DNA repair-deficient mutants, were put in wells of aluminum plates in Exposure Panels (EPs) and exposed in space at the outside of Exposure Facility, Japanese Experimental Module of ISS since May 2015. After one-year exposure, the first set of EPs were retrieved into the ISS pressurized area in June 2016, and returned to the ground laboratory in September 2016. Cell-aggregate of dried-deinococcal cells with 100 m-thickness irradiated with sunlight corresponding to 3.4 × 103 kJ/m2 (110-315 nm) UV dose were dead. Quantitative-PCR analysis revealed that intact DNA (%) in the 100 m-thick sample was less than 1%. On the other hand, cell-aggregates with over 500 m-thickness were alive. We tested the survival of DNA repairdeficient mutants, D. radiodurans KH311, rec30 and UVS78. From comparison of their surviving fractions between ground control and space samples, we found that DNA damage such as singleand double-strand breaks as well as base damage were induced by space factors. Intriguingly, base damage was only detected from cell-aggregate exposed to space. We concluded that the cell-aggregates with 100 m-thickness were dead by UV-irradiation, while the 500 m-thick cell layer is sufficient to protect subsurface cells from UV-radiation in space. In addition, UV-induced pyrimidine dimers and ionizing radiationand space vacuum-induced double-strand breaks were also detected in space exposed samples. These results highlight the importance of microbial cell-aggregates as an ark for interplanetary transfer of microbes as we hypothesized in massapanspermia (Kawaguchi et al., 2013). We also report survival and DNA damage detected from cell-aggregates exposed to space for two-years exposure.

F3.1-0006-18 IMPACT OF SIMULATED MARTIAN CONDITIONS ON BACTERIAL STRAINS FROM MARS ANALOGUE SITES

Kristina Beblo-Vranesevic, kristina.beblo@dlr.de

DLR - Inst. of Aerospace Medicine, Cologne, Germany Maria Bohmeier, maria.bohmeier@dlr.de

DLR - Inst. of Aerospace Medicine, Cologne, Germany Petra Rettberg, petra.rettberg@dlr.de

DLR - Inst. of Aerospace Medicine, Koeln, Germany MASE-Team

Schwendner P., Perras A., Moissl-Eichinger C., Gaboyer F., Westall F., Garcia-Descalzo L., Gomez F., Malki M., Amils R., Monaghan E., Ehrenfreund P., Vannier P., Marteinsson V., Cabezas P., Walter N., Cockell C.S. (Coordinator)

During the project "Mars Analogues for Space Exploration" (MASE) several microbial isolates were obtained from extreme terrestrial environments. Some of these strains were subjected to Mars relevant environmental stress factors in the laboratory under controlled conditions;

e.g. radiation, low water activity, high salt concentrations, or oxidizing compounds. All sampling, isolation, and cultivation steps, as well as the stress tests were performed under anoxic conditions.

So far, five only distantly related microorganisms are under detailed investigation: Buttiauxella sp. MASE-IM-9, Clostridium sp. MASE-IM-4, Halanaerobium sp. MASE-BB-1, Trichococcus sp. MASE-IM-5, and Yersinia intermedia MASE-LG-1. It was shown that tolerance to desiccation and to ionizing radiation, applied separately, was not correlated as it is known for example for deinococcal representatives. If desiccation and exposure to radiation were applied together typical additive effects as well as an enhanced radiation tolerance could be observed. Additionally, the survivability after exposure to oxidizing compounds applied as single stress was tested. The survival after addition of hydrogen peroxide / perchlorate for dedicated time points (15 minutes; 24 hours) was very divers. The comparison of the five microorganisms revealed that Trichococcus sp. MASE-IM-5 was the most sensitive strain and survived only 20 mM hydrogen peroxide for 15 minutes and 24 hours, respectively. The most tolerant organism was Buttiauxella sp. MASE-IM-9 which was able to survive 230 mM hydrogen peroxide for both tested time points. In between, the other Bacteria were arranged with different tolerances against hydrogen peroxide (Buttiauxella sp. MASE-IM-9 > Yersinia intermedia MASE-LG-1

> Halanaerobium sp. BB-1 > Clostridium sp. MASE-IM-4 > Trichococcus sp. MASE-IM-5). Comparable strain specific results were obtained after the addition of different perchlorates.

In general, the strategy of the MASE project has proven to be useful to gain new model organisms. The isolated and characterized MASE strains have so far unknown high tolerances against cell damaging treatments and may serve as model organisms for future space exposure experiments.

F3.1-0007-18 VIABILITY OF THE SOIL AND PERMAFROST MICROBIAL COMMUNITIES AFTER IRRADIATION WITH ACCELERATED ELECTRONS UNDER SIMULATED MARTIAN AND OPEN SPACE CONDITIONS

Vladimir Cheptsov, cheptcov.vladimir@gmail.com Lomonosov Moscow State University, Moscow, Russia Elena Vorobyova, esautin@yandex.ru

It was assumed that the putative biosphere of Mars could be viably cryopreserved and had been stored for billions of years in anabiotic state like microbial communities of Arctic and Antarctic permafrost deposits have been preserved till now for millions of years. In this case the main factor causing cell's death should be ionizing radiation.

We irradiated arid soil ancient Arctic permafrost microbial communities with up to 1 MGy doses of accelerated electrons (1 MeV) in conditions of low pressure (0.01 Torr) and low temperature (-130°C) which are the key factors of subsurface layers of Martian regolith to assess possible duration of survival of putative Martian biota in anabiotic state in subsurface of the planet. Results of culturing, epifluorescence microscopy, multisubstrate testing, GC-MS of lipids and Illumina sequencing of 16S rRNA genes of control and irradiated samples will be discussed. In general it was found that living cells and microbial biomarkers could be reliably detected in irradiated soil samples. Among the bacteria cultured from irradiated samples the representatives of Advenella, Arthrobacter, Brevundimonas, Chryseobacterium, Clavibacter, Dyadobacter, Massilia, Microbacterium, Micrococcus, Microvirga, Planococcus, Planomicrobium, Pontibacter, Rufibacter and Spirosoma genera were detected.

Taking into account the ionizing radiation intensity on the Mars' surface the resistance to 1 MGy dose of irradiation in simulated conditions proves that if there was an Earth-like biosphere on the early Mars microorganisms could survive in the shallow subsurface layer of the Martian regolith for not less than 13 million years after climate change. With increasing depth and decreasing radiation intensity, the possible duration of viable cryoconservation of the microorganisms could be assessed as 33 million years at 2 m depth (estimated depth of sampling by the ExoMars 2020 mission) and at least 200 million years at 5 m depth (the horizon below which the only background radiation is presented). Moreover, the results of the study could be applied for estimation of possible survival duration of microorganisms in small space bodies like meteorites, asteroids, comets to assess the probability of the panspermia. The obtained data point out that the radioresistance of native microbial communities being entrapped into the complex natural substrates is significantly underestimated.

This work was supported by Russian Science Foundation (grant № 17-12-01184).

F3.1-0008-18 ADAPTATION STRATEGIES OF HALOPHILIC BACTERIA TO CHLORATES AND PERCHLORATES IDENTIFIED ON MARS' SURFACE

Regina Izquierdo Robles, regina.izquierdorob@uaem.edu.mx Universidad Autónoma del Estado de Morelos, Cuernavaca, Mexico Sandra Ignacia Ramírez Jiménez, ramirez_sandra@uaem.mx Universidad Autónoma del Estado de Morelos, Cuernavaca, Mexico

The search for life beyond Earth is mainly focused on finding a planet or satellite that could potentially sustain life, it means by having physical and/or geochemical factors where life as we know it, can be preserved. These factors can be summarized as the availability of liquid water, of chemical elements to synthesize biomolecules, and the presence of an energy source to sustain a metabolism [1]. On the other hand, the study of extremophiles, organisms that require at least one extreme condition to subsist, has a great impact in Astrobiology because they allow to understand the limits of life. Among the extreme conditions where extremophiles have been identified we find high or low temperatures, absence of oxygen or light, highly acidic or alkaline locations, or salty environments [2]. Geological evidence shows that there were floods on Mars. According to the Phoenix Mars Lander Mission these floods can only be found in Martian slopes where liquid water is enriched with chlorates and perchlorates which can allegedly lower water's freezing point to 80 K. As these chemical compounds are highly hygroscopic they allow water to remain liquid over Mars' surface for short periods of time [3]. We explore the possibility offered by this scenario to determine if Bacillus pumilus, a halotolerant bacterium, Cobetia marina, a moderate halophilic bacterium, and Psycrobacter cryohalolentis a psycrohalophilic bacterium, can survive to modified environments added with $Mg(ClO_4)_2$, $NaClO_4$, $KClO_3$, and $NaClO_3$ that mimic the salty conditions of Mars floods.

Cryomyces antarcticus, isolated from the McMurdo Dry Valleys in Antarctica, a Mars analogue on Earth, has already been chosen as one of the best eukaryotic models for astrobiological investigations for its stunning resistance to temperature cycles (-20°C/+20°C) and high temperature(+90°C), saline concentration (up to 25% NaCl), UV exposure (up to 5x105kJ/m2) and ionizing radiation (60 Co, up to 55.81 kGy). The fungus survived and recovered the metabolic activity even after 1.5 years of real space exposure (10−4Pa vacuum, -20°C/+47°C, 439 MJ/m2UV ir-radiation) and simulated Martian conditions (Mars-like CO_2 atmosphere, 980 Pa). STARLIFE is an international consortium which aims to investigate the responses of astrobiological model systems to different types of ionizing radiation, simulating the galactic cosmic rays, to deepen knowledge on the biological effects and risks in space. Here, we report the preliminary data on the resistance in terms of survival and ultrastructural and DNA integrity of a cryptoendolithic black fungus Cryomyces antarcticus after the irradiation with high-energy charged particles (He, Ar and Fe), as part of the cosmic rays spectrum. The irradiation experiments have been performed at the HIMAC facility (Heavy Ion Medical Accelerator) at the National Institute of Radiological Sciences (NIRS) in Chiba, Japan; doses ranged from 0 up to 1000 Gy. The resistance of this eukaryotic model to cosmic rays as the high-energy charged particles here tested gives insights of astrobiological relevance, including search for life on Mars, Lithopanspermia Theory, planetary protection and for a safer design of manned space missions.

F3.1-0010-18 EVOLUTION OF ORGANIC MOLECULES UNDER MARS SURFACE-LIKE UV RADIATION CONDITIONS SIMULATED IN SPACE AND LABORATORY

The detection and identification of organic molecules at Mars are of primary importance for astrobiology, as some of these molecules are life precursors and components. While in situ exploration missions are searching for them at the surface of the planet, it is essential to understand how organic molecules evolve and are preserved at the surface of Mars. Indeed the harsh conditions of the environment of Mars, such as ultraviolet (UV) radiation or oxidative processes, due for example to iron-bearing minerals and perchlorate ions, could explain the low abundance and diversity of organic molecules detected so far [1][2]. In order to get a better understanding of the evolution of organic matter at the surface of Mars, we exposed organic molecules under Mars-like UV radiation and oxidative environments. Similar organic samples were exposed in two experiments: directly to the Sun radiation, outside the International Space Station (ISS) on the EXPOSE R2 facility; and under the flux of a wide range UV lamp in the laboratory with the MOMIE experiment. The EXPOSE R2 facility was placed in low Earth orbit (LEO), outside the International Space Station (ISS) in 2014, to be exposed to the Solar radiation. One of the EXPOSE R2 experiment, called PSS (Photochemistry on the Space Station), was dedicated to astrobiologyand astrochemistry-related studies. Several of the PSS samples were prepared for the study of the evolution of organic molecules under Mars-like surface radiation conditions. Organic samples have been exposed directly to the Sun under KBr filters (UV transmission >200 nm) from November 2014 to February 2016, mimicking the UV radiation conditions of the surface of Mars. Four types of samples were exposed in the form of thin layers of solid molecules: pure deposits of adenine, adenine mixed with nontronite (a clay mineral detected on Mars), pure deposits of chrysene and glycine mixed with nontronite. The MOMIE (Mars Organic Matter Irradiation and Evolution) experiment has been set up to study the evolution of organic matter under simulated martian UV radiation within the laboratory [3][4]. Organic samples are in this case exposed under a UV lamp (200-400 nm) as thin homogenous films (a fraction of µm thick). Adenine, chrysene and glycine were studied in this experiment as well, allowing us to compare their evolution with the results in LEO. Uracil was also studied. Perchlorate salts effect on organic evolution was investigated. To characterize the evolution of our samples, analyses by infrared spectroscopy (IRTF) were performed: before and after exposure in LEO, for the PSS samples, and continuously along the experiment for the MOMIE samples. These analyses allowed determining whether each molecule is preserved or photodegraded, and if so, its photolysis rate. Most of the studied molecules were rapidly degraded under Mars-like UV radiation. On the other hand, uracil seems to form new bigger compounds in Mars-like UV radiation conditions. The effect of nontronite and perchlorates on organic molecules preservation has been investigated as well. We also compared results from LEO with laboratory data.

Exploration of the solar system is a priority research area of the AstRoMap European Astrobiology Roadmap (Horneck et al., 2015) [1], focusing on several research topics, such as “Life and Habitability” andan other one is “Biomarkers for easy the detection of life”. Therefore, “space platforms and laboratories”, as the EXPOSE setup installed outside the ISS, are essential to gain more knowledge of spaceand planetary environments, which might be an essential basis for improvement of the robotic and human interplanetary exploration (Space, Moon, Mars, Encedalus, Titan, Europa). At the exposure platform EXPOSE-R2 on the ISS (2014-2016), samples of the astrobiological model lichen Circinaria gyrosa [3,4,5,6], a specie which was exposed 18 months to space and simulated Mars-like conditions during the BIOMEX experiment

[2] (Biology and Mars Experiment, ESA), was investigated, to study Mars’ habitability and resistance to space conditions. The data obtained by this biomarker-study after being exposed to Mars-like conditions will support the analysis of data obtained during future instrumental detection operations in future space missions on Mars (i.e. ExoMars or Mars 2020). After the return of the samples in June 2016, the first preliminary analysis showed a quick and complete recovery of metabolic activity of the control samples exposed to space vacuum and Mars-like atmosphere. In contrast, the samples directly exposed to solar UV radiation showed slow recovery, in reference to their observed original activity. Recent results will be presented that show biomolecular changes of the DNA analysed by PCR-based [7, 8] and complementary sequencing techniques, in correlation with the previous results showing changes in metabolic activity and changes in viability (Electron and fluorescence microscopy techniques), as well as in morphology/ultrastructure - a potential effext due to space vacuum and Mars atmosphere. In addition, the biogeochemical variations have been examined with spectroscopic analyses (Raman) to look for possible degradation of cell surfaces and pigments which were in contact with terrestrial rocks, and Martian analogue regolith. Moreover, differences were observed between samples irradiated directly with solar UV radiation and samples positioned in the shielded area as darkcontrol. These experiments will contribute to answer questions of the habitability of Mars, on the likelihood of the Lithopanspermia Hypothesis, on the capability to detect biomolecules by life-detection instruments exposed to an extraterrestrial environment and will be of relevance for planetary protection issues.

A central, long-standing goal of the astrobiology program that holds promise for both major scientific discoveries and exciting the general public is to understand life in outer space and on other celestial bodies. One strategy towards achieving this goal is to determine the potential for terrestrial microbial life to adapt and evolve in space environments. Identifying the limits of terrestrial life in space and the accompanying molecular adaptations is a prerequisite for developing predictions and hypotheses about life on other worlds. The ability of microorganisms to survive in a wide range of conditions encountered in space would support the hypothesis that terrestrial life might not be a local planetary phenomenon, but instead could expand its evolutionary trajectory beyond its planet of origin. This would, in turn, support the notion that terrestrial life may not be unique and similar life forms might exist elsewhere in the Universe. In order to facilitate studies on the impact of the space environment on biological systems, we have developed GEMM (Gene Expression Measurement Module) - an automated, miniaturized, integrated fluidic system for in-situ measurements of gene expressions in bacterial samples. The project has been funded through the ASTID program. The GEMM instrument is capable of (1) lysing bacterial cell walls, (2) extracting and purifying RNA released from cells, (3) hybridizing it to probes attached to a microarray and (4) providing electrochemical readout, all in a microfluidics cartridge. Its first application on a nanosatellite platform is to cultivate and measure gene expression of the photosynthetic bacterium Synechococcus elongatus, a cyanobacterium known for its metabolic diversity and resilience to adverse conditions, under light and dark cycles exposed to polar orbit for a period of 6 months. The integration and end-to-end technology validation of this instrument will be discussed. In particular, results demonstrating that the instrument properly measures gene expression after cellular lysis, nucleic acid extraction, its purification, and hybridization to an electrochemical array will be presented and compared to commercial microarray

analysis. Finally, a proposed version of GEMM that is capable of handling both microbial and tissue samples on the International Space Station will be briefly reviewed.

F3.1-0013-18 PREPARING FOR ROBOTIC ASTROBIOLOGY MISSIONS TO LAVA CAVES ON MARS: THE BRAILLE PROJECT AT LAVA BEDS NATIONAL MONUMENT (N. CA, USA)

Jennifer Blank, jennifer.g.blank@nasa.gov

Planetary caves offer direct access to the subsurface, have stable thermal environments, and are protected from harsh surface conditions such as cosmic radiation and small-scale bombardments. These features may enhance preservation of biosignatures over long periods of time and make caves an attractive astrobiology target in the search for evidence of life beyond Earth. BRAILLE (Biologic and Resource Analog Investigations in Low Light Environments) is a NASA analog research project focusing on lava caves. The BRAILLE team is using the NASA Ames CaveR rover to deploy a scientific payload (cameras and spectrometers) and execute astrobiology science and mapping activities, robotically, in a lava cave. Our field site is Lava Beds National Monument, in Northern California, USA; 3 caves selected for our initial work (Valentine, Hopkins-Chocolate, and L300) have a range of human visitation and lava flow ages. CaveR is shephered by engineers inside the cave, but operations are planned and directed from a surface science and engineering team, located in a mission control center a few minutes away. In tandem, we are conducting an integrated field and laboratory study at the same locale to characterize the microbial life and associated secondary minerals or biominerals, explore the mineral-microbe continuum, and assess resources (water, nutrients, energy sources) that can limit and/or sustain microbial life there. We will present initial results from our first field campaign at Lava Beds and our concept of mission operations to simulate planetary cave exploration. This work was supported by the NASA PSTAR program NNH16ZDA001N.

On Mars and the icy worlds, the liquid water required for life may be cold, salty, and under pressure. High solute concentrations depress the freezing point of water, broadening the range of potentially habitable regions. Sulfate salts, along with chlorides, are important in Mars regolith with Ca, Fe, Mg, and Na counterions. Hygroscopic sulfate and (per)chlorate salts may form deliquescent brines with low eutectic points on Mars. While the bulk ocean of Europa may not be highly saline, pockets or layers of liquid water intercalated with ice may have high salinities, as might be the case for Callisto and Ganymede. Enceladus may have pockets of alkaline soda brines, while the frigid waters of Pluto may be rich in ammonia. We have been examining bacterial responses to high solute concentrations using heavy salt brines and sugars. Our organisms were isolated from natural environments rich in NaCl (Great Salt Plains, OK) or MgSO4 (Hot Lake, WA; Basque Lake, BC), oligosaline common soils, and spacecraft assembly facilities (NASA JPL). The collections include Halomonas, Marinococcus, Nesterenkonia, and Virgibacillus isolates that grow at 10% NaCl (1.7 M) or 2 M (50%) MgSO4. We have examined the anions chloride, nitrate, (per) chlorate, phosphate, and sulfate coupled in every combination with the cations Ca, Fe, Mg, K, and Na. Salts of borate, Cs, and Li also have been tested. Strong growth was commonly observed in salts at 1 M, including LiCl, MgCl2, MgSO4, KNO3, K2SO4, and NaCl. such as Cs and borate, seemed toxic. Comparisons between salts and among other solutes (sugars) suggest that water activity or chaotropicity alone were not dictating cellular responses to specific solutes. Growth at >2M Mg or >25% chlorate was unexpected. However, we observed strong growth at the MgSO4 saturation point (67% at 25 °C). Furthermore, we observed slow growth at the eutectic points for MgSO4 (43% at -4 °C) and K chlorate (3% at -4 °C), the first demonstration of microbial growth in eutectic brines with astrobiological relevance. We continue to examine microbial survival and recovery from non-permissive conditions, where salinities or temperatures stop growth. Salty cold water on the icy satellites may be under considerable hydrostatic pressure. We are currently investigating the interplay of pressure, salinity, and temperature with microbial survival. Measuring the toxicity of solutes at extremely high concentrations and low temperatures helps to define extraterrestrial habitable regions and informs us about the types of microbes on spacecraft that pose greater risks for forward planetary contamination. Supported by awards from NASA, Research Opportunities in Space and Earth Science (ROSES), Planetary Protection Research (09-PPR09-0004 and 14-PPR14-2-0002) and Kansas INBRE NIGMS NIH (P20 GM103418).

F3.1-0015-18 VENUS' SPECTRAL SIGNATURES AND THE POTENTIAL FOR LIFE IN THE CLOUDS

Planetary Science Institute, Washington, Colorado, United States

The lower cloud layer of Venus (47.5-50.5 km) is an exceptional target for exploration due to the favorable conditions for microbial life, including moderate temperatures and pressures (60 C and 1 atm), and the presence of micron-sized sulfuric acid aerosols. Nearly a century after the ultraviolet contrasts of Venus' cloud layer were discovered using Earth-based photographs, the substances and mechanisms responsible for the changes in Venus' contrasts and albedo are still unknown. While current models include sulfur dioxide and iron chloride as the ultraviolet absorbers, the temporal and spatial changes in contrasts, and albedo between 330-500 nm, remain to be fully explained. In this presentation, therefore, we will discuss the potential for microorganisms to survive within Venus' lower clouds and contribute to the observed bulk spectra. In summary, we will provide an overview of Venus spectroscopy, compare the spectral and physical properties of Venus' clouds to terrestrial biological materials, discuss the potential for a coupled iron and sulfur metabolism in the clouds, and review conceivable mechanisms of transport from the surface towards a more habitable zone in the clouds. Together, our lines of reasoning suggest that particles in Venus' lower clouds contain sufficient mass balance to harbor microorganisms, water, and solutes, and potentially sufficient biomass to be detected by optical methods. Looking ahead, these comparisons warrant further investigations into the prospect of biosignatures in Venus' clouds.

F3.1-0016-18 SURVIVAL RATE OF SPORES UNDER NEAR-SURFACE CONDITIONS OF ICY WORLDS

Edith Fayolle, edith.c.fayolle@jpl.nasa.gov

Adrian Ponce, ponce@caltech.edu

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Icy-Ocean worlds like Europa or Enceladus likely represent our best targets for finding nonEarth life in our Solar System, owing to the presence of an ocean under their ice shell. Microorganisms formed there can potentially migrate to the surface via plumes, ice shell tectonics, or in chaos regions, and be accessible to an eventual landed mission. While a detection on the surface is unlikely due to the harsh UV and energetic particle irradiation to which these moons are subject, the near-surface (mm-cm) provides slightly more hospitable conditions and is accessible without the need for deep drilling.

The goal of our work is to investigate micro-organism survival under the temperature, radiation, and chemical conditions found near the surface of icy worlds. To accomplish this, we chose bacterial spores, a dormant bacterial state, as our model micro-organism because of their known resilience under extended and extreme conditions. In our laboratory, spores can be irradiated by UV photons using an Ar arc lamp lamp or an electron gun under high vacuum to simulate Europa-like conditions. They can be cooled cryogenically in the 10 - 300 K range, and molecular films are deposited by introducing gaseous mixtures that condense on the cooled spore samples.

Here we present survival fractions of Bacillus Subtilis spores irradiated by UV photons (and keV electrons) under a range of temperature and in different chemical environments. We discuss the origin for the observed variations with temperature and the

impact of shielding versus that of chemical reactions by different ice compositions and discuss the expected survival time of Bacillus Subtilis spores under Europa-like conditions with respect to latitude.

F3.1-0019-18 BIOSPHERE SUBSTRATE AND ITS PARAMETERS RANGE

Yegor Morozov, yegormorozov@ibp.ru

Institute of Biophysics SB RAS; Siberian State Aerospace University, Krasnoyarsk, Russia Mikhail Bukhtoyarov, mikebukhtoyarov@gmail.com

Siberian Federal University, Krasnoyarsk, Russia

For providing the maximal carrying capacity and expansive potential of a planetary system (PS), optimal utilization of the orbital material is required. It raises the question of suitability of various objects in a planetary system for the purpose of terraforming and developing full-scale open biospheres. The term “Biosphere Substrate” (BS) is introduced for celestial bodies, like terrestrial planets or big gas giant moons, suitable to sustain a full-scale open biosphere after terraforming. The purpose of the work is to examine the range of parameters for a biosphere substrate. Most importantly, to be a BS, a celestial body gravity should sustain a full-scale open breathable atmosphere dense enough after terraforming in astrophysical time scale comparable to the lifecycle of a planetary system. Extremely high gravity is also the limit for complex life forms. The gravity is the main parameter that is the most difficult to be influenced, thus the range of object sizes fitting the BS definition is examined. The capability of a celestial body to retain breathable atmosphere during a time interval comparable to the planetary system life cycle depends on its magnetic field strength. The lower boundary of the objects sizes fitting the BS definition is studied on the basis of their capability to hold hot convecting interiors for strong enough magnetic fields during a PS life cycle. As the chemical composition of a BS’s surface, hydrosphere and atmosphere can be drastically adjusted in most cases by importing asteroid and cometary material, this factor in most cases does not determine whether a celestial body can become a BS. But for water worlds where any solid material to build biological bodies and industrial structures can be more than thousand kilometers deep, chemical composition can become an issue, while this problem can be solved to some extent by importing solid materials (asteroids). Also, concentrations of some chemical elements and compounds in extremely toxic quantities in crust might be an obstacle to develop a full-scale open biosphere. Thus, the range of chemical compositions for celestial bodies of suitable sizes is also reviewed. The temperature is another important parameter, as a molten celestial body cannot become a BS in near term, but can become a BS when it cools enough. The temperature factor and capabilities to adjust it are also estimated. For a full-scale open biosphere development, there must be a source of energy. A BS orbit can go inside the circumstellar habitable zone, or can be partially inside and partially outside it for highly elliptical orbits. Possibilities to extend a circumstellar habitable zone with large orbital light diffusers and light concentrators are researched. For planets with solid crusts, their rotation can be adjusted by hitting asteroids and comets strictly tangentially with high velocities to gain required spin. But for water worlds and tidally locked satellites, rotation can be an

issue. The rotation factor is also examined. The work attempts to introduce a new concept and the term that can be used for further terraforming research, developing a mathematical model of its limits. Our estimations are required to be discussed with a wide range of relevant specialists in the linked fields of studies, such as astrophysics, especially exoplanets characterization professionals; astrochemistry; astrobiology; planetary science, etc. To provide the basis for this discussion, the article suggests preliminary estimations of the parameters crucial for selection of BS candidates.

LIFE SCIENCES AS RELATED TO SPACE (F)

THE EVOLVING CHEMICAL UNIVERSE: FROM PROTO-STARS TO THE ORIGIN OF LIFE: PART 1 (F3.2)

F3.2-0001-18 INTRODUCTION TO THE EVOLVING CHEMICAL UNIVERSE

Eric Herbst, ericherb@gmail.com

University of Virginia, Charlottesville, Virginia, United States

The formation of stars and planets in dense, cold regions of the interstellar medium is a complex process with a number of intermediate and overlapping evolutionary stages, such as dense prestellar cores, hot cores, protostars, and protoplanetary discs. A significant portion of our knowledge of these stages comes from the spectroscopic study of molecules in the gas and on dust particles, as detected at assorted wavelength regions, mainly via rotational and vibrational transitions. During the formation of stars and planets, molecular complexity is built up via both gas-phase and solid-state reactions, contributing to the inventory of organic molecules in new exo-planets. Still larger organic molecules, including PAHs and fullerenes, are not as directly connected with star formation. In this Event, sessions are organized to include the formation and observation of complex organic molecules in diverse sources including the atmospheres of new planets, as well as assorted ideas concerning the origins of life from the organic molecules produced both in external sources such as comets and protoplanetary discs as well as in the atmospheres of young planets.

F3.2-0002-18 COMPLEX ORGANIC MOLECULES IN COLD CORES

Aurore Bacmann, aurore.bacmann@univ-grenoble-alpes.fr

Institut de Planétologie et d'Astrophysique de Grenoble (IPAG), Grenoble, France

As likely precursors of prebiotic molecules in space, complex organic molecules have been the subject of intensive investigation. Long thought to be characteristic of the hot cores of star forming regions, they are now found in a wide range of regions with various physical conditions, including prestellar dense cores, i.e. at a stage even prior to the formation of protostars. The unexpected detections of terrestrial-like complex organic molecules in these cold (10 K) sources questioned our understanding of their formation mechanism, since these species were first thought to originate from warm chemistry. In this contribution, recent observational results of complex organic molecules in prestellar cores will be presented, addressing their inventory, spatial distribution and what we can learn about their formation mechanisms. I will then highlight the remaining challenges and future progress we can expect in the coming years.

F3.2-0003-18 DETECTION AND MODELING OF COMPLEX ORGANIC MOLECULES IN GALACTIC-CENTER HOT CORES

Robin Garrod, rgarrod@virginia.edu

University of Virginia, Charlottesville, United States

The interstellar medium (ISM) is replete with molecules, and high-mass star-formation regions in particular are host to some of the most complex organic molecules yet detected outside of our solar system. Millimeter/sub-millimeter wavelength spectral data from the ALMA telescope allows us to explore the chemistry of such regions in much greater detail than ever before. The ALMA 3mm line survey EMoCA ("Exploring Molecular Complexity with ALMA") of the chemically-rich Galactic Center source Sagittarius B2(N) has not only identified several new molecules in that source, but has led to the identification of new hot cores - a total of five are now known to exist.

I will give a brief overview of the molecular detections made toward Sag B2(N). I will also present chemical kinetics models of the coupled gas-phase and grain-surface/ice-mantle chemistry occurring in Sag B2(N) related to these molecules, with an emphasis on the treatment of the recently-detected branched carbon-chain molecule iso-propyl cyanide (i-C3H7CN). I will also assess the possibilities for the presence and detectability of other branched carbon-chain molecules in the ISM.

Cyanamide (NH2CN) is thought to be an important pre-biotic molecule, as it is converted to urea in liquid water (Kilpatrick 1947). Despite being detected in external galaxies (Martín et al. 2006; Aladro et al. 2011), NH2CN has only previously been detected twice in the Milky Way, in Sgr B2 (Turner et al. 1975) and Orion KL (White et al. 2003). Here we report the first detection of NH2CN surrounding two solar-type protostars, using data from the Atacama Large Millimeter/submillimeter Array Protostellar Interferometric Line Survey (PILS) of IRAS 16293-2422 B and observations of NGC1333 IRAS2A taken with the IRAM Plateau de Bure Interferometer. Towards IRAS 16293B, we also detect the deuterated and 13C isotopologues of NH2CN, constituting the first interstellar detection of NHDCN.

LTE analysis shows that the deuteration of cyanamide (1.7%) is similar to that of formamide (NH2CHO), perhaps suggesting a common molecular precursor to both. The NH2CN/NH2CHO abundance ratio varies between the sources, being 0.2 for IRAS 16293-2422B and 0.02 for IRAS2A. These values are comparable to observed values for Sgr B2. We use the threephase chemical kinetics model MAGICKAL to investigate the formation and destruction of this molecule. Production of NH2CN on the surface of grains through the combination of NH2 and CN radicals was added to our network, and it is demonstrated that our model can reproduce observed gas-phase abundances of NH2CN, depending on the choice of the gas-phase density. The NH2CN/NH2CHO abundance ratio is still too low however, which is perhaps related to overproduction of NH2CHO.

F3.2-0005-18 JWST CAPABILITIES FOR COMPLEX MOLECULES

Adwin Boogert, aboogert@hawaii.edu

University of Hawaii at Manoa, Honolulu, Hawaii, United States

Knowledge of the molecular content of dense clouds, embedded protostars and protoplanetary disks is fundamental to our understanding of the chemical trail leading to the formation of life. Millimeter-wave spectroscopy, in particular using the powerful Atacama Large Millimeter Array (ALMA) interferometer, is able to image molecules with permanent dipole moments down to scales of 10 AU in the closest star forming regions. Infrared spectroscopy enables observations of species without permanent dipole moments (e.g., CO2, CH4, C2H2, .) as well and also of the vibrational modes of dust and ices. It traces molecules down to spatial scales (tenths of AU) smaller than ALMA because the transitions can be observed in absorption against the continuum emission from stellar photospheres or hot dust. The James Webb Space Telescope (JWST), to be launched in Spring of 2019, will offer unprecedented sensitivity, spatial resolution, and spectral coverage at a spectral resolution suited for detailed observations of gas and solid state molecules in the infrared. JWST will enable observations of the vibrational modes of ices in environments and for sample sizes not possible before. Ices are a key location of molecule formation and studying their composition and structure directly is important (as opposed to after sublimation). The need for spectra of analogs of interstellar ices produced in laboratories is highlighted. I will also present which ice observations are planned at the beginning of the JWST mission as part of the Early Release Science program "Ice Age".

F3.2-0006-18 TWO DIMENSIONAL CARBON CHEMISTRY IN THE ISM: LABORATORY AND OBSERVATIONAL INVESTIGATIONS OF AROMATIC MOLECULES

Brett McGuire, bmcguire@nrao.edu

National Radio Astronomy Observatory, Charlottesville, Virginia, United States

In the last 50 years of astrochemical research, the realm of one-dimensional carbon chemistry (i.e. carbon chain molecules) has been well explored. Life, however, relies on two and three-dimensional carbon - branches, rings, bridges, and so forth. Here, we present the first rotational detection of a six-membered ring molecule in the ISM, benzonitrile, using deep GBT observations of TMC-1 combined with high-precision laboratory spectroscopy. We then explore the formation chemistry of this two-dimensional carbon molecule using a combined laboratory, quantum chemical, and modeling approach. We demonstrate the synthesis of cyclic species (benzene and benzonitrile) from simple, acyclic precursors, providing definitive evidence for facile bottom-up generation of two-dimensional carbon chemistry in the ISM.

F3.2-0007-18 INTERSTELLAR FULLERENES

Jan Cami, jcami@uwo.ca

University of Western Ontario // SETI Institute, London, Canada

Cosmic Fullerenes in Planetary Nebulae

Jan Cami, Jeronimo Bernard-Salas, Els Peeters, Isabel Aleman, Marcelo Leal-Ferreira, Bram Ochsendorf, Roger Wesson, Dave Stock, Stavros Akras, Xander Tielens, Nick Cox, Ciska Kemper, Greg Sloan, George Pagomenos, Albert Zijlstra, Alessandra Candian, Heather MacIsaac, Viktor Staroverov

In recent years, fullerenes (and in particular C60) have been detected in a variety of astrophysical environments – from the circumstellar carbon-rich surroundings of evolved stars to interstellar reflection nebulae and young stellar objects. Understanding how these species form, evolve and respond to their environment yields important insights into astrochemistry and the characteristics of large aromatics in space, thought to be the main reservoir of organic material in space.

In this talk, I will present an overview of what we have learned about cosmic fullerenes from multi-wavelength astronomical observations, theoretical calculations and recent laboratory experiments, and show how fullerenes have significantly changed our understanding of interstellar chemistry. I will discuss the conditions that appear to be conducive to the formation and/or detection of fullerenes, and highlight some of the difficulties we still face in understanding the formation of fullerenes, especially in planetary nebulae.

F3.2-0008-18 SPACE FULLERENES, PAHS & DIFFUSE INTERSTELLAR BANDS

Bernard H. Foing, bernard.foing@esa.int ESA/ESTEC, Noordwijk, Netherlands

C60 was discovered in 1985 from a mass spectrometer peak by Kroto, Curl, Smalley al, for which they got the Nobel Prize in Chemistry in 1996. It was then produced in macroscopic quantities by Kratschmer et al in 1990, that allowed to confirm the structure of soccer ball geometry, and started a revolution in research and application, to the delight of chemists, physicists, astronomers, architects and UEFA-FIFA fans. In 1994 Foing Ehrenfreund reported the discovery of two near IR diffuse bands coincident with C60+ bands, with abundance of up to 0.5 % of cosmic carbon .The interstellar bands detected at OHP observatory at 9577 and 9632 A were consistent with C60+ spectra in frozen matrix lab measured in 1992 by D'Hendecourt, Fostiropoulos and Léger and other groups. The DIBs assignment as C60+, largest (and most beautiful) interstellar molecule was celebrated by H. Kroto, and confirmed in subsequent observations (ESO, CFHT, etc. and recently by latest near gas phase laboratory experiments. The quest for fullerenes, PAHs and large organics in space and Diffuse Interstellar Bands (DIBs) research has advanced since 20 years. DIB observational surveys, DIB families, correlations and environment dependences, resolved substructures indicative of rotational contours by large molecules. DIBs carriers have been linked with large organic molecules observed in the interstellar medium such as IR bands (assigned to PAHs, with some new bands detected by Spitzer assigned to fullerenes, Cami et al 2010), Extended Red Emission or recently detected Anomalous Microwave Emission (AME). Fullerenes and PAHs have been proposed to explain some DIBs and specific molecules were searched. These could be present in various dehydrogenation and ionisation conditions, for example fully dehydrogenated (Vuong, Foing 2000), in a form similar to graphenes (Nobel prize Physics 2010). Infrared measurements confirm the presence of vibrational bands of fullerene compounds in circumstellar environments. Ground based astronomical surveys confirmed the C60+ band detection, and allow to use fullerenes as probes of interstellar processes and environments. Experiments in the laboratory and in space (on FOTON BIOPAN, ISS EXPOSE, OREO Cubes) allow to measure the survival and by-products of these molecules.

F3.2-0009-18 COMETARY CHEMISTRY: COMPLEX MOLECULES

Steven Charnley, steven.b.charnley@nasa.gov NASA/GSFC, Greenbelt, Maryland, United States ALMA Comet Observation Team

M. A. Cordiner, S. N. Milam, M. J. Mumma, A. J. Remijan, J. Boissier, G. Villanueva, L. Paganini, D. Bockelée-Morvan, N. Biver, Y.-J. Kuan, Y.-L. Chuang, D. C. Lis, J. Crovisier, Iain Coulson, D. Minniti

I will summarize what is currently known of the chemistry of comets. Sublimation of nuclear ices near perihelion generates the coma - a multi fluid plasma whose understanding requires consideration of a variety of chemical processes. Compositional studies, from ground and space, especially of organic molecules, isotopologues, and ortho-para ratios can provide important clues as to their origins, and to their possible role in providing water and biomolecules to the early Earth.

Laboratory studies of meteorites and cosmic dust from asteroids and comets reveal a multitude of organic compounds of astrobiological and astrochemical interest. Isotopic, structural, and chemical studies suggest some of these materials have interstellar origins. Yet there are also signatures of subsequent chemical synthesis and alteration within the solar nebula and the interiors of planetesimals.

Among meteorites thought to derive from asteroids, organic compounds are most abundant in carbonaceous chondrites that have undergone hydrothermal alteration. Some meteoritic organics have elevated D/H and 15N/14N ratios that resulted from isotopic fractionation during low-T ion-molecule and grain-surface chemistry in cold molecular clouds and the outer protoplanetary disk [1]. These signatures were obscured by aqueously mediated chemistry and thermal processing in asteroid parent bodies, forming amino acids and other prebiotic molecules. Chondritic porous interplanetary dust particles (IDPs) collected in the stratosphere are thought to derive from comets based on their primitive properties and high atmospheric entry velocities. Large H and N isotopic anomalies are more common in IDPs than most meteorites, suggesting better preservation of primordial organics [2]. Yet, owing to their small sizes (10 µm), the nature of organic matter in cometary IDPs is not well known. Rosetta studies of comet 67P dust particles revealed organic species that resemble macromolecular material that is ubiquitous in carbonaceous chondrites [3].

Primitive meteorites and cometary IDPs contain µm-sized organic nanoglobules that often have large H and N isotopic anomalies. Coordinated in situ isotopic and organic measurements suggest that these organic nanoglobules formed prior to their incorporation in their parent bodies and may derive from interstellar environments [1]. Chemical measurements of organic globules in meteorites by in situ laser desorption-laser ionization mass spectrometry show high concentrations of organic species containing a carbonyl functionality such as formaldehyde

(H2C=O) and acetaldehyde (CH3C=OH). Since aldehydes and ketones readily undergo condensation/polymerization reactions, their association with nanoglobules is consistent with the suggestion that nanoglobules formed via carbonyl condensation reactions [4]. The presence of free carbonyl species indicates partial hydration of nanoglobules during parent body hydrothermal alteration.

NASA and JAXA are flying sample return missions to primitive, potentially organic-rich asteroids. The OSIRIS-REx [5] and Hayabusa2 [6] missions will map asteroids Bennu and Ryugu, respectively, in detail and return regolith samples to Earth. Laboratory analyses of these pristine asteroid samples will provide unprecedented views of asteroidal organic matter relatively free of terrestrial contamination within well-determined geological context. NASA also recently selected the proposed CAESAR comet sample return mission for phase A study within the New Frontiers 4 program. This mission would return the first direct sample of a comet nucleus (67P) to Earth in 2038 [7, 8]. Studies of extraterrestrial materials and returned samples are essential to understand the origins of Solar System organic material and the roles of comets and asteroids to providing the starting materials for the emergence of life.

F3.2-0011-18 THE DIVERSITY OF REFRACTORY ORGANIC MATERIAL IN COMETS

Diane Wooden, diane.h.wooden@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States Rhonda Stroud, stroud@nrl.navy.mil

Naval Research Laboratory, Washington, United States

Organic matter exists in comets (most notably in 81P/Wild 2 [Stardust], 67P/ChuryomovGerasimenko (67P/C-G) [Rosetta], chondritic porous IDPS, and UCAMMs) and in primitive carbonaceous chondrites that likely retain some chemistry that reflects an origin in the prenatal cold molecular cloud (Alexander+2017). Heavy isotopic enrichments, 15N/14N and possibly D/H, signify preserved molecular cloud organics. In the cold outer disk, if grains are lofted above the disk mid-plane then organics likely experience significant UV processing (Ciesla+2012). In remote sensing of comet comae, organics in the dust are considered refractory or semirefractory. Semi-refractory organics have limited comae lifetimes and produce distributed sources of molecules (H2CO and CO). A close flyby of 67P/C-G's nucleus (10-15 km) reveals a distributed source of glycine, methyl amine and ethylamine (Altwegg+2016). Cometary samples and primitive meteorites have two types of organic matter: (1) acid-insoluble organic matter (IOM), which is a macromolecular polymer with a mixture of aromatic and aliphatic moieties, and (2) labile, soluble organics, which includes the amino acids, such as glycine (Stardust, Elsila+2009). Meteoritic IOM is robust, withstanding experimental temperatures of 1200 K (Dobrica+2011, Cody+2008). Nanoglobules are a type of IOM; they have a distinct physical structure, but often share the same chemistry as the other IOM from the same meteorite. Moderate-sized PAHs (20 C-atoms) are detected in Stardust samples (Clemett+2010). Refractory organic IOM is ubiquitous yet has a great diversity of abundances between cometary samples. IOM is in primitive chondrites, 67P/C-G (Rosetta), 81P/Wild 2 (Stardust), 1P/Halley, 26P/Grigg-Skjellerup, UCAMMs, anhydrous IDPs, and in chondritic porous IDPs (CP IDPs) and larger cluster IDPs (e.g., Fray+2016, Fomenkova+94, Busemann+09, Dobrica+2011, Dobrica+2012). 81P's refractory organic matter is of two types (De Gregorio+2011): nanoglobules of highly aromatic refractory organic matter and polyaromatic carbonyl-containing organic matter, which is similar to IOM in primitive meteorites and IDPs. Fray+2017 estimate that 50% of carbon in 67P/C-G is in IOM. 67P/C-G's organics appear to lack the soluble organic matter, aliphatic carbon, amino acids, and PAHs (Fray+2016). Other notable aspects of the diversity in IOM in cometary samples are the ranges of atomic ratios of N/C, O/C, and H/C, and the range of isotopic enrichments of 15N/14N and D/H.

On 30 September 2016 the European Space Agency's Rosetta spacecraft softly crash-landed on comet 67P/Churyumov-Gerasimenko and brought an intense period of more than 2 years of continuous investigation to an end. Rosetta data led to many discoveries about the origin of the material and the processing in our early Solar System. Among the payload instruments, ROSINA, the mass spectrometer suite, obtained fundamental properties of the comet by analysing the gases emanating from its nucleus. Besides detecting many organic molecules never seen in space before, ROSINA was also able to measure precise isotopic abundances for noble gases as well as D/H in water, NH3 and H2S. By following the comet from 3.8 AU to perihelion and out again to 3.8 AU desorption patterns could be followed for individual species, allowing deeper insights into the nature of cometary ice. Some of the findings clearly point to unprocessed ice from the prestellar stage which allows to study chemistry in the presolar cloud more or less "in situ". Detailed data analysis is still ongoing and many more results from the gas mass spectrometers are evolving. The most important of these findings like e.g. nitrogen isotopes and complex organics will be discussed in the presentation. The impact of those findings on the question of astrobiology are discussed. Finally, from the noble gases, we can deduce an answer to the question "How much material was delivered by comets to the early Earth?"

F3.2-0014-18 VOLATILE LINKS BETWEEN IRAS16293-2422B AND 67P/C-G

Maria Drozdovskaya, maria.drozdovskaya@csh.unibe.ch University of Bern, Bern, Switzerland

Ewine Van Dishoeck, ewine@strw.leidenuniv.nl Leiden University, Leiden, Netherlands

Martin Rubin, martin.rubin@space.unibe.ch University of Bern, Bern, Switzerland

Jes Kristian Jørgensen, jeskj@nbi.ku.dk University of Copenhagen, Copenhagen, Denmark Kathrin Altwegg, altwegg@space.unibe.ch University of Bern, Bern, Switzerland

Comet 67P/Churyumov-Gerasimenko has been studied with unique in situ measurements by various instruments aboard the Rosetta spacecraft. Data from ROSINA, COSAC, VIRTIS and MIRO have shown that the comet has a rich molecular inventory and that there is a complex relationship between production rates and correlations between various species. The currently available data on 67P/C-G is one of the best probes of the innate protosolar disk that evolved into our modern day Solar System. Similar chemical richness, including large complex organic species, extends beyond the Earth and our Solar System as attested by countless observations towards highand some low-mass protostars. One of the best-studied low-mass systems is IRAS16293-2422, which is thought to be analogous to the earlier phases of our Solar System. The region has been surveyed with the large unbiased Protostellar Interferometric Line Survey (PILS) with ALMA. This dataset has allowed this region to be studied within an unprecedentedly wide spectral range at high spectral and spatial resolutions; thereby, uncovering its full chemical inventory and the spatial distribution of the detected species. This ALMA data on IRAS16293-2422 can be used to probe the extrasolar chemical content and the Rosetta measurements of 67P/C-G as a Solar System diagnostic. By deriving the relative ratios for simple species and complex organic molecules, direct comparisons can be drawn between the two to go after the origins of the chemical content of our Solar System. In this talk, results of such a comparative study will be presented, based on relative ratios of major and minor volatile species and the derivation of relative ratios within hierarchical families (e.g., formaldehyde, methanol and ethanol) to access the degree of relative complexity stemming from common parent species. These results give clues to the different radicals available in the ices for subsequent synthesis of larger molecules, shedding light on the dominant pathways to chemical complexity and the physical conditions that optimize such enrichment. The carried out comparative work between protostars and 67P/C-G gives hints on the uniqueness of the ingredients to life.

F3.2-0015-18 ORGANIC CHEMISTRY IN PROTOPLANETARY DISKS

Yuri Aikawa, aikawa@astron.s.u-tokyo.ac.jp University of Tokyo, Tokyo, Japan

Protoplanetary disks are the formation site of planetary systems. Earth-like planets are formed via coagulation of solid material. Since volatiles are one of the essential ingredients of habitable planets, distributions of volatiles among the solids and the gas phase, and their dependence on disk radius (i.e. snow lines) have been studied theoretically and observationally. While the molecular composition of volatile material would be significantly altered inside the planetesimals and their coagulation processes, comets may preserve their initial molecular composition, at least partially. A link between cometary molecules and ices and organics in disks has long been discussed.

Although the icy water, the dominant component of ice, is detected via the observations of absorption bands for edge-on disks and via scattered light for bright sources, direct observations of minor ices in disks are difficult. Alternatively, observations of molecular line emissions could tell us the gas-phase abundance of organic molecules, which can be used to estimate their abundances in ice mantles. The combination of observations and modeling of physical and chemical structures is important, since there are radial and vertical gradients of density, temperature, and UV radiation field in the disk.

Various organic molecules are detected in protoplanetary disks. As for simple molecules, such as HCO+, DCO+, CN, H2CO and carbon chains, their spatial distributions have been revealed by ALMA, and are discussed in relations to their formation paths, snow lines, and dust evolution. Complex organic molecules (COMs) such as CH3OH and CH3CN, have also been detected. Theoretical models show that their abundances and distributions depend on various parameters including photodesorption yield and turbulent diffusion.

F3.2-0016-18 CHEMICAL CHARACTERIZATION OF EXTRASOLAR PLANETS

Nikku Madhusudhan, nmadhu@ast.cam.ac.uk University of Cambridge, Cambridge, United Kingdom

Exoplanetary discoveries in the past two decades have unveiled an astonishing diversity in the physical characteristics of exoplanetary systems, including their orbital properties, masses, radii, equilibrium temperatures, and stellar hosts. Exoplanets known today range from gasgiants to nearly Earth-size planets, and some even in the habitable zones of their host stars. Recent advances in exoplanet observations and theoretical methods are now leading to unprecedented constraints on the physicochemical properties of exoplanetary atmospheres, interiors, and their formation conditions. I will discuss the latest developments and future prospects of this new era of exoplanetary characterization. In particular, I will present some of the latest constraints on atmospheric chemical compositions of exoplanets, made possible by state-of-the-art high-precision observations from space and ground, and their implications for atmospheric processes and formation conditions of exoplanets. The emerging framework for using atmospheric elemental abundance ratios for constraining the origins and migration pathways of giant exoplanets will be discussed along with their implications for smaller rocky planets. A survey of theoretical and observational directions in the field will be presented along with several open questions on the horizon.

F3.2-0017-18 DREAMING OF ATMOSPHERES

Ingo Waldmann, ingo@star.ucl.ac.uk

University College London (UCL), London, United Kingdom

The field of exoplanetary spectroscopy is as fast moving as it is new. Analysing currently available observations of exoplanetary atmospheres often invoke large and correlated parameter spaces that can be difficult to map or constrain. This is true for both: the data analysis of observations as well as the theoretical modelling of their atmospheres. Modelling both sets of correlations in data and modelling is key to understanding the nature of exoplanet atmospheres. In this talk I will discuss how these improvements in machine learning can be applied to exoplanetary spectroscopy to solve some of said correlations in the parameter space. By designing deep neural networks, we can significantly speed up data analysis and interpretation and allow our current models to 'learn from experience'. Such AI driven systems will help to resolve model correlations, and allow us to build fully autonomous models. Finally, I will present a new deep neural network architecture, specifically designed to learn and classify data from the Cassini-VIMS instrument. This neural network takes both spectral and spatial distributions of surface or cloud compositions and can be shown to significantly out-perform traditional labelling techniques.

F3.2-0018-18 LIGHTNING AND CYANIDE CHEMISTRY ON EXOPLANETS

Paul Rimmer, pbr27@cam.ac.uk

University of Cambridge, Cambridge, United Kingdom

Hydrogen cyanide (HCN) is a key molecule for a wide variety of prebiotic synthesis mechanisms, and it is therefore useful to determine how much HCN we expect on the surfaces of rocky exoplanets with N2-dominated atmospheres. To form HCN in an N2-rich environment, the first step is to cleave the N N triple bond, which requires energies in excess of 225 kcal/mol. This energy can take many forms, such as cosmic rays and solar energetic particles, UV photons, impacts, volcanism, and lightning. If there is any carbon and hydrogen in the same environment, some of that carbon will react with the atomic nitrogen to form the CN radical, which will proceed to HCN. If there is any oxygen in the environment, some of the oxygen will react with the atomic nitrogen to form nitrogen oxides (NOx). How much HCN vs NOx is produced is primarily determined by the C/O ratio.

I will use lightning-driven chemistry to illustrate this relationship between HCN and the C/O ratio.

I will discuss the application of a photochemistry-diffusion model (ARGO) using the STAND chemical network to a variety of atmospheres of different C/O ratios and different oxidation states of carbon. To model a lightning shock, this model is coupled to a hydrodynamics model (ATHENA). I show what range of HCN mixing ratios can be produced via lightning for this variety of environments. I then discuss how much HCN we can expect to rain out onto exoplanet surfaces, in comparison to the HCN concentrations necessary for prebiotic synthesis.

F3.2-0019-18 BASIC PROCESSES OF FORMATION AND EVOLUTION OF ICES IN PLANETARY AND INTERSTELLAR ENVIRONMENTS

Gianfranco Vidali, gvidali@syr.edu

Department of Physics, Syracuse University, Syracuse, New York, United States

Ices, whether coating sub-micron interstellar grains or larger planetary grains and bodies, are repositories of atoms and molecules that, under the appropriate conditions, might give rise to complex molecules, some of which are strong candidates for the formation of amino-acids and other molecules of interest to origin-of-life investigations. In this review, I will examine those processes that are key to the formation and evolution of ices, and present key studies to show how modern laboratory techniques are being used to study these processes.

I would like to acknowledge the work of my group at Syracuse University and the financial support by NSF through Astronomy Astrophysics Research Grants No.1615897 and No. 1311958.

F3.2-0020-18 FORMATION OF AMINO ACID PRECURSORS AND CARBOXYLIC ACIDS IN THE HADEAN EARTH'S ATMOSPHERE BY COSMIC RAYS AND SOLAR ENERGETIC PARTICLES FROM THE YOUNG SUN

Over the last 60 years, a large number of laboratory experiments have been perfomed to examine pathways of formation of bioorganic compounds such as amino acids in primitive Earth atmosphere. Earlier experiments with strongly reducing gas mixtures containing methane and ammonia exposed to spark discharges and ultraviolet light sources suggested efficient production of a number of biologicaly important amino acids. Since 1980s, however, it was estimated that the early Earth atmosphere was less reducing with N2 and CO2 as the major atmospheric constituents including small amount of reducing carbon species like CH4 and/or CO [2]. Simulation experiments suggested, however, that amino acid formation was restricted under these conditions [3]. Galactic and solar cosmic rays (also known as solar energetic particles, SEPs) are known as the sources of energetic particles penetrate the Eath's lower atmosphere and facilitate chemical reactions with atmospheric consituents. However these energy sources have been ignored in experiments with initiation of prebiotic chemistry [4]. Here, we examine possible formation of amino acids from slightly reducing gas mixtures by applying ionizing radiation to simulate the action of galactic and solar cosmic rays.

We condiucted three sets of laboratory experiments using energetic particles, spark discharge and UV light as dominant energy sources. In these sets of experiments we used 400 mL of gas mixture of N2, CO2 and CH4 introduced to a Pyrex tube together with 5 mL of pure water under 700 Torr total gas pressure with varied mixing ratios of CH4 and CO2. In the first set of experiments, the gas mixture was irradiated with 2.5 MeV proton beam produced in the Tandem accelerator at Tokyo Tech, Japan. In the second set we exposed the same composition of gas mixtures to spark discharges by using a Tesla coil to simulate lightning conditions during thunderstorms on Hadean Earth. In the third set of experiments, the gas mixtures were irradiated with UV light at (what wavelength range) produced by a xenon lamp. Each product was acid-hydrolyzed and was subjected to amino acid analysis by HPLC and GC/MS, both after derivatization. Carboxylic acids were determined by GC/MS after derivatization. Resulting gas mixtures were analyzed with a quadrupole mass spectrometer.

Amino acids were detected in the hydrolyzed products when gas mixtures of N2, CO2, CH4 and H2O were irradiated with 2.5 MeV protons at the initial the molar ratio of methane (rCH4) in the starting gas mixture as low as 0.5 %. This is in sharp contrast with our experiments under the spark discharge exposures when amino acids were detected only when rCH4 was greater than 15 %. The experiments with UV irradiation source did not yield amino acids or their precursors even when rCH4 reached 50 %.

Carboxylic acids including oxalic acid and glyoxylic acid were detected from unhydrolized products derived from N2-CO2 gas mixtures exposed to spark discharges and proton irradiation. We show that some free carboxylic acids could be formed in non-reducing atmospheres as well as slightly reducing atmospheres either by proton irradiation or by spark discharges. It was suggested that the mechanism of formation of amino acid precursors from N2-CO2-CH4-H2O mixtures was quite different from that of carboxylic acids.

Considering the availability of various sources of ionizing radiation fluxes on the primitive Earth, energetic protons appear to be an efficient factor to produce N-containing organics via abiotic nitrogen fixation than any other conventional energy sources like thundering or solar UV emission irradiated the early Earth atmosphere. The production of these energetic particles can be associated with galactic cosmic rays and solar energetic particle events (SEPs) associated with solar coronal mass ejections and superflares from the young Sun [6-8]. Our experiments appear to be in good agreement with the recent model of initiation of prebiotic chemistry including efficient production of HCN and N2O in the early Earth's atmosphere exposed to frequent SEP events associated with solar magnetic storms could have been efficient in supplying energy for efficient production of HCN and N2O [7]. Thus, solar energetic particle events could have promoted the production of bioorganic compounds in primitive Earth atmosphere. Further experimental studies on such effects are in progress.

F3.2-0021-18 HYDROGEN AND NITROGEN ISOTOPES FOLLOW DIFFERENT FRACTIONATION PATHWAYS IN STAR-FORMING CLOUDS

Kenji Furuya, furuya@ccs.tsukuba.ac.jp University of Tsukuba, Tsukuba, Japan Yuri Aikawa, aikawa@astron.s.u-tokyo.ac.jp University of Tokyo, Tokyo, Japan

Molecular isotope ratios are essential tools to investigate the origin of solar system materials and their possible chemical link with interstellar materials. The most primitive materials in the solar system, such as cometary ices, show the enrichment of both deuterium and 15N compared to the Sun. On the other hand, observations towards low-mass dense cores, where sun-like stars form, have found that molecules in the cold gas are highly enriched in deuterium, but do not show clear 15N enrichment. In particular, N2H+, which is a daughter molecule of N2 (i.e., possible main budget of gaseous nitrogen), is clearly depleted in 15N. It is unclear what the main 15N fractionation mechanism is, and why interstellar molecules in the gas phase tend to be depleted in 15N, while cometary volatiles are enriched in 15N.

In this presentation, we present results of a series of gas-ice astrochemical simulations including hydrogen and nitrogen isotopes, which traces the evolution from the formation of molecular clouds to protostellar cores. We find that nitrogen isotope fractionation mostly occurs in a molecular cloud by the combination of isotope selective photodissociation of N2 and ice formation. In the molecular cloud, where external UV radiation field is not fully shielded, N15N is selectively photodissociated w.r.t 14N2, which results in the enrichment of 15N in atomic nitrogen. As 15N-enriched atomic nitrogen is converted to ammonia ice and HCN ice via grain surface reactions, the bulk gas becomes depleted in 15N, while the icy species are enriched in 15N. Once external UV radiation field is sufficiently shielded (i.e., in dense cores), 15N fractionation does not proceed anymore and the molecular N/15N ratios established in the molecular cloud stage are largely conserved, because nitrogen isotope exchange reactions are not efficient even at 10 K. The 15N-rich ices could be eventually incorporated to protoplanetary disks, in which comets will form, while 15N is deficient in gases including N2H+ in dense cores. This situation is very different from deuterium fractionation; it is mostly driven by hydrogen isotope exchange reactions and becomes more efficient with time as long as temperature is cold. We compare the numerical results with the observations of dense cores and comets, and discuss possible observational tests for the 15N fractionation pathway.

F3.2-0022-18 MOLECULAR COMPLEXITY IN THE STAR FORMING REGIONS OF MAGELLANIC CLOUDS

Kinsuk Acharyya, kinsukacharyya@gmail.com Physical Research Laboratory, Ahmedabad, India Eric Herbst, ericherb@gmail.com

University of Virginia, Charlottesville, Virginia, United States

Recently, we studied chemical complexity in cold dense cores as well as hot core regions of the Large and Small Magellanic Clouds. These irregular satellite galaxies of Milky Way are metaland dust-poor, therefore, can serve as basic templates for the study of low metallicity early galaxies. Their relative proximity makes them excellent targets for observation. The dust temperature in these galaxies could also be higher compared with our Galaxy; this can have a profound effect on the synthesis of molecules in these galaxies. Our simulations show that both the cold, dense and hot core regions of LMC and SMC can exhibit rich chemistry. We found that important gas phase species, as well as water and CO2 ices, could be observed in abundant quantities. Our calculations show that some COMs can also be formed in reasonable amounts for hot cores in the Magellanic clouds when the initial grain temperature is lower than 25 K. In this presentation, I will discuss the complex organic molecules that are found in our Galaxy, and how their abundance varies in the Magellanic clouds. This comparison will help us to understand the role of metallicity and dust grain temperature in the formation of COMs.

F3.2-0023-18 DEUTERATION IN THE OUTFLOWS OF A LOW MASS PROTOSTAR SYSTEM HH212: AN ALMA OBSERVATION OF DEUTERATED FORMALDEHYDE

HH212, a nearby (400 pc) object in Orion, is a Class 0 protostellar system with a Keplerian disk and collimated bipolar SiO jets. Deuterated water, HDO and a deuterated complex molecule, methanol (CH2DOH) have been reported in the source. Here, we report the HDCO (deuterated formaldehyde)line observation from ALMA data to probe the inner region of HH212. We compare HDCO line with other molecular lines to understand the possible chemistry and physics of the source. The distribution of HDCO emission suggests it may be associated with the base of the outflow. The emission also shows a rotation but it is not associated with the Keplerian rotation of disk or the rotating infalling envelope, rather it is associated with the outflow as previously seen in C34S. From the possible deuterium fractionation, we speculate that the gas phase formation of deuterated formaldehyde is active in the central hot region of the low-mass protostar system, HH212.

F3.2-0024-18 IDENTIFICATION OF CANDIDATE MOLECULES FOR THE BUILDING BLOCKS OF LIFE'S EARLIEST POLYMERS

Nicholas Hud, hud@chemistry.gatech.edu

Georgia Institute of Technology, Atlanta, Georgia, United States

Chemists have yet to find a plausible prebiotic synthesis for RNA polymers, and most previously proposed mechanisms for prebiotic peptide synthesis are inefficient. We are exploring the hypothesis that RNA and polypeptides have both evolved from polymers with different chemical structures. We have found that molecules closely related to amino acids and the nucleobases of RNA, which were likely present on the prebiotic Earth, greatly facilitate the formation of polypeptides and RNA-like structures (Forsythe et al., 2015; Cafferty et al., 2017). The identification of molecules that may have served as precursors to the building blocks of extant polymers, or as prebiotic catalysts for biopolymer formation, has direct implications regarding which molecules that should be considered as possible signs of chemistries that can support the emergence of life in the universe. Furthermore, the possibility that life started with molecules that can be repeatedly cycled between their monomeric and polymeric states, as is still the case with extant biopolymers, suggests environmental characteristics that would have facilitated the formation and early evolution of functional biopolymers.

J. G. Forsythe, et al., Angew. Chem., Int. Ed. Engl., 2015, 54, 9871-9875. B. J. Cafferty, et al., Nature Commun. 2016, 7, 10.1038/ncomms11328.

Planetary water-rock interfaces generate free energy in the form of redox, pH, and thermal gra-dients; these gradients sustain life in terrestrial hydrothermal systems and are of great interest in the search for life on ocean worlds such as Europa and Enceladus. Sediments and chimneys pre-cipitated in hydrothermal systems formed by water-rock chemistry on the early Earth could have contained reactive minerals such as iron (-nickel) sulfides and iron oxyhydroxides (including green rust). These minerals may have promoted various reactions of interest to the emergence of life including amino acid synthesis, concentration and retention of organic products, phosphorus redox and polymerization, and rudimentary energetic processes by electrochemistry [1]. We have developed various experimental systems for simulating the effects of geochemical gradients on prebiotic reactions in seafloor / hydrothermal systems, including the formation and electrochemi-cal characterization of simulated hydrothermal chimneys and membranes, synthesis of reactive hydrothermal sediments over a range of pH / redox states, and concentration of phosphorus spe-cies in hydrothermal minerals. Vent systems constitute flow-through chemical reactors [2] and the suite of amino acids (or other organics) that may be found in a particular mineral system is determined by what is synthesized there, what is preferentially concentrated / retained there, and what is preserved against degradation under the ambient hydrothermal conditions. Consequently, the chemistry of organic and phosphorus species formed in vent systems would depend on the ad/absorptive capacity of the ambient minerals, and the mineral reactivity would correspondingly be affected by the presence of trace organic / phosphorus species. These emerging organic-mineral feedbacks in gradient systems, combined with the forced diffusion of products to encoun-ter different geochemical disequilibria in a porous sediment or chimney structure, warrant further experimental investigaton to determine how prebiotic chemistry may have proceeded on early Earth as well as ocean worlds.

F3.2-0026-18 PEPTIDE ORIENTED ORIGIN OF LIFE SCENARIO

Kosuke Fujishima, fuji@elsi.jp

Tokyo Institute of Technology, Tokyo, Japan

Life as we know is capable to harvest energy from surrounding environment and able to reproduce their organic constituents through chemical reaction sustained by metal-assisted polypeptides. Meanwhile evolvability of the system is maintained by exchange or vertical decent of genetic information carried by nucleotide polymers. Where and how did these polymers originated and integrated into the biological system? Are polymers able to bridge abiotic geochemical processes to biochemistry? To address these questions, I will overview several ongoing experimental approaches focusing on the abiotic synthesis of peptides in hydrothermal conditions, functionality of simple metallo-peptides and coevolution of peptides with RNA to understand the dynamic roles of peptides during the origin of life.

F3.2-0027-18 KINETIC MONTE CARLO SIMULATIONS OF ICE PROCESSING: FROM THE LAB TO INTERSTELLAR ENVIRONMENTS

Aspen Clements, ac8hq@virginia.edu

University of Virginia, Charlottesville, Virginia, United States
Brandon Berk, berkb@heritage.edu

Virginia, United States

Ilsa Cooke, irc5zb@virginia.edu Virginia, United States

Robin Garrod, rgarrod@virginia.edu

University of Virginia, Charlottesville, United States

Ices make up a critical component of the chemistry in various star-forming sources, including pre-stellar cores and protoplanetary disks. During the star-formation process, ices composed of simple molecules build up on the surfaces of interstellar dust grains. These ices are thought to be the precursors of complex organic molecules (COMs) that may later be delivered to planetary bodies and comets. The formation of molecules on grain surfaces, and the subsequent production of COMs, has been demonstrated in laboratory experiments. However, interstellar physical conditions can never be exactly reproduced, and the timescales are vastly different (minutes in the lab versus many thousands of years in the ISM), making the correspondence of the two regimes highly uncertain.

Here we use the off-lattice Monte Carlo kinetics model MIMICK to investigate the effects that various deposition parameters have on laboratory ice structures, and extend the study to interstellar conditions. We reproduce experimental trends in the density of amorphous solid water (ASW) for varied deposition angle, rate and surface temperature; ice density decreases when the incident angle or deposition rate is increased, while increasing temperature results in a more-compact water ice. Extrapolation of the model to conditions appropriate to protoplanetary disks, in which direct accretion of water from the gas-phase may be the dominant ice formation mechanism, indicate that these ices may be less porous than laboratory ices.

We extend our study to include a warm up phase like those used in temperature programmed desorption (TPD) experiments, where a mixed molecular ice is heated and thermal desorption is monitored. These experiments show CO has a unique desorption profile upon heating, caused by diffusion and subsequent trapping of CO in the porous water structure. We have utilized the model to replicate these TPD experiments and have found similar behavior is replicated, with CO trapped and released at high temperatures (60 K). The behavior of the system can be directly extrapolated to interstellar conditions using the same chemical code.

F3.2-0028-18 SIMULATIONS OF COMPLEX ORGANIC MOLECULE CHEMISTRY IN HOT CORES WITH AN IMPROVED THREE-PHASE MODEL

Liao Ling, liaoling@xao.ac.cn

Xinjiang Astronomical Observatory, CAS, Urumqi, China

Photodissociation and bulk diffusion are very important to the formation of intersteller complex organic moleculars(COMs). Motivated by the “multilayer” model and microscopic Monte Carlo model,we modified the “multilayer” model by added some mantle reactions include photodissociation and interstial diffusion. The self-shielding effects of CO and H2 ,reaction desorption and an accelerate Monte Carl algorithm are also included in our models. This new fully three phase model was used to simulate the process of chemistry in hot cores, including cold collapse stage and warm-up to 400K stage. Glycine(NH2CH2COOH) and related species, have possible to present in hot cores, are included in the network.The result show that abundant radicals are produced in mantle phase during the collapse stage, and when temperature increase radicals can diffuse and reaction to produce COMs in mantle phase. Methyl formate and dimethyl ether producted in mantle phase occurs over temperature 30-80K.Glycine produced in mantle phase occurs over temperature 70-130K.In addition, we study the effect of ratio of photodissotiation produce species enter to interstial phase (alpha) and the ratio of diffusion energy and desorption energy (Eb/Ed) for mantle phase on the formation of COMs. The result show that the COMs increase with the alpha grow(but only a little bit).When alpha equal to 0.5 and Eb/Ed equal to 0.7 ,the model can reproduce the observation results.

F3.2-0029-18 CHEMICAL EVOLUTION: ROCKS AND MINERALS AND THE CHEMISTRY OF LIFE'S ORIGIN

Stefan Fox, stefan.fox@uni-hohenheim.de

Institute of Chemistry, University of Hohenheim, Stuttgart, Germany

Our current understanding is that the first life forms came into existence through chemical evolution. About four billion years ago, the number, amount and complexity of abiotic organic molecules on Earth continuously grew, ultimately leading to the first protometabolisms. Already hundreds of minerals were present on Earth at this time [1]. It has been shown in laboratory simulation experiments that minerals could have played an important role in organic chemical evolution by protecting organic molecules against ultraviolet radiation and by altering organic reactivity. The evolutionary effectiveness of minerals in altering organic molecule reactivity has been demonstrated with the amino acid glycine. In the absence of minerals, heating of glycine resulted in a black polymer, while glycine that was intercalated in silicates—under otherwise identical conditions—gave oligopeptides [2, 3].

Other minerals are also important to the topic. Magnetite, for example, is involved in reactions that can proceed in deep-sea hydrothermal systems. It is produced in serpentinization reactions and can also act as a catalyst in Fischer-Tropsch syntheses. There has been debate over whether deep-sea hydrothermal systems are more of a source or sink for abiotic organic molecules. Minerals may have also played a key role in the origin of biological homochirality. Quartz and calcite, for example, form enantiomorphic and scalenohedral crystals, respectively. Prebiotic chiral molecules may have been enantioselectively adsorbed onto the mirror-image faces of such minerals.

Minerals could have provided metal ions to abiotically formed porphyrins [4] and metalloprotein precursors. Our laboratory experiments strongly indicated that prebiotic metal porphyrin complexes could have formed by the interaction of porphyrins with metal ions from minerals (e.g., Fe^{2+}). These complexes were potential early functional analogues of cytochromes and other proteins.

The study of the chemical evolution of glycine in the interstellar medium is one of challenging topics in astrochemistry. In this conference, we present the chemical modeling of glycine in hot cores using the state-of-the-art three-phase chemical model NAUTILUS, which is focused on the latest glycine chemistry. For the formation process of glycine on the grain surface, we obtained consistent results with previous studies that glycine would be formed via the reactions of COOH with CH2NH2. However, we will report three important findings regarding the chemical evolution and the detectability of interstellar glycine. First, with the experimentally obtained binding energy from the temperature programmed thermal desorption (TPD) experiment, large part of glycine was destroyed through the grain surface reactions with NH or CH3O radicals before it fully evaporates. As a result, the formation process in the gas phase is more important than thermal evaporation from grains. If this is the case, NH2OH and CH3COOH rather than CH3NH2 and CH2NH would be the essential precursors to the gas phase glycine. Secondly, since the gas phase glycine will be quickly destroyed by positive ions or radicals, early evolutionary phase of the hot cores would be the preferable target for the future glycine surveys. Thirdly, we suggest the possibility that the suprathermal hydrogen atoms can strongly accelerate the formation of COOH radicals from CO2, resulting in the dramatic increase of formation rate of glycine on grains. The efficiency of this process should be investigated in detail by theoretical and experimental studies in the future.

F3.2-0031-18 AN EXTENDED PUBLIC DEUTERIUM FRACTIONATION MODEL FOR THE ASTROCHEMICAL COMMUNITY

Deuterated species are unique and powerful tools in astronomy since deuterium-to-hydrogen (D/H) enrichment in molecular species provides clues about their original environment of formation, chemistry, and the ionization level of the medium. But the study of the deuterium chemistry is a challenging task because of the limited number of accurately determined rate coefficients and the sheer number of hydrogen-dominated reactions in astrochemical networks. Here, we will present a new extended publicly available deuterium fractionation model available in KIDA database which includes ortho/para chemistry of major protonated species.

We will try to highlight the following key questions:

How observing few selected deuterated species can be a very effective tool to characterize cold and dark media where most molecules are depleted?

Does spin chemistry change the deuterium enrichment of the ISM?

Prediction for future observations for deuterated species in dense cores and protoplanetary disks.

We will also show and discuss our recent observation to measure the D/H ratio of c-C3H2 in cold envelope of IRAS 16293-2422 as an application. We will also show our prediction to map the D/H ratio of essential molecules in protostellar envelopes and disks using ALMA (and ngVLA in the future).

F3.2-0032-18 EFFECT OF STOCHASTIC GRAIN HEATING ON COLD DENSE CLOUDS CHEMISTRY

Long Fei Chen, chenlongf@xao.ac.cn

Xinjiang Astronomical Observatory, Chinese Academy of Sciences, Urumqi, Xinjiang, China, China

The size and temperature of the dust grain plays an important role in the chemistry of molecular clouds. For a typical dust grain size (0.1 mum), its temperature keeps a constant value. However, due to the distribution of dust grain size in the molecular clouds, the temperature of small dust grains can reach a higher level because of the interaction with the interstellar radiation field. We considered a set of dust grain radius using the classical MRN grain size distribution, and using the Monte Carlo method to stimulating the real-time dust grain's temperature fluctuation, and applying it to a fully gas/grain reaction network. Finally, we present the time-dependent abundances of the gas-phase and grain surface species.

F3.2-0033-18 THE ESO DIFFUSE INTERSTELLAR BAND LARGE EXPLORATION SURVEY: FIRST RESULTS.

Jan Cami, jcami@uwo.ca

University of Western Ontario // SETI Institute, London, Canada
The EDIBLES consortium

Jan Cami, Nick L.J. Cox, Amin Farhang, Jonathan Smoker, Meriem Elyajouri, Rosine Lallement, Xavier Bacalla, Neil H. Bhatt, Emeric Bron, Martin A. Cordiner, Alex de Koter, Pascale Ehrenfreund, Christopher J. Evans, Bernard H. Foing, Atefeh Javadi, Christine Joblin, Lex Kaper, Habib G. Khosroshahi, Mike Laverick, Franck Le Petit, Harold Linnartz, Charlotte C.M. Marshall, Ana Monreal-Ibero, Giacomo Mulas, Evelyne Roueff, Pierre Royer, Farid Salama, Peter J. Sarre, Keith T. Smith, Marco Spaans, Jacco Th. van Loon

The ESO Diffuse Interstellar Band Large Exploration Survey (EDIBLES) is Large Programme that is collecting high-signal-to-noise (S/N) spectra of a large sample of O and B-type stars covering a large spectral range using the UVES spectrograph mounted on the Very Large Telescope (VLT). The goal of the programme is to extract a unique sample of high-quality interstellar spectra from these data that represent different physical and chemical environments, and to characterise these environments in great detail. An important component of interstellar spectra are the diffuse interstellar bands (DIBs), a set of hundreds of unidentified interstellar absorption lines that are commonly found in the spectra of reddened targets. With the detailed line-of-sight information derived from these high-quality spectra, EDIBLES will derive strong constraints on the potential DIB carrier molecules. EDIBLES will thus guide the laboratory experiments necessary to identify these interstellar "mystery molecules", and will turn the DIBs into powerful diagnostics of their environments in our Milky Way Galaxy and beyond. Here, we will present some of our first results showing the unique capabilities of the EDIBLES programme.

F3.2-0035-18 ROLE OF METAL OXIDES IN CHEMICAL EVOLUTION: INTERACTION OF VALINE AND GLYCINE WITH ALUMINUM, IRON AND ZINC OXIDES

Brij Tewari, brijtew@yahoo.com

University of Guyana, George Town, Guyana

Amino acids are essential components of living matter and the description of their initial polymerization to form peptides remains a major problem in establishment of reasonable origins of life scenario [1]. It has been proposed [2] that the prebiotic polymerization of the amino acids occurred in the absorbed state on mineral oxide surfaces because the reaction is thermodynamically unfavourable in aqueous phase. This could have occurred at the surface of the primitive earth and/or on interstellar space. Amino acid adsorption on mineral surfaces has attracted much interest because mineral surfaces may have played important role in prebiotic peptide bond formation [3]. The present work described interaction of amino acids (glycine and valine

) with alumina (acidic, basic and neutral), iron and zinc oxides. Glycine showed higher adsorption on all adsorbents in comparison to valine. Adsorption of amino acids on metal oxides surface follow the order: Alumina > iron oxide > zinc oxide. On alumina adsorption follow the order acidic > neutral > basic. Adsorption data obtained followed Langmuir adsorption isotherm and b and Qo values were calculated. Result of present study may indicate the importance of alumina in concentrating organic molecules form dilute aqueous solution in primeval seas during the course of chemical evolution on primitive earth. Detail will be presented. References: 1. Lambert J.F., Adsorption and polymerization of amino acid on mineral surfaces, Orig. Life Evol. Biosph. 39 (2009) 247. 2. Bernal, D. F3.2-0036-18 FORMATION OF COMPLEX ORGANIC MOLECULES IN COLD ENVIRONMENTS

Mi Wha Jin, mj2ua@virginia.edu

University of Virginia, Charlottesville, Virginia, United States Robin Garrod, rgarrod@virginia.edu

University of Virginia, Charlottesville, United States

According to the currently known scenario of complex organic molecules (COMs) formation, the COMs mainly form on the interstellar dust particles rather than in the gas-phase, and are effectively synthesized at temperature above 20-30 K due to immobility of heavy species at lower temperature. However, it has been observed in the past several years that some COMs actively form even at temperature as cold as 10 K, challenging the previous formation scenario. This research aims to address a new formation mechanism, so-called excited formation, by modeling the chemical evolution of acetaldehyde (CH_3CHO) in this cold environment. The following text suggests that the acetyl, the precursor of CH_3CHO, is synthesized by hydrogenation of CH_2 situated on top of a surface CO molecule. This significantly enhances a population of CH_3CHO in the cold environment, successfully reproducing the observational results, and application of this mechanism to other COMs (e.g. methyl formate) is being tested. Once this new mechanism is confirmed, more generalized scenario of COM formation can be provided, which is of considerable interest to the study of origins of life.

F3.2-0037-18 HYDROGENATION AND DEHYDROGENATION OF SUBSTITUTED BENZENE RINGS IN ASTROPHYSICAL ICE ANALOGS

Since the detection of methylidyne (CH) in 1937, more than 200 different molecules have been identified in the interstellar (ISM) and circumstellar (CSM) media. Some of these molecules freeze out at the cold temperatures (10-20 K) of such environments, leading to the forma- tion of molecular ices on the surface of dust grains. This provides extraordinary conditions for the formation of complex organic molecules (COMs), which could be produced by chemical transformation processes catalyzed by external agents, such as cosmic rays, photons and charged particles. In this context, ionization, fragmentation and protonation of molecules could occur, leading to the formation of distinct neutral, ionized and radical species, eventually enriching the gas phase with COMs after desorption processes. In this study, we use the electron-stimulated ion desorption (ESID) technique to determine the positively charged fragments desorbed from pure benzene (C6H6), chlorobenzene (C6H5Cl) and cyclohexane (C6H12)

astrophysical ice analogs. The samples are condensed at 125 K into a ultrahigh vacuum (UHV) chamber at 10−9 mbar base pressure. The ices are then bombarded by a focused electron beam of 2.3 keV. The positively charged ions desorbed from the ices are analyzed using the time-offlight mass spectrometry (TOF-MS) technique. Among the produced C6H+ species, we show that benzene and chlorobenzene present a remarkable resemblance: in both cases the protonated benzene ion (C6H+) is predominantly formed, and dehydrogenation is observed as far as the formation of the cyclohexatriyne cation, C+. Apart from dehydrogenation, we also observe that both molecules are capable of forming hydrogenated products up to the complete loss of aromaticity on the carbon ring, resulting in the production of the cyclohexane cation (C6H+) and the protonated cyclohexane (C6H12H+) species. For chlorobenzene, C6HnCl+ species are observed for n = 0 11, and the hydrogenation leads preferentially to C6H8Cl+ and C6H10Cl+. For cyclohexane ices, we show that the hydrogenation process is effective up to the formation of C6H+, evidencing a ring opening mechanism activation after electron impact. Finally, quantum chemical calculations are used to elucidate the ground state and low-lying isomers of the most produced molecular ions. We suggest that highly hydrogenated molecules, such as alkanes and cycloalkanes, could be formed in the ISM and CSM as desorption products of benzeneand substituted benzene-rich astrophysical ices.

F3.2-0038-18 SERACH FOR PROPARGYL ALCOHOL IN THE INTERSTELLAR MEDIUM

Propargyl alcohol (HC2CH2OH, PA) has yet to be observed in the interstellar medium (ISM) although one of its stable isomers, propenal (CH2CHCHO), has already been detected in Sagittarius B2(N) with the 100-meter Green Bank Telescope in the frequency range 18 26 GHz. In this work, we investigate the formation of propargyl alcohol along with one of its deuterated isotopomers, HC2CH2OD (OD-PA), in a dense molecular cloud. Various pathways for the formation of PA in the gas and on ice mantles surrounding dust particles are discussed. We use a large gas-grain chemical network to study the chemical evolution of PA and its deuterated isotopomer. Our results suggest that gaseous HC2CH2OH can most likely be detected in hot cores or in collections of hot cores such as the star-forming region Sgr B2(N). A simple LTE (Local thermodynamic equilibrium) radiative transfer model is employed to check the possibility of detecting PA and OD-PA in the millimeter-wave regime. In addition, we have carried out quantum chemical calculations to compute the vibrational transition frequencies and intensities of these species in the infrared for perhaps future use in studies with the James Webb Space Telescope (JWST).

F3.2-0039-18 STUDIES ON KNOWN AND POTENTIAL INTERSTELLAR PROTONATED MOLECULAR SPECIES

Majority of the known interstellar cations are protonated species believed to be the natural precursors for their corresponding neutral analogues formed via the dissociative recombination process. The protonation of a neutral species can occur in more than one position on the molecular structure thus resulting in more than one proton binding energy value and different protonated species for the same neutral species. In the present work, ab initio quantum calculations are employed to calculate accurate proton binding energies for over 100 neutral interstellar molecules of which majority of the neutral molecules are protonated in more than one position. From the results, protonated species resulting from a high proton binding energy prefers to remain protonated rather than transferring a proton and returning to its neutral form as compared to its analogue that gives rise to a lower proton binding energy (PBE) from the same neutral species. For two protonated species resulting from the same neutral molecule, the one that results in a higher PBE is more stable as compared to its counterpart that is responsible for the lower PBE for the same neutral species. Here, the most stable species are highlighted for all the systems considered.

F3.2-0040-18 ACHIEVING ACCURATE ROTATIONAL CONSTANTS FOR LINEAR CARBON CHAINS OF ASTROPHYSICAL INTEREST

Emmanuel Etim, emmaetim@gmail.com

Federal University Wukari, Taraba State, Nigeria, Wukari, Nigeria
Elangannan Arunan, arunan@iisc.ac.in

India

Linear carbon chain molecular species remain the dominant theme in interstellar chemistry. Their continuous astronomical observation depends on the availability of accurate spectroscopic parameters. Accurate rotational constants are reported for hundreds of molecular species of astrophysical, spectroscopy and chemical interests from the different linear carbon chains; CnH, CnH, CnN, CnN, CnO, CnS, HCnS, CnSi, CH3(CC)nH, HCnN, DC2n+1N, HC2nNC, and

CH3(C C)nCN using three to four moments of inertia calculated from the experimental rotational constants coupled with those obtained from the optimized geometries at the Hartree Fock level. The calculated rotational constants are obtained from the corrected moments of inertia at the Hartfree Fock geometries. The calculated rotational constants show accuracy of few kHz below irrespective of the chain length and terminating groups. The obtained accuracy of few kHz places these rotational constants as excellent tools for both astronomical and laboratory detection of these molecular species of astrophysical interest. From the numerous unidentified lines from different astronomical surveys, transitions corresponding to known and new linear carbon chains could be found using these rotational constants. The astrophysical, spectroscopic and chemical implications of these results will be presented. Keywords: Astrochemistry, Molecules, Spectroscopy, Carbon-chains

Oxidants are omnipresent in the solar system. They play a central role in the habitability of Mars and serve as tracers of energetics at the surfaces of the icy Galilean satellites. Hydrogen peroxide detected in the surface ice of Europa, Ganymede and Callisto by Galileo [1,2] most likely results from the impact of radiation. On Mars, oxidants have been implicated in the destruction of surface organics since the time of Viking in 1976 [3] and more recently, in the occurrence of (water-driven) recurring slope lineae [4]. Hydrogen peroxide was first detected in the martian atmosphere in 2003 [5,6], and perchlorates were first detected in the surface of Mars in 2008 by Phoenix in the polar region [7] and in the equatorial region by MSL/SAM in 2012 [8,9]. Homogeneous gas phase photochemistry, possibly aided by heterogeneous processes

[10] and electrochemistry [11] on airborne dust, results in the formation of peroxide in the atmosphere. While current techniques do not permit detection of peroxide in the martian surface, it is expected to be present in the surface and the regolith due to diffusion from the atmosphere [12] and radiolysis-initiated mineral chemistry in the surface [13]. The commonly accepted mechanism for the bulk of perchlorate production on Earth is photochemistry in the atmosphere [14]. That same mechanism fails at Mars, however. Alternate mechanisms proposed for Mars are formation in an ancient aqueous environment [15] and radiolysis of chlorine containing surface ice [16]. The latter mechanism seems more favorable for perchlorate formation on Mars [17], but further laboratory and modeling work is most desirable. References: [1] Carlson, R.W et al. F3.3-0002-18 ENVIRONMENTAL OBSERVATIONS OF PRESENT DAY MARS AND IMPLICATIONS FOR HABITABILITY

María-Paz Zorzano, zorzanomm@cab.inta-csic.es Centro de Astrobiologia (CSIC-INTA), Madrid, Spain Javier Martin-Torres, javmar@ltu.se

Lulea University of Technology, Luleå, Sweden

The history of life on Earth, as we known it, began about 3.8 billion years ago, initially with single-celled life forms that evolved to the variety of life forms that we know now. As for Mars, it has been recently concluded, based on the observations of NASA,s Curiosity rover at Gale crater, near the equator of Mars, that the physical, chemical, and energy conditions that were required to establish a habitable environment were present on Mars between 3.8 billion and 3.1 billion years ago [Hurowitz et al. 2017]. However, the habitability of present day Mars is still open to debate. An environment is defined as habitable if it is capable of supporting the activity (metabolic activity for survival, growth, and reproduction) of at least one organism [Cockell et al. 2016]. In order to investigate the present-day habitability of Mars, we review the Curiosity observations at Gale crater of the environmental and regolith properties that may affect life, based on our knowledge of life on Earth. We analyse the potential present day habitability of Mars as constrained by temperature, cosmic radiation, UV radiation, presence of carbon compounds, nitrogen, phosphate minerals, and Fe and S minerals, in a variety of redox states within the regolith, and, in particular, we discuss where and when liquid may be transiently stable on present day Mars [Martín-Torres et al. 2015]. We discuss where in the surface or subsurface of Mars life could exist and obtain energy from photosynthesis or chemosynthesis. Based on these parameters we discuss about the kind of instrument and sample measurements that may be required to assess unequivocally the habitability of present day Mars and the implications that this may have on the future exploration of Mars.

Since 1969 when Pimental first observed [1] what he thought was high amounts of methane in the martian atmosphere, the planetary science community and the public have been fascinated with the possibility that by analogy with Earth, the existence of Mars methane may be a signature of biological production [2]. Subsequent observations by Earth telescopes, orbiting spacecraft and a surface rover have been highly varied, puzzling and unpredictable: Mars methane has been a story of continued surprises and controversy.

We will review the observations of Mars methane to date, including ground-based observations of Krasnopolsky [3], the plumes seen by Mumma [4], the orbital measurements from Mars Express [5,6], and the more recent measurements from the Tunable Laser Spectrometer (TLS) instrument in the Sample Analysis at Mars (SAM) suite on the Mars Science Laboratory's Curiosity rover [7]. The TLS-SAM measurements have followed the theme of Mars methane in being surprising and disagreeing with models for both the background amounts and the high spikes sporadically observed. However, for the first time observations of Mars methane show repeatable seasonal variations that offer a mechanism for understanding and modeling the generation, transport and loss of this enigmatic gas. Sources and sinks will be carefully reviewed in light of contributions from possible microbial production, geophysical and chemical sources, surface uptake and release [8] and how atmospheric transport may play a crucial role as evidenced from the latest high-resolution wind-field modeling [9].

The detection of “fixed” nitrogen on Mars in the form of nitrate by the Sample Analysis at Mars (SAM) instrument suite on the Mars Science Laboratory (MSL) Curiosity Rover [1] has major implications for martian habitability. “Follow the nitrogen” has been proposed as a strategy in the search for both extant and extinct life on Mars [e.g., 2]. Nitrogen is so crucial to life on Earth that life developed metabolic pathways to break the triple bond of N2 and “fix” atmospheric nitrogen to more biologically available molecules for use in proteins and informational polymers. Sequestration of nitrate in regolith has long been predicted to contribute to the removal of N from the martian atmosphere [e.g., 3], and our detections confirm that nitrogen fixation was occurring on ancient Mars. But was this fixed N transformed once deposited, and if so, by what mechanism? An indicator of more complex chemistry would be reduced N, which has, as yet, not been definitively detected on Mars [4]. For example, reduced N in the form of NH3 or NH4+ would suggest reduction of nitrate by Fe(II) [5], or even biological fixation or ammonification of atmospheric N. Understanding our detections of nitrogen, particularly within the context of the habitable environment in Yellowknife Bay characterized by the MSL payload, is crucial to assess whether life ever could have existed on ancient Mars. We present 5+ years of analyses and interpretation of nitrate in solid martian drilled and scooped samples by SAM on MSL. Nitrate abundance reported by SAM in situ measurements ranges from non-detection to 681 ± 304 mg/kg [1,6] in the samples examined to date. The measured abundances are consistent with nitrogen fixation via impact generated thermal shock on ancient Mars and/or dry deposition from photochemistry of thermospheric NO. We review the integration of SAM data with terrestrial Mars analog work in order to better understand the timing of nitrogen fixation and mobility of nitrogen on Mars, and thus its availability to putative biology. In particular, the relationship between nitrate and other soluble salts, such as perchlorate, may help reveal the timing of nitrogen fixation and post-depositional behavior of nitrate on Mars [6]. We also discuss potential evidence from SAM data for reduced nitrogen compounds [7]. Finally, we discuss how a comparison of isotopic composition (delta15N) of nitrate with delta15N of atmospheric nitrate (delta15N 574‰, [8]) could to constrain atmospheric loss of N2 and model the evolution of the atmosphere on Mars.

In situ analyses of lacustrine mudstones (Murray formation) at Pahrump Hills, Gale crater, Mars show the presence of alkyl, aromatic, and sulfur-bearing organic volatiles upon heating to 500-860°C, as detected by the Sample Analysis at Mars (SAM) instrument suite onboard the Mars Science Laboratory's Curiosity rover. Organic-sulfur compounds, including thiophenes, dimethylsulfide and thiols were identified by gas chromatography-mass spectrometry (GCMS) and indicated in evolved gas analyses (EGA). Aromatic and alkyl hydrocarbon components were indicated by EGA. The molecular distributions observed are specific to samples and cannot be explained by SAM's instrument background. The EGA observations are at temperatures consistent with the pyrolytic cleavage of organic fragments from large molecules (macromolecules) indigenous to the mudstones, and some portion could be derived from the thermal release of organics entrained within minerals

Given that the release of organic-sulfur compounds occurs at high temperatures in the SAM oven, these compounds are most likely derived from sulfurized organics in the sediments and are not an artifact of sulfurization reactions in the oven. On Earth, sulfurization is a key process that aids organic matter preservation over geological time-scales by converting organic molecules into recalcitrant macromolecules. Organic matter of the lowermost Murray formation most likely underwent sulfurization either prior to deposition or during early diagenesis.

Multiple factors likely attribute to organic preservation in the Gale crater mudstones, however, sulfurization may be largely responsible for the greater abundance and the molecular diversity observed in the lower Murray formation.

F3.3-0006-18 THE INSTRUMENT HABIT (HABITABILITY, BRINE IRRADIATION AND TEMPERATURE) ON THE EXOMARS PLATFORM

Javier Martin-Torres, javmar@ltu.se

Lulea University of Technology, Luleå, Sweden María-Paz Zorzano, zorzanomm@cab.inta-csic.es

Centro de Astrobiologia (CSIC-INTA), Madrid, Spain

HABIT (HabitAbility, Brine Irradiation and Temperature) is an edge-breaking and multipurpose instrument: it is a surface station devoted to evaluating the habitability of Mars, but also an In-situ Resource Utilization instrument for future Mars exploration.

The search for present life and habitability on Mars is conditioned by the availability of liquid water. It has recently been shown that liquid water is stable on Mars in the form of brines [Martín-Torres et al., Nature Geoscience 2015]. Two other environmental conditions constrain the habitability of the near surface of Mars, the thermal range and the UV radiation dose [Rummel et al. Astrobiology, 2014]. The HABIT (HAbitability, Brine Irradiation and Temperature) instrument is dedicated to investigating the habitability on present day Mars by quantifying the availability of liquid water, the thermal ranges and UV doses. It includes the BOTTLE (Brine Observation Transition To Liquid Experiment) compartment to capture at night-time atmospheric water by deliquescence of four different types of salts: calcium perchlorate, magnesium perchlorate, sodium perchlorate and calcium chloride, and 3 environmental sensors devoted to monitoring the full diurnal and seasonal variations of the ground and air temperature, and the UV irradiance. These three sensors shall complement the existing environmental package of the spacecraft, which has Pressure and Relative Humidity sensors.

HABIT measurements will allow to constrain the habitability at the landing site in terms of metabolic and reproduction temperature, calculating the heat-flux and the UV biological dose, providing the Relative Humidity of the ground and air, to study the atmosphere/surface water interchange, provide information about winds (which shall be useful also for the rover drilling and sampling operations), and about thermal inertia and subsurface thermal profile and hydration level complementing the studies of the other platform and rover instruments. It will also provide the concentration of the atmospheric trace gas ozone (complementing orbiter observations from NOMAD-Trace Gas Orbiter) and atmospheric UV opacity (providing continuous monitoring of the dust cycle). The BOTTLE unit is furthermore designed as an ISRU (In-situ Resource Utilization) demonstrator that shall quantify the amount of water (and derived products such as H2 and O2) available for future landed missions on Mars. HABIT will provide environmental information that will allow for extra-long term climate and atmospheric monitoring and will measure for the first-time liquid water on Mars in a controlled way, while providing ISRU possibilities.

F3.3-0007-18 HABITABLE CONDITIONS ON MODERN MARS MOTIVATE A SEARCH FOR LIFE MISSION.

Carol Stoker, carol.stoker@nasa.gov

NASA/ARC, Moffett Field, California, United States Chris McKay, christopher.p.mckay@nasa.gov

NASA Ames Research Center, Wyoming, United States

The 2008 Phoenix Mars lander mission sampled ground ice at 68oN latitude. Mission results, considered along with climate modeling studies, suggest that high latitude ice-rich regolith at low elevations is habitable for life[1]. This talk will review the evidence and describe a low cost life search mission to search for modern life on Mars. The Phoenix lander dug with a robotic arm to reveal an ice table near the surface. Evidence for liquid water processes was observed including: 1) beneath 3-5 cm of dry soil, segregated pure ice was discovered in patches covering 10% of the area explored, 2) pure calcite mineral, which forms under aqueous conditions, was detected in the soil, 3) perchlorate salt, highly soluble in liquid water, was observed at varying concentrations with higher concentrations seen in soil clods[2]. Carbon and nitrogen sources are available to support chemoautotrophic metabolism. The Thermal Evolved Gas Analysis (TEGA) instrument searched for soil organics but perchlorate was discovered in the soil[3]; any organic carbon in the soil would not have been detectable due to reaction with perchlorate during the heating step used for releasing volatiles. While current climate conditions are too cold to support metabolism, climate modeling studies[4] show that variations in solar insolation associated with changes in the season of perihelion occurring on 25 kyr timescales and obliquity variations on 125 kyr timescales[5] cause warmer and colder periods to occur in the N. polar region. The current epoch is cold because orbital tilt is low and summer occurs at apehelion. As recently as 17 kyr ago, when summer solstice was at perihelion, temperatures were warm enough to allow pure liquid water to form at the surface[4]. At orbital tilts > 35o, insolation is equivalent to levels experienced in Earth's polar regions at the present time. At 45o temperatures allowing microbial growth persist to 75 cm depth[6]. Terrestrial permafrost communities are an example of possible life in the ice-rich regolith. Studies in permafrost have shown that microorganisms can function in ice-soil mixtures at temperatures as low as - 20oC, living in the thin films of interfacial water[7]. In addition, it is well established that ground ice preserves living cells, biological material, and organic compounds for long periods of time, and living microorganisms have been preserved under frozen conditions for thousands and sometimes millions of years[8]. If life survives in these areas, growing when conditions allow, biomolecular evidence of life should accumulate in the soils. The presence of habitable conditions on Mars that persist over geological timescales to the present suggests that searching for biochemical evidence of modern life is warranted. The Mars Icebreaker Life mission[9] was proposed with that goal to the NASA Discovery call in 2015 and a future proposal is planned. The mission plans to land in high latitude ice rich terrain with a payload designed to address the following science goals: (1) search for biomolecular evidence of life; (2) search for organic matter from either exogeneous or endogeneous sources using methods not impacted by the presence of perchlorate;

(3) assess the habitability of the ice bearing soils. The Icebreaker Life payload features a 1-m drill to auger subsurface icy material to the surface where it is delivered to payload instruments. Three instruments were proposed in Discovery 2015: The Signs of Life Detector (SOLID)[10] uses immunoassay to search for up to 300 biomolecules that are universally present and deeply rooted in the tree of Earth life. The Laser Desorption Mass Spectrometer (LDMS)[11] performs a broad search for organic compounds of low to moderate molecular weight with either biological or cosmogenic origin. The LDMS method is not impacted by the presence of perchlorate. The Wet Chemistry Laboratory (WCL) [3] detects soluble species of potential nutrients and reactive oxidants, providing insight into the habitability potential of icy soils. The Icebreaker payload fits on the same spacecraft/ lander used by Phoenix. The mission can be accomplished for modest cost, searching for a record of modern life on Mars while meeting planetary protection requirements.

F3.3-0008-18 MID-IR SPECTROSCOPY OF PERCHLORATES

David Summers, david.p.summers@nasa.gov

SETI Institute/NASA Ames Res. Center, Moffett Field, California, United States Richard Quinn, richard.c.quinn@nasa.gov

NASA/ARC, Moffett Field, United States Virginia Gulick, vgulick@seti.org

SETI Institute/NASA Ames Res. Center, Moffett Field, California, United States

The presence of perchlorates and other oxyhalides on Mars needs to be considered in the context of habitability and the preservation of biomarkers on Mars. It has been suggested that "activated halides" could play a role in the oxidizing nature of martian soils. More recently, perchlorate was recognized by researchers as one of a number of oxidized salts present in the Atacama Desert, but the roles of perchlorate and perchlorate formation as they may relate to the presence and preservation of organics on Mars have not been thoroughly explored. Following the discovery of perchlorate on Mars during the Phoenix Mission, products formed by perchlorate radiolysis were shown to reproduce the results of the Viking Biology Experiments. The reactive intermediates and secondary products that are formed in processes that generate and decompose perchlorate may have significant impacts on the chemistry of surface materials, soil habitability, preservation of biomarkers, and the ability to analyze organics.

The recent detection of perchlorate, and likely other oxychlorine species, in the subsurface (5cm) of ancient sedimentary deposits by MSL indicates that the formation and presence of reactive oxidants on Mars may not be limited to UV-processes in the regolith, as previously suggested. Results suggest that there are major spatial variations in oxidant distributions, even for samples collected in very close proximity (e. g., MSL John Klein and Cumberland samples). Data indicate the presence of different types of perchlorates, other oxychlorine species, and possibly other oxidants including ROS. Suggesting that the chemical alteration of geological materials is more extensive and complex than previously thought.

To support the detection and characterization of perchlorates on Mars, K+, Na+, Ca2+, Mg2+, Fe2+, Fe3+, and Al3+ perchlorate salts were studied to provide spectral data for detecting and characterizing their possible presence. To extend earlier work to the mid-IR, they were characterized by IR microscopy and Raman spectroscopy). This included anhydrous samples, samples with adsorbed water, and samples exposed to humidity during analysis to observe changes. With divalent cations, changes during hydration of peaks due to water at 1600 cm^2– and 5100-5200 cm^2– showed evidence of different peaks and different states.

F3.5-0001-18 COMPUTATIONAL STUDY OF THE FORMATION AND DETECTION OF PREBIOTIC MOLECULES IN ASTROPHYSICAL ENVIRONMENTS

Timothy Lee, timothy.j.lee@nasa.gov

Ames Research Center, NASA, Moffett Field, California, United States

In recent years, our group has studied the formation mechanisms of the various RNA and DNA bases (Uracil, Cytosine, Thymine, Guanine, and Adenine) in mixed water ices seeded with either pyrimidine or purine and irradiated under astrophysical conditions. Our computational studies have been used to interpret the results from laboratory experimental studies to help explain which bases are found, what other products are synthesized, and their relative abundances. One interesting conclusion from our work is that only condensed-phase formation mechanisms are found to be feasible with these multistep reaction mechanisms. We will describe our latest research in this series of studies and discuss what our results may mean for the origins of life studies. Our group has also been actively studying the formation of larger ringed organic compounds starting from small C2 organic species in the gas-phase, as occurs in the outflow of carbon stars or in the interstellar medium. Most of these studies have also been performed in collaboration with laboratory experiments. Finally, our group has used state-of-the art ab initio methods to study the spectroscopic properties of the resulting molecules, allowing for their detection in astronomical observations. All of these studies will be discussed.

F3.5-0002-18 FORMATION PATHWAYS OF COMPLEX ORGANIC MOLECULES IN SPACE

Natalia Inostroza, natalia.inostroza@uautonoma.cl

Universidad Autónoma de Chile , Santiago, Chile

Several theoretical astrochemistry and molecular astrophysics models are in agreement with observed interstellar molecules; nevertheless, many of those models are unable to reproduce molecular abundances, which have led us to develop new models and approximations to calculate important information (i. e. spectroscopic data) in order to reproduce the observed abundances in the ISM. Grain-surface chemistry involves predominantly hydrogenation and oxidation reactions and leads to the formation of simple species; e.g., H2O, CO, CO2, CH3OH, H2CO, CH4, and NH3. Energetic processes (through UV photons or cosmic rays) convert these molecules into complexes organic molecules (COM's) as dimethyl ether (CH3OCH3), ethanol (CH3CH2OH), acetaldehyde (CH3CHO), and methyl formate (CH3COOH)1. In addition, ion-neutral processes produce radicals, like H+ and OH-, which may react with other molecules2. In this work, the reaction between ice mantles of methanol and the hydroxyl ion as projectile has been calculated using the Bohr-Oppenheimer Molecular Dynamics Theory (1600 timesteps with wb97x/6- 31+g(d,p) level of theory. The projectile was vibrationally excited with different energies, from 10 eV up to 22 eV at 30K As a preliminary result, it a new chemical network of all reactions involved in the impact of OH radical with methanol was found. 15 of 24 reactions studied with minimal velocity resulted in CH3O (metoxy radical). 4 reactions show the methylenglycol as a primary product. The deprotonation of methanol and the formation of the methoxy molecule are in agreement with experimental data3. In all cases, carbohydrate formation is shown, i.e. formaldehyde and methylenglycol, thus, the methanol ice mantles could be an important source of carbohydrates in the interstellar medium, as well as a source of molecular hydrogen.

Kenji Furuya, furuya@ccs.tsukuba.ac.jp University of Tsukuba, Tsukuba, Japan Tetsuya Hama, hama@lowtem.hokudai.ac.jp Japan

We propose a new computational model to estimate adsorption energies of atoms and molecules to inter-stellar ice surface, in which large time-scale fluctuation at the low-temperature is incorporated approximately. Based on our model, we theoretically investigated the adsorption energies of C, N, and O atoms by using quantum chemistry calculations. The adsorption energies were 14100, 400, and 1440 K for C, N, and O, respectively, and these of N and O are well consistent with the experimentally reported values. Consequently, we found that the binding of N atom is purely physisorption, while that of C atom is chemisorption in which a chemical bond to an O atom of a water molecule is formed. The chemisorption of C atom indicated that the further chemical reactions might be possible to form molecules bearing a C-O bond. We also investigated effects of newly estimated adsorption energies onto simulated chemical compositions based on rate-equation method.

Interstellar ice dust grains are the place where prebiotic molecules that feeds nascent solar-like systems, including planets and planetesimals, form. Recent ALMA observation of complex organic molecules (COMs) in cold dark clouds and the upcoming JWST mission highlight the importance of the interplay between gas and dust to the formation and survival of COMs in space throughout the process of star and planet formation. In this talk, I will present recent laboratory work on the formation and destruction of COMs in the solid phase under dark molecular cloud conditions. During the talk, I will show and compare energetic (UV photolysis) and non-energetic (atom bombardment) routes. This laboratory work ultimately contributes to our understanding of the origin of life in the Universe.

Thanja Lamberts, lamberts@theochem.uni-stuttgart.de University of Stuttgart, Stuttgart, Germany

Desorption processes of adsorbate atoms and molecules on dust are very important for understanding chemical evolution. In warm regions above about 100 K, molecules on dust are efficiently released into gas phase by thermal desorption, while in colder regions, nonthermal processes like photodesorption dominates. The photodesorption of some molecules such as H2O and CO has been well-studied and in fact those rates were reported. However, photodesorption is significantly suppressed in cold dense regions at around 10 K where the UV field is very weak. Therefore, additional nonenergetic desorption process caused by heat of reaction, socalled chemical desorption or reactive desorption has been proposed. In recent years, attempts to determine the rate of chemical desorption for some molecules have been started experimentally. However, the reported values often have significant uncertainties probably due to the intrinsic difficulty in detection methods of a typical quadrupole mass spectrometer. It is still desirable to clarify the details of chemical desorption for various species. We here report the first infrared measurements on chemical desorption which efficiently occurred for reaction of H2S with H atoms at 10 K on amorphous solid water as an ice dust analogue. Our experiment clearly demonstrates that chemical desorption is more efficient than previously believed. The obtained effective cross section for chemical desorption indicates that the chemical desorption rate exceeds the photodesorption rate in typical dense clouds.

F3.5-0006-18 THE INFLUENCE OF WET–DRY CYCLES ON ORGANIC MOLECULES IN SIMULATED PRIMORDIAL ROCK POOLS

Hannes Lukas Pleyer, hannes.pleyer@uni-hohenheim.de

Institute of Chemistry, University of Hohenheim, Stuttgart, Germany Stefan Fox, stefan.fox@uni-hohenheim.de

Institute of Chemistry, University of Hohenheim, Stuttgart, Germany Henry Strasdeit, henry.strasdeit@uni-hohenheim.de

Institute of Chemistry, University of Hohenheim, Stuttgart, Germany

Rock pools on primordial volcanic islands could have acted as natural "chemical reaction flasks." They were regularly filled with seawater by tides or sporadically with freshwater by rainfall. Warm to hot environments, occurring at locations of geothermal activity, caused the evaporation of the water and enabled wet–dry cycling. Rock pools were associated with different igneous rock, minerals and weathering products thereof, such as clays. Particularly, clay minerals could have played an important role as they promote peptide formation under the influence of wet–dry cycles (see, e.g., Lahav et al., 1978) and can protect amino acids against thermal degradation in the dry state (Dalai et al., 2017). In order to perform laboratory simulations of prebiotic wet–dry cycles under strict exclusion of O2, we have designed a special apparatus (Fox et al., 2018). We tested its novel design by investigating the behavior of glycine (i.e., decomposition and peptide formation) in wet–dry cycles in the presence of clay minerals. In another set of experiments, we observed complexation reactions between a hydrophobic model porphyrin and metal ions (e.g., Fe2+ and Cu2+) of various minerals. These experiments demonstrated that wet–dry cycling could have been important for the formation of prebiotic metalloporphyrins. Detailed results of these and other experiments and a description of the setup and operating principle of the apparatus will be presented. Furthermore, the general role of rock pools in chemical evolution will be discussed against the background of our experimental results.

F3.5-0007-18 FLUORINE AND CHLORINE CHEMISTRY IN THE INTERSTELLAR MEDIUM

Kinsuk Acharyya, kinsukacharyya@gmail.com Physical Research Laboratory, Ahmedabad, India Eric Herbst, ericherb@gmail.com

University of Virginia, Charlottesville, Virginia, United States

We have studied the formation of fluorineand chlorine-bearing species for a variety of interstellar conditions using a gas-grain network. Our homogeneous (0D) models are designed for isothermal diffuse, translucent, and dense clouds, as well as warm-up regions. In addition to the regularly observed species, we have added a number of additional halogen-containing molecules and explored their gas-phase and grain surface chemistry. Other molecules include neutral species such as Cl2, ClO, and CCl, as well as the carbon-halogen species CH3Cl, and ionic species such as CCl+, ClO+, HF+, SiF+, and H2F+. Predictions are made for the abundances of these species as functions of time and comparisons are made with the observed abundances obtained for halogen species. The peak fractional abundance of the newly detected gas-phase

CH3Cl is predicted to be 10−10 - 5.4 × 10−8 in our warm-up simulations depending upon the density and the age of the pre-warm-up phase at which warm-up begins. These values can be compared with the observed abundance of methyl chloride in the hot corino IRAS 16293-2422 if the abundance of methanol is known. Finally, we have shown that the inclusion of halogenbearing species into our gas-grain network is not likely to affect the destruction rate of existing non-halogen-bearing molecules, but may affect their formation rate through the formation of intermediate radicals, as has already been shown for methyl formate.

F3.5-0008-18 OBSERVATIONAL DIAGNOSTICS OF TWO-FLUID TURBULENCE IN MOLECULAR CLOUDS - AS SUGGESTED BY SIMULATIONS

Dinshaw Balsara, dinshaw.s.balsara.1@nd.edu

University of Notre Dame, NOTRE DAME, Indiana, United States Sudip Kumar Garain, sgarain@nd.edu

University of Notre Dame, Notre Dame, Indiana, United States

The star-forming plasma in molecular clouds is indeed partially ionized. The low level of ionization in the plasma makes it possible to sustain several interesting phenomena that do not occur in single fluid MHD turbulence. In this talk we first analyze MHD wave propagation in such a partially ionized plasma, showing that only certain waves might propagate on the shorter length scales where ions and neutrals decouple. This length scale, known as the ambipolar diffusion length scale, is also interesting because the formation of molecular cores takes place on those length scales.

We then simulate this two fluid turbulence and analyze its properties. Several trends are shown to conform to the theoretical analysis in the previous paragraph. Based on that, we extract observational diagnostics associated with linewidth-size relationships of isophotologues and also density PDFs. The first diagnostic is shown to match up with observed data. The second diagnostic is entirely new, and awaits observational confirmation. Taken together, these two diagnostics might give us a different handle on the direction of the magnetic field in three dimensions. Further theoretical analysis of the turbulence is also presented.

Observations of complex organic molecules in metal-poor environments will be crucial information for understanding organic chemistry in high-redshift galaxies where the metallicity was significantly lower than the present solar neighborhood. The Small Magellanic Cloud (SMC) is a nearby star-forming dwarf galaxy, whose metallicity is lower than typical Galactic values by a factor of five. Here we report the first detection of a complex organic molecule, methanol (CH3OH), in the SMC based on submillimeter observations towards a high-mass young stellar object with the Atacama Large Millimeter/submillimeter Array. Besides CH3OH, we also detect the dust continuum as well as emission lines of CS, C33S, H2CS, SO, SO2, H13CO+, H13CN, SiO, and tentatively HDS from the observed region. The target infrared point source is spatially resolved into two dense cores; one is associated with an embedded high-mass young stellar object, another is not associated with an infrared source but shows rich molecular lines. The first detection of CH3OH in the SMC has a strong impact on the formation of complex organic molecules in metal-poor environments. The fractional abundance of CH3OH gas in the observed dense core is estimated to be (0.5–2) x 10–8, which is comparable with those of similar

Galactic cold sources despite a factor of five lower metallicity in the SMC. This would indicate an enhanced production or a suppressed destruction of gas-phase CH3OH in the observed SMC source compared to Galactic counterparts. The gas temperature is estimated to be about 10 K based on the rotation analysis of CH3OH lines, suggesting that non-thermal desorption would contribute to the production of gas-phase CH3OH in the observed dense core. This work provides observational evidence that an

organic molecule like CH3OH, which are largely formed on grain surfaces, can be produced even in a significantly lower metallicity environment compared to our Galaxy.

Complex organic molecules (COMs) play an essential role in the emergence of life. Understanding how, when and where COMs (including potentially prebiotic molecules) are formed is one of the most critical questions in the “Cradle of Life” science theme of astronomy. COMs have been detected in prestellar cores, protostars, and protoplanetary disks. Is it possible to preserve part of the molecular content during protostellar stage which can be incorporated into comets? By looking at the cometary compositions, observations of solar-type protostars can help to address this fundamental question. In this context, here we will present our observations towards the solar-type protostar IRAS 16293-2422 in the 3mm band of the IRAM 30m telescope along with current ALMA observations. We will describe how an integrative study using observations and chemo-dynamical simulations (using the state-of-the-art gas-grain-bulk (3 Phase) chemical-kinetic model) can help us to understand the chemical composition both on the surface as well as on the coma of comet 67P/C-G observed by the COSAC and ROSINA instruments onboard Rosetta spacecraft.

Comets play a major role in the study of the physico-chemical processes that took place in our early Solar System. Moreover, they could have brought organic compounds to the primitive Earth that contributed to the chemical evolution that lead to the origin of life on Earth [1]. Thanks to groundbased observations and space missions, it is possible to measure the composition of these small bodies. Although most of the gaseous molecules detected in cometary atmospheres are produced from the sublimation of nucleus ices, other sources have to be taken into account, such as distributed sources, which provide further insight about the composition of the nucleus. Glycine, the simplest amino acid, has detected in the atmosphere of comet 67P/ Churyumov-Gerasimenko by the instrument ROSINA (Rosetta Orbiter Spectrometer Ion and Neutral Analysis) aboard the Rosetta probe. Its density presents a particular profile as a function of the distance from the nucleus [2]. In order to interpret these observations, a numerical model has been developed to calculate the abundance of glycine in the atmosphere of the comet 67P as a function of the distance from the nucleus, and derive its initial abundance in the nucleus. Three cases have been considered: (i) glycine emitted directly and only from the nucleus, (ii) glycine emitted from the sublimation of solid glycine on the particles ejected from the nucleus and (iii) glycine embedded in water ice and emitted from the sublimation of this ice from the particles ejected from the nucleus. The last two cases are called distributed source. Our results show that a unique source from the nucleus does not explain the profile of density measured by ROSINA. The best fit to the observations corresponds to a distributed source of glycine embedded in sublimating water ice from dust particles. We will discuss the abundance of glycine in these dust particles resulting from this modelling, and consequences on the chemical mechanisms that could have led to its formation in the cometary ices.

F3.5-0012-18 THE ROLE OF COSMIC RAYS IN SETTING THE CHEMICAL CONTENT OF PROTOPLANETARY DISK MIDPLANES

Maria Drozdovskaya, maria.drozdovskaya@csh.unibe.ch University of Bern, Bern, Switzerland

Catherine Walsh, cwalsh@strw.leidenuniv.nl Leiden Observatory, Leiden, Netherlands Ruud Visser, visserr(at)umich.edu Michigan, United States

The chemical evolution of volatiles in protoplanetary disks begins in the earliest prestellar phase of star formation. Under the dark, cold conditions of cores the initial icy mantles of grains are built up. Already at this point, grain-surface chemistry starts to set the composition of these icy layers. Cosmic rays play a pivotal role here by setting the abundances of radicals available for the synthesis of more complex molecules and also for maintaining low abundances of gaseous molecules directly via spot heating and indirectly via reactive desorption. Protoplanetary disks are built up from the collapsing core materials, which are exposed to variable intensities of UV irradiation and heating. Cosmic rays continuously play a sub-dominant role in chemical processing during the collapse of the system and also in the outer, lower density regions of disks. Only in the innermost, high-density regions do they become attenuated. In this talk, the history of the protoplanetary disk composition will be unraveled with the help of sophisticated physicochemical models for a range of cosmic ray ionization rates (expansion of Drozdovskaya et al. 2014, 2016). The models will be used to access the degree of importance of cosmic rays in setting the abundance of volatiles in protoplanetary disk midplanes. Cometary data will be contrasted against the modeled volatile quantities, taking into account a range of possible cosmic ray ionization rates.

F3.5-0013-18 ORIGIN OF COMPLEX LIFE GIVING MOLECULES THROUGH GAS, GRAIN, ICE, CLAY AND OCEAN CHEMISTRY

Sandip Kumar Chakrabarti, chakraba@bose.res.in

S.N. Bose National Centre for Basic Sciences, Kolkata, India

In the cold and tenuous environs of interstellar medium dusts act as catalysts to produce the simplest molecules in space. During the collapse of a proto-stellar cloud, through repeated gasgrain interaction these simple molecules become more complex. In presence of cosmic rays, ice chemistry can contribute to further complexation. After these are bombarded by comets and meteorites on planetary surfaces two more processes, namely the clay chemistry and the ocean chemistry may be very important to have life giving molecules. I review these processes and conjecture some essential requirements on the way to producing the biomolecules. Observations of the key molecules at each stage, or at least the precursors would be required to pinpoint the complete route to life out of the sea of random processes.

F3.5-0014-18 DEUTERATION OF THE INTERSTELLAR MEDIUM

Despite the low elemental abundance of atomic deuterium in the interstellar medium (ISM), observational evidence suggests that several species, both in the gas phase and in ices, could be heavily fractionated. The high abundance of some abundant and simple interstellar species could be explained by considering the chemistry that occurs in interstellar dust. Because of its simplicity, the rate equation method is widely used to study the surface chemistry. However, because the recombination efficiency for the formation of any surface species is highly dependent on various physical and chemical parameters, the Monte Carlo method is best suited for addressing the randomness of the processes. We carry out Monte-Carlo simulation to study deuterium enrichment of interstellar grain mantle under various physical conditions. Moreover, we explore various aspects of deuterium enrichment by constructing a chemical evolution model in both gaseous and granular phases (by considering the rate equation method). Depending on various physical parameters, gases and grains are allowed to interact with each other through the exchange of their chemical species. Obtained deuterium fractionation of some abundant interstellar ions is then used to predict the ionization degree around the various region of a molecular cloud. This gas-grain model is further utilized to predict the abundances of some new complex deuterated species. Quantum chemical calculations were implemented in our computation to prepare the reaction pathways of these deuterated species and supplement our results with the observation-specific information. The simple radiative transfer method is also used to justify our results.

F3.5-0015-18 COMPLEX MOLECULES AND DEUTERATION IN A PRISTINE JET-DISK SYSTEM, HH212

Dipen Sahu, dipenthink@gmail.com

Physical Research Laboratory, Kolkata, India Chin-Fei Lee, cflee@asiaa.sinica.edu.tw

Academia Sinica, institute of Astronomy and Astrophysics, 106, Taiwan, China Ankan Das, ankan.das@gmail.com

Indian Centre for Space Physics, Kolkata, India

The HH212 is a Class 0 protostar in Orion. The source has bipolar jet and a rotating disk. The disk shape is like a hamburger as recently resolved by an ALMA observation. Complex molecules like methanol(CH3OH), formamide (NH2CHO), methanethiol (CH3SH) and deuterated complex moleculeCH2DOH has been observed in the rotating environment near the disk surface and central hot source. There are other molecules, e.g., deuterated water (HDO), deuterated formaldehyde (HDCO) which has been observed near the central source and in some cases in the outflow region. The deuteration of molecule mainly occurs in cold prestellar phase via the reaction pathways involving the H2D+ ion. Here, we will discuss the origin of complex molecules (6 atoms or higher) in disk environment and deuterium fractionation in different regions of the HH212 system. Studying deuterium fraction of molecules like methanol and formaldehyde, we speculate possible reaction pathways of molecules in gas phase or dust/grain phase

F3.5-0016-18 PRESENCE OF HIGHER ORDER THIOLS IN STAR-FORMING REGION

Alcohol and thiol have a similar chemical structure where only O atom in alcohol is replaced by S atom in thiol. In the Interstellar medium, an interesting relationship exists between the alcohol and thiol. Methanol and ethanol are widely observed and 1-propanol was recently claimed to have been detected in Orion KL. Methanethiol (chemical analog of methanol) has been firmly identified in the diverse region of the ISM. Presence of ethanethiol (chemical analog of ethanol) towards the dense and warm region of the ISM such as Orion KL, Sgr B2 is questionable. Higher order thiols could be observed in these regions. Here we study the formation of monohydric alcohols and their analogous thiols. Based on quantum chemical calculation and chemical modeling, we find that the Tg conformer of 1-propanethiol is a potential candidate of astronomical interest. We present various spectroscopically relevant parameters of this molecule to assist its future detection in the warm region of the interstellar medium.

F3.5-0017-18 A SYSTEMATIC STUDY OF PRE-BIOTIC ALDIMINES AND AMINES IN HOT CORES

Milan Sil, milansil93@gmail.com

Indian Centre for Space Physics, Kolkata, India Prasanta Gorai, prasanta.astro@gmail.com Indian Centre for Space Physics, Kolkata, India Ankan Das, ankan.das@gmail.com

S.N. Bose National Centre for Basic Sciences, Kolkata, India

A thorough understanding of the formation of biomolecules in space is an demanding topic of scientific interest for a very long time. Among almost 200 interstellar and/or circumstellar species (most of them are organic in nature) detected in space, aldimines and amines are basic building blocks of amino acids which are the main biological components for life formation. We consider six isomeric groups (CH3N, CH5N, C2H5N, C2H7N, C3H7N and C3H9N) containing at least one aldimine or amine to review the presence of amines and aldimines within the ISM. The simplest amino acid, namely, glycine could have been formed by the reaction between methanimine and formic acid. Again methylamine could be produced by two successive hydrogen addition reactions with methanimine. In that sense, they are both the precursor of simplest amino acid. Methanimine (CH2NH) from CH3N and methylamine (CH3NH2) from CH5N isomeric group were detected in Sgr B2 a few decades ago. Recently, the presence of ethanimine (CH3CHNH) from C2H5N isomeric group has been discovered in the ISM towards Sgr B2(N). This prompted us to investigate the possibility of detecting any aldimine or amine from the very next three isomeric groups in this sequence; i.e., C2H7N, C3H7N and C3H9N. We employ high level quantum chemical calculations to estimate accurate energies of all the species considered. According to calculated chemical abundances, enthalpies of formation, optimized energies, and expected intensity ratio, we found that ethylamine (also the precursor of glycine) from C2H7N isomeric group, (1Z)-1-propanimine from C3H7N isomeric group, and trimethylamine from C3H9N isomeric group are the most viable candidates for the future astronomical detection. Based on our quantum chemical calculations and from other approximations (from prevailing similar types of reactions), a complete set of reaction pathways to the synthesis of ethylamine and (1Z)-1-propanimine is prepared. Moreover, a large gas-grain chemical model is employed to study the abundance of these species in the ISM. Our modeling results suggest that ethylamine and (1Z)-1-propanimine could efficiently be formed in hot-core regions and could be observed with present astronomical facilities.

F3.5-0018-18 A NEW CHEMICAL MODEL OF THE LOW-MASS PROTOSTAR IRAS 16293- 2422

Gwendoline Stephan, gs6dz@virginia.edu

University of Virginia, Charlottesville, Virginia, United States Robin Garrod, rgarrod@virginia.edu

University of Virginia, Charlottesville, United States Eric Willis, ew2zb@virginia.edu

University of Virginia, Charlottesville, Virginia, United States Jes Kristian Jørgensen, jeskj@nbi.ku.dk

University of Copenhagen, Copenhagen, Denmark

IRAS 16293-2422 (hereafter IRAS16293) is a deeply embedded low-mass protostar at a distance of 120 pc from the Sun. It has been identified as a binary, with sources A and B separated by 620 AU. The ALMA survey PILS (Protostellar Interferometric Line Survey) has identified a rich chemistry toward IRAS 16293 (Jorgensen et al. 2016., [1]), including the first detections toward a low-mass source of the complex organic molecules glycolaldehyde (CH2OHCHO), ethylene oxide (c-C2H4O) and propanal (C2H5CHO).

We have run chemical simulations of IRAS16293 using the coupled gas-phase, grain-surface, and ice-mantle chemical kinetics model MAGICKAL (Garrod 2013, [2]). However, the simple, single-point treatments that are used in hot core-type models to reproduce generic physical conditions in such sources do not appear to completely reproduce the observed abundances. It is likely that more specific, self-consistent treatments are required for the spatio-temporal evolution of the physical parameters such as gas density, temperature, and UV radiation field strength.

We present physical/chemical simulations of IRAS16293 as a spherical symmetric core with a single protostellar heating source. We compute the density profile by combining the observationally determined profile of Schöier et al. [3] with a free-fall collapse, assuming that the final stage of stage collapse corresponds to the current state of IRAS16293. Thus, we obtain the spatiotemporal evolution of the density that we then feed into the radiative transfer code RADMC- 3D (Dullemond 2012, [4]) to produce temperature and radiation field intensity profiles. These physical parameter profiles are then used in MAGICKAL for specific trajectories, to obtain the evolution of the chemical species abundances, including complex organics. Preliminary chemical abundances and spectral simulations are presented with comparisons to recent PILS detections. These represent the most chemically-complex simulations to date of IRAS16293.

S.N. Bose National Centre for Basic Sciences, Kolkata, India

In case of Astrochemistry, the main application of radiative transfer is the estimation of molecular abundances from line spectra. Using LTE approximation is comparatively easier as it requires a minimal amount of parameters but not suitable to use at lower densities because at lower densities Tex < Tkin. The non-LTE approximation is required in such cases but it often requires molecular collision data as an additional input which is often missing. Recently, Sil et al. (2017) and Gorai et al. (2017) proposed ethylamine, (1Z)-1-propanimine and propargyl alcohols as strong candidates for future astronomical detection. Here, we have performed both the LTE and non-LTE calculations for these species under various physical circumstances. In absence of measured or calculated collisional data files, we have used our estimated collisional rate (which was parametrized to have an educated estimation). for the non-LTE calculations. Calculated LTE and non-LTE transitions are compared under various physical condition.

Indian Centre for Space Physics, Kolkata, India Elangannan Arunan, arunan@iisc.ac.in

India

There are numerous complex organic molecules containing carbon and oxygen atoms which show either C-C-O or C-O-C bonding backbone. This paper examines altogether 51 C-C-O and C-O-C bonding backbone molecules from ten different isomeric groups (C_2H_2O, C_3H_2O, C_2H_4O, $C_2H_4O_2$, C_3H_4O, C_2H_6O, $C_2H_6O_2$, C_3H_6O, $C_3H_6O_2$, C_3H_8O) to summarize the present astronomical status of these molecules. Accurate calculations of enthalpy of formation of these molecules show that the isomers with C-C-O backbone are more stable than the C-O-C backbone. Interestingly, a detailed analysis of relevant astromolecules indicates that most of the observed astromolecules have the C-C-O backbone. As a matter of fact, of all the molecules examined in this study, 80% of the astronomically observed species have the C-C-O backbone while only 20% have the C-O-C backbone. In general, interstellar abundance of a molecule is controlled by some factors such as kinetics, formation and destruction pathways,thermodynamics etc. A proper consideration of these factors could explain the observed abundances of these molecules. All these possible key factors will be discussed during the presentation.

Johannes Kästner, kaestner@theochem.uni-stuttgart.de University of Stuttgart, Stuttgart, Germany

The darkness readily observed between the stars on a clear night is far from empty. The low temperatures (T = 10 K) in dark molecular clouds combined with the low particle densities (n= 104 cm3) make it seem unlikely for chemistry to take place efficiently. The chemistry that occurs can be partly explained by the presence of ice-coated dust grains on which molecules freeze out and, when they find each other, react. These grains act both as a molecule reservoir and as an energy sink for exothermic reactions. As such they allow a rich chemistry to occur.

To be able to explain, or better yet, to make predictions on astronomical observations, it is crucial to have an accurate understanding of the elementary processes that occur on these icy grains. They consist - amongst others - of adsorption, diffusion, reaction, evaporation, and energy dissipation. In this talk I aim to provide an overview of computationally feasible methods that allow the above processes to be quantified.

Adsorption and evaporation are both dictated by the binding energy of species on the surface. I will comment on several recent works that have shown that binding of atoms and molecules is not well-described by a single binding energy or orientation, but rather that a distribution should be considered.

For barrierless reactions, the orientation of the reactants with respect to each other as well as on the surface plays a role in determining which reactions can take place. Radical-radical reactions often have various possible outcomes and branching ratios need to be defined. In this presentation I will discuss an approximate way to calculate such branching ratios, which pitfalls may arise in doing so and point out what the influence of surface molecules can be.

Barriers at cryogenic temperatures, on the other hand, can only be overcome when tunneling is invoked as a crucial component of the reaction mechanism. Hydrogen is very abundant in the interstellar medium and many surface reactions involve H transfer reactions, ultimately leading to the formation of saturated species. I will elaborate on recent findings of the influence of an ice environment on reaction rate constants, how and when an ice can be approximated without taking into account all degrees of freedom, and how the rate constants are to be interpreted in the light of astrochemical mean-field models and observations.

Especially for reactions with H atoms, the competition between diffusion and reaction needs to be taken into account in astrochemical models. However, diffusion rate constants for H atoms have been shown to range over many (10) orders of magnitude and therefore competition with reaction depends heavily on the assumption which binding sites are most probable. I will comment on the competition under various assumptions, i.e., high and low H and H2 coverage.

Finally, energy dissipation after reaction is taken care of by the third body of the reaction, which is the icy grain itself. There is currently relatively little known on how the energy is distributed between various rotational, vibrational, and/or translational modes as well as on which typical timescales are involved. I propose a method based on a phonon projection scheme to understand energy dissipation on an atomistic level.

F3.5-0023-18 THERMODYNAMICS EQUILIBRIUM ON GAS PHASE UNDER LOW PRESSURE AND LOWER TEMPERATURES

Natalia Inostroza, natalia.inostroza@uautonoma.cl

Universidad Autónoma de Chile , Santiago, Chile

E.J.P Fuentes, galo288@gmail.com

Universidad Mayor, 000, Chile

More than 200 organic and inorganic molecular species consisting of up to 13 atoms have been identified in space, of which about 10% are molecular ions. The rich variety of the observed molecules implies that much more relevant yet undiscovered species must be involved in the formation and destruction processes of theirs. However, the formation of these molecules it has not been yet fully understood. The formation/destruction pathways of molecules via gas phase or grain-surface pathways must be very sensitive to the activation energy barrier, isomerization process and electronic state from both reactants and products. The majority of, if not all, hydrocarbons with more than two carbon atoms have at least two and often more isomers with similar frequencies (within a few cm-1) for their vibrational transitions. Also, the number of isomeric form increase as the number of atoms in molecules is increasing. Also, reaction networks made by the Astronomers and astrophysics are not saying anything regarding the structure isomer possibility, is because is not well known the isomeric effect on the structure and chemical reactivity in those kinds of reactions. If so, it must be considered few aspects regarding isomerization and electronic state of molecules. In this work, we would like to present a theoretical study of reaction channels and spectroscopic constants for essential astrophysical molecules as SiC3H+, SiC3H, and HCO+. The geometries and vibrational frequencies of the most relevant isomers and cations were optimized with the hybrid density functional method B3LYP/cc-pvTZ with the non-local correlation functional of Lee and the Dunning's correlation consistent basis set cc-pvTZ (Dunning 1989). We included CCSD(T)/cc pvTZ single point energy to obtain more reliable energies using the B3LYP/cc-pvTZ geometries. Anharmonic spectroscopic parameters for the ground electronic state of the most stable structures were also obtained from anharmonic force fields using second-order perturbation theory at B3LYP/cc-pvTZ level of theory. Our data is helpful for understanding structures and properties of SiC3H+, SiC3H, and HCO+ families, being valuable data for their detections in the interstellar space and laboratory. Knowing which molecules are in the interstellar medium will allow a better understanding of what types of chemical reactions are possible in space.

Solar UV radiation is a major source of energy for initiating chemical evolution towards complex organic structures, but it can also photo-dissociate even the most complex molecules. Thus, solar UV can erase the organic traces of past life at the surface of planets, such as Mars, destroy organic molecules present on meteorites and micrometeorites, influence the production of distributed sources in comets or initiate chemistry in Titan's atmosphere. In the interstellar medium, the UV radiation field emitted by stars in the galaxy is also responsible for the chemical evolution and the extraordinary diversity of organic molecules detected.

PSS (Photochemistry on the Space Station) was a Low Earth Orbit (LEO) experiment, implemented from mid-2014 to early 2016 on the EXPOSE-R2 platform outside the International Space Station. Its goal was to improve our knowledge about the chemical nature and evolution of organic molecules with astrobiological implications in space environments. It was a new step in a series of experiments conducted outside the MIR space station, in the ESA BIOPAN and previous EXPOSE facilities. In PSS, both vented and sealed cells were used allowing exposure of both solid and gaseous samples. Five kinds of experiments was carried out exposing molecules related to different environmental factors of astrobiological significance: the interstellar medium, comets meteorites, Titan, Mars, as well as a set of samples to test the stability of biochips in space.

In this talk we will describe the PSS experiment and focus on some results related to the stability of some prebioticaly relevant compounds such as glycine, the simplest amino acid, and nucleobases such as uracil, guanine and adenine. These molecules were both exposed in Low Earth Orbit and studied in the laboratory in order to derive their photochemical lifetime if they are ejected from comets on dust particles and orbit around the Sun before reaching the Earth as micrometeorites. The results can lead to better understand the contribution of cometary particles in the establishment of an organic reservoir on primitive Earth.

This work reports the computational studies and chemical modelling on one of the main themes in interstellar chemistry; the interstellar carbon chains molecular species such as Cn, H2Cn, HCnN and CnX (X = N, O, Si, S, H, P, H, N). These sets of molecules account for about 20% of all the known interstellar and circumstellar molecules. Their high abundances, therefore, demand serious attention. High-level ab initio quantum chemical calculations are employed to accurately estimate the enthalpy of formation, chemical reactivity indices, global hardness and softness, and other chemical parameters of these molecules. Chemical modeling of the abundances of these molecular species has also been performed. Of the 89 molecules considered from these groups, 47 have been astronomically observed, and these observed molecules are found to be more stable with respect to other members of the group. Of the 47 observed molecules, 60% are odd-numbered carbon chains. Interstellar chemistry is not actually driven by thermodynamics, but it is primarily dependent on various kinetic parameters. However, we found that the detectability of the odd-numbered carbon chains could be correlated due to the fact that they are more stable than the corresponding even-numbered carbon chains. Based on this aspect, the next possible carbon chain molecule for astronomical observation in each group is proposed. The effect of kinetics in the formation of some of these carbon chain molecules is also discussed.

F3.5-0027-18 INVESTIGATIONS OF PHOTOCHEMISTRY AND SPECTROSCOPY OF INTERSTELLAR ICY MOLECULES AND MATERIALS UPON EXCITATION WITH FUV LIGHT

Bing-Ming Cheng, bmcheng@nsrrc.org.tw

National Synchrotron Radiation Research Center, 30076, Taiwan, China

FUV photochemistry and spectroscopy of interstellar icy molecules and materials attract interest because information from these studies yields detailed knowledge about chemical transformations in extraterrestrial environments. To study the photochemistry and spectroscopy of solid interstellar molecules and materials, we have performed experiments using far-ultraviolet light dispersed from synchrotron beamlines coupled to the Taiwan Light Source (TLS) at National Synchrotron Radiation Research Center (NSRRC) in Taiwan. Taking the advantage of the unique property of synchrotron, we are exploring the FUV photochemistry and spectroscopy of interstellar icy molecules and materials with exciting prospects. In this presentation, we will discuss the FUV photochemical processes of icy molecules containing N2 and O2. These investigations improve our understandings of the transformations of oxygen and nitrogen species and open windows for perceptions of the mechanisms of photolysis in a solid phase. Also, we will present the first direct experimental evidence that diamond nanoparticles containing nitrogen-vacancy (NV) defects are capable of emitting red photons upon exposure to FUV radiation. The knowledge is crucial for the identification of NV as the carrier of extended red emission (ERE) bands detected in diverse astrophysical environments. Our results provide strong evidence that nanodiamonds are a major component of cosmic dust in the interstellar medium. Our model lends strong support to the notion that diamond nanoparticles are a major component of interstellar dust in space.

Introduction: The Mapping Imaging Spectrometer for Europa (MISE) is being designed as a high-optical throughput pushbroom spectrometer that can collect measurements within Europa's challenging radiation environment. MISE is planned to cover a spectral range from 0.8-5 µm with a spectral sampling of 10 nm. With an instantaneous field of view of 250 µrad/pixel and a swath width of 300 pixels, this design yields 25 µm/pixel spatial sampling in a swath 7.5 km wide at 100 km altitude, and 10 km/pixel scale full disk images at 40,000 km. MISE could return composition information for each pixel in the image measured. MISE could be used to identify and map the distributions of organics, salts, acid hydrates, water ice phases, altered silicates, radiolytic compounds and warm thermal anomalies. Mapping the composition of specific landforms is critical to understand surface and subsurface geologic processes, including recent or current activity. High spatial resolution compositional mapping is also essential for detecting small outcrops of potentially recent endogenic material.

Assessing Habitability and Potential Biosignatures: MISE is suited for assessing habitability and potentially detecting biosignatures. A potentially habitable environment is one that is capable of supporting life, though it may not be inhabited [1]. The generally accepted ingredients for an environment capable of hosting life as we know it include a source of "free energy" (available to do work of some sort), organics, and liquid water. In addition, contact of liquid water with rock, providing a source of the elements needed for biological processes, is also assumed to be essential. Given the determination that a global layer of liquid water exists below Europa's crust, three lines of evidence will be investigated to assess habitability: 1) presence and distribution of organics including complex organics such as amino acids; 2) salt chemistry of the ocean; and 3) evidence of current and recent surface change as a proxy for internal activity. A biosignatures are any substance that provides evidence of past or present life [2]. The challenges and potential for biosignature detection with MISE will also be explored and will focus on the key question: what types of biosignatures might be present and preserved on the surface that are detectible by MISE? [1] McKay C. P. (1991) Icarus, 91(1), 93-100. [2] Europa Lander

F3.6-0002-18 DETECTING LIFE IN ICY WORLDS: KEEP IT SIMPLE

Kenneth H. Nealson, knealson@usc.edu USC, Los Angeles, California, United States

Looking for life in any extraterrestrial environment should revolve around a few major assumptions that one hopes must be common to all life: 1) life will need a structure capable of separating the living interior from the non-living exterior environment - i.e., it will be membrane-bound and therefore cellular; 2) life will have an elemental composition that distinguishes it from the non-living world; and, 3) life will have a complex chemical composition that distinguishes it from non-life. No matter how one defines it, life will need energy and a way to store that energy and use it as needed. Of necessity, this will require a structure that separates the metabolism of the life form from the exterior environment. This should be recognizable as a cell-like structure, and should be the first goal of life detection. Life on our planet is distinguishable from non-life by its elemental composition. Any small structures can be easily tagged as potential life by its elemental composition (C,N,P,H,O with a predictable cadre of minor elements). There are no abundant minerals that contain anything near the elemental ratio of earthly life, and one might expect a similar situation for life anywhere. Not that it be the same as our earthly life, but that it be distinct from the abiotic part of the environment. Elemental analysis of cell-like structures will separate the cell-like inorganics from the potential life forms. Find the structures and measure their composition. While organics such as amino acids, fatty acids, and sugars can be found "everywhere", life on our planet is rather picky about which of these components it has chosen. Of the hundreds of amino acids that could be formed (many of which have been detected in meteorites and interstellar space), only 20 are major components of earthly life. Furthermore, their abundance is in no way predictable by thermodynamics - they are in the abundance needed to make life's complex proteins. The same can be said of fatty acids - their abundance in living systems, which can be easily measured, is not consistent with thermodynamics: life makes what it needs. When structures are found, make simple organic measurements - amino acid and fatty acid content - it doesn't have to be like earthly life, but it needs to be something unique for life. These ideas will be discussed with thermodynamic calculations to back them up and suggestions for making the measurements.

F3.6-0003-18 SEARCHING FOR LIFE IN AN OCEAN WORLD: THE ENCELADUS LIFE SIGNATURES AND HABITABILITY (ELSAH) MISSION CONCEPT

Jennifer Eigenbrode, jennifer.eigenbrode@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States Christopher P. McKay, chris.mckay@nasa.gov

Johns Hopkins University Applied Physics Laboratory, Laurel, United States ELSAH team

Elena Adams, et al.

The Enceladus Life Signatures and Habitability (ELSAH) mission concept aims to directly sample the plume of Enceladus, a moon of Saturn, to search for evidence of life and to assess the habitability of its subsurface ocean. It was proposed to New Frontiers 4 in 2017 and was judged selectable. ELSAH was awarded technology development funding to develop cost-effective techniques that limit spacecraft contamination and thereby enable life detection measurements on cost-capped missions.

Through repeated flythroughs of the plume, the Cassini Mission has shown that the ice particles originate from a interior ocean, that the ocean is slightly salty, that hydrothermal activity is occurring and water is in contact with rock, that organic material, sulfur and nitrogen are present in forms that can be used by biology, and that there are chemical energy sources that on Earth can sustain metabolic activity.

ELSAH flies to Enceladus to follow up on these exciting discoveries, and to determine if life is present in the ocean. As the spacecraft flies through the plume, it will collect ice particles and then melt them. The resulting liquid sample will then be delivered to the analytical instruments that are capable of identifying four key life signatures: 1) relative concentrations of proteinogenic amino acids, 2) amino acid enantiomeric excess, 3) lipid molecular patterns, and 4) lipid distributions. Together these four measurements will be used to assess if ocean life is present on Enceladus and its signatures are found in the plume particulates. The same measurements will also support the detection of abiotic signatures, assessing the role that cometary and meteoritic material may be directly contributing to the organics in the plume. In addition, ELSAH will measure properties of the ice-water plume particles (pH, salinity, etc.) to further understand the habitability of the ocean and corroborate Cassini findings. Imagers will document surface and vent features on Enceladus to further our understanding of plume sources.

The Enceladus ocean may be the most characterized habitable environment for extant life beyond Earth known today and the Enceladus plume is beckoning as a door of opportunity for us to study its ocean without having to land or drill through the ice cover. ELSAH builds on these prospects to address NASA's goal to search for life in our Solar System and open a new frontier in space science.

A major lesson learned from the Viking Mission search for life on Mars, that should be applied to Icy World exploration, is that an appropriate understanding of the exploration environment is needed to inform both instrument design and interpretation of results. Target biosignatures may be affected by naturally occurring changes in environmental conditions over time, well as by rapid perturbation of samples from their natural environments during sample excavation and analysis. A lack of a priori understanding of the Viking lander environmental context resulted in both false positives (Labeled Release Experiment) and false negatives (Viking Gas Chromatograph Mass Spectrometer), which have taken decades to recognize and resolve. The 2016 Europa Lander Science Definition Team (SDT) Report has now defined a model payload for an anticipated Europa mission focused on the search for life. The primary classes of mission instruments selected by the SDT are an Organic Compositional Analyzer (OCA), a Microscope for Life Detection (MLD), and a Vibrational Spectrometer (VS). The specific instruments baselined by the SDT for each instrument class are: a Gas Chromatograph-Mass Spectrometer (OCA-class); combinations of spectroscopy and atomic force microscopy or optical light microscopy (MLD-class); and a Raman and Deep UV fluorescence spectrometer (VS-class). Consideration of the Europa Lander SDT-defined science traceability matrix and model payload in the context of lessons learned from Viking is guiding our development of a microscope for life detection, the Luminescence Imager for Exploration (LIfE), with submicron dark-field and fluorescence imaging, as well as integrated microfluidic sample handling and processing capability. This NASA COLDTech-funded development entails modification of a 2U cubesat fluorescence imager, designed and built at NASA Ames Research Center, for the autonomous study of microbial biology in low earth orbit. In addition to using this modified platform to search for potential biostructures using UV-Vis optical imaging, our goal is to characterize critical sample geological and chemical parameters. These measurement parameters, which include sample pH, conductivity, and redox potential, not only provide major science return independent of the presence or absence of chemical and/or structural indicators of life, they are also used as information drivers for the autonomous processing of samples for fluorescence imaging. Through automated measurement and control, the sample environment is manipulated to allow staining of key chemical and structural indicators of microbial life (proteins, lipid membranes, nucleic acids) for fluorescence microscopic detection. We will discuss LIfE technologies and measurement strategies in the context of the search for biomarkers in poorly understood and changing environmental conditions.

An extremely powerful approach in the search for life on icy worlds is to search for molecular biosignatures [1]. On planetary missions, these biosignatures could be sought directly from a physical sample in situ using techniques that take a holistic approach to assessing the chemical inventory. This is possible by not only searching for the presence of known, potentially biogenic organic molecules (such as proteins, DNA, RNA, etc.), but also by capturing a broadly representative chemical profile of the population of molecular species and structures (e.g. intrinsic complexity, ligand and carbon-number patterns, and stereochemical properties). This approach, in which relative populations of molecules and molecular properties are measured objectively, enables a thorough, low-ambiguity means for biosignature identification.

Enacting a semi-exhaustive and universal molecular search for life on an astrobiology mission presents significant technical challenges, and necessitates new, highly-integrated approaches to be implemented in space-ready instrumentation. Mass spectrometry (MS) has a long history of successful spaceflight implementation and for the identification of molecules in an unknown sample it is a powerful technique. However, each environment and mission opportunity levies unique challenges and requirements on a mass spectrometer investigation, with a key missionspecific factor being the proper design of the sampling "front end" of the MS, as this is the interface between the sample and its analytical detector. In order to compile the broadest possible inventory of organic molecules required for a universal search for life, the investigation must efficiently transfer a statistically unbiased majority of the sample's native organics into a mass spectrometer where they can be analyzed. No single technique is capable of accomplishing this transfer efficiently for all possible molecules encompassing a wide range of chemical properties. In particular, one such parameter that strongly determines the optimal route to transfer a molecule into a mass spectrometer is its polarity. To gain access to both polar and non-polar organics more than one analytical technique will need to be interfaced with the MS.

Gas chromatography-MS (GC-MS) is readily amenable to the analysis of non-polar, volatile, and semi-volatile molecules; however, it is generally challenged when presented with polar, water-soluble, less-volatile organics. For the water-soluble fraction, liquid-based separation techniques such as capillary electrophoresis are analogous to GC in their ability to sensitively and quantitatively elucidate molecular structure when coupled to MS. Significant progress in liquid extraction, liquid sample handling, liquid separations, and the interfacing of liquid analyses to mass spectrometers has been made in the last decade. These functionalities are now ready for incorporation into an MS-based instrument suite in order to provide the remaining capabilities needed for the most exhaustive, universal search for life at the molecular level. This capability will be particularly important on missions to ocean worlds such as Europa or Enceladus where a spectrum of complex water-soluble organic molecules would be expected to govern the potential emergence of life and its biochemistry.

This presentation will present the current state of the art in instrument developments from the past several years and describe how they could be leveraged to support an MS-based instrument suite capable of analyzing gas, liquid, and solid samples representing a broad and robust approach to analysis of potentially-biogenic organic molecules on icy worlds.

The WATSON Project

Bolek Mellerowicz, Madylene Willis

We are developing a down-borehole deep-UV (248 nm) fluorescence/Raman instrument coupled to an ice drill for in situ analysis and characterization of glacial ice microenvironments. Referred to the as the Wireline Analysis Tool for Subsurface Observation of Northernice sheets (WATSON) Project, the ultimate goal of our program is to provide an understanding of microbial and organic distribution in terrestrial ice cores as well as develop in situ techniques adaptable for the exploration of the ice crusts of Ocean Worlds and the polar ice caps of Mars.

Subsurface ice environments, such as those in Greenland, provide a historical record of the microbial surface for a microbiome trapped in ice. The current assessment of these low bioload environments, from 100 to 1000 microbial cells per mL, is that their distribution is confined to discrete depositional layers and in brine channels. However, the spatial distribution of microbes and organic and their correlation to dust particles and brine channels, and has not been demonstrated in natural ice cores. Understanding this provides 1) an understanding of the “habitable” zones within ice 2) provides a unique assessment of whether the bioload is active and 3) demonstrating that down-borehole sensing can be used to target areas of organics/microbial layers.

In early April of 2017, we conducted a field campaign to the Greenland ice sheet near Kangerlussuaq, Greenland. We used a Kovacs manual coring drill to acquire several 14-cm and 9-cm ice cores over several locations on the ice sheet. Each core was scanned in the field using a multi-band UV-fluorescence system to obtain a baseline for contamination. The cores were then shipped and stored at the Subzero Research Facility at Montana State University. After shipment and storage, the core sections were rescanned in a 1000 class cleanroom/cold room using a UV-fluorescence system to assess contamination from transport and storage. Core sections were then cleanly cut and spectral maps of the freshly exposed surface taken. Following the examination of the spectral maps, key layers were systematically sectioned, scanned sagittally, and then melted and the bulk melt examined for total organic carbon (TOC), total nitrogen (TN), epifluorescence microscopy, scanning electron microscopy (SEM), and Excitation/Emission Maps (EEMs). These traditional bulk analysis techniques were used to ground truth the spectral maps.

We observed that the contamination from the exterior of the core extended up to 2 cm into the core and appeared as spectral hot spots and diffuse organics signatures, correlating to a TOC level of up to 1 ppm; a value that was 10x greater than the interior. The spectral and spatial diversity of the 150 ppb TOC interior shows that the lateral distribution of organics and microbes are highly clumped in some layers but diffuse in others. analytical instrumentation allows us to spatially map and characterize features of interest that correlate to more traditional bulk melt methods to understand habitable zones within the ice and factors than drive these distributions.

A combination of intact capture and in-situ detection of organic molecules from extraterrestrial environments is a key step towards understanding the variety and distribution of the building blocks of life other than the terrestrial one. The best candidate in terms of technical feasibility of our time is to sample currently ejecting icy plumes of the Satrun’s satellite Enceladus.

While gas chromatography/mass spectrometry (GC/MS) has been dominantly used as successful and robust organic detection system in space, it is not suited for the separation and detection of non-volatile, heat-degradable organic molecules. Using polypeptides as a candidate molecule target, we we able to separate 16 out of the 17 tripeptides consisting of abiotically available amino acids by using capillary electrophoresis (CE). This can be regarded an example of possible bio-signatures that can be found in habitable extraterrestrial environments such as deep habitats of internal oceans of satellites of gas giants like Enceladus.

We further used these peptides for the simulated Enceladus sample return using hypervelocity impact experiment facility at the same encountering velocity (i.e., 4-6 km/s) as flying through sampling mission to its plumes like the LIFE mission concept. As a result by using the spaceproven 0.01g/cc aerogels, two peptide peaks corresponding to negatively charged peptides were detected, thus representing a full simulation of the capture, extraction and analysis of peptides from plume particles. Since the aerogel module is crushable and can be soaked with the electrophoresis agents/solutions and injected to capillary, this media can be used for in-situ wet analysis, in addition to previously known usage for sample return missions.

Planetary protection is considered to be one of the most crucial challenges to enable sample return missions from “Ocean Worlds”, internal oceans of icy satellites as potential deep habitat such as Enceladus and Europa, due to the risk of backward contamination of bringing back potential biology-related matters or at most, possible extraterrestrial living signatures to the Earth.

Here we propose an innovative technological solution for both life detection and planetary protection of such returned samples, namely by conducting all major life signature searches, which are also a critical path of quarantine processes of planetary protection, inside the Earth return capsule, prior to open the canister and expose to the terrestrial environment.

We plan to test the latest sample capture and recovery methods of preparing multiple aliquot chambers in the sample return capsule. Each aliquot chamber will trap, for instance, plume particles and ambient volatiles during the spacecraft flying through Enceladus plumes so that respective analyses can be performed focusing on volatiles and minerals (i.e., habitability for life), organics (i.e., ingredients for life), biosignatures (i.e., activity of life) and for archiving the samples for future investigations at the same time.

In-situ analysis will be conducted under complete containment through an optical interface port that allows pre-installed fiber optic cables to perform non-contact measurements and capillary tubing for extraction/injection of gas and liquids through metal barriers to be punctuated inside a controlled environment.

Once primary investigations are completed, the interior of the capsule will be sterilized by gamma rays and UV irradiation. Post-sterilized aliquot chambers will be further analyzed under enclosed and ultraclean environment at BAL 2-3 facilities, rather than BSL4. We consider that this is an unique solution that can cope with severe requirements set for the Category-V sample returns for astrobiology-driven missions.

We will report the design, development, and laboratory testing of the Sample Processor for Life on Icy Worlds (SPLIce) system, a microfluidic sample processing "front end" to enable autonomous detection of signatures of life and measurements of habitability parameters on Ocean Worlds. Multiple versions of this monolithic fluid processing-and-handling system (mass 0.5 kg) are under development to support two nominal mission scenarios: a fly-through of Enceladus' icy plumes, which is expected to yield 2 µL of ice particles/m2 of collector area per pass at 20 km elevation, and a Europan lander, the drill-based sampling system of which is anticipated to deliver 1 - 5 mL of icy solids.

The analytical instruments and sensors for which SPLIce sample preparation sequences are being explicitly tailored and developed include microchip capillary electrophoresis [1] combined with laser-induced fluorescence detection; mass spectroscopy detection [2] of samples following either derivatization and separation by gas chromatography, or separation by capillary electrophoresis; a suite of electrochemical sensors, including ion-selective electrodes [3]; and multiwavelength fluorescence microscopy.

The SPLIce monolithic-manifold processes, distributes blanks, standards, controls, and samples by integrating a wide range of fluidic functions under autonomous control, including: 1) retrieval of fluid samples from a sample collection chamber; 2) onboard multi-year storage of dehydrated reagents, including fluorescent labeling compounds, contained in multiple isolated microchambers; 3) integrated pressure, pH, redox potential, and conductivity sensors; 4) filtration, retention, and fluorescent staining of insoluble sample fractions for characterization by microscopy; 5) dilution or vacuum-driven concentration of samples tailored to instrument detection capabilities; 6) removal of gas bubbles from fluid; 7) directional flow control; 8) active, multiple flow-path routing and 9) metered microvolume pumping. Current SPLIce design and prototype test results will be presented. Preliminary test results will be presented for these functionalities as implemented by the first laboratory.

A key goal for astrobiology is the search for evidence of life on other worlds - in particular Mars, Europa, and Enceladeus .In the near term such a search will be conducted by rovers. Experience with the Mars Exploration Rovers, Spirit and Opportunity, shows that it is difficult for the rovers to obtain samples. For this reason, a method for detecting organic chemicals and/or microorganisms without collecting a sample is needed and UV fluorescence is a strong candidate. Indeed non-contact determination of microbial content using native/intrinsic fluorescence is already in use in the food, pharmaceutical, and water quality industries [2]. Traditional methods for determining microbial content in such environments require sample collection followed by laboratory analysis. This procedure disturbs the soil environment, requires time for transit, and alters the sample as it is analyzed possibly rendering the soil useless for further stud- ies. The capability to directly determine soil microbial content in situ without contacting or disturbing the soil is important when studying fragile or extreme ecosystems on Earth, such as cryptobiotic crusts. Many molecules found in living cells exhibit characteristic fluorescence. Characterization of fluorescence involves both an excitation wavelength range and an emission wavelength range. In biological systems, the emission wavelength range often overlaps the excitation wavelength range, so these ranges must be judiciously chosen. Results suggest emission wavelength is generally 50 to 100 nm longer than the excitation wavelength. The emission intensity is directly related to the amount of the specific biomolecule present and to the intensity of the excitation [1]. References: [1] Smith, H.D et al. 2012. Astrobiology. Because liquid water is regarded as a prerequisite for life, icy ocean worlds such as Europa and Enceladus are the focus of several planned or proposed NASA and ESA fly-by missions. Water plumes originating from the subsurface ocean have been observed on Enceladus, and there have been suggestions that similar processes may be at work on Europa. Further, micrometeoroid impacts onto the surface are known to eject material into the local environment. These observations indicate that the environment around these bodies is rich with dust from both the subsurface oceans and the surface itself and that fly-by spacecraft with time-of-flight spectrometers will be able to study the ocean chemistry on icy worlds, including the potential detection of amino acids or other complex organic molecules. With the creation of a cryogenically cooled ice target for the dust accelerator facility at the NASA SSERVI Institute for Modeling Plasma, Atmospheres, and Cosmic Dust (IMPACT), it is now possible to study actual dust impacts into ice water doped with amino acids or other types of complex organic molecules at speeds relevant to fly-by spacecraft. Ice surfaces are prepared either by vapor deposition or by flashfreezing an aquatic solution of desired composition. Iron dust is accelerated to 3-50 km/s and impacted onto the surface. Time-of-flight mass spectra of the dust impact ejecta show that amino acids and even the more fragile di-peptide amino acid chains can survive impact and be detected. Future experiments will probe characteristic fragmentation patterns that can be used to identify amino acids even after breakup. Results from recent and ongoing investigations will be presented.

Evaporite minerals formed in ancient and modern environments can preserve fluids and chemical biomarkers which are products of the halophilic microbial life that once inhabited the ancient aqueous environment. Recent work conducted on modern hypersaline evaporitic systems shows likely pathways in which biomarkers and fluid inclusions were preserved, and how to quantify biomarkers from field site salts both for microbiology measurements and future in-situ planetary investigations. Similar evaporites utilized in our studies have been detected on Mars from orbit via the CRISM spectrometer onboard the Mars Reconnaissance Orbiter as well as likely to be on the surfaces of icy moons Europa and Enceladus, in addition to brine systems.

Applying Raman spectroscopy, bacterial qPCR, next generation DNA sequencing techniques, and optical mineral-microbial mapping, we have determined the likely preservation conditions and metrics within brine and evaporite samples in modern timescales with the goal of illustrating the differences between younger salts and ancient evaporitic preservation. Moreover, we are establishing methods for specifically extracting biomarker evidence from hypersaline systems such that the measured biogenic material is 1:1 to the preserved setting.

The purpose of this work is to take our current state of knowledge from the modern evaporite preservation within our fieldsite at the

northern arm of Great Salt Lake to the Permian environment where these hydrated minerals have recorded waters as well as potential microbial life previously residing in ancient water columns in the region. This relationship has allowed us to make inferences on the relative timeline of chemical biomarker production and how that effects the physical biosignatures of the mineral evaporite record.

The Permian salts examined consist of halite (NaCl) with visible traces of graphite, potash

(KCl) with significant Fe microtextures embedded within the salt matrix, and polyhalite ($K_2Ca_2Mg(SO_4)_4$· a complex fine-grained sulfate. All three mineral sets are a product of 255 Myr ponding from

Zechstein Sea waters and preserved 1.2km below the Earth's surface.

F3.6-0012-18 A NEW APPROACH TO IN-SITU BIOMARKER EXTRACTION AND ANALYSIS FOR OCEAN WORLDS

With in-situ lander missions being considered for a variety of Solar System targets, robust and streamlined instrumentation for analysis of surface material is needed. In particular, the search for extinct or extant life on these bodies requires low-risk techniques that minimize the amount of solvent needed for operation. Life detection for planetary applications has thus far relied upon high-temperature extraction and separation techniques that degrade organics and can complicate the analysis. To address these issues, we have developed an online, automated, Supercritical CO_2 Extraction - Supercritical Fluid Chromatography (SCE-SFC) benchtop instrument in a proof-of-concept study for extraction of relevant biomarkers from aqueous or mixed samples. Extraction and analysis with supercritical CO_2 sidesteps some of the major analytic challenges of conventional techniques such as pyrolysis and conventional liquid extractions with GC-MS, and requires minimal sample preparation and minimal organic solvent waste.

Supercritical CO_2, with higher diffusivity and lower viscosity than typical organic solvents, is a stable inorganic extraction fluid that is increasingly used for industrial and environmental analyses. Over the past decade, our team has worked to evaluate supercritical CO_2 as a method for low-temperature (40 °C) extraction of polar and nonpolar organics [McCaig et al. 2016,

Menlyadiev et al. 2018). Although initial studies were focused primarily on Mars in-situ analysis applications, we have now successfully extended this method to analyze lipophilic biomarkers from water samples without degradation of organics or interference from salt. In principle, this extraction technique can be used to extract from a variety of sample types of varying water content. To further broaden the applicability of this technique,

we have now begun to integrate supercritical CO2 extraction technology with supercritical fluid chromatography into a single life-detection instrument that can extract and separate a wide variety of organics (including chiral species) from complex sample materials in their native states. We have successfully demonstrated on-line supercritical extraction, separation, and detection of lipophilic biomarkers with this instrument, and are now testing its range with more polar biomarkers.

The plumes emitted by the south pole of Enceladus may provide access to material from the global ocean that is believed to be under the thick icy surface. If supplied by the bulk fluid of the ocean, the plumes may provide an opportunity to look for extant life on Enceladus without having to penetrate the ice cap, or even land on the surface of the moon. What remains uncertain is how likely it is that signs of life, if present, will make it into the plumes and how the process of plume formation and capture will affect our ability to determine the presence of extant life vs. chemical precursors. In this paper, we present experimental results on capture of bacteria during droplet and ice crystal formation and the effects of medium velocity capture on survivability of these bacteria.

From Cassini INMS data, plumes on Enceladus contain mostly water with small amounts of volatile gases embedded within, and are ejected into the vacuum of space. We have initiated a series of tests to experimentally determine whether bacteria can survive ejection into vacuum and to explore different conditions that may promote or hinder survival during this process.

We find that concentration of bacteria in droplets formed by expansion into a vacuum is straindependent, consistent with many other studies on sea spray and "bubble scrubbing." We settled on Serratia marcescens as a test organism because of its concentration in escaping bubbles, both in atmosphere and under vacuum. We studied controlled bubble formation (with use of a micro-bubbler) in atmosphere, as well as spontaneous bubbling from both degassed and fully oxygenated solutions in vacuum. We found that S. marcescens is able to grow and form colonies under both conditions down to at least -15 °C when captured onto frozen nutrient agar. Capture of spontaneous bubbles onto plastic Petri dishes led to no bacterial survival, even at room temperature.

To determine the effect of ice formation on bacteria survivability in cold plumes, we have also developed a cold Enceladus ice crystal generator, where we co-mix water containing bacteria with pressurized liquid CO2 in a two-fluid external-mixed nozzle. The expansion of the gas from the nozzle cools the water droplets and freezes them to produce snow crystals with bacteria, which are then collected for survivability and impact shock studies. These ice grains were packed into a stainless steel sample chamber and a 20 mm bore propellant-driven plate impact gunwas used to launch a projectile at this chamber at a velocity of 850 m/s. Following impact, the liquid was retrieved from the sample and spread onto plates to determine survivability from colony counts.

F3.6-0014-18 CREATIVE INSTRUMENTATION FOR IN-SITU ELECTROCHEMICAL CHARACTERIZATION OF GEOCHEMICAL GRADIENTS IN PLANETARY MINERALS

Jet Propulsion Laboratory, Pasadena, California, United States

NASA's future missions will focus on discovering evidence of life under extreme environments. In addition to bio-signatures in a global scale such cold arid planets (Mars) and icy worlds (Europa), localized geochemical systems that host gradients are also of great interest for determining the potential for life to thrive or to originate in these environments. Such gradient-driven systems include, for example, layering of minerals of varying oxidation states in the Martian subsurface or in Earth's seafloor sediments; chemical precipitates separating fluids of different pH or Eh such as in a hydrothermal vent; or radiation-induced oxidant production in planetary ices. A challenge is that these simulated precipitates are redox sensitive and evolve over a relatively short lifetime (1-4 hrs) necessitating viable in-situ, non-destructive techniques. Promising techniques for such studies are electrochemical methods, which are particularly suited for characterizing interfaces and chemical gradients. For planetary applications, microbial reactions in water-mineral environments have important geobiological and geochemical implications which are preserved at these interfaces for future in-situ electrochemical analyses. Combined with recent advances in electrochemical instrument technologies, new methods have been developed toward integrating portable, electrochemical systems (i.e., software controls, sensors, detectors, etc.) without compromising measurement sensitivity and robustness for ex-situ and/or in-situ chemical characterization. JPL has already made significant progress in developing these new technologies, particularly electrochemical impedance spectroscopies (EIS) for in-situ characterization of geochemical materials (i.e., soils ice mineralogy, and brines) [1][2]. More recently, we have adapted electrochemical techniques life detection purposes such as measuring amino acids. Combined microstructure enhanced electrodes enable concentration

levels to be measured in the parts-per-billion (bbp) range which represents a 100x enhancement in sensitivities relative to our state of the art remote-sensing capabilities typically deployed for space exploratory programs [3]. We have also successfully developed electrochemical systems with a programmable microelectrode array using more advanced driver controls to perform continuous monitoring and real-time characterization of simulated planetary vent systems. This technique was successfully utilized in laboratory simulations of astrobiological / emergence of life processes on early Earth. It can also be used with other rocky planets, as well as icy moons, which emulate localized geochemical disequilibria that can support potential microbial life or drive prebiotic carbon fixation (prior to any microbial interaction such as on early Earth). Along with discussions on instrument technologies for future astrobiology applications, we will highlight some of our group's successes and preliminary results of geochemical experimentation using various electrochemical techniques. • References: [1] S. F3.6-0016-18 KEY PROBLEMS OF LIFE'S ORIGIN: NECESSARY AND SUFFICIENT CONDITIONS FOR STARTING CHEMICAL EVOLUTION AND TRANSFORMING IT INTO BIOLOGICAL ONE

Sergey Bartsev, bartsev@yandex.ru

Institute of Biophysics, SB RAS, Krasnoyarsk, Russia

According to science methodology any hypothesis to become a theory has to obtain experimental confirmation. The same requirement has to be applied to modern hypotheses on life's origin. The problem of the origin of life will be resolved when some experiment produces an "entity" that can be identified as "life". However a plan of experiments on the origin of life must necessarily be based on preliminary theoretical development, which should define the conditions for the origin of this "entity" and propose a credible scenario, i.e. a scenario compatible with contemporary physical and chemical laws. For instance, the scenario of self-assembling a primitive living cell directly from a set of chemical compounds is not verifiable experimentally due to the probability of this even is so low that the methodology of natural sciences deems this variant of the emergence of life unrealistic. Oparin (1924) suggested that modern-type cells "had originated from simpler forms through sequential changes and improvements". The same idea was mentioned casually by Haldane (1929). These studies provided a basis for postulating that biological evolution had been preceded by chemical evolution, which resulted in the occurrence of cells that were chemically similar to the modern type. To resolve the paradox of the discrepancy between the actual existence of life on Earth and zero probability of a living cell emerging by self-assembly from scratch, the probability of the formation of the primitive precursor stages must be quite perceptible. Hence, chemical evolution is a necessary component of any scientific scenario of the emergence of life. At the present time, general scientific notions can only provide a basis for defining the necessary conditions for the emergence of life. Whether the list of necessary conditions is complete is a very difficult question, and whether it is sufficient can only be determined experimentally. One cannot construct a specific scenario of chemical evolution without defining its outcome - the product resulting from chemical evolution and the phase in which it is transformed into biological evolution. The literature analysis shows that researchers' attitudes to the outcome of the scenario of chemical evolution can be of two kinds:

studies attempting to find out the conditions and stages of the origin of life on Earth, as we know it; b) studies examining the conditions and stages of the emergence of any life form conceivable scientifically. In fact, any idea of the outcome falls within one of the two frameworks of research, which we conveniently denote by Earth Life Origin (ELO) and General Life Origin (GLO), respectively. The differentiation between ELO and GLO frameworks is a critical issue, as it concerns fundamentally different approaches to the problem of the origin of life. Specific drawbacks and advantages of these ways are discussed.

F3.6-0017-18 CHEMICAL ANALYSIS OF LIPOPHILIC BIOMARKERS USING CARBON DIOXIDE AS A SOLVENT

The search for life in the solar system is currently one of the major goals in space exploration, and in-situ analysis of complex organic molecules is a key component in the effort to evaluate habitability of other worlds. Robust chemical analysis techniques are essential in this endeavor, especially those that can enable detection and identification of unknown complex molecules at low concentrations with high precision.

Previous missions to Mars have employed primarily pyrolysis - and to a lesser extent liquid extraction combined with derivatization - as sample preparation techniques, followed by separation by gas chromatography and detection by mass spectrometry. We have been developing instrumentation that can extract, separate and detect organic molecules using CO2 as a solvent in its supercritical state. This approach completely avoids derivatization and the use of organic solvents, and the extraction and separation is performed at mild temperatures (30-60

°C) as opposed to high-temperature techniques such as pyrolysis [1, 2]. This reduces the risk of degradation and of unwanted reactions between the native compounds and other species.

Our developed methodology involves extraction of lipophilic biomarkers, pre-concentration on a solid-phase trapping material, and release (elution) followed by separation using chromatography with mass spectrometry detection. In modern-day analytical chemistry, supercritical fluid extraction and chromatography has become immensely popular due to its faster analysis time, however, it typically requires mixing the supercritical CO2 with a polar organic solvent to break molecular interactions [3]. We have completely avoided organic solvents by saturating the supercritical CO2 with water and by identifying suitable chemistries of the trap and chromatography columns.

Although we have previously demonstrated supercritical CO2 extraction of organics from solid samples [4, 5], we have recently modified the method to enable extraction of organics from aqueous samples with high salt content, such as is expected on Europa [6]. Here, we demonstrate how a completely automated quantitative analysis (including extraction, separation and detection) of intact lipids, such as free fatty acids, heterocycles and pigments, from aqueous samples in the presence of salts can be performed under mild conditions by using supercritical CO2 as a solvent at a benchtop scale.

F3.6-0018-18 PANSPERMIA IN SOLAR SYSTEM: A COMPARISON OF POSSIBLE SOURCE BODIES

Leszek Czechowski, lczecho@op.pl University of Warsaw, Warszawa, Poland

We consider here conditions for origin of life in the early Enceladus and other bodies and possible proliferation of the life. Enceladus is the smallest body in the Solar System where volcanic activity is observed. According to [1]: "For life to have emerged [.] chemically transducible energy was essential. The serpentinization process is emerging as an increasingly likely source of that energy. Serpentinization of ultramafic crust would have continuously supplied hydrogen, methane, [.] " (see also [2]). [3] consider the following reaction of serpentinization: (forsterite)

+ (enstatite) + 2(water) -> (antigorite). It releases 241 000 J per kg of serpentine produced. Calculations (e.g. [4]) indicate that in Enceladus the total mass of its silicate is 6.97 1019kg and most of this mass could undergo serpentinization. Investigating thermal conditions in its core leads [4] to the conclusion that it was an appropriate place for origin of life. The hypothesis that Enceladus could be a cradle of life in the Solar System was presented in [5] and [6]. [6] indicated a few possible mechanisms and scenarios for transport of simple organisms from the interior of Enceladus to terrestrial planets of the Solar System. In the present paper we compare possibility of transport of living organisms from Europa, Ganymede, Titan, Mars and the Earth to other celestial bodies in Solar System. Several mechanisms of transport are considered - impacts, volcanism, gravity assistance, Poynting-Robertson effect and others. We conclude that interior of Enceladus offers good conditions for origin of life. Moreover we find that transport of living organisms from the interior of Enceladus is more probable than from any other celestial body.

Of the non-terrestrial environments within our Solar System, Europa's global liquid water ocean is arguably the most likely to be habitable. As such, understanding the habitability of Europa's ocean is of great interest to astrobiology and is the focus of missions currently being considered for further exploration of Europa. However, direct analysis of the ocean is unlikely in the foreseeable future. As such, our best means of constraining the subsurface ocean composition and its subsequent habitability currently is by further study of Europa's surface chemical composition. Recently, there has been a body of work published that looks at the chemistry of frozen brines representing putative ocean compositions. Here we take a simplified model of a four ionic component (Na, Mg, SO4, Cl) solution and map out what minerals are formed upon freezing as a function of relative ionic concentration, pH, etc. A 'flow-chart' of the freezing sequence was developed based on both published and recently acquired experimental results. In performing this exercise, we are able to begin making meaningful links between observations of the surface chemistry and the chemical environment of the internal ocean.

F3.6-0020-18 IN SEARCH FOR BIOMARKERS ON PLANETARY BODIES

Isik Kanik, isik.kanik@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Sabrina Feldman, sabrina.m.feldman@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

One of the major goals in the exploration of space is the search for evidence of life in the solar system. Organic analyses and biomarker detection will play a pivotal role in this endeavor as part of in situ robotic missions to planetary bodies by major space agencies such as NASA and ESA. Looking beyond Earth recent efforts in searching for chemical signatures of life have focused primarily on Mars, Europa, Enceladus, and Titan which may have biochemistry similar to that of life on Earth.[1] A primary goal of searching life on other bodies should be to search for specific biomolecules that would be conclusive evidence of life. One of the main difficulties in this endeavor, however, is that biologically relevant properties of biomarkers rapidly disappear over time intervals of thousands to millions of years due to hydrolysis, racemization, and other forms of chemical degradation.[2] As a result distinguishing between biological and non-biological origins of potential biomarkers that could plausibly be present on planetary bodies is extremely challenging. Lipids are waxy, organic molecules soluble in nonpolar solvents that are utilized by organisms to form cell membranes, and eventually buried and preserved in sediments. Also, they also arguably the most useful molecular biomarkers for studying the origins and evolution of life on earth over the past 3 billion years. Membrane lipids were found in 2700-million-year old kerogen-rich shales.[3] Carboxylic acids are potentially stable over geological time scales in ices as well as in cold anoxic sedimentary materials. Analysis of the types and distribution of carboxylic acids present in planetary materials can potentially indicate biological activity as well as the relative contributions of hydrothermal and exogenous delivery. In this presentation, we argue that lipids which are essential to life with best potential of surviving under the harsh planetary conditions (over long geological time scale of several millions to billions of years) should be on the top of our list for future life-detection missions to Mars, Europa, Enceladus, Titan, and other planetary bodies. We also review new technologies under development for lipid biomarker analysis both in searching for life and for understanding the geochemical and perhaps biological evolution that has occurred on planetary bodies.

We assume that large amount of amino acids have been synthesized on Titan's surface by asteroid's impacts, and they are stored on the dark and cold surface. To simulate the impact reactions, impact experiment using a light gas gun has been carried out. A polycarbonate projectile (7.1 mm diam.) is accelerated to 7.0 km/s, injected into a pressurized chamber (10 inch diam, 25 cm high), which is filled with 100 kPa of nitrogen, and hits an iron target (76 mm in diam.). The target is cooled by liquid nitrogen, and ice or ice + hexane can be added on the surface. After the impact, a hot gas plume generates for about 100 μs, which has temperature of about 5000 K and strong CN emission. After the impact, deposited black soot is carefully collected, part of which is refluxed using pure water. The sample is dabsylized and analyzed using HPLC [1]. As a result we could obtain many kinds of amino acids (glycine, alanine, leucine, serine etc.). About 2 nmol of glycine and 0.9 nmol of alanine are included in 1.0 mg of the soot. By the 2D chromatograph method, both D and L type alanine isomers are detected. It is conjectured that in the hot gas plume, C_2 molecules react with N_2 molecules to make CN radicals. Other radicals react with CN to make amino acids during the cooling process after the impact. We believe that the asteroid's impacts also could do further reactions and diffuse organic materials into the underworld. We are doing further experiment to make clear the synthesis properties. Inorganic precipitate membranes play an important role in biomineralization, chemobrionics, and origin-of-life research. We produce such membranes in a microfluidic device at the reactive interface between laminar streams of an alkaline solution and a metal salt solution. The steep chemical and pH gradients across the membrane can experimentally simulate the geochemical gradients in the hydrothermal vents. We show that in the presence of acetyl-phosphate, the membrane causes the formation of pyrophosphate which might have served as the energy currency of early life emerging in hydrothermal vents. The latter product is identified by aqueous 31P-NMR spectroscopy from samples removed from the microfluidic device. This result demonstrates the usefulness of microfluidics-based synthesis for origin-of-life studies that require the exploration of vast parameter spaces. Furthermore, the membrane experiments simulating habitability in hydrothermal vents can also involve polyphosphates compounds which are curial for life and could be a biosignature.

Capillary electrophoresis (CE) has tremendous promise for in situ planetary investigations. Depending on the detection method used, CE allows the analysis of a wide range of organics as well as inorganic ions. In general, the detection method is selected based on the properties of the analytes of interest. For example, laser-induced fluorescence is the preferred method for the analysis of amino acids as it provides unparalleled sensitivity. On the other hand, for analysis of inorganic ions, conductivity detection is a better and simpler candidate. Choosing a specific method for a specific analyte works well when analyzing relatively well understood samples in a lab on Earth. However, analyzing unknown samples, like the ones expected on alien worlds, presents a more challenging scenario. An ideal in situ instrument would allow the analysis of multiple analytes (like salts and amino acids) with a single detection system. Capacitively coupled contactless conductivity detection (C4D) is a method that is widely used in conjunction with CE. C4D allows the detection of any charged species, as such, it would allow the simultaneous analysis of inorganic salts and charged organics. We are developing CE-C4D methods to simultaneously analyze inorganic and organic ions (i.e. calcium, sodium, perchlorate, amino acids, carboxylic acids etc.), as they are likely to be present at the same time on samples collected from the most relevant astrobiology targets like Mars, Enceladus, or Europa. Soluble salts present are of importance to biological activity, prebiotic organic synthesis, and the thermophysical properties of most liquid mixtures. Amino

acids are the building blocks of proteins and are essential for all terrestrial life. The distribution of amino acids on a sample is one important potential indicator for determining the presence of life. CE-C4D does not require derivatization of the sample, providing an attractive and robust alternative to other more labor-intensive detection methods. Although CE-C4D cannot yet achieve the sensitivity of some optical methods, it can be used as a screening platform before performing more sensitive analyses that required more sample preparation. Using CE-C4D as a screening platform is especially useful because it can help determine the proper sample preparation steps before analysis with other techniques. For example, the presence of salts in combination with organics can sometimes hinder their detection by methods that require derivatization. So, it is essential to identify the ions present in the sample in order of select the proper technique to successfully detect organic biosignatures. CE-C4D has a small footprint and analyses take less than 10 min so it can be readily integrated to other more complex instrumentation. Moreover, the CE-C4D protocols could be adapted to the environmental requirements of a variety of astrobiologically interesting targets like Europa, Enceladus, or Titan. This type of instrument also offers key capabilities for human flight applications. For example, we are currently working in collaboration with SBIR partners on the development of a miniaturized instrument to monitor water quality in the ISS.

F3.6-0024-18 EXPLORATION OF ICY MOONS AROUND GIANT PLANETS: ASTROBIOLOGICAL ASPECTS

Athena Coustenis, athena.coustenis@obspm.fr Paris Observatory, Meudon, France

Vincent Boudon, vincent.boudon@u-bourgogne.fr Institut d'Astrophysique Spatiale, Dijon, France Alain Campargue, alain.campargue@ujf-grenoble.fr Université Grenoble 1, Grenoble, France

Vladimir Tyuterev, vladimir.tyuterev@univ-reims.fr Universite Reims Champagne-Ardenne, Reims, France

When looking for habitable conditions in the solar system, recent studies focus on the natural satellites of gas giants. Indeed, liquid water may be present underneath the surfaces of the natural satellites around Jupiter and Saturn [1]. And several of these satellites show in addition evidence for harboring organic chemistry in their atmospheres or exospheres, as well as energy sources. Measurements from the ground but also by the Voyager, Galileo and the Cassini spacecraft revealed the potential of these satellites in this context, and our understanding of habitability in the solar system and beyond can be greatly enhanced by investigating several of these bodies. Indeed, several of the moons show promising conditions for habitability and the development and/or maintenance of life. Europa, Callisto and Ganymede are hiding, under their icy crust, undersurface liquid water oceans which, in the case of Europa, may be in direct contact with a silicate mantle floor and kept warm by tidally generated heat. Titan and Enceladus, Saturn's satellites, were found by the Cassini-Huygens mission to possess active organic chemistry with seasonal variations, unique geological features and possibly internal liquid water oceans. As revealed by Cassini, the liquid hydrocarbon lakes currently distributed mainly at polar latitudes on Titan are ideal isolated environments to look for biomarkers. If the silicate mantles of Europa and Ganymede and the liquid sources of Titan and Enceladus are geologically active as on Earth, giving rise to the equivalent of hydrothermal systems, the simultaneous presence of water, geodynamic interactions, chemical energy sources and a diversity of key chemical elements may fulfil the basic conditions for habitability. These would be investigated with future space missions. Such potential habitats can only be investigated with appropriate designed space missions, like ESA's L1 JUICE and NASA's Europa Clipper mission. I will discuss current and future means of exploration, with a focus on JUICE and also laboratory and theoretical measurements within the ANR French project that led to new methane coefficients for Titan [2,3].

LIFE SCIENCES AS RELATED TO SPACE (F)

BIOSIGNATURE DETECTION IN THE SOLAR SYSTEM. PART II: MARS, EARTH, AND EXOPLANETS (F3.7)

F3.7-0001-18 EXTRATERRESTRIAL BIOSIGNATURES

Frances Westall, frances.westall@cnrs-orleans.fr CNRS, Orleans, France

The search for extraterrestrial biosignatures is conditioned, in the first place, by the kind of life that one expects to find. While biosignatures on exoplanets are necessarily restricted to those represented by life forms that have developed at least oxygenic photosynthesis or are even more evolved, our understanding of the emergence and evolution of life (as we know it) on Earth suggests that extraterrestrial life forms on other planets and satellites in the Solar System are more likely to be represented by primitive, anaerobic chemotrophic microorganisms.

Great advances have been made over the past decades in our understanding of the nature of extremophiles and the limits of life. We know that life can inhabit ephemeral habitats for the brief periods that they are habitable. The vast majority of these kinds of habitats, for example endolithic, dry arid, salty, or icy environments to name just a few, are typified by oxygenic phototrophs as primary producers. Are these kinds of habitats suitable for chemotrophs as primary producers? What would the potential carbon, nutrient and energy sources be? What kinds of biosignatures would they produce and can these biosignatures be preserved on long geological time scales? Experimentation along these lines is essential to help us to know what to look for on another planet, how to look for it, how to sample it and how (where?) to analyse it.

The next decades will see sample return missions from Mars and missions to icy satellites, some of them potentially sample return missions. At the moment, with our limited understanding of the nature, distribution and preservation of biosignatures of chemotrophic life, we are searching almost blindly. The closest analogue to an anaerobic planet inhabited by chemotrophs is the early Earth [1]. This example shows us that chemotrophs are most "happy" cavorting in and around nutrient-rich hydrothermal systems, producing a significant amount of biomass that is durably preserved by hydrothermal silica over very long geological time scales. They also occur in oligotrophic settings but their biomass here is very low and subsequent biosignatures extremely subtle. Such findings, combined with experimental data on chemotrophs biosignature preservation in extreme environments, are what is needed to for mission planning and instrument development.

F3.7-0002-18 MARTIAN ENVIRONMENTS AND BIOSIGNATURES

Lindsay Hays, lindsay.e.hays@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Mountain View, California, United States

With increasing capabilities, the exploration of Mars and in particular, the search for life on the red planet continues to be of increasing importance to nations and space agencies around the world. However, the search for life on Mars has already resulted in two false positives that have significantly affected how we search for life outside the Earth. It is crucial to consider not only the biosignatures that should be sought but almost more importantly the most likely environments for their preservation and detection by the fleet of robotic missions currently in development. Five analog environments of interest have been evaluated by the mars analogue community, hydrothermal spring systems, subaqueous environments, subaerial environments, subsurface environments, and iron-rich systems [1]. All have strengths recommending them, as well as challenges to observations unique to each, and understanding these can help guide the astrobiological exploration of Mars. Additionally, the newly proposed tool, the Ladder of Life Detection [2], is a unique tool that helps to focus on rigorous investigations of specific biosignatures, or combination of biosignatures, most likely to yield a positive result in the search for life.

F3.7-0003-18 BIOSIGNATURE SEARCHES WITH THE LUVOIR DECADAL MISSION CONCEPT

Giada Arney, giada.n.arney@nasa.gov

Goddard Space Flight Center, Greenbelt, Maryland, United States

The Large UV-Optical-Infrared (LUVOIR) Surveyor is one of four mission concepts being studied by NASA in preparation for the 2020 Astrophysics Decadal Survey. LUVOIR is a general-purpose space-based observatory with a large aperture in the 8-15 m range and a total bandpass spanning from the far-UV to the near-infrared. This observatory will enable revolutionary new studies in many areas of astronomy, including planetary science within and beyond our Solar System. One of LUVOIR’s main science objectives will be to directly image rocky Earth-sized planets in the habitable zones of other stars, measure their spectra, analyze the chemistry of their atmospheres, and obtain information about their surfaces. Such observations will allow us to evaluate these worlds’ habitability and search for the presence of biosignatures. We will review the specific observational strategies needed for astrobiological assessments of exoplanetary environments with LUVOIR, including the wavelength range, spectral resolution, and integration time required for these habitability analyses and biosignature searches. The survey of the atmospheric composition of dozens of potentially habitable worlds would bring about a revolution in our understanding of planetary formation and evolution, and may usher in a new era of comparative astrobiology.

F3.7-0004-18 CHEMICAL BIOSIGNATURES: ALL THAT GLITTERS IS NOT GOLD

Henry Strasdeit, henry.strasdeit@uni-hohenheim.de

Institute of Chemistry, University of Hohenheim, Stuttgart, Germany Stefan Fox, stefan.fox@uni-hohenheim.de

Institute of Chemistry, University of Hohenheim, Stuttgart, Germany

Chemistry offers sophisticated analytical tools that allow the detection and identification of, for example, organic molecules even if present in only minute quantities. This makes chemical biosignatures attractive as means for life detection on other planets and moons. However, the various kinds of chemical biosignatures are not equally useful in the search for extraterrestrial life, and there are many potential pitfalls in interpreting them (Fox and Strasdeit, 2017).

The most important type of misinterpretation is probably false positive results. It occurs when terrestrial biogenic or abiogenic contaminants are mistaken as extraterrestrial biosignatures or when products of natural abiotic syntheses are not recognized as such. Terrestrial contamination is a permanent problem in many astrobiology space missions, especially in those to the surfaces of solar system bodies. False negative results are also possible. They may occur, for example, when a chemical compound simultaneously has productive abiotic and less productive biological sources. In such a situation the biotic source may be overlooked. Methane on other planets and moons is a candidate for this kind of chemical compound.

"Strong" chemical biosignatures have a low risk of misinterpretation. Homochiral polymers of defined length and sequence, such as proteins and polynucleotides, undoubtedly belong to this group. Abiotic organic syntheses almost always produce a continuous spectrum of molecules, as, for example, in the case of α-alkyl-α-amino acids. However, when only a subset of these molecules is found, this strongly indicates biogenicity (McKay, 2004). Stability over long periods of time of a chemical biosignature (or at least of easily recognizable alteration products thereof) also increases its "strength." One reason that some molecules are regarded as good biosignatures is because no natural abiotic syntheses of them are known. However, when an abiotic pathway is discovered—as was the case with porphyrins (Fox and Strasdeit, 2013)—the picture changes. "Weak" chemical biosignatures are by no means useless, but they need a stronger integration into the context (for example, the geological one) to avoid misinterpretation.

Recent findings on Mars, such as organic compounds, methane, reduced compounds for microorganism energy sources, possible presence of liquid water at Recurring Slope Lineae, tend to support the possible presence of living microbes near the surface of Mars. For in situ detection of microbial cells, we propose the Life Detection Microscope (LDM) which visualizes organic compounds by staining the samples with fluorescent pigments. The LDM scans a volume of 1 mm3 and detects organic compounds including cells and other biological materials in high sensitivity (<104 cells per gram clay). The fluorescent pigments have been selected to identify the fundamental features of cells by differentiating among organic compounds surrounded by membranes or enzyme activity: the mixed dye of SYTO24 and propidium iodide stains living cells in green and dead cells in red depending on their membrane permeability and CFDA-AM detects cells possessing esterase activity. The LDM is also equipped with a high resolution imaging system (1 μm/pixel) which visualizes detailed life forms as well as regolith and dust particles.

F3.7-0006-18 TRANSITS IN THE SOLAR SYSTEM AND THE COMPOSITION OF THE EXOPLANET ATMOSPHERES

Pauli Laine, pauli.e.laine@jyu.fi

University of Jyvaskyla, Jyvaskyla, Finland

Our knowledge about exoplanets depends on very limited measurements and resolution. Atmospheric compositions are limited only to hot Jupiters and Neptunes. Detection of possible biosignatures on Earth-sized planets is not possible today. However, upcoming space missions, e.g. TESS, JWST, CHEOPS, and PLATO will give us unprecedented access to exoplanet light curves and other observations. Before the new results arrive, it could be useful to collect the only known living planet's and other well known planet's light curves and spectra for the future comparison and habitability modeling. For this, we need to seek possibilities to measure Earth's and other terrestrial planet's transits, occultations, and reflections from different locations in the Solar System. I will present some past events and experiments, potential locations and events, probes, and their instruments that could be used, as well some limitations and challenges.

F3.7-0007-18 AGNOSTIC APPROACHES TO LIFE DETECTION

Sarah Johnson, sj599@georgetown.edu

Georgetown University, Washington, District of Columbia, United States Heather Graham, heather.v.graham@nasa.gov

University of Maryland, Washington, District of Columbia, United States

A key question in astrobiology is how to search for signs of life regardless of underlying biochemistry. Current strategies for biosignature detection rely mainly on identification of wellestablished and widely accepted features associated with terran life and signatures of biologic processes, such as particular classes of molecules and isotopic signatures, enantiomeric excesses, and patterns within the molecular weights of fatty acids or other lipids. Yet as we begin to explore icy moons of Jupiter and Saturn and other destinations beyond Earth, we must develop life detection methods that identify unknowable, unfamiliar features and chemistries that may represent processes of life as-yet unrecognized. Accomplishing this goal will entail not only developing new techniques but also synthesizing data with probabilistic approaches, as agnostic methods may trade definitiveness for inclusivity.

It is likely that the first terrestrial life was quite different from the current DNA world. Thus even if we assume that life arose on Mars from a chemical evolution similar to the terrestrial one, and that the primitive life on Mars was similar to the first terrestrial living system, it may have been very different from the present terrestrial life. Moreover, it is far from obvious that martian biological evolution followed the same ways than on Earth, because of a different evolution of the red planet and different physical and chemical conditions. Thus when searching for extant martian life, one should not look exclusively for life as we know it today on Earth. We should also - and as first priority - look for life similar to the early terrestrial life, and more generally life based on similar but not identical replicating macromolecules, as well as protein-like macromolecules. Search for extinct martian life must also take into consideration the large differences in environmental conditions on both planets. In particular, it is likely that the degradation of potential living systems, and biomolecules on Mars, will yield breakdown products quite different from what is observed on Earth (like humic and fluvic acids). Consequently, the search for molecular biosignatures of extant and/or extinct life on Mars must be largely open and use non molecular specific analytical tools, able of analyzing a very wide range of chemical families. This is the case with the MOMA instrumentation on the rover of the ExoMars 2020 ESA/Roscosmos mission. This presentation will discuss these important aspects of possible Martian biosignatures and the capabilities of the MOMA instrumentation to analyse them.

F3.7-0009-18 INFLUENCE OF TEMPERATURE ON FLUORESCENCE DETECTION LIMITS OF UBIQUITOUS TERRESTRIAL BIOCOMPOUNDS

Ilya Digel, digel@fh-aachen.de

Aachen University of Applied Sciences, Juelich, Germany Max Kuhlen, maxx.kuhlen@yahoo.de

Aachen University of Applied Sciences, Juelich, Germany

Finding appropriate criteria for recognizing, detection and comprehension of life phenomena is one of the “eternal” problems in astrophysics, geology, glaciology and marine ecology. Photometric technologies offer a repertoire of fast, simple and reliable identification and characterization methods for chemical compounds and microorganisms in their natural environments via their signatures. Very suitable for this purpose is fluorescence spectroscopy that allows quantitative measurements of an analyte in solution and provides information on dynamic processes on molecular environment down to the nanosecond timescale. Our approach primarily focused on fluorescence spectroscopy measurements of selected species of ubiquitous terrestrial bio-compounds as a model for future terrestrial and extraterrestrial applications. The main aims were (a) to verify that autofluorescence can be successfully used to differentiate between various biogenic compounds and (b) to determine their minimal dilutions/concentrations that could be still detected. We applied conventional fluorimetry to obtain cumulative spectra for bacteriorhodopsin, RNA, chlorophyll, histidine, ATP, NADH, tryptophan, phenylalanine, pyridoxine, riboflavin, arginine, alanine and FAD. For all 13 substances, 20 mL aliquots of six tenfold dilutions were prepared. The signals were plotted as a function of the concentration. The obtained results allowed determination of absorbance/emittance peaks characteristic for the examined molecular species. The lowest still detectable concentrations (0.1-1 M) were found for FAD, NADH, pyridoxine hydrochloride, tryptophan and riboflavin. L-histidine, L-arginine and L-alanine were only detectable starting from 1 mM. L-phenylalanine and ATP could be detected down to 10 M-concentrations. A further goal was to investigate the temperature dependency of intensity. For this, the fluorescence signal of all compounds was measured at peak intensity wavelength at 5°C, 25°C and 45°C. For tryptophan, L-phenylalanine, L-histidine, L-alanine, NADH, bacteriorhodopsin and pyridoxine hydrochloride, the highest measured sensitivity of the detection was at 5°C, and exceeded the 25°C-sensitifity approximately by factor 2. Interestingly, L-arginine, FAD and ATP demonstrated better detectability at 25°C. The information related to specific absorption/emission maxima will be used in designing and developing of compact LED-based fluorescence spectroscopy module that is supposed to be a part of the payload of the future autonomous sampling probes (for both terrestrial and space exploration missions).

F3.7-0010-18 THEORETICAL SEARCH FOR PHOTOSYNTHETIC PIGMENTS APPLICABLE TO THE M DWARF ENVIRONMENT USING AB INITIO CALCULATIONS AND THE MACHINE LEARNING

Yu Komatsu, yu.komatsu@nao.ac.jp Astrobiology Center, Mitaka, Japan

As planets around M dwarfs will be good targets in near future observations, detecting photosynthetic biosignatures is a possible way to find life there. The surface vegetation can be distinguished from disk-averaged spectra of the Earth as the vegetation red edge. However, a lot of uncertainties and assumptions lie in the extraterrestrial photosynthesis. At least, we can observe the photosynthesis on the Earth thoroughly and examine its possible form around different photoenvironment from the Sun. In this research, we focus mainly on absorption properties of photosynthesis at the molecular level and search strategically for photosynthetic pigments absorbing longer wavelength radiation. Under planetary atmospheres, available radiation varies depending on their niches, e. g. underwater, clouds. Therefore, excited states of the pigments in varieties of conditions are estimated using ab initio calculations and collected as a database for future observations. Starting with the existing pigments such as chlorophylls and bacteriochlorophylls, artificial pigments are calculated with minor difference like central metal, side chain or solvent as a result from another possible evolution. At least, under given radiation spectrum in surface environments of a planet, we can guess from the database whether the pigments can absorb available light effectively or not combined to possible structures and conditions. To design the new pigments strategically, machine learning methods are applied to explain electronic structures for lower excitation energy.

The detection and identification of organic molecules at Mars are of primary importance for astrobiology, as some of these molecules are life precursors and components. While in situ exploration missions are searching for them at the surface of the planet, it is essential to understand how organic molecules evolve and are preserved at the surface of Mars. Indeed the harsh conditions of the environment of Mars, such as ultraviolet (UV) radiation or oxidative processes, due for example to perchlorate ions, could explain the low abundance and diversity of organic molecules detected so far [1][2]. The MOMIE (Mars Organic Matter Irradiation and Evolution) experiment has been set up to study the evolution of organic matter under simulated martian radiation within the laboratory [3]. Organic samples are exposed under a wide range UV lamp (200-400 nm) as thin homogenous solid films (a fraction of µm thick), by a mean temperature of -55°C and a mean pressure of 6 mbar, close to Mars surface conditions. Most of the organic molecules studied so far were quickly destroyed under Mars surface-like

UV radiation conditions [4]. Uracil is a one-ringed heterocyclic compound, a nucleobase found in RNA, and has been detected in meteorites thus is likely to be found at Mars [5]. Pure uracil samples were irradiated for several weeks in the MOMIE experiment, as well as uracil mixed with perchlorate salts. To characterize the evolution of uracil samples, analyses by infrared spectroscopy (FTIR) were performed all along the experiment. These analyses allowed determining whether uracil is preserved or photodegraded, and if so, its photolysis rate. The FTIR successive analysis showed new absorption band appearance and increase along the UV irradiation. High-Resolution Mass Spectrometry (HRMS) analysis of irradiated uracil samples has shown that uracil seems to form polymers under martian-like UV radiation. These polymers are far more resistant to UV radiation. The effect of perchlorates salts on uracil evolution and preservation has been investigated as well. The MOMIE experiment allows to understand which organic molecules in situ missions should target, as some of them are quickly destroyed in Mars surface-like conditions while others are likely to form new compounds. Uracil polymers, formed by uracil molecules under Mars surface-like radiation conditions, would be very relevant compounds to search for at the surface of Mars.

The Mars Organic Molecule Analyzer (MOMA) is a key instrument on the Pasteur Payload of the ExoMars rover, which will operate in the harsh Martian environment. MOMA is a lightweight (sim12 kg), low power (75 W in average), dual-source, mass spectrometer-based instrument, utilizing a miniaturized linear ion trap (LIT). This instrument enables two modes of operation: i) pyrolysis/gas chromatography mass spectrometry (pyr/GC-MS); and, ii) laser desorption/ionization mass spectrometry (LDI-MS) at ambient Mars pressures. It will be the first to employ an LIT in space, as well as conduct LDI-MS on another solar system body.

MOMA will examine the chemical composition of samples acquired by a drill from depths up to 2 m where organics may be protected from radiation, oxidation and other mechanisms of degradation.

The LDI mode enables MOMA to examine nonvolatile organic compounds up to high molecular weights (1000 Da) that are not easily detected by GC/MS. The collected samples are irradiated by a 266 nm Nd:YAG laser (Laser Zentrum Hannover, e.V.) that can be programmed with 1 to 20 laser shots per burst, at laser energies from 13 uJ to 130 uJ, and is focused to a spot of diameter 400 um. Organics with strong UV absorptivity volatilize and photoionize well from most geological samples. Example compounds that exhibit such behavior are carboxylic acids, aromatic amino acids, nucleobases, polycyclic aromatic hydrocarbons, and kerogen. During LDI a carefully designed piston valve separates the sample held at Mars pressure from the much lower ion trap pressure. This valve is opened before laser irradiation allowing thereafter-ionized compounds to enter the trap via a pressure restricting tube. After irradiation, the valve is quickly closed allowing the LIT to analyze ions from the unprocessed sample and using Martian atmosphere as a buffer gas for ion cooling, removing the need for additional helium. The LIT also offers the ability to enrich low-abundance species and perform structural characterization of complex molecules via multi-frequency waveforms and tandem mass spectrometry techniques. Advanced ion manipulation is partially enabled by the Stored Waveform Inverse Fourier Transform (SWIFT) technique. SWIFT allows for the isolation of a selected mass range for enhanced signal detection, and tandem mass spectrometry (MS/MS) allows for the fragmentation of individual parent ions into a series of product ions. These advanced techniques could help to identify functional groups and the potential origins of compounds detected in the Martian near subsurface, thus enabling molecular structural information to be derived from Martian samples in situ.

In summary, the MOMA instrument provides a great opportunity to advance our knowledge of organic preservation and prospect for life on Mars. The mass spectral results can potentially provide guidance for the definition of analytical capability requirements for Mars Sample Return (MSR).

F3.7-0013-18 CHARACTERIZATION OF THE MARS ORGANIC MOLECULE ANALYZER (MOMA) CHROMATOGRAPHIC COLUMNS FOR ORGANIC MATTER INVENTORY AND ENANTIOMERIC RESOLUTION OF AMINO ACIDS ON MARS WITH THE EXOMARS 2020 MISSION

The Mars Organic Molecule Analyzer (MOMA) experiment will travel to Mars onboard the joint ESA/Roscosmos ExoMars 2020 rover. MOMA is a miniaturized chemical laboratory specifically dedicated to analyzing the organic and inorganic content of samples collected by the rover at the martian surface and subsurface down to 2 meters deep [1]. Through these measurements, MOMA will contribute to characterizing the potential past, present, and future habitability of Mars. MOMA will also go a step beyond habitability and will search for traces of life, or biomarkers, with its unique capability to separate the enantiomers of chiral amino acids, fundamental building blocks of terrestrial life [2]. To reach that goal, MOMA includes a gas chromatograph (GC) and a mass spectrometer (MS). Coupled together, these instruments will respectively separate the volatile compounds produced from heating or chemical treatment of the samples, and provide a spectral signature of each compound. This combination allows the identification of organic molecules. In order to achieve the separation of a wide range of volatile compounds potentially produced from sample treatment, the GC will include four capillary columns, each one dedicated to a specific range of chemical species. Now that the flight model of MOMA is finalized, and the range of operating conditions of the instrument under the Mars surface environmental conditions has been constrained, it is paramount to understand each column's general capability for detecting compounds of interest, and more particularly the specific capability for enantiomeric separation of the onboard chiral column. Evaluation of the column performance was performed on four capillary columns identical to those integrated in the flight model, and using a laboratory setting that allowed the reproduction of MOMA GCMS operating conditions expected to be used on Mars. A set of chemical compounds of interest for Mars surface science and astrobiology was selected and analyzed with the four columns. The use of these chemical standards allowed the optimization of column operating conditions (flow rate and temperature program) based on peak resolution and separation performance. We show that under these optimized operating conditions the columns can detect a wide range of organic and inorganic volatile compounds, and we provide here a first overview of these separation capabilities, with a specific focus on the enantiomeric separation achieved by the MOMA chiral column. These results were tested and validated using two different martian analog samples which underwent the MOMA thermal and chemical treatment processes. This paper presents the performances of the MOMA GC columns and their capability to detect a wide range of compounds, specifically chiral amino acids, on Mars and under the constraints of MOMA operating conditions.

The Mars Organic Molecule Analyzer (MOMA) experiment aboard the ExoMars 2020 rover will analyze the catalog of organic molecules present in samples collected at the surface and subsurface (down to 2 meters) of Mars. MOMA has two complementary analytical modes: Laser Desorption/Ionization-Mass Spectrometry (LDI-MS) and pyrolysis-Gas Chromatography-Mass Spectrometry (Pyr-GC-MS). In addition to the pyrolysis analysis, three types of

derivatization reagents are present in nine capsules (9 out of 30 total cups) and can be used to enable the analysis of refractory compounds by increasing their volatility and protecting labile chemical groups via (N-methyl-N-tert-butyldimethylsilyl-trifluoroacetamide - MTBSTFA, dimethylformamide dimethyl-acetal - DMF-DMA and tetramethylammonium hydroxide TMAH). MTBSTFA is the most versatile reagent. It is dedicated to analyze the labile compounds with a very high sensitivity. DMF-DMA preserves the chiral center of molecules and will allow for their enantiomeric separation. TMAH will be used to extract and characterize potential refractory compounds (macromolecules, kerogen, etc.) and protect polar compounds (alkylation) released from the pyrolysis experiment. In the context of the Exomars 2020 mission and the MOMA experiment, these three techniques have been optimized (volume of reagent, temperature, time of reaction) and tested on several martian analogues. The effect of the presence of perchlorate on each reagent has been examined. By using pyrolysis, DMF/DMA, MTBSTFA and TMAH derivatization chemistry, the MOMA experiment will be able to characterize the presence and the amount of key molecules indicating prebiotic chemistry and life (e.g. amino acids) as well as the enantiomeric ratio of key chiral molecules, used as a bioindicator. These measurements will also give us a first insight into the potential presence of living organisms in the soil of Mars.

F3.7-0015-18 THE LADDER OF LIFE DETECTION

Marc Neveu, marc.f.neveu@nasa.gov

NASA HQ/USRA, Washington, District of Columbia, United States
Lindsay Hays, lindsay.e.hays@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Mountain View, California, United States

NASA, Washington, DC, Wyoming, United States Mitchell Schulte, mitchell.d.schulte@nasa.gov NASA Headquarters, Washington, United States Michael New, michael.h.new@nasa.gov

NASA Headquarters, Washington, District of Columbia, United States

Life detection includes measurements seeking to find life: searching for biosignatures (features that evidence ongoing or past biological processes) and establishing context (properties and processes inherent to the sample's current and past settings). To guide the development of missions seeking to find life on Mars, ocean worlds, and exoplanets, we have built a Ladder of Life Detection (https://astrobiology.nasa.gov/research/life-detection/ladder) [1].

This tool, meant to be challenged and upgraded, lists features of life and assesses their potential for providing conclusive evidence for life through the following criteria: * Sensitivity includes all aspects of instrumental performance (e.g. selectivity, dynamic range). The instrument must detect the feature of life within set performance thresholds, to avoid instrumental false negatives.

* Discrimination from contamination interfering with the measurement, to avoid instrumental false positives and contamination by hardware or other samples. * Replicability: As many measurements and samples as needed to meet predefined goals and capture the heterogeneity of the setting. * Detectability: Physical, chemical, or geological conditions in the sample's current environment must not prevent the measurement to be made. * Survivability: The feature of life must not have been destroyed in the environments encountered by the sample between its synthesis and its measurement. * Reliability: is the propensity for the feature to be produced by life and distinguished from abiotic backgrounds from any of the environments encountered between feature synthesis and measurement. * Compatibility: The feature must be consistent with what is known of life. This criterion assesses the feature's genericity vs. specificity to life on Earth [2]. * Last-resort hypothesis: The measurement (alone or part of a set) must preclude an abiotic origin to a given statistical significance.

Features of life: The Ladder details the propensity for each feature to meet the above criteria. We combine this into a subjective "likelihood" that the feature is diagnostic of life. Features below are loosely ranked from highest to lowest likelihood. We encourage the community to refine this ordering. * Darwinian evolution takes place over many generations of organisms as conditions change. There is no widely accepted means to detect or measure it. It is not practical to detect in unexplored natural environments in the time frame of missions. * Growth and reproduction are evidenced by morphologies of concurrent life stages or a reproductive form, such as cell-like structures in multiple stages, including motility. * Metabolism: Organisms derive energy from their environment and convert it to forms used for growth, reproduction, or repair. Conversion is not fully efficient, so metabolism results in waste. Conversion and waste intermediates or products deviate from abiotic thermodynamic equilibrium or kinetically limited abiotic steady states. Such deviations include elemental or isotopic fractionations, colocation of oxidants and reductants, or a response to substrate addition. * Molecules and structures conferring function include polymers that support information storage or transfer (e.g. DNA, RNA) and functions such as catalysis (proteins), specific structural preferences in organic molecules (e.g. homochirality, repeating charge), and pigments (detectable by remote sensing). * Potential biomolecule components comprise organic compounds not found abiotically (e.g. hopanes, ATP, histidine), complex organics (nucleic acid oligomers, peptides, PAHs), and monomeric units of biopolymers. * Potential metabolic byproducts are distributions of species that differ from those resulting solely from abiotic thermodynamic equilibrium or kinetic steady state. They include distributions of elements present at trace levels in biological matter and patterns of complexity in mixtures of organics. * Biofabrics: Microbial communities can affect the morphology of their environment, creating laminations, mounds, or microbially induced sedimentary structures.

Beyond measurement interpretations and payload design, we anticipate that the Ladder will spur discussion and progress in life detection, leading to improvements to the Ladder itself.

F3.8-0001-18 FAST AND SETI

Lei Qian, lqian@nao.cas.cn

National Astronomical Observatories of Chinese Academy of Sciences, Beijing, China CRAFTS

Di Li, Weiwei Zhu, Yueling Yue, Zhichen Pan, Shen Wang, Tongjie Zhang

Five-hundred-meter Aperture Spherical radio Telescope (FAST) have listed SETI as a science goal. For this, FAST team have collaborated with Berkeley to develop a SETI backend. This backend will be used in the Commensal Radio Astronomy FAST Survey (CRAFTS) that is going to start soon. SETI will be done simultaneously with other observations. Currently, AI technology has been implemented in the FAST pulsar search. In the future, AI will play an important role in the FAST SETI studies.

The year 1998 marked the start of a collaboration in SETI activities between research institutions in Italy (now belonging to the Italian National Institute for Astrophysics, INAF)

and the SETI group at the University of California, Berkeley. In that year, a prototype of the SERENDIP IV was installed on the INAF 32-m diameter Medicina radio telescope (near Bologna, Italy) and used in piggy-back mode to conduct SETI observations for several years. In 2013, the new 64-m diameter Sardinia Radio Telescope (SRT), located near San Basilio, Italy, was inaugurated, and a six-month early science program was conducted in single-dish mode in 2016. Among the several scientific activities to which the SRT will be devoted, SETI is going to be a commensal one. A collaboration between the Italian research groups of INAF and the UC-Berkeley SETI team restarted in 2014; today, the status of the collaboration includes the following activities: 1) Analysis of data taken by the 100-m diameter Green Bank Telescope (GBT) and by the 64-m diameter Parkes radio telescope in the context of the Breakthrough Listen program; 2) SETI observations at SRT, e.g. observations of nearby stars, galaxies or surveys; 3) Development of a real-time KLT algorithm, suitable for SRT, GBT and the Parkes radio telescope; 4) Implementation of a pipeline for Fast Radio Burst searches using the KLT algorithm; 5) Porting of the instruments employed at GBT and the Parkes telescopes to the SRT for SETI, Fast Radio Burst and Pulsar studies; 6) Discussion about a possible participation of SRT in the Breakthrough Listen program, especially by exploiting a seven-feed S-band receiver (3 - 4.5 GHz) currently under development by the INAF team. We present the status of the aforementioned activities, a possible timeline for each of them and the future perspectives of such a collaboration.

F3.8-0003-18 THE BREAKTHROUGH LISTEN SEARCH FOR EXTRATERRESTRIAL INTELLIGENCE: CURRENT STATUS AND FUTURE DIRECTIONS

Andrew Siemion, siemion@berkeley.edu

University of California, Berkeley / Radboud University / SETI Institute, Berkeley, California, United States

Breakthrough Listen is a ten-year program designed to conduct the most sensitive, comprehensive and intensive search for evidence of intelligent life beyond the Earth ever undertaken. Employing the world's largest telescopes, operating across the electromagnetic spectrum, Breakthrough Listen will survey a million nearby stars, hundreds of nearby galaxies and the Milky Way galactic plane. Future extensions to the program will bring wide-field "all-sky" survey capabilities at both radio and optical wavelengths. The program is also investigating data mining approaches using extant and forthcoming survey data, including special focus on machine learning and artificial intelligence-based techniques.

Here we will review the status of the Breakthrough Listen program, briefly discuss recent results and instrument deployments, and detail plans for the near and mid-term future of the program

F3.8-0004-18 MODELING OF FAST RADIO BURSTS WITH THE KARHUNEN-LOEVE TRANSFORM

Nicolò Antonietti, nicolo.antonietti@gmail.com Italy

Fast radio bursts (FRBs) are highly energetic transient radio pulses that are believed to originate outside the Milky Way. FRBs are observed as broadband signals that only last a few milliseconds. Out of the 30 FRBs that have been observed to date, only one has been found to be "repeating", so there might be at least two classes of FRBs. By solving the mystery of their origin and progenitors, astronomers will be able to use FRBs to address a range of open questions about cosmology, intergalactic magnetic fields, and general relativity. Searching for transients such as FRBs involves the detection of dispersed pulses in noisy data. The KarhunenLoeve Transform (KLT) is a mathematical algorithm used to model stochastic processes in time. Unlike the widely used Fourier Transform (FT), the KLT is not limited to harmonic functions; it works well for both narrow and wideband signals; and it works well with both stationary and non-stationary input stochastic processes. Because of its features, the KLT has proven to be way more efficient in retrieving signals out of noise, despite being more computationally intensive and therefore slower. The KLT is therefore the most appropriate tool for modeling transient signals such as FRBs. In this work, we present the application of the relativistic KLT to a sample of FRB signals.

F3.8-0005-18 AN OPTICAL SEARCH FOR DIRECTED ENERGY SIGNATURES IN M31

Andrew Stewart, andrew.henry.stewart@emory.edu

University of California Santa Barbara, Santa Barbara, United States Qicheng Zhang, qicheng@cometary.org

Caltech / IPAC, Pasadena, United States Philip Lubin, lubin@deepspace.ucsb.edu

University of California, Santa Barbara, Santa Barbara, California, United States Scott Taylor, taylorgoleta@aol.com

United States

In realm of optical SETI, searches for pulsed laser signals have historically been preferred over those for continuous wave beacons. There are many valid reasons for this, namely the near elimination of false positives and simple experimental components often present in pulsed searches. However, due to significant improvements in laser technologies and light-detection systems since the mid-20th century, as well as new data from the recent Kepler mission, continuous wave searches can no longer be ignored. We propose a search for continuous wave laser beacons from an intelligent civilization in the Andromeda galaxy. Using only a 0.8 meter telescope, a standard photometric system, and an image processing pipeline, we expect to be able to detect any CW laser signal directed at us from an extraterrestrial civilization in M31, as long as the civilization is operating at a wavelength we can "see" and has left the beacon on long enough for us to detect it here on Earth. The search target is M31 due to its high stellar density relative to our own Milky Way galaxy. Andromeda is home to at least one trillion stars, and thus at least one trillion planets. This is an unprecedented number of targets relative to other past SETI searches. For this reason we call this project the Trillion Planet Survey.

F3.8-0006-18 A SEARCH FOR TECHNOSIGNATURES FROM 14 PLANETARY SYSTEMS IN THE KEPLER FIELD WITH THE GREEN BANK TELESCOPE

Jean-Luc Margot, jlm@epss.ucla.edu

National Radio Astronomy Observatory, Green Bank, West Virginia, United States UCLA Spring 2016 SETI Class

Akshay Shinde, Yashaswi Alladi, Srinivas Prasad MN, M. Oliver Bowman, Callum Fisher, Szilard Gyalay, Willow McKibbin, Brittany Miles, Donald Nguyen, Conor Power, Namrata Ramani, Rashmi Raviprasad, Jesse Santana

Analysis of Kepler mission data suggests that the Milky Way includes billions of Earth-like planets in the habitable zone of their host star. Current technology enables the detection of technosignatures emitted from a large fraction of the Galaxy. We describe a search for technosignatures that is sensitive to Arecibo-class transmitters located within 450 ly of Earth and transmitters that are 1000 times more effective than Arecibo within 14 000 ly of Earth. Our observations focused on 14 planetary systems in the Kepler field and used the L-band receiver (1.15-1.73 GHz) of the 100 m diameter Green Bank Telescope. Each source was observed for a total integration time of 5 minutes. We obtained power spectra at a frequency resolution of 3 Hz and examined narrowband signals with Doppler drift rates between +/-9 Hz s-1. We flagged any detection with a signal-to-noise ratio in excess of 10 as a candidate signal and identified approximately 850 000 candidates. Most (99%) of these candidate signals were automatically classified as human-generated radio-frequency interference (RFI). A large fraction (>99%) of the remaining candidate signals were also flagged as anthropogenic RFI because they have frequencies that overlap those used by global navigation satellite systems, satellite downlinks, or other interferers detected in heavily polluted regions of the spectrum. All 19 remaining candidate signals were scrutinized and none could be attributed to an extraterrestrial source.

F3.8-0007-18 SEARCHING FOR DELIBERATE SIGNALS FROM RED DWARFS

Seth Shostak, seth@seti.org

SETI Institute, Mountain View, California, United States

It’s been the tradition of SETI efforts to examine the vicinities of solar-type stars for radio and optical emissions that would betray the presence of intelligent beings. This conservative approach derives from the simple fact that the one example we have of intelligence orbits such a star. However, recent exoplanet discoveries suggest that red dwarf stars, despite having narrow habitable zones, also have large numbers of planets in these zones. Estimates suggest that 15

- 50 percent of these runty stars have at least one habitable planet. Additional advantages to searching red dwarfs for engineered signals include their abundance and their age.

The SETI Institute has embarked on a survey of 20,000 of the nearest red dwarf stellar systems, using its Allen Telescope Array. We report on the details of this experiment, and the results so far.

F3.8-0008-18 THE BREAKTHROUGH LISTEN SEARCH FOR INTELLIGENT LIFE: THE FIRST SETI RESULTS AND OTHER FUTURE SCIENCE.

J. Emilio Enriquez, e.enriquez@berkeley.edu

University of California, Berkeley, Berkeley, California, United States

The Breakthrough Listen (BL) Initiative is the largest campaign in human history on the search for extraterrestrial intelligence. The work presented here is the first BL search for engineered signals. This comprises a sample of 692 nearby stars within 50 pc. We used the Green Bank Telescope (GBT) to conduct observations over 1.1-1.9 GHz (L-band). Our observing strategy allows us to reject most of the detected signals as terrestrial interference. During the analysis, eleven stars show events that passed our thresholding algorithm, but detailed analysis of their properties indicates they are consistent with known examples of anthropogenic radio frequency interference. This small number of false positives and their understood properties give confidence on the techniques used for this search. We conclude that, at the time of our observations none of the observed systems host high-duty-cycle radio transmitters emitting at the observed frequencies with an EIRP of 1013 W, readily achievable by our own civilization. We can place limits on the presence of engineered signals from putative extraterrestrial civilizations inhabiting the environs of the target stars. Our results suggest that fewer than sim 0.2% of the stellar systems within 50 pc possess the type of transmitters searched in this survey. This work provides the most stringent limit on the number of low power radio transmitters around nearby stars to date. We explored several metics to compare our results to previous SETI efforts. We developed a new figure-of-merit that can encompass a wider set of parameters and can be used on future SETI experiments for a meaningful comparison.We note that the current BL state-of-the-art digital backend installed at the Green Bank Observatory is the fastest ever used for a SETI experiment by a factor of a few. Here we will describe the potential use of the BL backend by other groups on complementary science, as well as a mention the ongoing and potential collaborations focused in particular in the study of astrophysically powered radio emission from stars targeted by our program.

F3.8-0009-18 SETI@HOME ANALYSIS OF OBSERVATIONS OF 220 NEARBY STARS

Eric Korpela, korpela@ssl.berkeley.edu

University of California, Berkeley, California, United States Jeff Cobb, jeffc@ssl.berkeley.edu

University of California, Santa Cruz, Berkeley, California, United States David Anderson, davea@ssl.berkeley.edu

University of California, Berkeley, California, United States Dan Werthimer, danw@ssl.berkeley.edu

University of California, Berkeley, California, United States Vishal Gajjar, vishalg@berkeley.edu

University of California, Berkeley, Berkeley, California, United States

We present the SETI@home analysis of observations of 220 nearby start and 29 non-stellar targets taken in several radio band by the Breakthrough Listen project using the Green Bank Telescope. We describe the data taking process and the analysis pipeline, which utilizes a coherent de-chirp method to search through a large range of accelerating Doppler frames to find signals that are not frequency stable in the topocentric reference frame. We find that most of the high amplitude signal we detect are stable in the topocentric frame. Many have Doppler drift rates similar to what is expected for a satellite in low Earth orbit. We find none that are indicative of a stable frequency in the frame of the barycenter of the solar system. We will show some examples of the signals we detected and discuss their properties. No signals of demonstrably extraterrestrial origin were found.

F3.8-0010-18 ON THE BREAK THROUGH LISTEN AUTOMATIC SEARCH FOR PERIODIC BROAD BAND EXTRATERRESTRIAL SIGNALS

Nectaria Gizani, ngizani@berkeley.edu

Break Through Listen Lab, Berkeley SETI Research Center, Astronomy Department, UC Berkeley, Berkeley, California, United States

Break Through Listen

Andrew Siemion, Vishal Gajjar, Greg Hellbourg, J. Emilio Enriquez, Yunfan Zhang, Howard Isaacson, Danny C. Price, Matt Lebofsky, David H. E. MacMahon, Steve Croft, Griffin Foster, Jack Hickish, David DeBoer and Dan Werthimer

We report on the analysis tool to search for wide band repeating drifting signals in data of 'filterbank' format (raw radio telescope data converted in frequency channels versus time format). We test the pipeline by detecting Pulsars and FRBs using a wealth of stored Break Through Listen (BTL) data from the Green Bank BTL observational campaign in progress. We then extend the testing using BTL data from the Parkes Radio telescope for the southern hemisphere. The code will be updated to handle hd5 data format. Our final scope is to install the code widely for the BTL backend to run while data are being taken, thus contributing to the intelligent ET searching.

F3.8-0011-18 EMPIRICAL LIMITS ON THE EXISTENCE OF INTERSTELLAR PROBES IN THE SOLAR SYSTEM

Joseph Lazio, joseph.lazio@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Mark Hofstadter, mark.hofstadter@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Joseph Masiero, joseph.masiero@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

NASA has five robotic space probes on escape trajectories from the solar system (Pioneer 11, Pioneer 12, Voyager 1, Voyager 2, and New Horizons), and "interstellar probes" are among the concepts being voiced for consideration for future mission concepts. While none of these robotic probes will be operational on the time scale that it would take to reach another star, it is natural to ask whether another civilization might also be sending out interstellar probes. Serious consideration of such interstellar probes dates at least to R. Bracewell in the early 1960s, and the recent discovery of 1I/2017 'Oumuamua has rekindled some of that interest.

We consider what limits exist on interstellar probes in the solar system, using data available from planetary exploration and astronomical sky surveys. Perhaps not surprisingly, the completeness to which the solar system has been searched varies as a function of distance from the Sun. However, with notable exceptions, only extremely crude limits can be placed on the existence of interstellar probes.

Part of this research was carried out at the Jet Propulsion Laboratory, California Institute of Technology, under a contract with the National Aeronautics and Space Administration.

F3.8-0012-18 ARTIFACT SETI AS A FRUITFUL COMPLEMENT TO COMMUNICATION SETI

Jason Wright, astrowright@gmail.com

Pennsylvania State University, University Park, Pennsylvania, United States

Artifact SETI includes searches for waste heat, megastructures orbiting stars, and other evidence of engineering on large scales. Many such searches can proceed via interrogation in novel corners of parameter space of archival optical, infrared, and time domain data sets collected for other purposes. I present examples of how such searches complement communication SETI by enriching target lists, while also generating ancillary science through its false positives and detection of astrophysical exotica. I will also present the philosophy and results of a new graduate course in SETI at Penn State.

F3.8-0013-18 A REPORT ON THE IAA PERMANENT SETI COMMITTEE'S REVIEW OF THE SETI POST-DETECTION AND REPLY PROTOCOLS

Leslie Tennen, ltennen@astrolaw.com

Law Offices of Sterns and Tennen, Glendale, Arizona, United States
Duncan Forgan, dhf3@st-andrews.ac.uk

University of St Andrews, St Andrews, United Kingdom

In 1989, the SETI Committee of the International Academy of Astronautics (IAA) developed the "Declaration of Principles Concerning Activities Following the Detection of Extraterrestrial Intelligence." These SETI Post-Detection Protocols provided a mechanism to guide the procedures for verification and announcement of the confirmed detection of extraterrestrial intelligence. This was followed in 1995 by the "Draft Declaration of Principles Concerning Sending Communications with Extraterrestrial Intelligence" (Proposed SETI Reply Protocols). These Protocols were presented to the United Nations Committee on the Peaceful Uses of Outer Space, and received wide international approval and endorsement from institutions and individuals engaged in or otherwise concerned with the search for extraterrestrial intelligence.

SETI as a discipline has greatly expanded in the decades since the Protocols were written, thanks to advances in instrumentation and observational techniques, more sophisticated theoretical calculations and arguments, and a growing awareness of how to exploit astronomical data from a wide range of wavelengths for signs of intelligence.

In 2010 the SETI Post-Detection Protocols were revised to update and streamline its provisions (2010 Declaration of Principles). However, the revisions have not been adequate to keep pace with SETI's recent scientific and technological advances.

Moreover, the 2010 revisions did not address the revolutionary changes that have been made in the forms of media and information dissemination since the original Protocols were written

- namely the extensive reliance on the Internet and social media, and the concomitant decline in print and other traditional forms of mass communication, which if poorly handled places the credibility of SETI at risk. Recent studies have shown there is therefore a clear need for a fresh review of the Protocols.

As members of the IAA Permanent SETI Committee, the authors were tasked with initiating this review at its meeting during the 68th International Astronautical Congress in Adelaide in September, 2017. We will discuss the current status of this review, and our plans for a wideranging consultation to engage the SETI community, the international community (including scientists in all interested fields), as well as the general public. The aim is for a frank, open dialogue, that ensures as comprehensive a review as possible. This is believed to be the best route to achieve widely accepted, clearly articulated SETI Protocols that will be abided by the community, and will ultimately serve the interests of SETI as a recognized and well-respected academic discipline.

F3.8-0014-18 BREAKTHROUGH LISTEN TARGET SELECTION AT MEERKAT

Howard Isaacson, hisaacson@berkeley.edu

University of California, Berkeley, Berkeley, California, United States

The Breakthrough Listen Search for Extra-terrestrial Intelligence is poised to begin observations at the MeerKat Telescope in pursuit of its 1,000,000 star survey. By conducting commensal observations with other science programs on MeerKat pursuing a wide range of scientific goals and observation strategies, we plan to fully utilize the science capabilities of this next generation facility. Breakthrough Listen has previously focused on a targeted star survey of the Solar neighborhood with the Green Bank Telescope and a survey of the Galactic Plane with the Parkes Telescope. The MeerKat observations will expand the number of targeted star search by a factor of 1000, and will combine the telescope infrastructure of MeerKat with the digital instrumentation and analysis capabilities of Breakthrough Listen.

F3.8-0015-18 BEYOND INITIAL SIGNAL CATEGORIZATION AND SYNTACTIC ASSIGNMENT: THE ROLE OF METADATA IN DECODING AND INTERPRETING NONHUMAN SIGNALS

Denise Herzing, dlherzing@wilddolphinproject.org Florida Atlantic University, Boca Raton, United States Kathryn Denning, kdenning@yorku.ca

York University, M3J 1P3, Canada John Elliott, j.elliott@leedsbeckett.ac.uk

Leeds Beckett University, Leeds, United Kingdom

The processes involved in detecting, verifying, and deciphering an alien signal from space are vast. Although the first two aspects have been studied and thought out over the decades, the decipherment and interpretation process for any alien signal is less explored and has mainly focused on developing methods to discover, identify, and categorize the structural and syntactic content of a signal - to confirm intelligent agent credentials, as a precursor to semantic assignment. Ways forward are suggested by anthropology and animal behavior studies. Anthropologists study and interpret human cultures in various ways. Likewise, animal behaviorists study animals in a variety of ways through signal deconstruction and interpretation.

The data an animal behaviorist analyzes can vary from a physical signal to multiple signals within a social or behavioral context, including an immense array of metadata. Each level of information allows its equal level of interpretation. When scientists observe animal societies, they are usually extracting information by passive observation that involves trying not to disturb an animal performing its natural behavior. Signals are collected and matched with metadata (age, sex, behavioral activity), to allow the interpretation of meaning of an activity.

Some animal vocalizations are discrete, others are graded. Sequences of sound types show absolute and relative changes in the spacing between signals including prosodic aspects such as rhythm and synchrony. We search for the smallest unit of information, combinatorial features of units, and grammar and structure reflecting rules of order. And although patterns of modulation and encoding of information across taxa may provide insight into the data mining of an alien signal, the true interpretation of the meaning of information may rest in the metadata and contextual details used in the society itself. Although we may be able to discern the complexity and structure of a message, interpretation of the meaning of an alien signal may be impossible without such metadata, especially if the content goes beyond a mere greeting and factual statement of their location and biology.

Assuming that an intentional signal (vs. leakage) sent by an alien civilization would include a key for deciphering message content, our job for fully understanding may include searching

for embedded metadata, allowing us to interpret meaning in the message. The assumption here is that communicated patterns and rules would be purposely infused into the message itself, to help the naive receiver interpret the message. How might an alien transmission be encoded to create metadata to help any potential receiver of the information understand its significance? How do we think like a nonhuman when we are human? Studies from both animal behavior and anthropology can inform us of potential ways to look outside ourselves for new ideas. We propose that work of this kind should be an integral part of the SETI 'post-detection' portfolio of concerns, and in turn, that 'post-detection' preparatory work must be integral to SETI as a whole.

F3.8-0017-18 NONLINEAR DYNAMICS IN A POPULATION OF COMMUNICATIVE CIVILIZATIONS THROUGH CONTACTS BY COMMUNICATION CHANNELS AND A STRATEGY OF SETI

Alexander Panov, panov@dec1.sinp.msu.ru

Skobeltsyn Institute of Nuclear Physics, MSU, Moscow, Russia

Nonlinear effects in a population of extraterrestrial civilizations mean generally that civilizations can influence each other by a number of various ways. In this paper we study the situation when contacts between civilizations by communication channels may influence mean lifetime of civilizations in the communicative stage and mean "communication range" - the average limiting distance at which a given civilization can establish direct contact with another civilization. As the mathematical model in the paper shows, such a mutual influence of civilizations can lead to the appearance of a positive feedback loop, due to which at some point in time a very sharp phase transition from a state in which contacts among civilizations are rare (on average the number of partners by contact for one civilization is much less than one), to a state in which each civilization has on average one or more contact partners. The same feedback loop leads to the phenomenon of bi-stability in the population of galactic civilizations, when the same average frequency of the emergence of new civilizations, depending on the prehistory of the system, may correspond to a population with a small number of civilizations and a low probability of contacts, or a population with a large number of civilizations and frequent contacts. A strategy of SETI search in this context is discussed.

F3.8-0018-18 EVO-SETI SCALE FOR EXOPLANETS WITH LIFE

Claudio Maccone, clmaccon@libero.it

International Academy of Astronautics, Torino, Italy

The Evo-SETI Scale (Evo-SETI stands for "Evolution and SETI") is a scale of information measured in bits.

It ranges between zero (corresponding to the time of the origin of life on Earth, 3.5 billion years ago or a little more, like 3.8 billion years ago, or so) and 25,595 bits, that is today's value of the scale.

The straight line between these two values is the Scale measuring the EvoEntropy, i.e. the Shannon Entropy of Information Theory for a family of lognormal probability densities constrained between the time axis and the exponential curve representing the number of Species living on Earth at each instant between 3.5 billion years ago and now. In reality, this exponential is rather the mean value of the number of living Species in the 3.5 billion years of time, since many Species went extinct in the past. Mathematically speaking, we thus have a stochastic process with this exponential mean value and this is called Geometric Brownian Motion (GBM). This GBM turns out to be a lognormal process, and not a Gaussian process.

The relevant mathematics is rather difficult, and was developed by this author in a series of some ten highly mathematical papers published in the International Journal of Astrobiology and in Acta Astronautica since 2010.

But the meaning of the Evo-SETI Scale is quite neat: it shows "how much evolved" a certain Species is with respect to all other Species, both of the past and of the present. And if we replace "Species" with "Complexity", the Evo-SETI Scale becomes the Complexity Scale that we can extrapolate into the future in order to find how much more complex than Humans a certain ET Civilization will turn out to be when SETI, the Search for ExtraTerrestrial Intelligence, will put us in touch with Alien Civilizations.

In conclusion, our Scale really is an Evo-SETI Scale, combining both the past (Evolution) and the future (SETI) into a unique, highly mathematical scheme.

F3.8-0019-18 A MATHEMATICAL AND SCIENTIFIC MESSAGE FOR ACTIVE SETI

Douglas Vakoch, dvakoch@meti.org

METI, San Francisco, California, United States Michael Matessa, mmatessa@gmail.com

METI, San Francisco, California, United States Carl DeVito, devito@math.arizona.edu

METI, San Francisco, California, United States Andrew Kaiser, andrewdkaiser@gmail.com METI, San Francisco, California, United States

On three successive days (October 16, 17, and 18, 2017), METI (Messaging Extraterrestrial Intelligence), a nonprofit scientific and educational organization, transmitted its first interstellar message as part a project called "Sónar Calling GJ273b." The target was a potentially habitable exoplanet named GJ 273b, orbiting Luyten's star, a red dwarf 12.4 light years from Earth. The project was initiated by the Sónar music festival to commemorate its 25th anniversary, and it was a collaboration between Sónar, METI, and The Institute of Space Studies of Catalonia (IEEC). This paper discusses the mathematical and scientific tutorial created by METI for the transmission.

METI's tutorial was sent in binary code at two frequencies, 929.0 MHz and 930.2 MHz, using the 32-meter, fully steerable parabolic antenna of the (European Incoherent Scatter Scientific Association (EISCAT) in Tromsø, Norway, which has a peak power of 2 MW. The tutorial was sent three times on each of three days at 125 bits per second, for a total transmission time of 11 minutes each day. By repeating the message each day, any extraterrestrial recipients will be able to correct errors that occur as the message traverses interstellar space.

The tutorial used a minimal number of key mathematical concepts to introduce fundamental physical concepts like time, frequency, and wavelength. For example, after introducing numbers, basic arithmetic functions, and Pythagorean triples, we describe sine waves through the ratios of sides of a right triangle.

METI's mathematical and scientific tutorial includes innovative features like a "cosmic clock" that lets extraterrestrials confirm that their understanding of time from our scientific message maps onto the passage of time they can observe throughout the transmission itself. An overall design feature we emphasized is that the form of the message is linked to the contents of the message. For example, we explain the notion of radio frequency by sending signals of different frequencies, and then describing the signals in mathematical terms.

F3.8-0020-18 DEVELOPING ETHICALLY INFORMED METI PROTOCOLS

Julia DeMarines, julia@bmsis.org

Blue Marble Space Institute of Science, Seattle, Washington, United States Chelsea Haramia, charamia@shc.edu

Spring Hill College, Mobile, Alabama, United States

No protocols exist to guide, prohibit, require discussion or consensus, prior to sending directed radio or optical messages intended to be intercepted or received by extraterrestrials. Thus anyone with the power and the know-how to operate radio and optical telescopes can freely send out information about our planet to potential onlookers. There is an ongoing debate within the greater SETI community regarding the concerns and risks of transmitting such messages. For example, a statement published in 2015 by the Berkeley SETI Research Center, and signed by several astrobiologists, states, "[i]ntentionally signaling other civilizations in the Milky Way Galaxy raises concerns from all the people of Earth, about both the message and the consequences of contact. A worldwide scientific, political and humanitarian discussion must occur before any message is sent." Here we present the need for ethicists, and philosophers in general, to be included in this discussion and propose a method for addressing the ethical arguments involved in transmitting intentional messages into space with the intent of supporting a cross-cultural and multidisciplinary METI protocol.

F3.8-0021-18 A THREE-STEPS ROAD MAP TO THE NEW FRONTIER: LOCATING THE NEAREST ETIS, AND THE ROLE OF ASTRONAUTS.

Jean-Loup Bertaux, jean-loup.bertaux@latmos.ipsl.fr LATMOS / UVSQ - IPSL - CNRS, Guyancourt, France

An obvious New Frontier for humanity is to locate our nearest neighbors technically advanced (ETI, extra-terrestrial intelligence), in response to the question "Are we alone in the Universe?" This quest can be achieved with three steps: 1. find the nearest exoplanets in the habitable zone (HZ) of their host stars. 2. find bio-signatures in their atmospheric and surface spectra.

3. find unvolontary signs of advanced technology (city lights at night, radio signal leaks). We argue that steps 2 and 3 will require large space telescopes that need to be oriented to targets already identified in step 1 as hosting exoplanets of Earth or super Earth size in the habitable zone. We show that non-transiting planets in HZ are 3 to 9 times nearer the sun than transiting planets, the gain factor being a function of star temperature. The requirement for step 1 is within the reach of a network of 2-4 m diameter ground-based automated telescopes associated with HARPS-type spectrometers. The search should be done by increasing distance from our sun. Steps 2 and 3 will require the building in space of large size telescopes, which elements could launched separately, and be assembled in space by astronauts, in a fashion similar to the way was built the International Space Station. The telescopes could also be placed on the moon or at Lagrange L2 point. Since ETI can spot us, we must be able to spot them. Communication is an independent matter to be discussed separately. The author acknowledge support from the Russian Government Grant 14.W03.31.0017.

F3.8-0022-18 CHARLES CROS AND NIKOLA TESLA, PIONEERS OF INTERPLANETARY TELEGRAPHY

Florence Raulin-Cerceau, florence.raulin-cerceau@mnhn.fr Museum National d Histoire Naturelle, Yerres, France

The birth of SETI (Search for Extraterrestrial Intelligence) is usually dated from 1959 (note 1) with the famous Cocconi and Morrison publication emphasizing that microwaves frequencies were the most appropriate for interstellar communication (note 2). In 1960, American astronomer Frank Drake was the first to put this hypothesis into practice with the Project Ozma. Since then, a lot of searches have been undertaken -in radio or optical frequenciesto attempt to intercept alien signals from advanced technological civilizations. Another aspect of communication is sending messages, known as METI (note 3) (Messaging to ExtraTerrestrial Intelligence, another term is ActiveSETI), which seems to be less prevalent than SETI but perhaps even more debated. Some messages have been sent to the stars during the past decades, generally more for symbolic purposes than to start a "conversation" with other -very far and unknownplanets. Recently, however, the discovery of potentially habitable exo-Earths revived the question of messaging to alien civilizations, since these exoplanets represent now concrete targets. Considering a historical perspective, sending messages to other planets is not a new idea. Pioneering projects were proposed during the nineteenth century to communicate on an interplanetary scale. The latter half of the nineteenth and the very beginning of the twenti- eth century were particularly prolific periods on that question, and many efforts were made to elaborate schemes to contact our neighboring planets through an interplanetary telegraphy. Developments in the field of terrestrial communications (electrical telegraphy, telephone) and intense Martian observations suggested it could be achievable to "talk to other planets", especially Mars. In this paper we focus on French inventor and poet Charles Cros (1842- 1888) and Serbian-American inventor and physicist Nikola Tesla (1856-1943), who have been among the most active and convinced pioneers of interplanetary telegraphy. Their projects are discussed here, even if they have never been put into practice.

1 In fact, the acronym SETI was not used before 1975. 2 Giuseppe Cocconi and Philip Morrison, Searching for Interstellar Communications, Nature, 184 (4690) 844- 846 (1959). 3 The acronym

METI was coined by Russian scientist Alexander Zaitsev in 2005 (http://www.cplire.ru/html/rasr/irm/Dra

F3.8-0023-18 A SEARCH FOR TECHNOSIGNATURES FROM TRAPPIST-1, LHS 1140, AND

10 PLANETARY SYSTEMS IN THE KEPLER FIELD WITH THE GREEN BANK TELESCOPE AT 1.15-1.73 GHZ

Pavlo Pinchuk, ppinchuk@physics.ucla.edu

Thomas Ayalde, Chad Bloxham, Arjun Boddu, Luis Chinchilla-Garcia, Micah Cliffe, Sara Gallagher, Kira Hart, Brayden Hesford, Inbal Mizrahi, Ruth Pike, Dominic Rodger, Bade Sayki, Una Schneck, Aysen Tan, Yolanda Xiao

As part of our ongoing search for technosignatures, we collected over three terabytes of radio astronomy data in May 2017 using the L-band receiver (1.15-1.73 GHz) of the 100 m diameter Green Bank Telescope (GBT). These observations focused primarily on planetary systems in the Kepler field, but also included scans of the recently discovered TRAPPIST-1 and LHS 1140 systems. We will present the results of our search for narrowband signals in this data set with techniques that are generally similar to those described by Margot et al. (2018, https://arxiv.org/abs/1802.01081). We will also describe several improvements to our search algorithms that make the identification of radio-frequency interference (RFI) more robust. In particular, we describe improvements to the characterization of signals that we resolve in the frequency domain.

LIFE SCIENCES AS RELATED TO SPACE (F)

INNOVATIVE APPROACHES TO SPACE HABITATION (F4.1)

F4.1-0001-18 BIOSPHERIC LIFE SUPPORT - INTEGRATING BIOLOGICAL REGENERATION INTO PROTECTION OF HUMANS IN SPACE.

Mauricio Rocha, mautrock@gmail.com Brazil

In the nineties, the Biosphere 2 project innovated, by assembling a set of Earth biomes samplesplus an organic ag one, inside a closed Mars base-like structure, next to 1.5 ha under glass, in Arizona, US. The crew of 8 inside completed their two years contract, though facing setbacksthe system failed, e.g., to produce enough food/air supplies. But their "failures" were as meaningful as their achievements for the future of life support systems (LSS) research. By this period, the Russians had accumulated experience in extended orbital stays, achieving biological outcomes inside their stations. After reaching the Moon, the US administration put the space program as part of a "détente" policy. Alongside the US space shuttle program, the Russians were invited to join the new International Space Station (ISS), bringing to that pragmatic project their physical-chemical LSSthen a top air/water regenerative technology. Present US policy keeps the ISS operational, extending its service past its planned retirement (2016). The extension will allow partner agencies to deploy new experiments there, resuming basic research focusing more forward-looking goals. For deep-space, since consumables logistics becomes more difficultand habitability an issue, with diminishing Earth's view, further research has been recommended. Four major areas have been identified for human protection: (1) radiation mitigation; (2) highly recyclable bio-regenerative (BR) LSS; (3) micro-gravity countermeasures including artificial gravity (AG), and (4) psychological safety. To contribute to the efforts to address these issues, a basic lab/virtual iterative research has been proposed, assuming (in a worst case scenario) that: I) It won't be possible to send people to long deep space missions, safely, with the current (low quality of life) support technology (ISS micro-gravity 'up-gradings'); II) The alternative to implant a Mars surface human supportive biosphere would also not be possible either, due to evolutionary restraints (life could adapt and survive, but not necessarily to favor humans). From the above considerations arises the question: Would an average approach be possible where, by applying the artificial gravity concept to S/Cs, a fragment of Earth bioregenerative environment could be integrated inside reusable manned vehiclesthus enhancing its habitability/autonomy in long deep space missions? For this research question a provisory answer has been provided. And to test it, a small AG+BR bench simulator (plus computer methods) has been devised. Since massive AG systems aren't advisable inside ISS for stability reasons, any future AG+BR trials must be run in association, but outside ISS structure.

F4.1-0002-18 FUNCTIONAL SUBSTANCES WHICH CONTRIBUTE TO DRY HEAT TOLERANCE OF A TERRESTRIAL CYANOBACTERIUM IT NOSTOC SP. HK-01

Shunta Kimura, shuntakimura0130@gmail.com University of Tsukuba, Tsukuba, Japan

Midori Ong, s1410655@u.tsukuba.ac.jp University of Tsukuba, Tsukuba, Japan Toshisada Suzuki, t-suzuki@ag.kagawa-u.ac.jp Kagawa University, Kida-gun, Japan

Kaori Tomita-Yokotani, yokotani.kaori.fn@u.tsukuba.ac.jp University of Tsukuba, Tsukuba, Japan

Terrestrial cyanobacteria can be utilized for bio-chemical circulation in closed bio-ecosystems because of their photosynthetic ability, nitrogen fixation ability, utility as food and tolerance to harsh environments. Dried colonies of a terrestrial cyanobacterium, Nostoc sp. HK-01 (hereafter HK-01), have high tolerances to vacuum, UV, gamma-rays, heavy particle beams and extreme temperatures. Environmental tolerances are important for transportation in outer space. HK-01 was adopted as a biological material for the "TANPOPO" mission (JAXA et al.,), because of their high environmental tolerances. The "TANPOPO" mission is performing space exposure experiments on the Japan Experimental Module (JEM) of the International Space Station (ISS). The results of these experiments will show the ability of HK-01 to survive in space. HK-01 has several different types of cells in its life cycle. Akinete (dormant cell) is the cell type which has a tolerance to dry heat in HK-01 (Kimura et al., Biol. Sci. Space, 2015; 2017). Some functional substances which provide tolerance against heat exist in the akinete cells. In this study, we investigated the properties of low molecule compounds which are accumulated in akinetes of HK-01, to prevent protein aggregation during exposure to heat (Kimura et al., Am. J. Plant Sci., 2017). Our results suggested that the compounds have some function as a compatible solute, which contributes to the dry heat tolerance of akinetes of HK-01.

F4.1-0003-18 BUILDING THE CONDITIONS FOR LIVING TOGETHER, A MAJOR KEY TO SUCCESSFUL SPACE HABITATION

Guy Pignolet, guy.pignolet@science-sainte-rose.net Science Sainte-Rose, Sainte-Rose - La Réunion, France Emeline Legros, e.lgs181@gmail.com

ENSAM Ecole Architecture, Le Port - La Reunion, France

While a lot of research is dedicated to the material conditions to make a sustainable life possible on board of space habitation, a lot of design still has to go in building environments that will facilitate the « living-together ». Half-way between well-known Biosphere-2 and the entire Planet Earth which is the base for our primary experience, Reunion Island, a French/European community at the opposite of California with respect to the Planet, is considered as a remarkable model for good living-together. Attention may be given to an understanding of the special conditions of the environment in the island that allow for this success. What are then the possibilities of downsizing the structures involved in this environment to transfer them to the architectural design of space habitation ?

F4.1-0004-18 CHLAMYDOMONAS-COMMUNITY BIOREACTOR

Sandra Podhajsky, sandra.podhajsky@ohb.de OHB-System AG, Bremen, Germany

Klaus Slenzka, klaus.slenzka@ohb.de OHB-System AG, Bremen, Germany Marcy Frioult, marcy.frioult@ohb.de OHB System AG, Bremen, Germany Nathanael Warth, nathanael@warth-fn.de OHB System AG, Bremen, Germany

The primary requirement of a bioregenerative life support system is to handle the complexity of variable environmental conditions in an efficient and sustainable way. For an entire system design it is mandatory to understand the behavior of each subsystem under these variable conditions. In a modular approach the biochemical and physicochemical inand outputs of each subsystem need to be investigated and optimized before combining several to a more complex and bigger system.

Within the scope of ModuLES (Modular Life Support and Energy Systems), initiated and funded by the German Space Agency, DLR, a photobioreactor (PBR) with the unicellular microalgae Chlamydomonas reinhardtii was selected as the starting point of this research. The PBR and its subsystems were designed to understand the behavior and physiology of Chlamydomonas in a closed system - in regards to the production of oxygen under a given supply of carbon dioxide, nutrients and light energy.

On ground, Chlamydomonas is the most researched unicellular algae around the globe, but when considering cultivating it in a microgravity environment over a long duration of time, several areas show up, which have never been researched. In general, research on ground is conducted in an open system, but for spaceflight application, a closed system is a basic requirement. Thus, the importance to understand the general behavior and physiology is a prerequisite for successful operation of a PBR in space.

Additionally, it is important to allow a community of algae, bacteria and fungi to develop and coexist within the closed system of the PBR, because in future steps of ModuLES, the PBR will be connected to other modules to slowly build up a life support system. Latest when connecting the PBR to a second module it will not be operating under sterile conditions any longer. Thus, the ModuLES-PBR will be filled with a sterile algae solution, but under non-sterile conditions, allowing contamination to occur.

The design is based on a chemostatic process, allowing the investigation of environmental impacts on the microalgae-community, with a set of sensory devices and a sampling unit supporting the physiological research. With these results the next step to a turbidostatic performance can be completed.

As an interface to other subsystems an oxygen removal and carbon dioxide supply over a liquid to gas exchange system is implemented. To achieve the recycling of media, a filtration, analysis, and resupply unit is designed to reduce the needed resupply mass for spaceflight applications to a minimum.

To understand the required flexibility of an MRU to sustain a community-PBR, upper and lower limits of specific media components were tested and the recovery of the community documented in tests. Based on this data and the design adjustments to the media recycling system, the obtained performance data can be used to design the next ModuLES level, the next module which will couple to the PBR.

F4.1-0005-18 GENES OF TERRESTRIAL CYANOBACTERIA WHICH ARE EXPECTED TO BE USEFUL IN SPACE ENVIRONMENTS.

Cyanobacteria are photosynthetic organisms which produce oxygen (O2) on the earth. Terrestrial cyanobacteria are living in extreme environments. Some terrestrial cyanobacteria have tolerance to desiccation and the ability of nitrogen fixation. The habitats of a terrestrial cyanobacterium, Nostoc commune, range from polar environments to desert environments. N. commune has extracellular polysaccharides, tolerance to desiccation and the ability of nitrogen fixation, and its abilities are expected to be useful for agriculture and terraforming. Recently, we analyzed the genome sequence of terrestrial cyanobacteria including Nostoc sp. HK-01 (NIES-2109, hereafter HK-01) isolated from a crust of N. commune. HK-01 survives under low atmospheric pressure such as on Mars and dried HK-01 can tolerate high temperatures and high levels of gamma radiation. Here, we are trying to analyze useful genes for extreme environments using various cyanobacterial genome sequence data, and we will discuss the genes expected to function in space environments.

F4.1-0006-18 SUITABLE UTILIZATION OF TREES AND CYANOBACTERIA WITH REGOLITH FOR HABITATION ON MARS

We have been suggesting that woody plant materials are very useful and important for habitation on Mars. During our research, we have found that woody plants have several properties which can be utilized for therapy and materials for energy and construction on Mars. The cell wall components of woody plants can also be utilized on Mars for construction. It has been well known that cellulose is like a reinforced bar and lignin is like concrete. Hemicellulose is connected to cellulose and lignin. It has been reported that there are possibilities that the bark of tree can be used as vacuum sealant, because those substances are not soluble in water, and can be used as charcoal for the purification of various liquids. On the other hand, cyanobacteria are candidate organisms to be first introduced into Mars's environments. Both of these materials, wood and cyanobacteria, have several components which have protect against UV radiation. Here, we will show some way of using them for habitation on Mars.

F4.1-0007-18 CHLOROPHYTUM PLANTS - CARBON MONOXIDE ABSORBERS

Lyalya Tirranen, tiran@ibp.ru

Institute of Biophysics, SB RAS; International Scientific Centre for Organism Extreme States research, Presidium of Krasnoyarsk Scientific Centre, SB RAS, Krasnoyarsk, Russia

Inst. of Biophysics SO RAN, Krasnoyarsk, Russia

In previous experiments (Gitelson J.I. et.al., 2003), in the air of the habitableroom of the closed ecological system (CES), the presence of toxic impurities was revealed. In particular, carbon monoxide (CO) was discovered. The problem of air purification from harmful substances is one of the most urgent problems in the world. Carbon monoxide is the most difficult issue to deal with. The aim is to identify the ability of Chloropytum plants to absorb carbon monoxide. An answer is needed: can indoor plants growing in a sealed chamber clean the air of gaseous impurities, in particular of carbon monoxide? Blooming adult evergreen Chlorophytum plants (Chloropytum sp.) growing in terrestrial conditions were used as research objects. Research methodology. Blooming adult Chlorophytum plants grew in tightly closed glass vials of 13 and 18 liters, into which carbon dioxide was added daily. Carbon monoxide was supplied according to the scheme of the experiment. The content of carbon monoxide in the air was measured by means of a "Polar" gas analyzer.The measurement range for carbon monoxide was 0 to 5,000 mg/m3. The measurement principle was electrochemical. The content of carbon monoxide in the air of sealed chambers was measured with a "Polar" gas analyzer. 3 experiments were conducted. 26 cases were studied: The first experiment revealed the ability of Chlorophytum plants to absorb carbon monoxide. In the second experiment we found the dependence of air purification upon the volume of the studied air. The third experiment revealed a direct correlation between the mass of photosynthesizing plants and their ability to absorb carbon monoxide. We believe that Chlorophytum plants can be recommended for purifying the airfrom carbon monoxide in the habitable rooms of space and underwater stations.

F4.1-0008-18 THE POTENTIAL APPLICATIONS OF AQUAPONICS FOR BIOREGENERATIVE SPACE LIFE SUPPORT SYSTEMS

Mark Nelson, nelson@biospheres.com

Institute of Ecotechnics, Santa Fe, New Mexico, United States Charlie Shultz, richard.shultz@sfcc.edu

Santa Fe Community College, Santa Fe, New Mexico, United States

The integration of fish and plants in a closed-loop, symbiotic system is commonly referred to as aquaponics. The sustainable design of combined food production has led to many advances and new directions during the past decade. Aquaponics presents a promising new direction for enhancing bioregenerative life support systems for space because of its recycling design and high productivity of plants and fish. Researchers around the globe are now engaged in enhancing aquaponics system sustainability, while reducing inputs (water, fish feed, energy for moving water and supplying oxygen) at the same time increasing outputs in the form of edible food. New methodologies have created advances in these integrated systems, closing the loop of sustainability even tighter. Water use efficiency and nutrient cycling are the major advantages of aquaponic food production over other methods currently used. Decoupled, or dual-loop systems, have been developed that separate the two compartments (fish and plants) for optimization of each component. Nutrient solutions derived from mineralized fish effluents can easily be tailored for specific plants with the addition of small amounts of nutrient salts. This move toward isolating each unit also provides risk-mitigation in the event one of the systems fails. New aquaponics diets are being developed that are designed not just for fish but for the fish and plants by over-fortifying fish diets with additional plant nutrients. Other new directions in fish feed formulation includes replacing fish meal and oil with other sources of protein from plants, insects or algae. Fish feeds formulated with algae have the potential to enhance the nutritional quality of the fish protein by increasing the heart-healthy omega oil content of the final product. Many fish species have now been successfully cultivated in aquaponics systems, spanning a diverse range of temperature. Warm-water fish like tilapia (Oreochromis spp.) and cold water fish such as trout, sturgeon and salmon are successfully being integrated with plants in a beneficial union. The fish provide the majority of the nutrients while the plants clean the water allowing for recycling while creating a zero-discharge facility. Proper air handling allows cycling of the CO2 rich environment created from fish respiration through the plant component, increasing the photosynthetic rate and yield of plant crops, with the added benefit of oxygen being released by the plants. This paper covers the most recent advances in aquaponics in terms of food, energy and water production and use, all critical parameters to optimize for successful adoption as bioregenerative space life support systems.

F4.1-0009-18 CARDIOVASCULAR MEDICAL DEVICES PERFORMANCE UNDER MICROGRAVITY CONDITIONS

Fabio Diaz Palacios, fdiazp@ucb.edu.bo

Universidad Católica Boliviana "San Pablo", La Paz, Bolivia Universidad Catolica Boliviana "San Pablo"

Jhon Ordoñez Ingali Gabriel Antonio Rojas Silva Maritza Patricia Irahola Zalles Diego Rojas Arancibia

The occlusion performance of medical devices for congenital cardiopathies PDA-R and ASD-R were analyzed through a cardiac emulator brought under Microgravity conditions (10-6g) compared to the results obtained with Earth gravity. This experiment is mainly to comparatively determine the occlusion percentage of the aforementioned devices. Results were collected at Drop Tower of the ZARM Institute which provides the needed environment for experimentation.

F4.1-0010-18 "R-EVOLUTION OF ARCHITECTURE FROM EARTH TO SPACE

Ayşe Ören, info@ayseoren.com Turkey 1. Introduction As we embark on a journey for new homes in the new worlds to lay solid foundations, we should consider not only the survival of frontiers but also well-being of those to live in zero gravity.

As a versatile science, architecture encompasses abstract human needs as well.

On our new different direction in the course of the Homo sapiens evolution, we can do this with designs addressing both our needs and senses. Well-being of humans can be achieved by creating environments supporting the cognitive and social stages in the evolution process.

Space stations are going through their own evolution process. Any step taken can serve as a reference for further attempts. When studying the history of architecture, window designing is discussed in a later phase, which is the case for building a spaceship as well.

We lean on the places we live both physically and metaphorically. The feeling of belonging is essential here, entailing trans-humanism, which is significant since the environment therein is like a dress comfortable enough to fit in, meeting needs without any burden.

Utilizing the advent of technology, we can create moods and atmospheres to regulate night and day cycles, thus we can turn claustrophobic places into cosy or dream-like places.

Senses provoke a psychological sensation going beyond cultural codes as they are rooted within consciousness, which allows designers to create a mood within a space that tells a story and evokes an emotional impact.

Colour, amount of light, sound and odour are not superficial. As much as intangible, they are real and powerful tools with a physical presence.

Tapping into induction, we can solve a whole system based on a part thereof. Therefore, fractal designs may not yield good results unless used correctly in terms of design although they are functional, which makes geometric arrangement critical.

F4.1-0011-18 INTERACTION OF PLANTS AND ILLUMINATING ENVIRONMENT ON THE EMOTION AND SLEEP OF HUMAN IN ISOLATION ENVIRONMENT

Hui Liu, liuhui87@buaa.edu.cn

Institute of Environmental Biology and Life Support Technology, School of Biological Science and Medical Engineering, Beihang University, Beijing, China

Wenzhu Zhang, 1010225017@qq.com Beihang University, Beijing, China Hong Liu, lh64@buaa.edu.cn Beihang University, Beijing, China

The emotion and sleep of the crew members in missions of deep space and deep sea exploration are topics of special interest because of the isolation environment. Variable detections have found that sleep and emotion are closely linked. And plants could significantly regulate human's psychology, emotion and sleep through their own color, smell, landscape and release of negative oxygen ions. In addition, the illuminating conditions of the environment in which people were located also had a significant influence on the human emotion and sleep. But there were few reports on the interaction of plants and light environment on human emotion and sleep. Here, we demonstrated the interaction of plants and light environment on the sleep and emotion of volunteers working in closed cabins of "Lunar Palace I", and all the volunteers had no sleep or psychological problems. In this research, three species of plants which had different characteristics in smell and color, and three color temperature levels which were commonly used in people living environment were selected. Through the orthogonal tests of plants and illuminating environment were taken out in the cabins, emotion, blood pressure, heartbeat, electrocardiogram, cortisol, alpha salivary amylase concentration and sleep conditions of volunteers were measured and analyzed. To explore the interaction and mechanism of plant and illuminating environment on human emotion and sleep in isolated environment, and provide scientific basis for improving the physiological and psychological conditions of people in the isolation environment.

F4.1-0012-18 TOLERANCE OF THE CELL LAYER OF NOSTOC SP. HK-01 AGAINST UV RADIATION

Reiko Ajioka, s1430286@u.tsukuba.ac.jp University of Tsukuba, Tsukuba Ibaraki, Japan Shunta Kimura, shuntakimura0130@gmail.com University of Tsukuba, Tsukuba, Japan

Midori Ong, s1410655@u.tsukuba.ac.jp University of Tsukuba, Tsukuba, Japan Hiroshi Katoh, katohiro@gene.mie-u.ac.jp

Mie University, 1577 Kurimamachiya, Tsu, Mie, Japan Kaori Tomita-Yokotani, yokotani.kaori.fn@u.tsukuba.ac.jp University of Tsukuba, Tsukuba, Japan

Cyanobacteria have several abilities to qualify as candidate organisms that can grow in extreme environments, such as on Mars. Dry colonies of a cyanobacterium, Nostoc sp. HK-01, can tolerate several elements of space environments. It has been reported that cyanobacteria have the ability to produce extra-cellular substances (ES), which are protective against UV radiation. The intra-cellular substances may have the same abilities as ES. We investigated the correlation between the protective abilities of ES and intra-cellular substances against UV radiation and the cell layer. Here, we show the relationship between the thickness of the cell layer and the tolerance against UV radiation in Nostoc sp. HK-01. Detailed information about the relationship between cell layer thickness and tolerance against UV radiation would contribute to calculating the number of cells which need to be transported to extraterrestrial environments for space agriculture.

F4.1-0013-18 CHARACTERIZATION OF BACTERIAL CELLULOSE PARAMETERS FOR CLOTHES PRODUCTION IN SPACE USING KOMBUCHA MICROBIAL CONSORTIUM

Agata Kolodziejczyk, fichbio@gmail.com ESTEC, Noordwijk, Netherlands

Kamil Kamiński, Magdalena Jarosz, Joanna Grudzień, Ricarda Schroeder, A. Kolodziejczyk

Kombucha is one of the most popular microbial consortium tested in space and simulated space conditions. It consists of multispecies bacterial component producing bacterial cellulose and multispecies fraction of yeasts producing probiotic brewing. Bacterial cellulose can be used in multiple forms such as paper, bandage, threads, electrophoretic membranes and clothes. Here we tested three different microbial consortia: native kombucha, kombucha with added purple bacteria Rhodobacter sphaeroides and kombucha with added cyanobacteria Synechocystis sp. PCC6803. Bacterial cellulose was transformed into fabric by lyophylization process or air drying. FTIR, ion leaching, membrane interaction with water and SEM methods were employed to determine biological, chemical and physical properties of obtained bacterial cellulose. We characterized and compared critical parameters for cellulose production: mass, energy, transparency, thickness, acidity, vitality and biocontamination. Obtained bacterial celluloses were tested during simulations of space missions by analog astronauts in the Lunares habitat in forms of wristand armbands. Sweat absorption and interaction with skin was analyzed.

Our results suggest that kombucha can be used for clothes production in space. Simple breeding, strong resistance for deleterious space environment and multifunctional applications of kombucha consortium make this microbial population the best candidate for in situ nanocellulose production.

Plant cultivation in closed environments is challenging and several key technologies necessary for space-based plant production are not yet space-qualified or remain in early stages of development. The European-funded Horizon H2020 EDEN ISS project has the goal to develop and demonstrate higher plant cultivation technologies and procedures, suitable for future deployment on the International Space Station and from a long-term perspective, within Moon and Mars habitats. Over the last four years, the EDEN ISS consortium designed and tested essential plant cultivation technologies using an International Standard Payload Rack cultivation system for potential testing on-board the International Space Station. Furthermore, a Future Exploration Greenhouse was designed with the focus on future planetary bio-regenerative life support system deployments. A dedicated greenhouse system, called the Mobile Test Facility, was designed, built and deployed to the German Neumayer III research station in Antarctica. In addition to producing biomass that will be returned to partner laboratories for analysis the facility provides the overwintering crew of 10 people with fresh vegetables during their isolation phase. The presentation gives an overview of the EDEN ISS research objectives, associated milestones and reports on the status of the analogue mission in Antarctica. In addition, the designed and implemented subsystems are described. Further, an overview of the assembly, integration, and test phase that took place in 2017 at the DLR Institute of Space Systems is given.

F4.2-0002-18 EXPERIMENTAL MODEL FOR TESTING CLOSURE TECHNOLOGIES OF MATTER TURNOVER PROCESSES

The experimental model of closed ecosystem for testing the technologies aimed at their use in the sequel for full-scale closed ecosystems including a human has been discussed. The experimental model under study provides full closure with respect to gas exchange and water and allows utilization of human wastes and inedible plant biomass. By means of physical-chemical method, purification of gas medium from pollutants has been provided. The system allows realizing the human participation in the system gas exchange with the help of a gas contour. The results of the technologies' tests in the given system demonstrated detection possibilities of their positive and negative characteristics in the process of durational many months'experiments in the conditions of full airtightness. The experimental model of closed ecosystem developed can be used at the testing and modifying stages of new technologies for their further use in future stations of space application. The study was supported by the Russian Science Foundation (Project no.14-14-00599).

F4.2-0003-18 TIME SCALE: TOWARDS THE NEXT GENERATION RESEARCH AND TECHNOLOGY DEMONSTRATION PLATFORM FOR LIFE SUPPORT SYSTEMS ON THE INTERNATIONAL SPACE STATION

Irene Karoliussen, irene.karoliussen@ciris.no

NTNU Samfunnsforskning AS, Trondheim, Norway Øyvind Mejdell Jakobsen, oyvind.m.jakobsen@ciris.no NTNU Social Research, Trondheim, Norway

Karl Eric Hancock, karl.eric.hancock@ciris.no NTNU Social Research, Trondheim, Norway Ann-Iren Kittang Jost, a.i.kittang.jost@ciris.no NTNU Social Research, Trondheim, Norway

As part of the EU Horizon 2020 project TIME SCALE, a flight concept for cultivation of higher plants and algae platform has been developed. This will allow life scientific research and technology demonstration on the International Space Station to benefit future closed regenerative life support system as part of human space exploration. The concept consists of several subsystems that allow environmental control, plant health monitoring and water and nutrient management. It is modular with possibility to exchange of e.g. a Plant cultivation chamber with an Alga cultivation chamber. The main focus in the project has been on the Crop cultivation system. Particular emphasize has been on the water and nutrient system and the Plant cultivation chamber since lesson learned from previous space experiments show that these subsystems are challenging under reduced gravity conditions, i.e. there is a knowledge and technology gap in this area. To demonstrate this flight concept on ground a Crop cultivation system prototype has been designed and developed. The system has an automated recycling of water and nutrients in a closed water loop, including a gradual increase of the nutrient concentration corresponding to the plant life cycles and nutrient demand. As part of the prototype verification tests, lettuce will be cultivated for 20 days. During the final test eight individual macro-nutrients (ions) will be automatically monitored via the new and state of the art CleanGrow multiion-sensor system. This presentation will outline the TIME SCALE Crop cultivation system prototype functionalities, the final test results with lettuce, as well as, the future potential utilization in flight operations.

F4.2-0004-18 IMPORTANCE OF AIR MOVEMENTS FOR PROPERLY CONTROLLING GAS AND HEAT EXCHANGES BETWEEN PLANTS AND THE ATMOSPHERE UNDER ALTERED GRAVITY CONDITIONS

Yoshiaki Kitaya, kitaya@envi.osakafu-u.ac.jp Osaka Prefecture University, Sakai, Osaka, Japan Hiroaki Hirai, hirai@envi.osakafu-u.ac.jp

Osaka Prefecture University, Sakai, Osaka, Japan

Free convection can effortlessly occur with uneven temperature distribution and air movements are induced by convection even in a closed chamber with no forced ventilation system on Earth. However, very little free convection would occur under a microgravity condition in space. The limited free convection would reduce plant growth by limiting heat and gas exchanges on plant leaves. Plant growth facilities in space require being highly reliable for long durations over multiple plant life cycles with little manual control. Restricted free air convection under microgravity conditions in space would limit plant growth by retarding heat and gas exchanges between leaves and the ambient air. Proper air movement is essential for promoting plant growth not only in the vegetative growth stages but also in the reproductive growth stages, especially in space. Considerable effort must be directed toward the development for controlling air movement and for enhancing the heat and gas exchanges between plants and the ambient air, and consequently promoting the growth of healthy plants and normal reproduction in a closed plant production system under altered gravity conditions in space.

The increased public and private attention for long-term human spaceflight missions to the Moon or Mars stimulates the development of robust regenerative life support systems (RLSS). With a primary focus to minimize the mass of the crew's metabolic consumables, water is the foremost candidate for recycling. In the international Space station (ISS), a physico-chemical system is in place to recovering water from urine and condensate. This system has a relatively high demand for energy and chemicals, only achieves around 70-80% water recovery, and does not allow for the treatment of grey water (e.g. from a shower). To improve these aspects, a novel integration of biological, physical and chemical unit processes was developed within the framework of ESA's RLSS programme MELiSSA (micro-ecological life support system alternative).

First, a grey water treatment system was developed reaching up to 95% water recovery, based on ultrafiltration and reverse osmosis. This system was subsequently upscaled, incorporating also a nanofiltration stage, and validated on the antarctic station Concordia, recovering 75% of the water at ESA hygiene standards. Second, a urine treatment system was conceived, using nitrification as core process. Initial process development was with a packed-bed reactor at MELiSSA's pilot plant in Barcelona on synthetic medium. The process was subsequently optimized to treat urine at maximum conversion efficiencies and rates (up to 1 g N/L/d). Third, an integrated water treatment unit breadboard (WTUB) was established to treat a flow of urine, condensate and shower water generated by one person. The previously validated membrane filtration and nitrification processes were complemented with precipitation, avoiding scaling, and electrodialysis, facilitating the filtration stages. Continuous operation for 3 months showed a total water recovery of around 86%, respecting main ESA hygiene standards. Current research efforts are mainly oriented to adapt the biological process (nitrification) to Space conditions, for instance at the level of defining the microbial consortium, investigating the effects of radiation and implementing a bubble-less aeration system.

MELiSSA's integrated biophysicochemical system WTUB was demonstrated to reach technology readiness level (TRL) 4. This opens up opportunities for more efficient water recovery in future spaceflights, while being compatible with strategies to recover and reuse nutrients from the concentrated and precipitated streams for food production.

F4.2-0006-18 EVALUATION OF A SIMULTANEOUS NITRIFICATION-DENITRIFICATION AND A TWO STAGE MEMBRANE-AERATED BIOLOGICAL REACTOR FOR PRE-TREATMENT OF HABITATION WASTE STREAMS IN SUPPORT OF CLOSED LOOP RECYCLING SYSTEMS

Maryam Salehi PourBavarsad, maryam.salehi@ttu.edu Texas Tech University, Lubbock, Texas, United States Ritesh Sevanthi, ritesh.sevanthi@ttu.edu

Texas Tech University, Texas, United States William Jackson, andrew.jackson@ttu.edu

Texas Tech University, Lubbock, Texas, United States Kensie Mason, kensie.s.mason@ttu.edu

Texas Tech University, Lubbock, United States

Biological stabilization of habitation waste streams has successfully been demonstrated in membrane aerated biological reactors (R-CoMANDAR) for multiyear periods. These systems have demonstrated biological pre-treatment of a variety of waste streams ranging from an ISS composition (urine + flush and humidity condensate) to a possible Early Planetary Base wastewater (urine, flush water, hygiene wastewater, and laundry). Biological pre-treatment can be used to reduce organic matter and convert organic N to NOxor N2. These conversions stabilize the waste stream, reducing downstream growth potential, lower the pH to prevent ammo- nia volatilization and scaling, and can be used to produce N2 for resupply of a habitation atmosphere. The use of biological treatment can also allow for elimination of hazardous pretreat, reducing consumables. As part of our ongoing work, we designed and operated two micro-gravity compatible systems to evaluate the benefit of incorporating denitrification into biological processing of habitation waste streams. We evaluated two systems, a single stage MABR and dual stage MABR-Packed Bed. The single stage system was operated to achieve simultaneous nitrification-denitrification (SNDN) by controlling bulk DO while the dual stage system maintained fully aerobic conditions in the MABR and anoxic conditions in the packed bed. Each system has been operating for over 2 years. We report on an overall comparison of treatment using single stage aerobic conditions, SNDN operational regime, and two stage aerobic-anoxic operation to evaluate the system with the best overall attributes to support recycling of space habitation waste streams. We present rates and overall conversion efficiencies of carbon oxidation, nitrification, and denitrification. We also report on effluent pH, off gas composition, and effluent stability as measured by distillation quality, biological stability, and effluent pH.

MELiSSA project is developing regenerative Life Support technologies for long-term Space missions. It is conceived as a series of compartments, each one performing a specific function, forming a complete cycle, inspired in the terrestrial ecological systems, providing the main functionalities of food production, atmosphere regeneration, water recovery and including as well waste treatment. Each one of the compartments is colonized with specific bacteria or higher plants depending on its dedicated function. The MELiSSA Pilot Plant is a facility conceived for the demonstration of this concept, using laboratory rats as a demonstrator of the crew. In an initial phase, the individual compartments of the MELiSSA Pilot Plant were designed, manufactured, installed, characterized and operated in continuous mode during longterm series of experiments. This has also allowed developing the corresponding mathematical models and control loops, these being intrinsic components of the approach followed within MELiSSA. Following this, the connection of compartments has become the main target of the facility.

The gas phase connection of the photobioreactor based on the culture of the cyanobacteria Arthrospira platensis, producing oxygen, and the animal isolator with rats (mock crew) as oxygen consumers was tested in several experiments of continuous connection with duration of 4-5 weeks. It has demonstrated

good robustness and the ability of the control system to adjust the dynamics of the oxygen production compartment to that of the oxygen consumption compartment, while maintaining a desired percentage of oxygen in the gas phase of the animal compartment. The key variable used to adjust the production of the photosynthetic compartment to the consumer's compartment is the illumination intensity in the photobioreactor, governed by the control system of the MELiSSA Pilot Plant. To note, the demand of oxygen by the consumers is changing following 12 hours day/night periods. The results show a very precise adjustment of the operation of the integrated system and a fast capacity of the control system to drive the oxygen level to a given set point. The evolution of the different variables of the integration, such as oxygen production and CO2 consumption in the photobioreactor, the oxygen consumption and CO2 production in the animal compartment, the illumination intensity, percentage of oxygen in the gas phase and operational conditions of the system at several experimental conditions will be discussed.

The liquid phase connection of the previously described photobioreactor and the nitrifying packed-bed bioreactor based on the co-culture of Nitrosomonas winogradsky and Nitrobacter europaea immobilized on a polystyrene support was tested for a period of six months of continuous operation at different experimental conditions. The experiments provided a validation of the oxygen production in the photosynthetic bioreactor being fed by the outlet of the nitrifying bioreactor. Several residence times have been tested including different inlet flows and light intensity levels in the photosynthetic bioreactor and nitrifying compartment loads. It is also demonstrated that the nitrifying bioreactor can meet the nitrate requirements of the cyanobacteria Arthrospira platensis.

The Arthrospira-B experiment is the first experiment in space ever allowing the online measurements of both oxygen production rate and growth rate of Arthrospira sp. in batch photobioreactors running in ISS. A 4 bioreactors system was integrated in the ISS Biolab incubator. Each reactor is composed of two chambers (gas/liquid) separated by a PTFE membrane and have been running in batch conditions. Oxygen production is measured by online measurement of the pressure increase in the gas chamber. The experiments are composed of several successive batch cultures for each reactor, performed in parallel on ISS and on ground. In this work, a model for the growth of Arthrospira sp in these membrane photobioreactors is proposed and the simulations results obtained are compared to the experimental results gathered in microgravity and on ground. The photobioreactor model is based on a light transfer limitation model, already used to describe and predict the growth and oxygen production in small to large scale ground photobioreactors. This approach is completed by a model for pH in the liquid phase. This permits to consider the pH increase associated to the bicarbonate consumption for the biomass growth. A membrane gas-liquid transfer model is used to predict the gas pressure increase in the gas chamber. Substrate limitation, pH inhibition, as well as oxygen inhibition must be considered in the biological model. A good fitting is achieved between experimental and simulation results when a good mixing of the liquid phase is maintained. These data show that microgravity has no first order effect on Arthrospira growth rate in a photobioreactor operating in space in ISS. Keywords: MELiSSA, Arthrospira sp., photobiobioreactors, model, flight experiment

F4.2-0009-18 LONG-TERM LIFE SUPPORT EXPERIMENT FOR SURVIVAL ON THE MOON: 'LUNAR PALACE 365'

Hong Liu, lh64@buaa.edu.cn Beihang University, Beijing, China

A 365-day bioregenerative life support experiment 'Lunar Palace 365', was carried out in the upgraded closed integrative experimental facility, Lunar Palace-1, facing the long-term autonomous survival of humans in the future lunar base. The completed Lunar Palace-1 contains two plant cabins and one comprehensive cabin with a total area of 500m3. It comprises a series of modules with different functions such as higher plant cultivation, insect rearing, waste treatment, crew living and material storage. In the higher plant cultivation module, 35 species of crops including wheat, soybean, chufa, potato, carrot and leafy vegetables have been cultivated to achieve the complete recycling of vegetarian food, water and oxygen for four crew members. In the insect rearing module, yellow mealworms were fed with fermented inedible biomass to provide animal proteins for the crew. Waste treatment module consists of two sub-modules: solid waste treatment and wastewater treatment. In the solid waste treatment module, parts of the inedible plant biomass and the crew's feces were mingled and fermented in the solid waste bio-convertor to produce soil-like substrate and CO2. Thus, the gas balance could be maintained and the system closure could be increased. Sanitary kitchen wastewater and urine were treated by biological methods in respective circulation. Moreover, the stability of the artificial closed ecosystem with four biological links, 'human-plant-animal-microorganisms', were tested in various circumstances such as the crew shifts and the loss of power. The experiment 'Lunar Palace 365' has achieved a higher degree of food supply and system closure than the previous research. In addition, we also studied the psychological changes of crew members with different combinations during the long-term bioregenerative life support experiment and the interaction with gut microbiome, the developmental succession of environmental microorganisms, the impact of light environment and plant environment on human beings.

F4.2-0010-18 CHALLENGES OF ANTARCTIC PLANT PRODUCTION. LESSONS LEARNED FROM THE DEPLOYMENT AND PRELIMINARY OPERATIONAL RESULTS FROM THE EDEN ISS PROJECT

Matthew Bamsey, matthew.bamsey@dlr.de

DLR, Institute of Space Systems, Bremen, Germany Daniel Schubert, daniel.schubert@dlr.de

German Aerospace Center (DLR), Bremen, Germany Eberhard Kohlberg, eberhard.kohlberg@awi.de

AWI, Bremerhaven, Germany

Dating back as far as the early 1900s, people have been constructing plant production systems in Antarctica. In the early years, these plant production systems were typically small and expeditioner driven. Current systems, such as the EDEN ISS Mobile Test Facility are more complex, use the latest in controlled environment agriculture technology and begin to provide non-negligible impact on overwintering crew diets while minimizing their environmental footprint. Although EDEN ISS, like other Antarctic greenhouse projects focuses on providing fresh food to overwintering crewmembers, it differs from the bulk of these projects in that it has the primary focus of taking advantage of Antarctica's remoteness, extreme environment and stringent environmental regulations to advance space-based production systems. The EDEN ISS project also distinguishes itself from many other Antarctic greenhouse projects in that its development involved several years of planning and design mirroring space system development pathways. This includes a space systems engineering focused process throughout its design, testing and then subsequent deployment and operational phase. This work presents a number of the key lessons learned from the EDEN ISS design phase; assembly, integration and test phase; two month field team deployment phase and from the facility's first few months of operation. Preliminary results from the facility, including leakage, crew time requirements, water use, acoustic tests and power requirements are also presented. These and the results of an assessment of the implemented space system design process are described so as to help future Antarctic greenhouse developers and those using Antarctica as a space analogue site for this purpose, to refine their initial assumptions and improve their overall designs.

F4.2-0011-18 ADAPTIVE LIGHTING SYSTEM FOR SPACE PLANT GROWTH

Yuliy A. Berkovich, berkovich@imbp.ru

Institute for Biomedical Problems RAS, Moscow, Russia Oleg Ochkov, chopic@bk.ru

IMBP, Moscow, Russia

Oleg Perevedentsev, perevol@imbp.ru

Institute of Biomedical Problems, Moscow, Russia Advanced Space Life Support

Yuliy A. Berkovich, Oleg Ochkov, Oleg Perevedentsev

Currently, optimal LED lighting inside plant growth facilities (PGF) is considered constant during plant growth period. However, there is evidence of drift of photosynthesis under constant lighting and various crop demands of lighting with plant age. It follows that the optimal lighting mode can drift along with advancing plant age. Adaptive control procedure involves continuous automatic search of current lighting parameters which provides optimal plant growth ability. Adaptive Lighting System (ALS) for space PGF includes closed plant growth chamber with red and white LEDs luminary and CO2 gas analyzer (GA). PPFD from every type of the LEDs can be controlled by microprocessor (MP) independently of one another. Periodically, the infrared GA measures the decrease in the concentration of CO2 associated with the crop apparent photosynthesis (AF). The MP collects signals from the GA and calculates the crop photosynthetic rate and then merit functional during measurement time. In the capacity of merit functional for space PGF we have taken a product of the crop photosynthetic rate by current photosynthetic efficiency in the time. Gradient and simplex algorithms have been effectively used for search of current optimal lighting parameters. ALS has been tested with Chinese cabbage (Brassica chinensis L.). Total photosynthetic photon flux density (PPFD) and red/white light ratio (X1 and X2, correspondingly) have been used as optimization factors. The factor X1 can be changed from 100 µmol/(m2s) to 900 µmol/(m2s), factor X2 - from 0 to 1.5. Also, we have investigated the crop apparent photosynthesis response on abrupt changes in the level of PPFD (500 µmol/(m2s) to 900 µmol/(m2s) and back) or light wavelength (440 nm to 660 nm and back). It has been shown that transients are non-periodic and last less than 1.5 minutes. At the same level of PPFD, AF of the crop under red light was about 1.5 times higher than under blue one, regardless of the age of the plant. The crop AF reaction on simultaneous alteration of total PPFD and light wave length has been nonlinear. It was shown that ALS can't track exactly a maximum of the merit functional because of time drift during vegetation. So search algorithm's parameters should be justified experimentally to come close to optimal lighting regime during plant growth. The ALS efficiency could be estimated by comparison of plant growth results with ALS and under the best continuous LED lighting.

F4.2-0012-18 APPROBATION OF A PHYSICAL-CHEMICAL METHOD OF ATMOSPHERE PURIFICATION IN CLSS EXPERIMENTAL MODEL

Sergey V. Trifonov, trifonov_sergei@inbox.ru

Institute of Biophysics, SB RAS, Krasnoyarsk, Russia Yegor Morozov, yegormorozov@ibp.ru

Institute of Biophysics SB RAS; Siberian State Aerospace University, Krasnoyarsk, Russia

In the experimental CLSS model a multi-month experiment was developed at the Institute of Biophysics SB RAS to grow higher plants (models of the phototrophic link CLSS) using biological and physical-chemical products for processing organic waste (human exometabolites and inedible plant biomass). This model is closed and has a unique atmosphere that simulates the composition of the CLSS gas medium equipped with methods of engaging in intrasystem mass turnover of organic waste. As such methods were considered technologies of the soil-like substrate (SLS) and the reactor of "wet" combustion in hydrogen peroxide. The presence of volatile organic compounds - gas products formed during the "wet" incineration of waste - requires the use of any methods of cleaning the atmosphere. As such, a method for high-temperature cat- alytic oxidation was developed. The developed method for high-temperature purification on a platinum catalyst differs from the previously optimized heating system (presented at IAC 2016), which allows reaching higher temperatures (up to 900 ° C and above) and obtaining a gas purged of organic compounds from the wet-combustion reactor, which is confirmed massspectrometric method of analysis. The increased temperature and capacity of the catalytic chamber also make it possible to obtain purified gas at higher flow rates. The presence of this system of catalytic atmosphere purification opens the possibility of a full-scale inclusion of the "wet" combustion reactor in mass-transfer processes of CLSS. This paper presents the results of experiments to test the physical-chemical method for cleaning the atmosphere of a hermetic chamber with plants (representatives of the phototrophic link of CLSS) during different periods of time - from several days to several weeks. This study was carried out in the IBP SB RAS and supported by the grant of the Russian Science Foundation (Project No. 14-14-00599).

F4.2-0013-18 UNRESOLVED PROBLEMS IDENTIFIED IN CLASSICAL STUDIES

Frieda B. Taub, taub@uw.edu

University of Washington, Seattle, Washington, United States

At least three issues were identified but not resolved in the early studies of biological life support systems. (1) Jack Myers and colleagues developed algal-mouse O2/CO2 exchange systems that required volume adjustments because a liquid-gas system has very different pressure responses than a gaseous system. (2) Many of the early nutritional studies were badly flawed and better techniques are now being used. If single cells are to be a significant part of a diet, nucleic acids and chlorophyll degradation products were identified as potential problems. (3) Can the chemical energy of waste products be re-introduced into the food cycle or must they be completely oxidized and then re-energized via photosynthesis? Fish (Tilapia) have been raised on human fecal material. These issues may still deserve study.

F4.2-0014-18 BREADBOARD VERIFICATION OF A NOVEL TECHNOLOGY TRAIN TO RECYCLE NUTRIENTS AND WATER FROM URINE FOR HUMAN SPACEFLIGHT

Jolien De Paepe, jolien.depaepe@ugent.be Universiteit Gent, Gent, Belgium

Universiteit Gent, Gent, Belgium

Peter Clauwaert, peter.clauwaert@ugent.be Universiteit Gent, Gent, Belgium

Siegfried Vlaeminck, siegfried.vlaeminck@uantwerpen.be Universiteit Antwerpen, Antwerpen, Belgium

One of the major challenges for long-term Space exploration and habitation is the requirement of a regenerative life support system (RLSS) to provide food, water and oxygen for astronauts, since missions over long distances cannot rely on extensive resupply (Lasseur et al. 2010). Urine, one of the main waste streams in a RLSS, is an important water recovery target, since urine consists for more than 90% out of water, and water supply is responsible for over 90% of the mass of the life support consumables (Tamponnet et al. 1999). Additionally, urine presents the major flux of nitrogen in a RLSS and is rich in other macroand micronutrients (Clauwaert et al. 2017). Currently, on board of the International Space Station (ISS), vapour compression distillation (VCD) is used to recover water from urine, yielding a water recovery percentage of only ~74%, while consuming hazardous and toxic chemicals (chromium trioxide and sulfuric acid) to prevent fouling, and requiring ~315 W (Carter 2009). Moreover, the VCD unit faces severe scaling problems due to uncontrolled calcium sulphate precipitation, which requires extensive maintenance, and the nutrients end up in a toxic brine, limiting nutrient recycling in the RLSS.

Within the framework of MELiSSA (Micro-Ecological Life Support System Alternative), a breadboard installation has been developed to recover water and nutrients from urine, by combining biological

and physicochemical unit processes. First, crystallization removed 93% of the calcium and 82% of the magnesium from the urine, safeguarding the downstream processes from scaling. Second, a moving bed biofilm reactor oxidized >90% of the organics (COD, chemical oxygen demand), preventing biofouling in the electrodialysis (ED) unit. In addition,

>90% of total Kjeldahl nitrogen (mainly present as the uncharged molecule urea) was converted into nitrate by means of nitrification in order to stabilise the urine and to be able to capture the nitrogen in a non-volatile form in ED, avoiding the risk that ammonia volatilisation can pose to the crew. Third, ED was used to extract nutrients from the filtered (0.1 μm) effluent of the bioreactor. Approximately 70% of the nutrients were concentrated in 15% of the ED feed stream. The precipitates, rich in phosphorus, and the ED concentrate, rich in nitrogen and potassium, can be recovered as fertilizers for crop production. Due to nitrification, nitrogen is present in the ED concentrate as nitrate, which is, in most cases, the preferred nitrogen source for plants. The ED diluate is low in nutrients and salts, which makes it a suitable stream for water recovery through membrane filtration.

This novel technology train opens up opportunities for efficient water and nutrient recovery from urine during long-term Space missions through smartly integrating chemical, biological and physical/electrical separation and conversion mechanisms. The testbed facility, sized for one crew member, has been successfully operated in a laboratory environment, corresponding to level 4 on the technology readiness level (TRL) scale. Implementation in Space, however, requires improvement of the long-term stability and performance, and adaptation to the Space conditions.

Space Agencies' human spaceflight plans include as possible future destinations the Moon, asteroids and Mars. The long duration of these missions and its further distance to Earth will require reducing the dependence on Earth's resources as much as possible. A potential solution is the use of a hybrid Life Support System (LSS), combining physico-chemical and biological technologies. The experiment PBR@LSR (Photobioreactor at the Life Support Rack) will be launched to the International Space Station in November 2018 to demonstrate the functionality of such a hybrid life support system. A second objective is to prove the feasibility of nonaxenic long-term cultivation of microalgae (Chlorella vulgaris) for up to 180 days under space conditions. The experiment and development of the µg adapted photobioreactor was initiated in 2014 by DLR and the Institute of Space Systems (IRS) of the University of Stuttgart with Airbus Defence and Space as prime for the flight hardware. The hybrid approach will be demonstrated by the connection of the photobioreactor to the European Life Support Rack (LSR, also known as ACLS - Advanced Closed Loop System). The LSR uses physico-chemical technologies to collect and process the carbon dioxide produced by the astronauts into oxygen, by using a solidamine absorber, a Sabatier reactor and water electrolysis. A highly concentrated CO_2 surplus from the LSR will be fed to the biological component, the PBR, which will produce oxygen and biomass. Every two weeks a partial liquid exchange will allow harvesting biomass and providing fresh nutrients. Relevant sensors (CO_2, O_2, pH, cell density, etc.) will allow evaluating the performance and stability of the experiment and several algae suspension samples will be taken at different intervals and returned to Earth to evaluate the radiation and µg influence on the algal cells. Various experiments were carried out in three breadboards on ground to investigate both biological and technical aspects, in order to design the flight experiment. This presentation gives an overview of the knowledge gained in ground experiments, the design and construction of the flight experiment and the planned operations.

F4.2-0016-18 ADVANCED CANDIDATE CROP ANALYSIS CAPABILITIES AT THE UNIVERSITY OF GUELPH'S CONTROLLED ENVIRONMENT SYSTEMS RESEARCH FACILITY

Thomas Graham, tgraham@uoguelph.ca University of Guelph - CESRF, Guelph, Canada

Understanding how candidate crops respond to the variety of interacting and variable environmental parameters that govern growth and development is critical for optimizing life-support services; it is also critical to ensuring resiliency in the face of inevitable perturbations within the overall life-support system. The Controlled Environment Systems Research Facility at the University of Guelph (Guelph, Ontario, Canada) is home to an extensive suite of whole plant and canopy-scale controlled environment chambers designed to evaluate variable light intensity and spectra (including ultraviolet and far red), atmospheric pressures, atmospheric gas compositions, vapour pressure deficits, carbon dioxide concentrations, and temperature profiles, etc. The net whole plant effect (e.g., net carbon exchange rate) of interactions between these variables, or isolated responses to single environmental parameters, are measured in real time. The range of capabilities will be discussed as they pertain to crop performance in bioregenerative life-support scenarios.

F4.3-0001-18 INTEND TO MASTER THE SOLAR SYSTEM? TAKE CARE OF THE RELIABILITY OF BIOLOGICAL LIFE SUPPORT SYSTEMS

Sergey Bartsev, bartsev@yandex.ru

Institute of Biophysics, SB RAS, Krasnoyarsk, Russia

The statement that the key purpose of space LSS is to ensure the safety of the crew and preserve its health and performance can be considered as trivial. But then it follows logically that the reliable functioning of the LSS should be chosen as the key parameter of any LSS optimization criteria. Between 1996 (Bartsev et al., 1996) and 2003 (Gitelson et al., 2003), a number of papers were published on the problems of ensuring the reliability of the BLSS for long-term missions. At the same time there was practically no substantive discussion of the problem. Sometimes the attitude towards the reliability of the BLSS becomes curious. For example, in the ESA document (Dussap CG TN3: Definition of the Ideal Facility for Life Support Issues, REGLISSE-2003), the statement "Safety is the number one priority of all flight hardware systems" is located in paragraph number 14 (page 22). Recently, a number of papers devoted to the problem of reliability of BLSS have appeared (Holubnyak, Rygalov, 2009, Jones, 2009, Jones, Kliss, 2010; Jones, Ewert, 2010; Jones, 2012). At last, it was noted that studies on the reliability of the BLSS for long-term missions should be started as early as possible. Why? According to well-known formulae for estimating the mean time between failures (MTBF) of technical ssystems it follows that in order to guarantee sure operation of the BLSS for 2 years (the lower confidence limit of MTBF) with a reliability of 99.5%, it is necessary that during a 10-year test of one experimental BLSS there should not be a single failure (15 years in the case of one failure and 25 years in the case of 4 failures). There are no established methods of assessing BLSS reliability due to their hybrid construction - the availability of technical and biological parts. So the reliability of a BLSS depends both on the reliability of the engineering units and on the stability of the ecological component with respect to the failures of technical units considering as perturbations of ecological regeneration unit. In addition, the ecosystem can be disturbed by the appearance of mutants, which can be considered as the introduction of a new species. The evaluation of the reliability of the BLSS with respect to external disturbing (destructive) impacts presupposes conducting critical experiments leading to the destruction of ecological part of BLSS. The problem is that experiments on the destruction of manned BLSS are unacceptable, but similar experiments are necessary to create a technology for building reliable BLSS. Possible approaches to solving this problem are discussed. However it has to be stated that the lack of interest in the search for effective solutions to the mentioned above problems, which is also indicated by the low activity of researchers in F4.3 Event, manifests the lack of a true intention to master outer space.

F4.3-0002-18 DYNAMIC SYSTEM MODELING AND STABILITY ANALYSIS OF ELEMENT CYCLING IN BIOREGENERATIVE LIFE SUPPORT SYSTEM

Yao Du, du-yaoo@outlook.com Beihang University, Beijing, China Yuming Fu, fuyuming1981@gmail.com

Laboratory of Environmental Biology and Life Support Technology, School of Biological Science and Medical Engineering, Beihang University, Beijing, China

Hong Liu, lh64@buaa.edu.cn Beihang University, Beijing, China

Establishing bioregenerative life support system (BLSS) is crucial for building bases on the moon and mars as well as the long-term deep space exploration. To ensure the system run steadily for long time, it is important to notice the process of elements cycling and analyze the stability of the system. The purpose of this work is to establish a dynamic system mathematical differential equations model for the elements cycling process of the 4-biological-link complex system which consists of plants, animal, human and microorganism, called LUNAR PALACE

365. Plant module, animal module and microorganism module were in the dynamic change, and the life activities like photosynthesis of plants and respiration of animal (which we selected yellow mealworm as animal module) drived the vital elements (C, H, O, N) to flow within the system. The crew was in a stable state, and it drived the C, N element in the food to the other modules. Meanwhile, we also integrated the effect of non-biological factors such as temperature, light intensity etc. on the flow of elements in this mathematical model. The interaction of all the biological modules in the 4-biological-link system was able to maintain the balance of the oxygen and carbon dioxide. Based on the establishment of a valid mathematical models by principles of physiology and ecology and the data we collected, we simulated and analyzed the stability of the system in MATLAB/ Simulink. By observing the process of the elements cycling in 4-biological-link, the methods to improve the stability of BLSS and to optimize the design are put forward in theory. The results of the two crew exchange experiments and the simulation demonstrate that feedback characteristics of the biology in this system could eliminate external disturbances and restore the system to be relatively stable state.

F4.3-0003-18 ANALYSIS OF THE KEY FACTORS AFFECTING THE RELIABILITY OF BIOLOGICAL REGENERATION LIFE SUPPORT SYSTEM

Jingfei Hu, hujingfei24@163.com Beihang University, Beijing, China Dawei Hu, dwhu@163.com Beihang University, Beijing, China Hong Liu, lh64@buaa.edu.cn Beihang University, Beijing, China

Abstract:The Bioregenerative life support system(BLSS) is the key technology for long-term manned deep space exploration. BLSS includes units of plant cultivation, animal breeding, microbial treatment solid waste, water treatment cycle utilization, air management and temperature and humidity control subsystems. Hence BLSS involves not only complex mechanical and electrical subsystems but also more complicated biological subsystems. It is a necessary for BLSS to maintain long-term stable and efficient operation for the safety of crew. Once a certain unit fails and cannot be dealt with timely and effectively, it may cause catastrophe for crewmember and the overall system.In the research,analysis of the key factors that affect the reliability of biological regeneration system is quite significant for system operation continuously.Based on the " Lunar Palace 365" experiment, the key factors affecting the reliability of BLSS will be comprehensively investigated and analyzed in order to lay a foundation for further development and improvement of BLSS.

Keywords: BLSS; reliability analysis;mathematical modeling; computer simulation.

F4.3-0004-18 A HEURISTIC METHOD OF FINDING STABILITY-INCREASE FUNCTIONS

Mikhail Saltykov, saltykoff.mixail@yandex.ru Institute of Biophysics, SB RAS, Krasnoyarsk, Russia Sergey Bartsev, bartsev@yandex.ru

Institute of Biophysics, SB RAS, Krasnoyarsk, Russia

Adequate assessment of the dynamic behavior of Closed Ecological Life Support Systems (CELSS) is a prerequisite for effective environmental management in general. Apparently, the only tool for obtaining such an assessment is mathematical modeling of ecosystems. However, in order to constitute tools for obtaining adequate forecasts, ecosystem models have to demonstrate general properties that do not contradict the properties of natural ecosystems. Traditional ecosystem models show that increased complexity of an ecosystem leads to its decreased stability. However it contradicts typical patterns observed for real ecosystems. Possible explanation of this contradiction is that these models are built by analogy with models of chemical kinetics; each species is considered as an auto-catalyst consuming nutrients at a strictly fixed ratio, similar to rate coefficients of chemical reactions. Previous research showed that models with non-fixed ratios of nutrient consumption (or "flexible" metabolism models) can demonstrate a positive relationship between complexity and stability. At the same time it remains unclear what kind of "flexibility" is sufficient to provide similar to natural biodiversitystability dependence. Another "complementary" objective is to determine conditions that lead to negative diversity-stability dependence. Reproducing this feature in models is important since this negative dependence sometimes appears in nature and has to be demonstrated by models. An analytical approach to selecting that kind of modifications which increase Lyapunov's stability of traditional models is suggested. Quantitative estimation of stability for different models at different numbers of species was conducted. It was analytically shown that "flexible" metabolism models can be considered as modifications of traditional models with increased stability. A computer-based experiment with "flexible" models also demonstrates increased Lyapunov's stability with an increasing number of species. However, "flexible" ecosystem models can be unstable ecologically: some species can be eliminated due to increased lack of resources with an increasing number of species.

F4.3-0005-18 ELISSA: A LIFE SUPPORT SYSTEM (LSS) TECHNOLOGY SELECTION, MODELLING AND SIMULATION TOOL FOR HUMAN SPACEFLIGHT MISSIONS

Gisela Detrell, detrell@irs.uni-stuttgart.de

Institute of Space Systems, University of Stuttgart, Stuttgart, Germany Jochen Keppler, keppler@irs.uni-stuttgart.de

Institute of Space Systems, University of Stuttgart, Stuttgart, Germany Stefan Belz, belz@irs.uni-stuttgart.de

Institute of Space Systems, University of Stuttgart, Stuttgart, Germany

The LabVIEW-based simulation tool ELISSA (Environment for Life-Support Systems Simulation and Analysis) allows analysis and comparison of different Life Support System (LSS) designs and optimization. The tool development started in the mid-90's at the Institute of Space Systems (IRS), University of Stuttgart and is continuously being upgraded. The simulation tool, based on a time-discrete method, includes a wide library of LSS potential components for future long duration missions, including technologies currently in use and in development. Both regenerative physico-chemical and biological components are included in the four defined subsystems: air, water, food and waste management. Each component is modeled according to available reference data: from specifications for existing technologies or experimental data or physical and chemical fundamentals for those in development. Special focus is set on updating the components with experimental data from the research carried out at the IRS lab, for example for fuel cell or photobioreactor models. A user-friendly interface allows the selection of the LSS components and other mission specific parameters such as size of the crew, mission duration, initial consumables or tank sizes. Depending on the computer capability, a simulation of 500 days can last a couple of hours, with a time step of 60 seconds. The result of the simulation is the evolution of the system over the mission time, which enables an adapted sizing of the system: the components, tanks and required consumables. To compare different LSS designs, ELISSA generates as an output parameter the Equivalent System Mass (ESM). Complementary, two extra tools were developed in the last decade: PreLISSA (Preparation Tool for Life Support System Simulation and Analysis), designed to carry out trade-offs based on time-averaged operation and ReLISSA (Reliability tool for Life Support System Simulation and Analysis) for a reliability analysis. This poster presents an overview of the current status of ELISSA, PreLISSA and ReLISSA. An example of a Mars Mission system study and future development possibilities are presented.

F4.3-0006-18 MODELING OF SOLID WASTE TREATMENT UNIT IN BLSS

Guanghui Liu, 1527818201@qq.com Beihang University, Beijing, China Dianlei Liu, 872550080@qq.com Beihang University, Beijing, China Dawei Hu, dwhu@163.com

Beihang University, Beijing, China Hong Liu, lh64@buaa.edu.cn Beihang University, Beijing, China

A bioregenerative life support system (BLSS) is an artificial closed ecosystem which provides basic human life support for long-duration and far-distance space activities such as lunar bases. Solid waste treatment unit is an important part of BLSS. It plays a vital role in the gas and material cycle of the whole system. From May 2017 to May 2018Lunar Palace 365 Experiment was conducted in Lunar Palace 1, an integrative experimental facility for Permanent Astrobase Life-Support Artificial Closed Ecosystem. In the experiment, solid wastes such as plant straws and human feces were treated with microbial aerobic fermentation in a bio-convertor. Dynamic model and parameters of the microorganism and substrate balance, water balance and heat balance process was determined. And the integral model of solid waste treatment unit was developed. CO2 production rate, water content, microorganism and substrate weight in Lunar Palace 365 Experiment were predicted using the model. The predicted results and actual test results were compared and analyzed. This research result has an important significance in effectively improving the predictability and controllability of BLSS.

F4.3-0007-18 DESIGN AND IMPLEMENTATION OF SOFTWARE FOR DIETARY MANAGEMENT IN SPACE PERMANENT BASE

Ming Zhao, zhaoming@cau.edu.cn

China Agricultural University, Beijing, China

Controlled Ecological Life Support System (CELSS) is one of key technologies for establishment of permanent base on the surface of the Moon or Mars. The configuration and closure of CELSS largely depends on the astronaut's diet. Thus, it is necessary to set up a dietary management system for astronauts in the CELSS.

In this paper a dietary management system was especially designed for CELSS. Through this dietary management system a more reasonable and comprehensive recipe for astronauts could be obtained so that reasonable configuration and closure of CELSS would be gained as well. Database was used to store the biochemical data of Chinese daily edible vegetables. The dietary reference intakes for astronauts were developed according to nutritional recommendations of Chinese Nutrition Society, as well as considering the effects of the space environment on human's diet and physiology. The integrated criteria for plant screening were summarized, which were employed as constraints of the optimization process along with the nutritional requirements.

Optimal results of a more reasonable and comprehensive recipe for astronauts in CELSS could be obtained by means of the multi-objective programming method. It could be used to provide assistant decision support for the CELSS designers.

F4.4-0001-18 HISTORICAL PARALLELS OF BIOLOGICAL SPACE FLIGHT EXPERIMENTS ON SOYUZ, SALYUT, MIR AND SHENZHOU

Galina S. Nechitailo, spacemal@mail.ru

Inst. of Biochemical Physics RAS, Moscow, Russia Alexey Kondyurin, kond@mailcity.com

University of Sydney, Sydney, Australia

Human exploitation of space is a great achievement of our civilization. After the first space flights a development of artificial biological environment in space systems is a second big step. First successful biological experiments on a board of space station were performed on Salyut and Mir stations in 70-90th of last century such as - first long time cultivation of plants in space (wheat, linen, lettuce, crepis); - first flowers in space (Arabidopsis); - first harvesting of seeds in space (Arabidopsis); - first harvesting of roots (radish); - first full life cycle from seeds to seeds in space (wheat), Guinness recorded; - first tissue culture experiments (Panax ginseng L, Crocus sativus L, Stevia rebaundiana B; - first tree growing in space for 2 years (Limonia acidissima), Guinness recorded. As a new wave, the modern experiments on a board of Shenzhou Chinese space ships are performed with plants and tissue culture. The space flight experiments are now focused on applications of the space biology results to Earth technologies. In particular, the tomato seeds exposed 6 years in space are used in pharmacy industry in more then 10 pharmaceutical products. Tissue culture experiments are performed on the board of Shenzhou spaceship for creation of new bioproducts including Space Panax ginseng, Space Spirulina, Space Stetatin, Space Tomato and others products with unique properties. Space investments come back.

To sustain human Space exploration missions where no resupply from Earth or other planets is possible, adequate life support systems need to be developed. The recycling of water and nutrient, combined with in-situ production of oxygen and food can be achieved thanks to the metabolic capabilities of living organisms, including bacteria. Nitrogen is an element of key importance to produce food that meets the nutritional requirements of the crew, and several biotechnological processes for its recovery have been proposed. The European Space Agency's Life Support System (MELiSSA) for instance, houses nitrogen conversions in the CI thermophilic anaerobic hydrolytic compartment and in the CIII nitrifying compartment, to recover a nitrified stream for cyanobacteria (CIVa) or edible higher plant (CIVb) production. But Space is a challenging environment for life: microgravity, temperature, UV and cosmic radiation can affect survival, health and functionality of humans, microorganisms, animals and plants. To validate nitrogen recovery bioprocess for Space application, ammonia oxidizing bacteria (Nitrosomonas europeae ATCC 19718 and Nitrosomonas ureae nm10), nitrite oxidizing bacteria (Nitrobacter winogradskyi ATCC 2539 and Nitrospira moscoviensis M1) and a ureolytic heterotroph (Cupriavidus pinatubonensis 1245) were exposed to the Lower Earth Orbit conditions of the International Space Station (ISS) for 7 days. Additionally, Nitrosomonas europeae ATCC 19718, Nitrobacter winogradskyi ATCC 2539, Cupriavidus pinatubonensis 1245, and three mixed communities (one for urine nitrification, one containing anammox and one containing ammonia-oxidizing archaea, AOA) were exposed to 20 ± 4°C, hyper and -gravity and between ca. 20 and ca. 40 mGy of radiation over 44 days FOTON-M4 flight, obtaining a radiation dosage which is about the double as inside the International Space Station (ISS) for the corresponding period. Our results shows that temperature control during storage influence is more important than LEO/radiation-exposure, since the activities observed after the Space flights were generally comparable to the control exposed to similar storage conditions on Earth. The mixed microbial communities were more rapidly (3 days) reactivated compared to the pure cultures and the synthetic microbial communities (10 days), however their nitrifying activity show greater variability following LEO exposure. No clear influence of the key ammonia/nitrite oxidizing genera and community eveness/diversity was found.

Our results indicate not only that the bacteria involved in these conversions can withstand Space travel and storage under space flight conditions, but also be reactivated efficiently after space flight for application in a regenerative life support system. Overall, successful preservation of all the key metabolic nitrogen conversion functions was achieved. For the first time, the potential of ureolysis, nitrification, denitrification and anammox is validated after flight exposure, encouraging future Space applications for N-related microorganisms.

F4.4-0003-18 MOLECULAR BIOLOGY OF BACTERIAL BIOFILMS IN THE HUMAN SPACEFLIGHT ENVIRONMENT

Wayne Nicholson, wln@ufl.edu

University of Florida, Merritt Island, Florida, United States Michael Morrison, mmorrison2015@ufl.edu

University of Florida, Merritt Island, Florida, United States Patricia Fajardo-Cavazos, pfajardo@ufl.edu

University of Florida, Merritt Island, Florida, United States

An important microbiological issue which has emerged during long-duration human spaceflight is the interaction of resident microbes with various materials, leading to biocorrosion and biodeterioration in space habitats. Notably, bacterial biofilms have been implicated in contamination and biofouling of potable water systems in long-duration spacecraft such as the Space Shuttles, space station Mir, and the International Space Station (ISS). Recent results from ISS experiments indicate that spaceflight can promote biofilm formation in it Pseudomonas aeruginosa and it Escherichia coli, and can promote invasive growth of the yeasts it Saccharomyces cerevisieae and it Candida albicans. It is thus important to understand how exposure to the spaceflight environment influences biofilm formation in microbes.

The well-studied Gram-positive bacterium it Bacillus subtilis has long served as a model organism for studies in space biology and astrobiology. it B. subtilis is a frequent isolate from ISS surfaces, and biofilms containing it B. subtilis were reported from the Space Shuttle water system. In two recent missions to the ISS (BRIC-21 and BRIC-23), we measured transcriptomic responses of it B. subtilis to the spaceflight environment. In both experiments we observed significant up-regulation of transcripts associated with biofilm formation in flight (FL) samples when compared to matched ground control (GC) samples. Specifically up-regulated in FL samples were transcripts originating from: (i) the it epsABCDEFGHIJKLMNO operon, which encodes the extracellular polysaccharide (EPS) biofilm component poly-N-acetylglucosamine;

(ii) the it tapAsipWtasA operon, encoding major protein components (TasA and TapA) of biofilms, and (iii) it bslA, encoding the hydrophobic surface layer protein BslA. In addition, transcripts of the biofilm regulatory genes it slrA and it kinD were also consistently up-regulated in FL samples. These results represent the first molecular evidence from any bacterial species for up-regulation of biofilm gene expression under microgravity conditions.

The results above strongly suggest that it B. subtilis may preferentially form biofilms under spaceflight conditions. Unfortunately, the standard laboratory strain of it B. subtilis used in the spaceflight transcriptome studies, strain 168, has lost the capacity to form robust biofilms during the course of its >60-year history of laboratory domestication. We therefore propose to investigate biofilm formation in spaceflight using the “wild” ancestral it B. subtilis strain NCIB3610. The molecular aspects of biofilm formation in this strain have been studied intensively and its genome has been completely sequenced and annotated. We will present an update on our plans for investigating NCIB3610 biofilm formation in matched FL vs. GC samples on ISS and results from pre-launch experiments. Supported by NASA Space Biology grant NNX14AT38G.

F4.4-0004-18 EFFECTS OF SIMULATED MICROGRAVITY ON GROWTH, PHYSIOLOGY AND PHOTOSYNTHETIC MACHINERY IN SYNECHOCYSTIS SP. PCC 6803

Use of plants as a bioregenerative life support system has been widely accepted and envisaged in space research. However, very little information has been explored using unicellular photosynthetic cyanobacteria as a promising component of life support system. Cyanobacteria offer several advantages like increased metabolic adaptability, reduced payload, simpler nutritional requirements, less space and are good source of nutritious food, therefore serving themselves as an organism of choice for space research. In the present work, Synechocystis sp. PCC 6803 was used as a model organism for photosynthetic study in simulated microgravity condition. Briefly, the actively grown culture of Synechocystis was exposed on 1-D clinostat for five days continuously at 25° C. Control (1 g) was kept next to the clinostat with all environmental conditions same as for microgravity. The obtained result showed a significant alteration in protein profile as well as biochemical changes in microgravity grown culture compared with the control. However, there was no significant difference in growth in control and microgravity grown culture. Simulated microgravity promoted the synthesis of photosynthetic pigments compared to control. Further, the effects of simulated microgravity on the phycobilisome complex, the principle photosynthetic machinery will be discussed. Finding of this study would give insight into the current challenges and improvement in cyanobacterial studies in space.

F4.4-0005-18 ABILITIES OF A CYANOBACTERIUM, NOSTOC SP.HK.01, TO UTILIZE ITS OWN CELLS IN DEFENCE AGAINST UV RADIATION

Mie University, 1577 Kurimamachiya, Tsu, Mie, Japan

We have been studying the tolerances to space-environments of a cyanobacterium, Nostoc sp. HK-01 (hereafter referred to as HK-01), for over ten years. We have already found that dry colonies of HK-01 had high tolerance to UV. It has been reported that some components in extracellular polysaccharide (EPS) have been tolerant to UV, but more details were not deeply investigated. There is a possibility that there is a relationship between the number of cells and defense against exposure to UV. The thickness of cell layers may be related to tolerance to UV radiation. Several dry colonies of HK-01 were investigated after exposure to UV radiation. Cells with and without EPS were also tested after exposure to UV radiation. In the results of tested colonies of HK-01 under several condition after the UV radiation. The results obtained after exposure to UV radiation showed that there is a correlation between the thickness of layers of cells and their survival rates. We will discuss those results and future space agriculture using HK-01 on Mars.

Fungal growth has been detected aboard the Russian Space Station (Mir) and the International Space Station (ISS), promoting biodegradation of the spacecraft materials and compromising life-support systems [1-2]. Defining filamentous fungi biofilms is currently in debate among the scientific community. Nevertheless these are indeed associated with higher tolerance and resistance to adverse conditions [3-5]. To better monitor and control fungal contamination during long duration spaceflight missions, the NASA-funded project "Biofilm in Space (BFS)" comprises a spaceflight experiment aboard the ISS, planned to be launched late 2018/early 2019 on a SpaceX flight. It will study growth and biofilm formation in microgravity also testing coupons of different materials (such as quartz, aluminum silicone, and polycarbonate developed by the Saarland University), in the search for spaceflight-relevant antimicrobial surfaces.

To mature the experimental design to be spaceflight ready, several pre-flight tests need to be performed. For this, one of the tasks of the German Aerospace Center (Institute of Aerospace Medicine, Cologne) is to define and optimize the culturing conditions for the fungus Penicillium rubens on the space hardware: the 12-well BioCell (developed by BioServe Space Technologies). Because growth in the BioCell will inevitably differ from common laboratory containers (such as flasks or multi-well plates), it is important to assess: i) growth and biofilm formation in the BioCell; ii) growth and adherence to coupons compared with planktonic growth iii) needed adaptations for the space-proven culturing system. An initial approach tested P. rubens growth in the 12-well BioCells, both in simulated microgravity provided by clinorotation (µ x g) and in ground static control (1 x g), as well as its adherence to two different material coupons - cellulose membrane and aluminum.

Results revealed fungal growth on all the 12-wells of the BioCell culturing system, within the tested 48h and 96h of incubation in both µ x g and 1 x g conditions. Biomass measurements showed more adhered biomass in cellulose membrane coupons (average 100% increase) than in aluminum coupons (average 3% increase). Additionally, fluorescence microscopy of couponattached biomass disclosed their hyphal structure and surrounding matrix. The 12-well BioCell was established as an adequate culturing system for growth of P. rubens in the upcoming spaceflight experiment aboard the ISS. This marks an important step in having new methodologies to study filamentous fungi biofilms that will help to develop the appropriate contamination-control measures, both on Earth and in space.

One of the major concerns for long-term exploration missions beyond the Earth's magnetosphere, is radiation risks. These risks arise primarily from solar energetic particles (SEPs) and galactic cosmic rays (GCRs). With the goal of manned Mars exploration, the production of fresh food during long duration space missions is critical for meeting astronauts' nutritional and psychological needs. However, the biological effects of space radiation on plants have not been sufficiently investigated and characterized. This comprises a significant knowledge gap in terms of future NASA interplanetary missions and for establishing permanent inhabited bases.

This pilot study is to evaluate the effect of simulated GCRs on Arabidopsis thaliana seeds using the NASA Space Radiation Laboratory (NSRL) facility at Brookhaven National Lab (BNL). The imbibed Arabidopsis seeds were exposed to two simulated GCR scenarios of combined ions including protons, helium, oxygen, titanium, and/or iron ions. The exposures were conducted acutely or at a low dose rate over a 4 hr time period. Some seeds were also exposed to individual high-LET ions (protons, helium, or titanium ions). Control and irradiated seeds were then transferred to a hydroponic system for growth within an environmentally controlled chamber with light intensity at 150 mol·m-2·s-1. Six days after planting, morphological parameters were measured to evaluate radiation induced damage in the seedlings. Simulated GCR induced transcriptomic changes in 10 day Arabidopsis seedlings were also investigated using the same

GCR scenarios mentioned above.

Exposure to simulated GCRs or individual high-LET ions had no impact on the germination rate of both control and irradiated seeds. However, the morphological changes of the seedlings cultured from irradiated seeds were found to be doseand ion quality-dependent, with heavier ions causing more severe damages. Transcriptomic profiles were significantly altered in the seedlings exposed to charged particles. Estimate hits/tracks per imbibed seed, root meristem and shoot meristem regions in a mature Arabidopsis embryo were also determined. More experiments need to be performed to complete the study using more doseand time-points and to explore the mechanisms underlying heavy ions induced damage in Arabidopsis and other model plant organisms, especially those that have been identified as potential candidate crops for astronaut consumption and have been or will be grown on ISS.

F4.4-0008-18 TOWARD BIOTECHNOLOGY IN SPACE: HIGH-THROUGHPUT INSTRUMENTS FOR IN SITU BIOLOGICAL RESEARCH BEYOND EARTH

Fathi Karouia, fathi.karouia@nasa.gov

University of California San Francisco/NASA Ames Research Center, Moffett Field, California, United States

Kianoosh Peyvan, kia@peyvan.org

Peyvan Systems Inc., Seattle, United States Andrew Pohorille, andrew.pohorille@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States

Over the last two decades high throughput methods have revolutionized the field of biology. The key components of this new approach are genomics, proteomics and metabolomics, collectively known as "omics". They are aimed at studying content and activity of the full complement of genes, proteins and metabolites, respectively, in an organism or a consortium of organisms. Even though omics approaches are relatively new, they are already widely used and have yielded many important insights to biology and medicine. In the half-century of space exploration multiple lines of evidence have accumulated to state with near-certainty that effects of space environments are not limited to a single gene or even a small number of genes, or a single subcellular component, but instead influence many genes and cell functions. This implies that they should be studied using global, integrative methods. This, in turn, means, that omics approaches are not only helpful, but are indispensable for space biology. To achieve the expected advances from omics technologies, the current paradigm of performing data analyses post-flight should change to include omics tools for in situ research. However, developing omics instruments for space applications remains a challenge even in the case of mature methods. Among contributing factors are the need for substantial miniaturization and automation, compatibility of all protocols and materials with conditions in space, safety issues and the requirements for low power and operation independent of the direction of the gravity vector. We will discuss which omics technologies are currently amenable to adaptations for space applications and how these adaptations can be achieved. We will review ongoing efforts aimed in this direction and discuss scientific benefits that they might bring. In this context, we will argue that, with sufficient commitment, at least some instruments for high-throughput measurements could be ready for deployment on-board spacecraft in the next 2-3 years. Once developed and deployed, omics tools can be used for a wide variety of high-value studies on biological systems ranging from microorganisms to humans that hold significant potential for discoveries in space biology, biotechnology, pharmacology and medicine.

F4.4-0009-18 STUDIES OF PLANT GENE EXPRESSION AND FUNCTION STIMULATED BY SPACE MICROGRAVITY

Jinying Lu, lujinying2001@sina.com

China Academy of Space Technology, Beijing, China Huasheng Li, yeshuasheng@163.com

China Academy of Space Technology, Beijing, China Min Liu, mliu@genetics.ac.cn

China Academy of Space Technology, Beijing, China

One of the important questions in space biology is how plants respond to an outer space environment i.e., how genetic expression is altered in space microgravity. In this study, the transcriptome of Arabidopsis thaliana seedlings was analyzed as part of the Germany SIMBOX (Science in Microgravity Box) spaceflight experiment on Shenzhou 8. A gene chip was used to screen gene expression differences in Arabidopsis thaliana seedlings between microgravity and 1g centrifugal force in space. Microarray analysis revealed that 368 genes were differentially expressed. Gene Ontology (GO) analysis indicated that these genes were involved in the plant's response to stress, secondary metabolism, hormone metabolism, transcription, protein phosphorylation, lipid metabolism, transport and cell wall metabolism processes. Real time PCR was used to analyzed the miRNA expression including Arabidopsis miR160,miR161, miR394, miR402, miR403, and miR408. MiR408 was significantly upregulated. An overexpression vector of Arabidopsis miR408 was constructed and transferred to Arabidopsis plant. The roots of plants over expressing miR408 exhibited a slower reorientation upon gravistimulation in comparison with those of wild-type. This result indicated that miR408 could play a role in root gravitropic response.

F4.4-0010-18 SURVIVAL OF BACTERIA IN ALTERED GRAVITY: ADAPTATION STRATEGIES AND IMPLICATIONS IN PLANETARY PROTECTION

Modern College of Arts, Science and Commerce, Shivajinagar, Pune, India Vinaya Shinde, rebecca.thombre@gmail.com

Modern College of Arts, Science and Commerce, Shivajinagar, Pune, India

Gravity is a major parameter for the survival of micro-organisms in space. Micro-organisms need to evolve complex adaptation strategies to survive in hyper gravity stress. Organisms experience altered gravity in space and when spacecrafts or rockets eject or land on surfaces. For validating the ability of interplanetary travel or survival in Space, the survival of micro-organisms in altered gravity is imperative. These organisms' micro-organisms can stay dormant during stress or adapt to the stress and revert to their metabolically active state when they encounter favourable environment. The study of such survival in altered gravity also is important while devising planetary protection strategies as ejection of microflora from Earth in outer space is a major concern. The present investigation focused on studying the growth and physiology of bacteria and its antimicrobial resistance pattern in hypergravity of 223 g. The effect of hypergravity on cell membrane integrity and permeability and cellular stress was studied by using membrane leakage assays. The survival strategies of bacteria in inhabitable environment are useful to device an appropriate measures to reduce the contamination from spaceflights and spacecrafts and to strengthen Planetary protection.

China Space laboratory TianGong No.2 is a very good platform for space science research as a long time orbiting spacecraft. A long period of growth and development of higher plants was studied by using its microgravity environment to understand and elucidate the role of gravity in the whole process of plant growth and development. In this paper, a space experiment devicethe spatial culture apparatus of higher plants was developed. According to the experimental design, Arabidopsis seeds and rice seeds began to germinate in space until the flowered and fruited for the whole life cycle. Some of them were brought back to the ground by the astronauts. The device is designed as the main box and return unit. The main box contains enclosed culture space and electrical control part, and the return unit is attached to the main body. The main box and the return unit have the environment monitoring, liquid management and illumination function adapting to the space environment; The main box of the length of sunshine and short sunshine culture area, respectively, two sterile culture units and color camera for observation, the design of a fluorescent camera to observe the gene expression of the sample. 2016 MidAutumn Festival, the experimental device with TianGong No.2 launch, and successfully carried out the experiment, the return unit with sample returned according to plan. The researchers got a lot of valuable data.

In order to study the growth and development of advanced plants under microgravity conditions, the live imaging technique and advanced plant culture device have been developed. This paper will introduce the live imaging technique and the device used in the Tiangong-2 spacecraft and SJ-10 recoverable satellite. These experiments focus the influence of plant behaviors in space environments. The experiment samples were Arabidopsis and Rice. There were two cameras and one fluorescence camera in the advanced plant device. The flowering gene expression was investigated with transgenic GFP through the fluorescence camera. When the devices were carried in space, the pump put water into culture unit and the life support were controlled well, such as the temperature, humidity, light intensity. The experiment in space has been carried out more than 1 year. In the process of seed germination, seedling growth, flower and fruit, serial real-time images were successfully obtained. The experimental results in space were concluded.

Jet Propulsion Laboratory, Pasadena, California, United States

Fusarium oxysporum is a filamentous asexual ascomycete that is ubiquitous in soil and notorious for fusarium wilt, a deadly vascular wilting syndrome in plants. Strains are classified into formae speciales “special forms” based on the host it can infect and at present, there are over 100 formae speciales that have been classified. While well known for its pathogenicity in plants, oxysporum extends beyond plants to infect humans as well. It is an emerging opportunistic pathogen that is the leading cause of invasive fungal infections in immunocompromised patients.

Two F. oxysporum isolates (denoted F3 and F4) were cultured from the dining table of the US segment of the International Space Station during an ongoing Microbial Tracking study, the first time this species has been isolated from a built environment and from the space environment. The genome was paired-end sequenced on the Illumina Hi-Seq platform and assembled de novo with AbySS. The genomes of F3 and F4 were compared to 100 formae speciales using (i) EF1 alpha sequence typing and (ii) the presence/absence of 100 effector genes that are unique to different formae speciales. Single nucleotide polymorphism analysis was also performed using

PhaMe to assess how similar F3 and F4 were to their closest neighbors on the phylogenic tree. The genomic characterization

shows that F3 and F4 are the same strain but are distinct from the 100 strains that they were compared against, and possibly represent a novel strain.

A recent study published by our group comparing the virulence of Aspergillus fumigatus ISS isolates to that of ground isolates showed ISS isolates to be more virulent in a zebrafish model. That study prompted the examination of the virulence potential of F3 and F4 and an F. oxysporum isolate collected in the aftermath of the Chernobyl disaster. Immunocompromised Caenorhabditis elegans strains, AU1 (sek-1) and AU37 (glp-4;sek-1) were exposed to fungal conidia for 40 hours. Results demonstrated that ISS isolates displayed higher lethal phenotype compared to the ground control. The Chernobyl isolates consisted of the ground isolate (Gr) and its derivative exposed to space flight (Sp). The Sp strain demonstrated significantly higher killing ability suggesting that this strain was effected by microgravity exposure.

This study highlights the importance of further analysis of Fusarium and other fungal strains that have been exposed to the space environment as the biology of these isolates may have important implications in the medical, pharmaceutical and agricultural fields.

F4.4-0014-18 "WELLBEING IN LONG DURATION SPACE TRAVELS

Ayşe Ören, info@ayseoren.com Turkey

Introduction As we embark on a journey for new homes in the new worlds to lay solid foundations, we should consider not only the survival of frontiers but also well-being of those to live in zero gravity.

As a versatile science, architecture encompasses abstract human needs as well.

On our new different direction in the course of the Homo sapiens evolution, we can do this with designs addressing both our needs and senses. Well-being of humans can be achieved by creating environments supporting the cognitive and social stages in the evolution process.

Space stations are going through their own evolution process. Any step taken can serve as a reference for further attempts. When studying the history of architecture, window designing is discussed in a later phase, which is the case for building a spaceship as well.

We lean on the places we live both physically and metaphorically. The feeling of belonging is essential here, entailing trans-humanism, which is significant since the environment therein is like a dress comfortable enough to fit in, meeting needs without any burden.

Utilizing the advent of technology, we can create moods and atmospheres to regulate night and day cycles, thus we can turn claustrophobic places into cosy or dream-like places.

Senses provoke a psychological sensation going beyond cultural codes as they are rooted within consciousness, which allows designers to create a mood within a space that tells a story and evokes an emotional impact.

Colour, amount of light, sound and odour are not superficial. As much as intangible, they are real and powerful tools with a physical presence.

Tapping into induction, we can solve a whole system based on a part thereof. Therefore, fractal designs may not yield good results unless used correctly in terms of design although they are functional, which makes geometric arrangement critical.

F4.4-0015-18 BIOREACTOR WITH REMOTE SCIENCE OPERATING MODE PIGGYBACKED ON TIANZHOU-1 CARGO TRANSPORT SPACECRAFT

For successful work and life of astronauts, researchers, etc. in space flights, long stay at space stations and space settlements, optimal engineering systems for life support are needed, allowing to solve technical and psychological problems. In this respect, it is worth to consider plants in cosmos as one of the units in a life-support system. Modern development of biotechnologies makes it feasible to receive materials with new improved properties for plants growing. Formulation and components proportions changes in nutrient medium are capable to modify plant properties considerably. We have devised a nutrient medium in which essential metals such as iron, zinc and copper were added as electro neutral nanoparticles instead of metal salts. Such replacement is appropriate through unique nanoparticles properties: metal nanoparticles are less toxic than metal ionic forms; produce prolonged effects, serving as a depot of elements; nanoparticles introduced in biotic doses stimulate metabolic processes of the organism; nanoparticles action is multifunctional. LJ-king pepper was used for cultivation on a nutrient medium with iron, zinc and copper nanoparticles in different concentrations. Pepper plants grown on the nutrient medium with metal nanoparticles showed better morphometrical and physiological characteristics than controls: seedlings and plants were compact with the developed and active root system.

F4.4-0017-18 CELL GROWTH AND DIFFERENTIATION ASSOCIATED WITH MASS TRANSPORTATION UNDER MICROGRAVITY

Cells are able to sense gravity change through different mechanisms. It is hypothesized that cells possess the specialized structures for gravity perception (direct mechanism), are affected by the changes in physical features of gravity-dependent microenvironment (indirect mechanism), or work in a cooperative way from both mechanisms. To address the issue, we develop a novel space cell culture system (SCCS), mainly consisting of precisely-controlled flow chamber and gas exchange unit, to elucidate the responses of endothelial cells and mesenchymal stem cells (MSCs) under microgravity environment in SJ-10 recoverable satellite. Our data indicate that different mass transport patterns could alter cellular metabolism. Moreover, endothelial cells and MSCs are regulated by microgravity and respond differentially in initiating cytoskeletal remodeling, dysregulating signaling pathways relevant to cell adhesion, or directing hepatic differentiation. These results provide an insight in understanding the mechanosensing and mechanotransduction of mammalian cells under space microgravity.

F4.4-0018-18 SPACE SHIP WITH LARGE SELF-REGULATED ECOLOGICAL SYSTEM FOR DEEP SPACE FLIGHTS

Alexey Kondyurin, kond@mailcity.com University of Sydney, Sydney, Australia

Future long term space activity with human crew requires self-regulated ecological system to provide water, air and food for crew. Modern theoretical and experimental investigation results show that a sustainable ecological system can be made, but it requires large enough area and volume, which cannot be provided with modern space ship and space station technologies. The large volume frame can be created with using of inflatable construction, which can be directly cured in space environment. Large size space ship with self-ecological system is proposed and discussed.

The study was supported by Humboldt Foundation, ESA (contract 17083/03/NL/SFe), NASA program of the stratospheric balloons and RFBR grants (05-08-18277, 12-08-00970 and 14-08- 96011).

F4.4-0019-18 INFLUENCE OF MAGNETIC VACUUM ON THE LIVING CYCLE AND SURVIVAL OF DROSOPHYLA MELANOGASTER

Nadiia Sheykina, sheykina@ukr.net

National University of Pharmacy, Kharkov, Ukraine

Not only the absence of gravity takes place in space flight but the magnetic field is also changes. Sometimes it is very small. So the experiments in magnetic vacuum are needed. All experiments were fulfilled in the artificial magnetic field inductance of which was equal to 20 nT - 3 µT. The artificial magnetic field was created in µ-metal shield with the reminded magnetic field 20 nT. The direction of the artificial magnetic field was vertical. The samples were the pure lines of Drosophila MelanogasterCantonese -S and Muller-5 and the line of wild type Wild. Under standard conditions the living cycle for Cantonese -S was equal to 12 days and for Muller-5 - 16 days. It was revealed that for pure lines the living cycles slowed down on 3 days while treating in magnetic fields under 3 µT. The first generation didn't give the posterity, i.e. perished. For Wild type the cycle slowing was equal to 2 days. The imago emerges on the 17-th day after laying. The second generation of Wild also perished on the stage of the third generation development. The results obtained correlate to the ones obtained by other authors under the conditions of zero gravity.

F4.4-0020-18 GENOMICS OF A MICROGRAVITY-EXPOSED STRAIN OF CLADOSPORIDIUM CLADOSPORIOIDES - A RADIATION-TOLERANT FUNGUS ISOLATED FROM THE CHERNOBYL NUCLEAR POWER PLANT ACCIDENT

Jet Propulsion Laboratory, Pasadena, California, United States

A radiation-tolerant strain of Cladosporidium cladosporioides isolated from the failed block of the Chernobyl nuclear power plant and flown on the International Space Station was characterized and compared with control specimens kept on the ground. This radiation-tolerant fungus was selected for this study to ascertain the effects of microgravity and the space environment on the growth and physiological responses of this organism to spaceflight. Fungi are known to produce many secondary-metabolites, especially when stressed. Some of these secondarymetabolites have become medically important drugs. Differences detected in genomic content between flightand ground-control specimens allude to adaptations that may be important for survival in space, and may provide the opportunity for novel drug discovery. Changes detected in transcriptomic content between flightand ground-control specimens indicated acclimatization responses that may be important for survival in space, and provided evidence that these potentially important secondary-metabolites were being produced in the space environment. The characterization and comparison of both flightand ground-control specimens demonstrated differences in this radiation-tolerant fungal strain that may lead to the discovery of useful natural compounds.

F4.4-0021-18 SEROTONIN METABOLISM UNDER EFFECT OF IONIZING RADIATION AND HYPOGRAVITY

Viktor Kokhan, viktor_kohan@hotmail.com

State Scientific Center of Russian Federation, Institute of Biomedical Problems, Russian Academy of Sciences, Moscow, Russia

Kseniya Lebedeva-Georgievskaya, kseniagb@gmail.com

Central nervous system dysfunctions caused by ionizing radiation and hypogravity are a key factor hindering deep space missions (Kokhan et al., 2016). For the ground-based modeling of space flight factors, male Wistar rats were exposed to ionizing radiation (heavy charged particles and γ-quanta in combination; R) and hypogravity (in the antiorthostatic suspension model; AS). Several groups of animals were subjected to both single exposure to R or AS factor, and their combinations. The obtained data indicate that effects of AS and R factors in combination demonstrate synergetic and antagonistic effects on psychoemotional status, cognitive abilities and monoamine metabolism. Surprisingly, the combined effects of these factors lead to the neutralization of the negative effects (hypolocomotion, decreased orientation and exploratory behavior, cognitive impairments) arising from the separate action of R and AS factors. The effect of the AS factor led to a limited activation of the serotoninergic system. Whereas addition of the R factor led to the spread of activation on all the studied brain structures. We have obtained the first evidence that 5-HT2a receptor in the prefrontal cortex and D2 receptor in the hippocampus can be involved in the aforementioned neutralization effect. We suggest that these biomolecules can be potential targets for pharmacological correction of the pathophysiological effects of R and AS factors during deep-space missions.

F4.4-0022-18 THE BEHAVIOR OF THICK-TOED GECKOS DURING THE FLOTATION IN WEIGHTLESSNESS.

Valery Barabanov, valbaraban@yandex.ru

Research Institute of Human Morphology, Moscow, Russia Victoria Gulimova, gulimova@yandex.ru

Research Institute of Human Morphology, Moscow, Russia Rustam Berdiev, rberdiev@gmail.com

Sergey Saveliev, braincase@yandex.ru

Research Institute of Human Morphology, Moscow, Russia

The purpose of the research was to study the behavior of 15 female Turner's Thick-toed Geckos (Chondrodactylus turneri GRAY 1864) during a 30-day orbital experiment on the unmanned spacecraft "BION-M" No. 1. In weightlessness, geckos maintained their ability to attach to the surfaces using the subdigital pads of their toes. On average, geckos spent in the attached position 99.91% of the video recorded flight time, and only 0.09% accounted for the flotations. In quiescent geckos, spontaneous detachments of some limbs (hanging) were also observed. The detachments of hind limbs occurred in 52.3% of cases, more often than all other possible detachments taken together. Upon detachment from the surface of all four limbs without the immediate recovery of attachment, the geckos started to float, while continuing to be motionless, perhaps being asleep or dormant. That is why all flotations were divided into 2 main groups: 1 - active (flotation begins in moving and exactly awake gecko); 2 - passive (flotation begins in quiescent, possibly sleeping gecko - PF). The PF group in turn was subdivided into: 1 - short flotation (SF), when the gecko drifted from the surface to a distance of no more than 2.5 cm, and 2 - long flotations (LF, the distance was more, than 2.5 cm). SFs were more frequent and accounted for 262 cases (58.2%) of the total number of flotations (450 cases). The active geckos, when starting to float, and the floating quiescent geckos, when resuming their active condition, immediately restored the attachment by a number of behavioral responses. The discovered geckos' responses to PF were similar to the behavioral reflexes triggered by a fall under terrestrial conditions: 1 - the ventral extension of the limbs, 2 - the skydiving posture, and 3 - postural righting reflex. Ventral extension of limbs was described in weightlessness for the first time. In SF it was enough to restore the attachment, but in LF we observed all 3 reactions with high frequency (91.5, 95.7 and 82.4% of all cases of LF of quiescent geckos correspondingly), although they did not lead to quick restoration of attachment. It is known from literature, that the skydiving posture in ground-based conditions creates useful aerodynamic forces, making gliding or directed aerial descent possible and reducing the impact force when landing. In

weightlessness the dilated limbs increase the likelihood of contact of the flotating gecko with any surface and restore the attachment. This reflex actuated regularly after the activation of geckos in long flotations during the entire orbital flight. The righting reflex in thick-toed geckos in the flight experiment was manifested in incomplete (by 90°) or exaggerated (up to 270-360°) forms. The duration of turns calculated for 31 instances of rotation by 180° in geckos varied from 0.08 seconds to 0.64 seconds; with an average of 0.325±0.099 seconds. It is almost 3 times more slowly, than it was described in Earth conditions for flat-tailed house geckos by Jusufi et al. (2008). These differences can possibly be caused by both the species-specific features of animals and the effect of weightlessness on thick-toed geckos. It is known that, in terrestrial conditions, the postural righting reflex is stimulated by the signals from the vestibular apparatus about the incorrect position of the body relative to the gravity vector. The obtained data suggest that in animals, as in humans, in zero gravity spatial orientation illusions are possible. The number and frequency of individual flotations during the flight did not depend on the size and weight of the geckos. There were no animals without a single flotation episode, but the frequency of flotations varied both individually and depending on the condition of the geckos. The number of flotations in the quiescent geckos was 4.5 times higher than that of the same animals in an active state. Consequently, an active control of the attachment could become weaker or inexistent in animals in quiescent states or in a sleeping state. In active geckos the number of flotations during the flight was decreased compared to the first week of the flight. Hence, it is possible, that in weightlessness, geckos adapt to changes in environmental conditions by learning from their own experiences, and strengthening the active control of the attachment. In quiescent geckos the number of flotations did not change significantly during the flight. Individual variability in the frequency of flotations was found in the active and quiescent geckos during the flight. The findings show that the ability to attach to the surfaces is an important factor in the geckos' adaptation to the conditions of orbital flight. The behavioral responses that originated under terrestrial conditions can also be adapted to weightlessness and remain partially effective.

F4.4-0023-18 PROBLEM OF HYPOMAGNETIC CONDITIONS AT THE MOON, MARS AND AT MANNED FLIGHTS IN DEEP SPACE

The problem has already been discussed in our reports at COSPAR 37, 39, 40. It is shown that the absence of the usual geomagnetic field (GMF) will lead, as a rule, to undesirable consequences for astronauts at the near-moon station, during long-range space missions and at future lunar and Martian bases. Hypomagnetic conditions (HMC) will also adversely affect the biological elements of life support systems. HMC should be considered along with the weightlessness, cosmic radiationand other factors of the flight and outer space. Recently, various aspects of this problem have been discussed at conferences of different direction (for example, [1]) and in the literature (for example, [2]). In our recent studies it was shown that the germination of lettuce seeds irradiated with ions with high values of linear energy transfer in GMF weakened in 2.5•103 times leads to increasing of the percentage of cells with chromosomal aberrations and multiple aberrations more than twice compared with the irradiated seeds germinating under normal conditions. Therefore, there is a synergistic effect of these factors. Synergism of combined exposure of HMC and a very weak alternating (50 Hz) magnetic field (i.e., the factor is radically different from radiation) has also been revealed in our studies of the HMC effects on the growth of Japanese quail embryos. Accelerated loss of mineral matter from the animal (rat) bone tissue under the influence of simulated weightlessness and HMC was discovered by Chinese researchers [3]. This is an alarming phenomenon for manned astronautics. Probably we should expect the possible synergy of the impact of HMC and some other factors of flight

and outer space, which will need to be taken into account when norming board conditions. Questions of creations of collective analogue of GMF in the habitable volume of future spacecraft and on lunar and Martian bases by means of electromagnetic systems are considered in this report. This fundamentally solves the problem. The real possibility is also shown of creating individual analog of GMF (jacket, jumpsuit and cap [4]), including for work in spacesuits on the surface of the Moon and Mars.

F4.4-0024-18 SURVIVAL AND PHYSIOLOGICAL ADAPTATION OF EXTREMOPHILES IN RESPONSE TO HYPERGRAVITY STRESS

Priyanka Kulkarni, piyukul93@gmail.com

Modern College of Arts, Science and Commerce, Shivajinagar, Pune, India Rebecca Thombre, rebecca.thombre@gmail.com

Modern College of Arts, Science and Commerce, Shivajinagar, Pune, India

Life on other planets and the survival strategies of the organisms on the other planets is a subject of speculation. Hypergravity is a major aspect when survival of micro-organisms in space and other planets is concerned. The more the survival strategies of micro-organisms in hypergravity stress are studied, the more the enigma of the origin of life unfolds. Hypergravity is also related to ejection and travel of micro-organisms from one planet to other planet. The micro-organisms can stay dormant and travel from one place to other and again become active when they encounter a favourable environment. When the survival strategies in such inhabitable environment are studied, it is also possible to device an appropriate method to reduce the contamination from spaceflights and spacecrafts. The present investigation focuses on the survival of extremophilic organism to hypergravity. The adaptation strategies, intracellular ion sequestration and production of compatible solutes in altered gravity are reported herewith.

F4.4-0025-18 CREATION OF NUTRIENT MEDIUM USING NANOTECHNOLOIGY FOR PLANTS GROWING IN SPACEFLIGHTS

Galina S. Nechitailo, spacemal@mail.ru

Inst. of Biochemical Physics RAS, Moscow, Russia O Bogoslovskaya, obogo@mail.ru

Russian Academy of Sciences, Moscow, Russia I Olkhovskaya, ira.olh@rambler.ru

Russian Academy of Sciences, Moscow, Russia N Glushchenko, nnglu@mail.ru

Russian Academy of Sciences, Moscow, Russia

Quality life and fruitful activity of astronauts and researchers in conditions of spaceflights and prolonged work at space stations are only possible with life zone providing fresh air, natural food, comfortable psychological conditions, etc. The solution of that problem in cosmos is possible by use of high nanoand biotechnologies for plants growth. A priority should be given not only to a choice of species of plants able to grow in cosmos, but also optimization of cultivation conditions, including modifications of nutrient mediums, illumination and temperature. We are deeply convinced that just manipulations with growing conditions are a guarantee of success in the decision of this problem. To improve the method of plants growing on the artificial nutrient medium with balanced composition of elements necessary for growth and development of plants, we added essential metals Fe, Zn, Cu - in an electroneutral form as nanoparticles (NPs) instead of sulfates or other easily dissolving salts. Metal nanoparticles have some advantages in comparison with salts: NPs are characterized by prolonged and multifunctional actions; NPs are less toxic compared with salts; NPs are able to penetrate in plants tissues and stimulate vital processes in biotic dozes. A high reactivity of NPs, their active interactions with nutrient medium components, requires development of certain technological solutions for conservation of activity potential of nanoparticles in nutrient mediums. We developed an artificial nutrient medium with a balanced composition, including metal NPs for the efficient cultivation of plants in space flight conditions.

F4.5-0001-18 30 YEARS OF ACTIVITIES, AN OVERVIEW OF MELISSA PROJECT

Christophe Lasseur, christophe.lasseur@esa.int ESA, AG Noordwijk, Netherlands

Seeded in 1987 with a precursor flight experiment on board the Chinese rocket longue Marche, conceptualized and published in October 1988, and initiated in March 1989, the European project of regenerative life support, from its early days has followed a very progressive approach. Today, after almost 30 years of activities. The project gather a very large community from scientists to engineers, from universities to spin-off companies, from industry to space companies, from students to European civil servants. This large community distributed over 15 European countries is pursuing two main objectives: - Space life support system and - Terrestrial circular economy. It is correct to state that the key challenge of MELiSSA is: how to select, to assemble and to demonstrate processes and technologies to reach the highest degree of closure within the ALISSE criteria set: Mass, Energy, Efficiency, Safety, Reliability and Crew Time. Mainly due to these final objectives, the overall project is structured in a very progressive approach. Within Phase 1, Basic RD, the processes and technologies, generally at low TRL are characterize a stoichiometry's level, energy and safety, then static and dynamics models are elaborated for an integration in the overall system. After this intensive characterization, within phase 2 called: Preliminary Flight experiments, the critical space issues are identified (e.g. reduced gravity, multi-phases processes, radiations,.) and propose for flight experiment, generally in LEO. So far, the main part of the flight s experiments were done via International competition of the ILSRA ISS. From this already solid information the selected processes and technologies are integrated and demonstrated over a long period and with a living consumer, human but potentially animals too. The core of this activity is performed at the MELiSSA Pilot plant in Spain. In parallel, of these 3 phases run as well the Phase 4: Technology transfer, where already 3 spin-off company have been created. Initiated to transfer space technology to Earth, this phase is becoming more and more a platform of collaboration for join RD efforts. Phase 5, which has taken a reasonable amplitude over the last years: Education and Communication is led by the MELiSSA foundation and support Students and STEM activity (e.g. AstroPlants).

F4.5-0002-18 CLOSING NUTRIENT LOOPS FOR BIOREGENERATIVE LIFE SUPPORT SYSTEMS

Raymond Wheeler, raymond.m.wheeler@nasa.gov

NASA/Kennedy Space Center, Kennedy Space Center, Florida, United States

Estimates from Russian Bios-3 studies in the 1980s and NASA studies in the 1990s suggest that about 125 kg of fertilizer and acid (for pH control) would be required to grow enough plants to support one person for one year. About 90 kg of this total was fertilizer. These studies used hydroponic approaches and likely supplied excess nutrients to the plants to avoid stress, nonetheless, they provide a good reference point planning bioregenerative life support systems. For a crew of four for a 3-year Mars mission, this would amount to 125 kg person-1 yr-1 X 4 persons X 3 years, or 1500 kg of fertilizer and acid. Waste processing studies with inedible plant biomass have demonstrated that many nutrients can be recycled to grow more plants. Assuming 50% of the biomass is inedible and that you could recycle 50% of the nutrients from this biomass, this could reduce the fertilizer mass by 25%. This assumes the nutrient content of the inedible biomass is similar to the edible biomass, but many nutrients like N and K are often higher in the inedible leaves and stems, and hence the savings could be even greater. Likewise, more intensive treatment of inedible waste could increase recovery rates to 90% for many elements. Recycling human metabolic wastes, especially urine, could reduce fertilizer import costs even further. In addition, recovery of any nutrients from in situ regolith could further reduce imported fertilizer, and more studies are needed in this area. Strategies for reducing acid or base needed for pH control would also help, and using mixtures of nitrate and ammonium nitrogen fertilizer are one classic approach to mitigate pH changes.

F4.5-0003-18 FORMATION OF TURNOVER PROCEDURES IN A TENTATIVE MODEL OF AN ARTIFICIAL ECOSYSTEM

Alexander A. Tikhomirov, alex-tikhomirov@yandex.ru Inst. of Biophysics SB RAS, Krasnoyarsk, Russia Sofya Ushakova, sofya-ushakova@yandex.ru

Institute of Biophysics SB RAS; Siberian State Aerospace University, Krasnoyarsk, Russia Sergey V. Trifonov, trifonov_sergei@inbox.ru

Institute of Biophysics SB RAS; Siberian State Aerospace University, Krasnoyarsk, Russia Natalia Tikhomirova, n.tikhomirova@mail.ru

Institute of Biophysics, SB RAS, Krasnoyarsk, Russia Vladimir Velichko, vladimir_velitchko@hotmail.com Institute of Biophysics, SB RAS, Krasnoyarsk, Russia

Under creation of turnover processes, 2 concentration in the system atmosphere was succeeded to maintain at the level not limiting photosynthetic processes and being not harmful to a human (800 - 2000 ppm). The total 2 content in ECES was in average 344, the average daily 2 consumption equaled to 1309 and the time of one 2 turnover (cycle) was 6.3 h. 2 concentration did not lower than 20.8% and did not grow higher than 22.6%. The air breathed out by a human entered the system and the system air was consumed by a human. Thus, CO_2 and O_2 concentrations were maintained in the system in the specified limits simulating approximately 0.06 of human respiratory needs. Assimilating coefficient calculated equaled to 0.83. Considering O_2 concentration in the system to be a limiting factor for calculation 'a part of a human' then the ECES created corresponded to the estimated 'part of a human' varying in the limits of 5.4% ÷ 6,5%. Plants grown in ECES compartments could provide the daily human requirements with carbohydrates on 1.7 %, with vegetable oils on 5.5 % and with vegetable proteins on 6.4 %. Periodicity of the human involvement in a gas contour was determined according to the limits of 2 concentration inside the system, fluctuation of which were searched out in the diapason of 900 ppm - 2500 ppm. At the expense of the human periodic involvement into the system's gas contour both 2 and 2 concentrations were adjusted in the determined limits, and the latter remained in the limits of 21%-22.6% at that. Change dynamics in the mineral solution for plants of the following fundamental elements Ca, K, Na, N; Mg, P, S was investigated. Mineralized organic wastes of animal and vegetable origins were the sources of their supply. Considerable decrease of phosphorus content in the nutrient solution was discovered within one-month observations that demanded that biogen introduction from the stock to compensate mineral elements withdrawn with edible biomass from the SLS the inedible biomass of the plants grown by the hydroponics method on the expanded clay aggregate and by the water culture method in the amount necessary for K content restoration was inserted into the SLS. Solid and liquid human wastes also were the mineral elements' sources. These metabolites entered the reactor for physical-chemical oxidation from where the reactor gas after its purification came in the ECES,

and the liquid oxidized products were used to correct the nutrient solutions for irrigation of the plants cultivated by the hydroponics method on the expanded clay aggregate thus restoring the nutrient elements' concentration in the solution up to a necessary level. The edible biomass grown in the ECES could supply the human daily needs in a vegetable diet part approximately on 6%. The principal summands of the water cycle emerging in the ECES were 250ml of the correcting solution resulting in the process of physical-chemical oxidation of solid and liquid human wastes and 250ml of the extraction after the wheat straw watering. The rest of water generally contained in the nutrient solution for plants and in the plants' biomass. The daily water cycle was 12.9 l, and the time of one water cycle was 11.7 days. The chemical elements' content (, As, B, Be, Cd, Cu, Fe, Mn, Zn, etc.) in the intersystem water amounted either the tenth-hundredth parts of their MPC. It was established that the closure of more than 90% corresponded to Ca, Mg, S, N, and to 2 and

The lower closure (84%) was registered for, and the lowest (60%) - for. The ECES created let to raise and to solve a wide range of problems with respect to investigating the functioning mechanisms of matter turnover processes concerning terrestrial and space applications. The perfection of a deeper purification technology of the system gas composition, a total chemical and microbiological monitoring of nutrient solutions, and a technologies' creation for a higher closure level of the biogen sets should be noted in particular. The work has been performed under financial support of RSF grant (project 14-14-00599) at IBP SB RAS

F4.5-0004-18 RESEARCH ON SOLID WASTE TREATMENT AND REUSE IN LUNAR 365

Dianlei Liu, liudianlei010187@buaa.edu.cn Beihang University, Beijing, China Guanghui Liu, liugh1991@buaa.edu.cn Beihang University, Beijing, China

Hong Liu, lh64@buaa.edu.cn Beihang University, Beijing, China

Abstract: Bio-regenerative Life Support System (BLSS) is essential in human long-term space exploration, which could provide oxygen, food, water and other survival essentials. In addition, solid waste produced could be reutilized through fermentation treatment in this system. Solid waste treatment was considered as one of the most important rate-limiting steps in terms of material circulation and energy flow of BLSS. Solid waste including wheat straw, human and yellow mealworm feces were disposed in the continuous aerobic fermentation bio-convertor in "Lunar Palace 1" for 365 days of closed experiment with crews. During the fermentation process, the microbial diversity and compost putrescibility were demonstrated. Then the decomposed compost was used as fertilizer for wheat with Hoagland nutrient solution as the control. Meanwhile, the optimal planting way was selected through the solid waste treatment experiment. The evolvement process of microbial community were demonstrated and the feasibility of using the disposed solid waste as fertilizer for wheat was verified. The study reused the solid waste and improved the closure level of the BLSS. It is of great significance for the solid waste management for long-term space exploration.

In order to sustain human life in an isolated environment, an efficient conversion of wasted nutrients to food might become mandatory. This is particularly the case for space missions where resupply from earth or in-situ resource utilization is not possible or desirable. A combination of different technologies is needed to allow full recycling of e.g. nitrogenous compounds in space. In this presentation, an overview is given of the different essential processes and technologies that enable closure of the nitrogen cycle in Regenerative Life Support Systems (RLSS). Primary waste material is first refined through a set of biological and physicochemical stages to ensure efficient conversion of waste products into secondary building blocks, followed by the production of food through select biological methods. For each technology, bottlenecks are identified. Furthermore, challenges and outlooks are presented at the integrated system level. Space adaptation and integration deserve key attention to enable recovery of nitrogen for the production of nutritional food in space, but also in closed loop systems on earth.

F4.5-0006-18 DEVELOPMENT OF THE ATMOSPHERIC SYSTEM OF THE MELISSA PLANT COMPARTMENT BASED ON A MECHANISTIC MODEL OF PLANT GROWTH AND GAS EXCHANGES

Claude-Gilles Dussap, c-gilles.dussap@uca.fr Université Clermont Auvergne, Aubiere, France Lucie Poulet, lucie.poulet@uca.fr

Christel Paille, christel.paille@esa.int ESA/ESTEC, Noordwijk, Netherlands

The growth and development of higher plants are strongly influenced by environmental conditions (e.g. gravity, pressure, temperature, relative humidity, partial pressure of O2 or CO2) so that their use within bio-regenerative life support systems requires a thorough understanding of their growth mechanisms and behaviors for a wide range of environmental conditions. This is achieved within the frame of the MELiSSA (Micro-Ecological Life Support System Alternative) project led by the European Space Agency (ESA), with the design of the atmospheric system of the plant compartment alongside the development of a mechanistic physical model of plant growth and plant gas exchanges. This approach is based on the understanding of elementary phenomena and using the atmospheric system to validate the model, instead of following an empirical approach to build a mathematical description. Therefore, essential plant growth parameters are defined and a modular approach is followed to define essential sub-systems, whose sizes are based on mass balance related to plant growth. This includes elements balances, i.e. both carbon and oxygen balances. The system is designed to host plant shoots until harvest in a closed, controlled and automated environment, in which CO2 uptake and water vapor release are measured on-line, giving the clue for assessing uptake and production rates on the basis of conservation constraints, more than global quantities that are uncorrelated in terms of mass balances. The aim of this atmospheric plant growth system is to gain insight with respect to modelling, engineering and control aspects of the MELiSSA plant compartment and to improve the understanding of the processes. It is demonstrated how the selected design will be used for leading to knowledge modeling and understanding purposes of growth mechanisms of higher plants in close chambers, accounting for process parameters such as pressure, temperature, relative humidity, partial pressure of O2 and CO2, gas velocity and ultimately gravity.

F4.5-0007-18 STUDY ON THE APPLICATION EFFECT OF COLD TOLERANT BIOCONTROL AGENT PSEUDOCHROBACTRUM KIREDJIANIAE A4 IN BLSS

Zhihao Yi, evan308@hotmail.com Beihang University, Beijing, China Youcai Qin, qinyoucai07@163.com China

Yuming Fu, fuyuming@buaa.edu.cn Beihang University, Beijing, China Hong Liu, lh64@buaa.edu.cn Beihang University, Beijing, China

Bioregenerative Life Support System (BLSS) is an indispensable key technology for manned deep space exploration, such as lunar or martial base. The plant unit is the key unit of the BLSS, providing food for the crew, regenerating air through the photosynthetic CO2 absorption and O2 emission and preserving the crew's wellbeing. Wheat, as a staple food crop, plays a very important role in BLSS, because of its high nutritional value of seeds, richness in carbohydrates, and ability to produce further food products. The level of wheat crop production directly affects the amount of food in the BLSS. In order to ensure the healthy growth and of wheat and increase its yield, experiments were conducted to promote the growth of wheat by applying the low temperature-resistant biocontrol strain A4, which isolated and pre-selected during the experiment of "Lunar Palace 365" according to the special requirements of BLSS. During the experiment, the photosynthesis, chlorophyll content, superoxide dismutase activity, malondialdehyde (MDA) content in leaves, other physiological indexes and harvesting indexes were measured and analyzed. Microbial communities of wheat leaf surface and rhizosphere were determined to study the application of biocontrol agent A4 on wheat growth and yield promotion. The research is mainly focused on the regulation of microbial communities to ensure the healthy growth of wheat, and will provide a reference strategy for pathogen biocontrol and growth promotion of wheat in BLSS.

F4.5-0008-18 WHY DID CARBON BECOME THE PSEUDO-LIMITING FACTOR IN AQUATIC CLOSED ECOLOGICAL SYSTEMS?

Frieda B. Taub, taub@uw.edu

University of Washington, Seattle, Washington, United States

Closure from the atmosphere forces us to observe processes that we would overlook in an open system where CO2 and O2 exchanges are unlimited. Our early Closed Ecological Systems (CESs) with a C:N ratio of 26.4 were not intended to become carbon limited with pH values in excess of 11, but that was the result, with a mixture of green algae (Ankistrodesmus, Scenedesmus, and Selenastrum) and associated bacteria. Those with grazers (Daphnia) developed pH values in excess of 10. The C:N ratio of 105 was more satisfactory. C:N ratio of 422 did not result in more algal in vivo fluorescence, and resulted in shorter survival of Daphnia populations than 105. Reasons for the high C:N ratio may include the ability of one of our species, Scenedesmus to form high lipid cells with a C:N ratio of 51, but other mechanisms may also be involved. Our CESs do not receive CO2 gas from an external source, as is common in many sub-system experiments, which would control pH and obscure unexpected CO2 uptake.

F4.5-0009-18 BIO-ELECTROCHEMICAL OXIDATION FOR CO2 RECOVERY IN REGENERATIVE LIFE SUPPORT SYSTEMS

Peter Clauwaert, peter.clauwaert@ugent.be Universiteit Gent, Gent, Belgium

Long term manned space missions or extraterrestrial habitation will require a regenerative means of supplying the basic resources (i.e., food, water, oxygen) necessary to support human life. The MELiSSA concept established within the European space agency is a closed loop compartmentalized artificial ecosystem designed to recycle solid organic wastes (e.g., inedible food waste and feces) for the regeneration of food, water, and oxygen for human consumption. Carbon recycling in this loop depends on decomposition of organically bound carbon to CO2 followed by fixation of CO2 by phototrophic microorganisms and higher plants that serve to provide the food and oxygen. A challenge at this moment for the MELiSSA-loop is closing the carbon cycle, by completely oxidizing the carbon in the organic waste and non-edible parts of the plant into CO2. Optimization of a thermophilic membrane fermentation reactor for primary waste treatment has been demonstrated to achieve organic matter degradation efficiencies up to 65%, but with a maximum of 15% carbon recovery as CO2. The balance of carbon remains as soluble organic compounds (mainly volatile fatty acids; VFAs), biomass, and undigested solids. In this study we demonstrate the feasibility of coupling thermophilic fermentation to bio-anodic oxidation in a microbial electrolysis cell (MEC) to drive carbon recovery towards CO2. Bioanodic oxidation has the potential to favor CO2 production over methane, and provide in-situ pH control by electro-migration of hydroxyl ions produced at the cathode across an anion exchange membrane. A five liter fermentation reactor treating a standardized waste composed of red beets, lettuce, wheat straw, toilet paper, and feces was operated continuously for over two years to produce realistic effluents for MEC experiments. The fermentation achieved similar performance to past experiments with an organic matter degradation efficiency of 50% and a VFA production efficiency of approximately 35%. Lab scale MEC batch tests on the permeate showed high removal efficiencies for all VFAs (80-100%) after 7 days with COD and carbon

removal efficiencies of 72% achieved. Further tests with synthetic feed were performed to test bio-anode acclimation and stability, and to quantify carbon flow through the reactor. Columbic efficiencies indicate 70% conversion of carbon from acetate and butyrate to CO_2 at this stage, though higher conversion may be possible with further process development and optimization. This coupled process could increase CO_2 recovery from 15% to 40% on total carbon input in these tests. Additional integration of thermal chemical treatment of the remaining biomass and undigested solids CO_2 recovery has the potential to reach at least 85%.

F4.5-0010-18 EXPERIMENTAL ASSESSMENT OF PHYTOPATHOLOGICAL RISKS IN CELSS

Inst. of Biophysics SB RAS, Krasnoyarsk, Russia

Year-long experiment with non-sterile CELSS conducted in the Laboratory of controlled biosynthesis of phototrophs revealed the following phytopathological risks for higher plants based life support system. The major risk is contamination of CELLS by phythopathogenic fungi of Fusarium species causing root rot of cereals. In our experiments it was estimated that one infected plant produces about 1500 conidia of Fusarium per day, and these conidia are ready to infect new plants in 6-8 hours after formation. In the system based on conveyor cropping this leads to fast spreading of disease via nutrient solution and accumulation of newly formed conidia in the substrate. No other soil borne pathogens were observed during all the time of experiment. Another risk is associated with previously undescribed bacterial stalk rot of wheat. The disease affects weakened plants and seems to be non-dangerous for plants growing under optimal condition. At least one case of mass death of plants was associated with poisoning plants by cyanobacterial toxins. Among agriculturally significant insect pests only thrips were found. Unexpectedly no phytopathogenic nematodes were observed despite on the fact that free living nematodes colonized the CELSS from the very beginning of the experiment. We assume that predatory fungi Arthrobotrys oligospora developed in the rhizosphere and feeding on the free living nematodes created a biological barrier to phytopathogenic nematodes.

The study was supported by the Russian Science Foundation (Project no.14-14-00599)

F4.5-0011-18 ABIOGENIC O2 CYCLE LOOP IN BTLSS

Yegor Morozov, yegormorozov@ibp.ru

Institute of Biophysics, SB RAS, Krasnoyarsk, Russia Alexander A. Tikhomirov, alex-tikhomirov@yandex.ru Inst. of Biophysics SB RAS, Krasnoyarsk, Russia

An experimental model with a purpose to test links compatibility and material flows closure of a new generation Bio Technical Life Support Systems' (BTLSS) technologies combined together prior to a manned experiment, is being developed at the Institute of Biophysics SB RAS. One of its aims is to verify and analyze the atmosphere composition safety for crew of the new closed ecosystem in a cycling period longer than several months. In the model, excess oxygen resulting from the process of organic wastes' "wet incineration" in hydrogen peroxide, is being removed by burning it in hydrogen obtained by an extra-system water electrolysis to compensate the model gas balance. In the model, hydrogen is being obtained by water electrolysis and is turning back into water after burning with atmospheric excess O2. An automation system to control the gases flow rates' balance and to prevent explosions is developed. In the planned full-scale experiment BIOS-4 with a crew of 3-4 people, the excess oxygen resulting from H2O2 decomposition in "wet incineration" reactor, will be used on H2O2 recovery. The processes of H2O2 synthesis most suitable for the BTLSS material cycle closure and gas requirements for the crew cabin atmosphere are being under study. The processes must be ecologically safe, energy efficient, adding minimal mass to the BTLSS, reliable and as simple as possible.

F4.5-0012-18 RELEVANCE OF LEDS LIGHTING OPTIMIZATION FOR SPACE PGF IN THE CONTEXT OF CELSS CLOSURE INCREASE

One essential way of CELSS closure increasing is to use plant growth facilities (PGFs) for space crew food production. At the present time the first biological component of a space LSS is small PGFs, aimed at supplying the crew with fresh vegetables and creating psychological comfort inside the cabin. Now all plant-growth projects for space PGFs include LEDs lighting. It was calculated that conveyor-type cylindrical PGF with 3 m3 of total volume and about 10 kW of energy consumption could provide of full CELSS closure concerning A and C vitamins for crew of 6. The results can be accomplished when crops lighting inside the PGF is strictly optimized. This work presents the procedure and results of lighting optimization for red (660 nm) and white (4000K) LEDs in respect to Chinese cabbage (Brassica chinensis L.) crop. An average photosynthetic photon flux density (PPFD), light spectral composition (red/white ratio) and pulsed light effect on the ascorbic acid yield and the plant physiological status were examined in the fractional 3-factor experiment. The lighting optimization criterion (Qv) was designed for the vitamin PGF as the maximum of squared crop biomass on its ascorbic acid concentration, divided by the light energy consumption. Maximal Qv ensures both high ascorbic acid yield and

LED luminary high functional efficiency. The regression model of optimization criterion was constructed based on the experimental

data. The analysis of the model allowed to determine the optimal lighting regime: 500 μmol/(m2s) time-averaged total PPFD; 1.5 red/white ratio and 30 μs light pulse duration with pulse repetition cycle 501 μs. This lighting regime has kept high level of the crop gas exchange, normal leaves structure, proper chlorophyll a and b content and sugar concentration favorable for the plant growth.

F4.5-0013-18 RESULTS OF TESTING OF THE IMPROVED EXPERIMENTAL MODEL OF THE BTLSS WITH PLANT WASTES AND HUMAN WASTES INCLUDED IN THE MASS EXCHANGE

Mass exchange processes in the new experimental model of the biotechnical life support system (BTLSS) constructed at the Institute of Biophysics SB RAS have a higher degree of closure than in the previous BTLSS, and, thus, the technologies employed in the new system are more complex. Therefore, before closing the loops of mass exchange processes for several months, the new model of the BTLSS was run to match the technologies employed to cultivate plants and the methods used to involve inedible plant parts and human wastes into the mass exchange with the CO2 absorption rate and the amount of the resulting O2. The plant compartment included vegetables grown on the soil-like substrate (SLS) (chufa, beet, carrot, radish, and lettuce), plants hydroponically grown on expanded clay aggregate (wheat, soybean, watercress), and plants grown in aquaculture (common glasswort and watercress). Nutrient solutions for hydroponically grown plants were prepared by using products of physicochemical mineralization of human wastes. Growing the plants in aquaculture enabled maintaining NaCl concentration in the irrigation solution for hydroponically grown plants at a level safe for the plants. Inedible plant biomass was added to the SLS. Three cycles of closing the system by gas were run, which lasted 7, 7, and 10 days. The comparison of the amount of CO2 fed into the system over 24 h (simulating human respiration) and the amount of CO2 daily exhaled by a 70-kg middle-aged human showed that between 1% and 4% of the daily emissions of CO2 were assimilated in the system, and about 3% of the average human daily O2 requirement accumulated in the system. Plant productivity was between 4 and 4.7% of the human daily vegetable requirement, or between 3 and 3.5% of the total human daily food requirement. Assessment of the level of essential for growth and development of plants macronutrients involvement into mass exchange processes was carried out. It

was shown that addition of gas from reactor of physical-chemical incineration of exometabolites during 10 days did not affect plants growth. Thus, testing of the BTLSS showed a match between the technologies employed to arrange mass exchange processes. This study was supported by the grant of the Russian Science Foundation (Project No. 14-14- 00599).

F4.5-0014-18 ESTIMATING FOOD SETS IN VIEW OF NASA'S NUTRITION REQUIREMENTS FOR LONG-DURATION MISSIONS

Vladimir Kovalev, kovalev49@mail.ru

Institute of Biophysics, SB RAS, Krasnoyarsk, Russia Nickolay Manukovsky, mana49@mail.ru

Institute of Biophysics, SB RAS, Krasnoyarsk, Russia Alexander A. Tikhomirov, alex-tikhomirov@yandex.ru Inst. of Biophysics SB RAS, Krasnoyarsk, Russia

Prior to making a space menu, it is necessary to estimate the suitability of food candidates (FCs) intended for Bioregenerative Life Support Systems. In our computer model FCs were represented as column vectors. Each column vector member represented the mass of nutrients in 100 g of FCs. A set of column vectors formed the "nutrient-FCs" matrix with the size 30x46, where "30" is the number of monitored nutrients and "46" is the number of FCs. FCs masses were considered as independent continuous variables with lower and upper bounds. FCs were programmatically selected from "nutrient-FCs" matrix according to the nutritional requirements stated in the NASA Constellation Program (C×P), document 70024 "HumanSystems Integration Requirements", section 3.5.1.3.1 (Cooper et al., 2011). Calculations were carried out in Matlab using the knitromatlab function. The best fit to the NASA's nutrition requirements was obtained after selecting nineteen FCs, i.e.: sodium chloride, water, rice, white potato, beet, cabbage, squash, sufflower oil, soybeans, chickpeas, cowpea, strawberries, onion, garlic, poultry, snail, tilapia, goat milk, and sugar. The total calculated masses of magnesium, potassium, thiamin, riboflavin, niacin, vitamin B12, vitamin E, vitamin K and omega 6 fatty acids in the set of selected FCs exceeded the corresponding normative daily intakes. However, we could not approve these results because the upper bounds for these nutrients are not established. The calculated masses of iron and phosphorus also exceeded the upper bounds designated for these nutrients. Conversely, we revealed the deficiency of pantothenic acid and vitamin D. Changing the number of selected FCs within 10-46 did not eliminate the nutrient misbalances. Implementation of NASA's nutrition requirement "2/3 of total protein should be in the form of animal protein" was a sufficient condition to support the scores above 100 for all indispensable amino acids.

F4.6-0001-18 VIABILITY AND BIOLOGICAL PROPERTIES OF BARLEY SEEDS UNDER SPACE AND MARS ENVIRONMENTS

Plants play an important role in supplying nutrients and oxygen to human under material recycle system in space as well as on earth, therefore, seed storage in space should be necessary to self-supply foods when number of astronauts would stay and investigate for a long-term habitation of orbit and the bases of the Moon and Mars. In order to understand the effect of real space environments on the preservation of seeds, the seeds of malting barley, "Haruna Nijo", were exposed to outside of the Russian Zvezda module of International Space Station. After 15-month exposure on-board the EXPOSE-R2 space platform, the seeds were transported to Earth, soaked in water, and germinated on the filter paper filled with water. The germination percentage of the seeds (SS) exposed under space vacuum and solar UV radiation (> 120 nm) was 67%, while that of the seeds (MS) exposed under Mars gas (95.55% CO_2, 2.70% N_2, 1.60% Ar, 0.15% O_2) at 1,000 Pa pressure and solar UV radiation (> 200 nm) was 100%. The surface color of SS seemed brown as it burned, compared with MS and ground control seeds (GS). The germinated seeds of SS, MS, and GS were transplanted to the Wagner pot filled with soil and cultivated for 5 months in the greenhouse. The agronomic properties of SS and MS, such as culm length, plant weight, 1,000 grain weight, number of main stem leaf, number of ear, or ripening ratio, were not different significantly from those of GS. From these results, barley seeds could survive space and Mars environments for the long-term habitation.

F4.6-0002-18 OPERATION OF AN ENCLOSED AQUATIC ECOSYSTEM IN THE SHENZHOU8 MISSION

Gaohong Wang, space@ihb.ac.cn

Institute of Hydrobiology, CAS, Wuhan, China Xiaoyan Li, lixiaoyan@ihb.ac.cn

Institute of Hydrobiology, CAS, Wuhan, China Yongding Liu, liuyd@ihb.ac.cn

Institute of Hydrobiology, CAS, Wuhan, China

Longterm spaceflight needs reliable Biological life support systems (BLSS) to supply astronauts with enough food, fresh air and recycle wasters, but the knowledge about the operation pattern and controlling strategy is rear. For this purpose, a miniaturized enclosed aquatic ecosystem was developed and flown on the Chinese spaceship Shenzhou-8. The system with a total volume of about 60 mL was separated into two chambers by means of a gas transparent membrane. The lower chamber was inoculated with Euglena gracilis cells, and the upper chamber was cultured with Chlorella cells and three snails. After 17.5 days flight, the samples were analyzed. It was found that all snails in the ground module (GM) were alive, while in the flight module (FM) only one snail survived. The total cell numbers, assimilation of nutrients like nitrogen and phosphorus, soluble proteins and carbohydrate contents showed a decrease in FM than in GM. The correlation analysis showed upper chambers of both FM and GM had the same positive and negative correlation factors, while differential correlation was found in lower chambers. These results suggested primary productivity in the enclosed system decreased in microgravity, accompanied with nutrients assimilation. The FM chamber endured lacking of domination species to sustain the system development and GM chamber endured richness in population abundance. These results implied photosynthesis intensity should be reduced to keep the system healthy. More Chlorella but less Euglena might be a useful strategy to sustain system stability. It is the first systematic analysis of enclosed systems in microgravity.

F4.6-0003-18 THE TECHNOLOGY OF INSTRUMENT FOR DETECTING MICROORGANISMS IN SPACECRAFT

Fangwu Liu, a2233k@163.com

Space life facilities

Tao ZhangWeibo Zheng Fangwu Liu

The occurrence of microorganisms in spacecraft due to contamination is a health risk to the astronauts and spacecraft. Therefore, certain microorganisms in spacecraft should be monitored and the abundance should be in the security line. Conventional detection methods may be not sensitive or do not provide rapid results allowing for immediate action. The quantitative realtime polymerase chain reaction (qPCR) technique has proven to be an effective method to detect and quantify microorganisms in a few minutes. The technique is highly sensitive and able to detect low numbers of microorganisms. However the traditional instrument for PCR does not meet the space requirements that are rapid, portable, and fully automated.In this study, a combined approach of PCR biochip and fluorescence detection camera is developed to isolate and identify the target microorganism. Microorganism in air is collected into an injector by an air pump automatically. Then nucleic acid is extracted in a liquid-tight system. PCR biochip is used to complete the PCR reaction while the camera monitors the product. Finally fluorescent probes are used in the PCR reaction to hybridize with the target sequence to generate a fluorescent signal detected by the camera whose core is an EMCCD, and quantify the amount of PCR product. This system is fully automatic and liquid-tight, which is required in the space science experimental facilities.

F4.6-0004-18 TRADE-OFF OF AGROFORESTRY PARKLAND TREE CONSERVATION AND CROPS PRODUCTION ACROSS THREE CLIMATIC ZONES IN BURKINA FASO

Tiga Neya, neyatiga@gmail.com

Kwame Nkruma University of Science and Technology, Ouagadougou, Burkina Faso

The exponential grow of population couple to food demand made land for agriculture more scarcely and oblige farmer to use the small area it can be for crop production. The trade-off between crop production and tree conservation in the farm was assessed across BouroumBourmoum, Sapouy and Ouahigouya municipalities in Burkina Faso. More than 3000 trees with 1154 trees in Bouroum-Bourom, 884 trees in Ouahigouya and 1054 trees in Sapouy were used. The mean tree canopy cover and tree cover in the farm were calculated. The three principal crop cropped (millet, red sorghum and white sorghum) yield were used to estimate the trade-off considering that the mean tree canopy cover constitute the potential no cropping area. The results revealed 66.25±12 (m2), 59.92±12(m2) and 42.1±12 (m2) Tree crown cover respectively in Bouroum-Bourom, Sapouy and Ouahigouya communes. The tree cover was 23.99±3.61% in Bouroum-Bouroum, 18.23±3.61 in Sapouy and 14.88±3.61 in Ouahigouya and the trade-off resulting to tree cover were 109.5 (kg), 247.6 (kg) and 252.8 (kg). Tree cover in the agroforestry system is higher and can be consider such as forest according to the definition of forest by (FAO 2012). The higher tree cover implying the higher trade-off in the agroforestry parkland should be mean causes by tree density reduction. There is urgent need to see how smallholders farmer can continuous to maintain tree diversity in there farm by carbon payment promotion. Keyword: smallholders, Trade-off, tree conservation, crop production, Burkina Faso

F4.6-0005-18 THE IMPACT OF HYPER-GRAVITY AND GAMMA-IRRADIATION ON PHYSIOLOGY OF WHEAT SEEDLINGS

Sandhya Singh, sandhya_c_singh@yahoo.co.in University of Pune, Pune, India

Pandit B. Vidyasagar, prof_pbv@yahoo.com

Swami Ramanand Teerth Marathwada University, Nanded, India 431 606, Nanded, India

Exposing plants to altered gravity and gamma radiation can provide us with a fundamental knowledge of plant behavior in such conditions, since the mechanisms involved in response of plants to these stresses is still unclear. The more we understand these mechanisms the more we can apply this information to take the journey of life beyond the boundaries of earth. Hence many experiments were performed on pre-imbibed wheat seeds (Lok-1 variety), wherein they were exposed to hyper-gravity stress (300g-1500g) and gamma-irradiation (Dose 20Gy-100Gy) separately. After exposure these seeds were grown in normal conditions and their growth, fluorescence parameters, and total proline content were observed on the 5th day of their growth. A gradual decline in overall growth and fluorescence parameters, with increase in hyper-gravity stress value (300g-1500g) or gamma-irradiation dose (20Gy-100Gy) was observed. Interestingly in the hyper-gravity studies a consistent increase in the total proline content was observed only till 1200g but the total proline content deteriorated thereafter for higher 'g' values. On the other hand gamma irradiation studies revealed that the total proline content continuously increased with increase in the gamma radiation dose (20Gy-100Gy). Later, pre-imbibed seeds were exposed to both stresses (combined as hyper-gravity (300g-1500g) + gamma-irradiation (40Gy)) and same parameters were studied revealing that there was comparatively greater decline in overall growth and fluorescence parameters of wheat seedlings. Also the total proline content gradually increased (from 300g+40Gy-900g+40Gy) with 900g+40Gy stress value having highest value of total proline content but the total proline content decreased subsequently for higher stress values (1200g+40Gy, 1500g+40Gy). Results obtained in the current research showed that exposing pre-imbibed wheat seeds to hyper-gravity stress, gamma radiation or both combined together may affect the proline biosynthesis and metabolism and also the photosynthetic process of wheat seedlings. Supported by Indian Space Research Organization (ISRO) and Board of Colleges University Development (BCUD), SPPU, Pune.

Shanghai Institute of Technical Physics, Chinese Academy of Sciences, Shanghai, China

In the space life science experiment, the presence and concentration of carbon dioxide, ethylene and other gas components have an important influence on the process and result of the experiment. In this paper, a multi-component gas detection device based on Fourier transform infrared spectroscopy is introduced. The spectrometer uses a wide-band infrared light source, an improved Michelson interferometer and a DTGS infrared detector. A long pathlength gas pool based on plane mirror reflection was designed. Compared with the traditional white cell, the gas pool has a smaller volume and the same optical path, which meets the volume constraint of the device. At present, the device has completed the prototype Set up, is carrying out relevant verification experiments. In the future, the device is expected to detect a variety of gases to meet the needs of fine control of the experimental process.

F4.7-0001-18 USING OF THE HERB IN SPACE FOODS

Naomi Katayama, naomik@nagoya-wu.ac.jp Nagoya Women's University, Nagoya, Japan Masamichi Yamashita, gadomy@gmail.com Task Force of Space Agriculture, Tokyo, Japan

The astronaut must do much work in a short time. The astronaut is exposed to much stress.For examples; Break of the hormone balance, Inappetence, Sleep shortage. Therefore the role that the meal serves as becomes big.It greatly participates in not only the health maintenance but also the mental health to consume a meal. Most of space foods are freeze dry, and the mineral is abundant, but it is necessary for the vitamins to add it particularly. When I think about it, the cultivation of the fresh vegetables with the spaceship is necessary. The Asian project team suggested cultivation of the herb in the space.The herbs were sweet basil, Dukung Abak, Hempedu Bumi and Chinese holly basil. Each herb has a fragrance ingredient.The fragrance ingredient stimulates human sense of smell. The fragrance ingredient increases an appetite. The good fragrance derives a good sleep. I can feel passage of time by observing a plant being brought up. It helps mental health to bring up a plant. We try that we bring up herb under a condition of the space. Because an experiment on the ground was over, we report it. The sweet basil which a germination rate has good is the rst candidate when we think about temperature and light quantity in the space. Three kinds of other herbs are slow-growing and germination-rate is lower than sweet basil. We think that probably we will send a sweet basil to the spaceship in space. After a sweet basil grew up in a spaceship, we analyze a fragrance ingredient. We will cook the sweeter basil and want to eat.

F4.7-0002-18 MONITORING OF AFTEREFFECT OF PROLONGED SPACE FLIGHT FACTORS ON SEEDS AND PLANTS OF LYCOPERSICON ESCULENTUM MILL

Lidiya Mishchenko, lmishchenko@ukr.net

National Taras Shevchenko University of Kyiv, Kyiv, Ukraine

There is a growing interest in space food and plant growing. Tomatoes (Lycopersicon esculentum Mill.) - one of the most popular vegetables in Ukraine, they are a valuable product of therapeutic and dietetic foods because they contain a significant amount of nutrients and essential to the human body minerals and vitamins, but by the content of carotenoids - lycopene and -carotene - is a powerful antioxidant. Therefore, tomato plants can be used successfully to astronauts on long space flights. We aftereffect was studied factors of space flight on the variety of tomato seeds Mir-1, which lasted (6 years) were on an orbital space station "Mir". Then, also after long-term of storage in 2011, seeds were sown in the laboratory and received seedlings grown in field conditions of Kyiv and Poltava regions of Ukraine. We have constantly monitored the observations of plants that have grown from this experimental "cosmic" seeds. Because plants grown constantly in the field natural infectious background, there was a high probability of their defeat pathogens of different nature, including viruses. The works of many authors proved reduce the concentration of carotene and lycopene in tomatoes with the defeat of viruses (Raithak, 2012). In addition, the control plants were observed symptoms of such that is a viral infection, namely in 2011 - leaves curl in 2012 - except leaves curl and even mosaics. The research results were confirmed in 2013, namely on the plants of "space" seed no symptoms of, and in control - detection of potato virus Y (method RT-PCR) and symptoms of leaf curl and mosaic. But then in 2016 in the conditions of the Kyiv region the control variant was identified by PVM (M-potato virus, tomato isolate) and TMV (tobacco mosaic virus). Earlier, in 2014, the MVP was detected in the Poltava region. For the first time in the period of long-term studies of the nature of twisting leafs of tomatoes in Ukraine, TMV has been detected in co-infection with PVM. The received sequences of the site of the gene of the capsid protein of tomato isolates PVM K-16 and Pol-14 are deposited in the Gene Bank under the numbers MF998090 and MF998089, respectively. It should be emphasized that in plant research, "economic" version seen much earlier (8 days) and mass flowering 4-5 days - ripening, compared with the control. Found that tomato plants of the variety Mir-1, which were grown under conditions of space flight aftereffect content of photosynthetic pigments exceeded under control, chlorophyll - 1.3 times, chlorophyll b - 1.5 times the amount of carotenoids was higher in 1,2 times. Chlorophyll ratio of the sum of carotenoids was 5.8 for research and version 5.1 in control. The ratio of chlorophyll a and b as in research form, and in the control has changed.

Solids content in the fruits of research exceeded option up to 0,6% of the total number of sugar at 0,67% phenolic compounds and 14 mg% control (p0.01). But resistance to disease, including late blight (on a scale SEV) according Ustymivsky research station in Poltava region. made in 2014 and 2015 - 9 points of control options and 5 and 7 in "Space" in 2014 and 2015, respectively. Year 2015 was favorable for the growth and development of vegetables, especially tomatoes, which showed a high yield. Harsh (severe) symptoms of viral infections in plants in 2017 was observed.In 2017, we observed, as in previous years, the earlier attainment of the fruits in the "space" variants, compared with the control. The average weight of the fetus was higher by 14% in the experimental version. Notably already in July, noticed lightweight twisting of the leaves and the mosaic in control. Our studies have showen no harmful aftereffects on seeds (Lycopersicon esculentum Mill.) under factors of long orbital space flight and the possibility of obtaining a quality crop of tomatoes grown from space seeds on Earth. These results can be used in modern biotechnologies and breeding.

F4.7-0003-18 DESIGNING AN ARTIFICIAL ECOSYSTEM DURING ANALOG LUNAR MISSIONS

Agata Rudolf, agata.rudolf@gmail.com

Lunares Analog Research Station www.lunares.space, Piła, Poland
Agata Kolodziejczyk, fichbio@gmail.com

ESTEC, Noordwijk, Netherlands

Future manned missions associated with colonization of Moon or Mars will be designed with accompanying organisms building stabilized artificial ecosystem to provide healthy food, optimal recycling of wastes and biological balance. During two analog Lunar Missions we designed and tested experimental artificial ecosystem based on algae, plants, insects and snails. We used two species of snails: Helix pomatia and Capea nemoralis; three species of insects: Gromphadorhina portentosa (Cockroaches), Hermetia illucens (Hermetia larvae) and Tenebrio molitor (Tenebrio larvae); five species of plants: Vigna radiata (Mung bean), Raphanus sativus (Radish), Glycine max (Soya bean), Allium cepa (Onion) and Petroselinum crispum (Persley), algae: Spirulina and photosynthetic cyanobacteria Synechocystis.

Animals, plants and photosynthetic microorganisms were selected considering their ecological relations between each other. The main aim was to close biomass cycle within selected group including analog astronauts on the top of designed ecological chain. Biological wastes generated by tested organisms were used as regolith soil fertilizer. Plants, insects and snails were used as food.

Experiments were performed during analog Lunar Test Simulation 0 in August 2016 at Queen Jadwiga Astronomical Observatory in Rzepiennik Biskupi, Poland, and during Lunar Expedition I in August 2017 at Analog Research Station in Pila, Poland. Procedures were performed at stable air temperature, air humidity, light intensity and atmospheric pressure. Body mass and food consumption of experimental species were measured and analyzed. We observed significant increase of plant growth in regolith simulants enriched with insect feaces. For snails and insects we observed, that more diverse food should be provided to sustain balanced growth and healthy populations. This result suggests that additional plant species should be incorporated into analyzed artificial ecosystem.

F4.7-0004-18 JOINT BIOCONVERSION OF PLANT INEDIBLE BIOMASS WITH MUSHROOM CULTIVATION AND YELLOW MEALWORM REARING WITHIN BIOREGENERATIVE LIFE SUPPORT SYSTEM

Xinbin Yang, yangxinbinzz@buaa.edu.cn Beihang University, Beijing, China Yuming Fu, fuyuming@buaa.edu.cn Beihang University, Beijing, China

Hong Liu, lh64@buaa.edu.cn Beihang University, Beijing, China

Long-term deep space activities for the future of mankind, such as the establishment of the Lunar or Martial base, the construction of bioregenerative life support system (BLSS) is crucial. In BLSS, it is expected recycle plant inedible biomass and produce animal protein as much as possible within the system to reduce external material supply. Yellow mealworm (Tenebrio molitor) is the best edible insect selected by the Food and Agriculture Organization (FAO). Its advantages include suitable nutrition composition, fast growth rate, high bioconversion efficiency, easy feeding and less occupied space. Our previous studies confirmed the feasibility of T. molitor as the animal link in BLSS to provide animal proteins for the crew by bioconversion of plant straws. However, the straws must be pretreated by microbial fermentation to be used as

T. molitor's feed. Oyster mushroom (Pleurotus ostreatus) is rich in cellulases and lignocellulases that efficiently degrade straws and provide people with abundant amino acids. In this study, we established a new method that combines mushroom cultivation with T. molitor rearing for bioconversion of plant inedible biomass (PIB). We cultivated P. ostreatus by using plant straws. After harvest, we fed T. molitor larvae (divided by group) in LUNAR PALACE 1 with mushroom residues (MR), while adding other PIB, such as leaves of strawberry, cucumber or carrot as supplements to stimulate and increase T. molitor's consumption of MR. We determined molitor's growth curves, MR digestion efficiency, immune properties and gut microbiota, analyzed the data above to determine the key nutrients that favor T. molitor's consumption of MR, major bacterial genus involved in the MR digestion, and the principal growth limit factor. Based on these results, we optimized the feed composition and verified it by experiments. This study has for the first time achieved to acquire animal proteins and amino acids by bioconversion of PIB, which further improved the system closure.

F4.7-0005-18 STUDY OF AMINO ACIDS COMPOSITION IN A TERRESTRIAL CYANOBACTERIUM NOSTOC SP. HK-01 IN ORDER TO INVESTIGATE ITS USEFULNESS AS A SPACE FOOD MATERIAL.

Midori Ong, s1410655@u.tsukuba.ac.jp University of Tsukuba, Tsukuba, Japan Yasuko Kimura, kimura@jumonji-u.ac.jp Jumonji University, Japan

Shunta Kimura, shuntakimura0130@gmail.com University of Tsukuba, Tsukuba, Japan

Kaori Tomita-Yokotani, yokotani.kaori.fn@u.tsukuba.ac.jp University of Tsukuba, Tsukuba, Japan

A terrestrial cyanobacterium, Nostoc sp. HK-01, is a photosynthetic and Nitrogen-fixing microorganism which can tolerate harsh environmental conditions, and it has attracted attention as a candidate microorganism for initial introduction to Mars. Nostoc sp. HK-01 has four types of cell morphologies: akinetes, vegetative cells, hormogonia and heterocysts. It also has extracellular substances (ES). We have indicated that Nostoc sp. HK-01 is rich in nutrients such as protein, carbohydrates and lipids, and it has been shown to be useful as a food resource. Nostoc sp. HK-01 produces a high level of protein but it has not yet been analyzed how much of each free amino acid it produces. In this study, we analyzed free the amino acids in Nostoc sp. HK-01, which are required by the human body. We investigated the amount of free amino acids of intercellular and extracellular of Nostoc sp. HK-01 which have different akinete ratios. We also investigated the amount of free amino acids after UV exposure to consider whether UV radiation can be used for cooking. As a result, colonies of Nostoc sp. HK-01 with a high amount of akinete cells have a higher amount of amino acid than colonies of Nostoc sp. HK-01 with a low amount of akinete cells. In the case of a low amount of akinete cells, the amount of extracellular free amino acids increased after UV exposure. We discussed the possibility of the function and usefulness of Nostoc sp. HK-01 as a space food material by considering the content of free amino acids.

F4.7-0006-18 APPLICATION TO SPACE FOODS OF THE DISASTER FOOD

Naomi Katayama, naomik@nagoya-wu.ac.jp Nagoya Women's University, Nagoya, Japan Shoko Kondo, naomik@nagoya-wu.ac.jp Nagoya Women, Nagoya, Japan

Yui Nakayama, naomik@nagoya-wu.ac.jp Nagoya Women, Nagoya, Japan

A long-term stay in the space of the human was enabled.The astronaut became able to stay in the long-term space for 1 from a half year.One of the pleasure in the space of the astronaut has a meal.The astronaut is chosen from each country.Therefore the space foods are full of variety.It wants to make the meal a universal meal to be able to do it.In addition, the space foods think about health and want to make a low salt diet.Nourishment balance of the meal eaten in space is regulated now.However, the meal which a hyperglycosemia level after a meal does not happen more than now is necessary.In addition, a low salt diet is necessary for hypertensive prevention.This accords with disaster food in the ground.The nutrient which is enough to take in the disaster foods for a long term is necessary.We need a meal suppressing the hyperglycosemia after a meal in a low salt diet as a disaster meal.Therefore I thought that we applied a disaster meal to space foods.We can store the disaster food at normal temperature for 3-5 years.It is necessary to be able to store the space foods at normal temperature more than three years.The nutrient that both the space foods and the disaster meal are short includes vitamins. We think that it is necessary to supplement it with a supplement about the intake of vitamins.This accords with disaster food in the ground.I thought about space foods menu with commercially available disaster food now in Japan.After all salt to take in per day increases.Most of the energy from carbohydrates is taken in.It is necessary to have vegetables.I think that it can make up for part of vitamins if I can make fresh vegetables in space. A supplement is necessary for the supply of vitamins.I think that multivitamin is good if possible.

F4.7-0007-18 KIBO INDUSTRY, INNOVATES IN AEROSPACE

Naomi Katayama, naomik@nagoya-wu.ac.jp Nagoya Women's University, Nagoya, Japan Jean-Philippe Paillard, paillard@kibo.asia France

The conquest of space is a true inspiration. Imagine a long-duration mission to a distant destination. What shall we take to produce our food? A cow, sh, chicken, or just eggs. In the current state of the animal production technologies are complicated and expensive to implement, except perhaps one: the breeding of edible insects. Based on industry KIBO is postulated in partnership with Space Agriculture Task Force and the university's department of Nutrition Nagoya most innovative research program is created in modern nutrition. This program is called Pegasus. Pegasus research program aims to develop food productions and modules applicable to the aerospace conquest. Kibo entomocole industry is the rst production company in Europe to human food, it aims to become the world leader by 2020. Kibo industry is particularly specialized in producing entomosource (products with insects). The rst phase of the program is to achieve an outcome cereal bar edible insect to aerospace. So we will present the issues and objectives of the project, for aerospace and us. Jean-Philippe Paillard is the KIBO industry CEO and Vice President of the FFPIDI insects farms federation. He is also the co computer alone authorization dossier on the market in Europe and therefore the privileged interlocutor of the General Directorate for Health and Customer Review on this topic. He intervened at the last conference on the insect organized by FAO in Wageningen and in the universities of Angers, Nantes, Lille.

F4.7-0008-18 AQUAPONICS INTEGRATED BY LETTUCE HYDROPONICS AND LOACH AQUACULTURE IN CELSS

Yoshiaki Kitaya, kitaya@envi.osakafu-u.ac.jp Osaka Prefecture University, Sakai, Osaka, Japan Yotsuba Shimakawa, yacmasrtnh@gmail.com Osaka Prefecture University, Sakai, Japan

Toshio Shibuya, shibuya@envi.osakafu-u.ac.jp Osaka Prefecture University, Sakai, Osaka, Japan Ryosuke Endo, endo@envi.osakafu-u.ac.jp

Osaka Prefecture University, Sakai, Japan Teruo Wada, wadoo@bioinfo.osakafu-u.ac.jp Osaka Prefecture University, Sakai, Japan Kenji Nakamura, k-nakamura@especmic.co.jp Japan

In aquaponics systems integrated by hydroponics and aquaculture, re-use of water and balance of nutrient elements are sustained between both cultures, using dissolved elements in feces from fish for plant growth. In order to operate aquaponics (lettuce hydroponics and loach aquaculture) in Controlled Ecological Life Support Systems, we evaluated possibility that dissolved elements in excretion from loach substitute nutrient elements for lettuce plants. We analyzed growth performances of lettuce and loach, and balance of nutrient elements especially for nitrogen between input and output of the whole system and nitrogen flow in the system. As a result, lettuce grew in aquaponics with a standard solution $\times$ 0.5 as well as hydroponics with standard solution. In nitrogen balance, almost all nitrogen supplied to the system was used by growing lettuce and about quarter nitrogen contained in the feed was accumulated in loach. However, some elements from feces didn't contain completely all required elements for lettuce growth.

F4.7-0009-18 USEFULNESS OF THE INSECT FOOD IN THE LONG-TERM SPACE STAY

Naomi Katayama, naomik@nagoya-wu.ac.jp Nagoya Women's University, Nagoya, Japan Yui Nakayama, naomik@nagoya-wu.ac.jp Nagoya Women, Nagoya, Japan

Masamichi Yamashita, gadomy@gmail.com Task Force of Space Agriculture, Tokyo, Japan

The meal is important in life in the space. The importance of space foods is not only health maintenance. The space foods are one of the Life-support system for a space trip. Time for meal is time of the relaxation of home life of the astronaut. However, the breeding of the large animal is still impossible in the spaceship now narrowly. If it is sh and an insect, the breeding in the spaceship is possible. We recognize an insect as ingredients on the earth. As for the insect, possibility to save a food shortage of the earth is expected in future. We suggested the space foods using the insect for 12 years. The cultivation of the insect is pushed forward now in Europe. We suggest a menu to have you know the space foods which took in an insect more. The insect which we used for this menu is silkworm-pupa, a grasshopper, a larva of a wasp and apple snail. The Japanese foods were registered with world's cultural heritage. Therefore we used an insect to make our Japanese foods. Space foods must be universal food. This is because the astronauts are recruited from the whole world. Space foods that a world astronaut eats and thinks to be delicious are necessary. We want to take in an insect in world cooking in future. The insect food includes essential amino acids and essential fatty acid. The insect is superior nutritionally. We will think that insect food is necessary more and more on both the space and the earth in future. The insect is precious ingredients relieving a food shortage for the human.

F5.1-0001-18 STATUS OF ANIMAL EXPERIMENTS ON INTERNATIONAL SPACE STATION AND ANIMAL CARE ACTIVITIES IN JAPAN

We would like to introduce status of Japanese animal experiments on International Space Station (ISS) in recent four years. Mouse Habitat Unit (MHU) was launched in August 2015, by the H-II Transfer Vehicle (HTV or 'Kounotori') 5 from Tanegashima island in Japan, which could house mice at most six months, both conditions of microgravity and 1 G on board with a short-arm centrifuge. The first experiment using MHU was started in 2016. The mice returned on earth in living condition, and the effect of space environment, including microgravity and cosmic radiation were investigated. Aside from MHU, some experiments were conducted only using germline cell or ES cell on ISS, for investigating the effect of space environment to these cells and their offspring. For Aquatic Habitat (AQH) experiments, 'Zebrafish muscle 2' was finished at December 2017 in Kibo module successfully. For animal care activities, a thirdparty inspection against JAXA IACUC activities and animal experiment status in JAXA was conducted at 2016.

F5.1-0002-18 GROUND BASED PARADIGMS TO INVESTIGATE THE NEUROBEHAVIOURAL EFFECTS OF ALTERED GRAVITATIONAL ENVIRONMENT IN RODENTS

Daniela Santucci, daniela.santucci@iss.it Istituto Superiore di Sanita, Rome, Italy

The effects of spaceflight on the nervous system physiology could have important implications for the prolonged stay outside Earth's gravitational field. In this view, both ground-based and space research using animal models represent useful tools to investigate the impact of gravity (hypergravity, microgravity and weightlessness) on the nervous system and behaviour. Data coming from these studies, besides acquisition of knowledge relevant for spaceflights and prolonged permanence of both humans and animals in space, could provide insight into basic biological phenomena underlying the plasticity of the nervous system and its adaptive responses to a changing environment. Most ground experiments employing animal models use the paradigm of hypergravity exposure with the expectation that behavioural and physiological reactions to this environment might help to explain reactions to the microgravity challenge faced by orbiting animals. An overview and perspective of ground-based experiments set up to investigate the effects of changes of gravitational environment on the neurobehavioural responses of CD-1 mouse will be reported and the short-, mediumand long-term behavioural and neurobiological consequences of hypergravity exposure both at adulthood and during early and late postnatal development discussed.

F5.1-0003-18 WHICH PRECOCIAL RODENT SPECIES IS MORE APPROPRIATE AS EXPERIMENTAL MODEL TO INVESTIGATE INFLUNCE OF ALTERED GRAVITATIONAL REGIME ON DEVELOPMENT OF THE HUMAN FETUS?

Slobodan Sekulic, slobodan.sekulic@mf.uns.ac.rs Medical Faculty Novi Sad, Novi Sad, Serbia Ivana Pericin-Starcevic, ipericin@gmail.com

Institute for Children and Youth Health Care of Vojvodina, Novi Sad, Serbia

Precocial rodents as a new experimental model to study the effects of altered gravitational condition on fetal development.

Slobodan Sekulic, Ivana Pericin-Starcevic

Previously published article reported that precocial rodents are more appropriate experimental model than altricial rodents for investigation of the influence of altered gravitational regime on development of the human fetus. Influence of altered gravity on depends on stadium of maturation of the bone, muscle and nervous system. Maturity of human fetus at birth is more similar to guinea pig than to altricial rodents such as rat, mouse or hamster. Also, precocial rodent species provide possibility for the first successful mammal reproduction in space because their mature visual and locomotor system alleviates breastfeeding immediately after birth (Sekulic SR et al. Precocial rodents as a new experimental model to study the effects of altered gravitational condition on fetal development. Microgravity, Science and Technology 2006; 18: 223-5.). Precocial rodents are different species with different taxonomy background. Question is which precocial species is more appropriate for experimental model. We considered species which are maximal weight is approximately 1kg. Comparison in relation to husbandary is possible for guinea pig and chinchilla. Chinchilla is less prone to negative stress reaction, have longer average duration of pregnancy than guinea pig (110 vs 63 days), and although have same range of the number of fetuses (1-6) it has in average lower number of fetuses compared to guinea pig (2 vs 3). Newborn mortality rate is similar in both species and largely depends on correct housing conditions (10-25%). Sand bath is necessary for hygiene of chinchillas to remove excess of the oil, keep its coat and skin clean, preventing infections. For sand bath necessary condition is gravity. Therefore experiments with hypergravity (rotating platform on Earth) and hypogravity condition (rotating platform in low Earth orbit) could be more appropriate for chinchilla. Experiments in microgravity conditions could be more appropriate with guinea pig. Disadvantages of lower number of fetuses in chinchilla could be overcome with ultrasound examination of the number of embryos/fetuses prior to start of the experiment, while alternative solution for sand bath could candidate this species for experiments in microgravity conditions. Using specimens for investigation before birth could be a solution to obtain more samples in spite of high neonatal death. Prenatal development of muscle, bone and nervous system

of the guinea pig is well described in published literature while data are largely missing for chinchilla. Up to date no experiments were done using precocial rodents to examine influence of altered gravitational regime to fetal development.

F5.1-0004-18 EFFECTS OF SPACE ENVIRONMENT ON SILKWORM EMBYRO DEVELOPMENT AND MUTAGENESIS MECHANISM

Anjiang Tan, bombyx@126.com

Shanghai Institutes of Biological Sciences, CAS, Shanghai, China

The silkworm, Bombyx mori, is a lepidopteran model insect with economic importance. The silkworm is originated from China and has been cultivated for thousands of years as the contributor of sericulture. During the long-term domestication, the silkworm has acquired many unique characteristics such as short life cycle, high fecundity, moderate sizes which are suitable for rearing in a limited area such as space environment. We participated in the project of SJ-10 recoverable satellite which carried silkworm embryos as one of 19 scientific experiments in 2016.Silkworm embryos have been were recovered from space successfully and preliminary experiments have been done to investigate influence of space environment on silkworm embryonic and post-embryonic development. Using the embryos carried by SJ-10 satellite, we plan to investigate difference of embryos between space environment and ground control groups at genomic, transcriptional and translational levels. Furthermore, using the genetic manipulation technologies such as transposon-based transgenesis and the CRISPR/Cas9 system, we will perform functional analysis on selected key genes to exploit their functions in silkworm embryonic and post-embryonic development. These studies will not only contribute to modern sericulture, but also exploit how space environment affects silkworm embryonic development and provides fundamental knowledge and experimental approaches for future space life science.

F5.1-0005-18 MICROGRAVITY INFLUENCES SHELL CALCIFICATION IN YOUNG MOLLUSK BULINUS AUSTRALIANUS

Xiaoyan Li, lixiaoyan@ihb.ac.cn

Institute of Hydrobiology, CAS, Wuhan, China Gaohong Wang, space@ihb.ac.cn

Institute of Hydrobiology, CAS, Wuhan, China Yongding Liu, liuyd@ihb.ac.cn

Institute of Hydrobiology, CAS, Wuhan, China

Abstract Calcified structures can be found in many living organisms, they take important part in gravitational sensing, organs supporting and soft tissues protecting. The calcification process changes in microgravity, but the mechanism is still to be disclosed. We used young mollusk Bulinus australianus to investigate shell calcification in microgravity. 6 snails at age of 1-2 months were randomly selected for flight and ground parallel experiments. After 17.5 days, we found shell from spaceflight reduced weight, accompanied with the changes of shell fine structures, microchemistry and polymorphism. The organic matrices secretion was decreased. The interlamella in nacreous layer disappeared and amorphous calcium carbonate deposited. Based on these findings, we proposed that the deficiency in organic matrices and unformed organic spatial structures caused uncontrolled mineral nucleation and transient amorphous calcium carbonate deposition. The amorphous tablets developed in a "twodimensiongrowth" mode, prevented calcium from further incorporation. Our findings provide new sights to calcification in microgravity, especially bone loss and relevant countermeasure.

Keyword: Microgravity. Calcification. Mollusk Shell. Amorphous Calcium Carbonate

F5.1-0006-18 POLYHYDRAMNIOS AS A EXPERIMENTAL MODEL FOR DECREASING MECHANICAL STRESS ON BONE AND MUSCLE DEVELOPMENT DURING SECOND HALF OF GESTATION

Slobodan Sekulic, slobodan.sekulic@mf.uns.ac.rs Medical Faculty Novi Sad, Novi Sad, Serbia

Fetus spontaneously moves from 7th week of gestation week until end of pregnancy. Absent fetal movements in neuromuscular diseases as well as in Fetal Akinesia Deformation Sequence are accompanied with hypomineralized and hypoplastic long bones. During last trimester of gestation fetus has outgrow intrauterine environment, buoyant forces only partially express effect, and fetus has 60-80% of its actual weight. During this period total amount of calcium in bone increase from 5g to 30g. The primary ossification centers in the diaphyses of the major long bones, shoulder, pelvic girdle, and phalanges of the hands and feet appear before the last trimester of gestation. The secondary ossification center in the distal diaphysis of the femur is present from the 33rd week of gestation onward. Before the thirtieth week of gestation in human fetus muscles comprised a great number of smaller type IIC fibers and scattered large type I fibers. After the thirtieth week, the percentage of type I fibers increased greatly to about 23%-50% at term. After the 24th week of gestation, the main factor in the increase in muscle cross-section area is the hypertrophy of muscle fibers. Polyhydramnios represents the excess of amniotic fluid, increase influence of buoyant force on fetus, and decrease mechanical stress on bone and muscle development during last trimester of gestation. While bone condition could be examined in noninvasive manner, investigations of the muscle condition include the biopsy. Experimental models could provide additional data. Altricial mammals are born with the myotubular stadium of muscle development of the extremities, contrary to precocial mammals, which have both types of muscle fibers mature at birth. Also altricial mammals at birth have only primary ossification centers, while precocial mammals have primary as well as secondary ossification centers. Chronic intravenous infusion of angiotensin 1 into fetal lambs (precocial mammal) caused polyhydramnios. Aquaporin 1 knockout mice could be model for polyhydramnios in altricial mammal. Comparison of the muscle and bone development in altricial and precocial mammals in polyhydramnios will provide comparative data related to influence of decreasing mechanical stress during fetal development. In literature there is no data about bone and muscle development in fetuses exposed to chronic polyhydramnios.

F5.1-0007-18 DIFFERENTIAL EXPRESSION OF HOMER SPECIFIC ISOFORMS AT THE NEUROMUSCULAR JUNCTION SUGGEST KEY MECHANISM RESPONSIBLE FOR SKELETAL MUSCLE ATROPHY DURING EXPOSURE TO MICROGRAVITY

Dieter Blottner, dieter.blottner@charite.de

Charité Universitätsmedizin Berlin, Berlin, Germany Guido Gambara, guido.gambara(at)charite.de Charité Universitätsmedizin Berlin, Berlin, Germany Sandra Furlan, sfurlan@bio.unipd.it

University of Padova, Padova, Italy Lian-wen Sun, sunlw@buaa.edu.cn Beihang University, Beijing, China Pompeo Volpe, pompeo.volpe@unipd.it University of Padova, Padova, Italy

Michele Salanova, michele.salanova@charite.de Charité Universitätsmedizin Berlin, Berlin, Germany

Introduction | The molecular mechanisms regulating skeletal muscle plasticity under extended period of disuse or exposure to microgravity (μG) are not yet fully understood. With the aim to further elucidate such mechanisms we have investigated Homer specific isoforms expression and subcellular localization in skeletal muscle soleus (SOL) and extensor digitorum longus (EDL) of adult rat and mice exposed to chronic disuse by hind limb unloading (HU) and of space-flown adult mice for 30 days in microgravity (Bion-M1, 2013). Hypothesis | Homer specific isoforms play key roles in disuse-induced neuromuscular junction (NMJ) remodeling and plasticity responsible for skeletal muscle atrophy following chronic unloading on Earth and under μG exposure. Methods | Muscle SOL and EDL from 3-weeks HU rats (n=4) and 30 days space-flown C57/black mice were used. In spaceflown animals, three different groups were investigated: The Bion-flight (BF) group (n=5), Bion-ground control (BG) and vivarium control (VC) group. Homer expression and subcellular localization was performed by using laser confocal microscopy, biochemical and Real Time-PCR (RT-PCR) analysis. Results | The immunohistochemical analysis of Homers at the NMJ of HU and Bion-M1 flown animals showed decreased of Homer fluorescence pixel intensity signals in SOL that were not seen in EDL of space-flown and ground control groups. Biochemical analysis in SOL of HU rats further support such results. Notably, by gene array analysis Homer1a, the dominant negative short Homer isoform, was up regulated after 30 days of exposure to μG whereas Homer2, the long

Homer isoform, was down regulated in muscle SOL but not in EDL. These results were further validated by RT-PCR analysis. Discussion | The results indicate that Homer specific isoforms are highly regulated at the skeletal muscle NMJ by muscle unloading conditions and that Homers are sensitive to μG in a muscle specific way.

F5.1-0008-18 STUDY OF P-GLYCOSIDE INTERACTION PROTEINS IN RAT BRAIN UNDER SIMULATED MICROGRAVITY-LABELED FREE COMPARATIVE PROTEOMICS APPROACH

Yujuan Li, lylyjlzh2006@163.com

Microgravity is responsible for redistribution of fluids in the body when in space that may lead to pharmacokinetic (PK) changes. PK change could occur at absorption, distribution, metabolism or excretion processes within the body. It may cause unexpected results regarding efficacy or toxicity of the administered drugs. The altered penetration of drugs in brain could threaten lives of astronauts. P-glycoprotein (P-gp) plays a very important role in drug disposition and maintaining stability of nervous system by effluxing toxics out of blood-brain barrier (BBB). Hence, the proteins interacting with P-gp are of utmost importance. The present study is aimed to investigate interaction proteins with P-gp in rat brain under simulated microgravity by using comparative proteomics approach. Rats were tail-suspended to simulate short (7-day) and long term (21-day) microgravity effect. Non-labeling proteomics strategy was employed to observe significantly differential expression of proteins interacting with P-gp in rat brain under simulated microgravity. The significant differential expression of proteins interacting with P-gp were elucidated by HPLCQ-TOF. Twenty-six (26) of common proteins were chosen from two groups. It was found that 20 proteins were continuously down-regulated, and two proteins showed continuous up-regulation respectively in 7 and 21-day microgravity exposed rats. Bioinformatics analysis revealed that all significantly differentially expressed proteins mainly participated in regulation of 13 kinds of biological process, including ATP hydrolysis coupled proton transport, ATP hydrolysis coupled transmembrane transport and so on. These proteins are found involved pathways including P-gp synthesis, transportation and degradation in cell, APT energy supply, and phosphorylation of P-gp mediated by CAMP/PKA pathways. Atp1b1 was identified by western blot to verify MS results. These findings provide clues for understanding the relation between interaction and changed function of P-gp in rat BBB under microgravity, which might be useful for stability of nerve system and safety of medication use in space travel.

F5.1-0009-18 PROTEOMIC CHANGES RELATED TO ENERGY METABOLISM AND OXIDATIVE STRESS IN THE LIVER OF RATS EXPOSED TO SIMULATED MICROGRAVITY

Yujuan Li, lylyjlzh2006@163.com

Beijing Institute of Technology, Beijing, China BIT life science-3

Chen Bo, Shibo Wang, Jingjing Guo, Liting Kang, Yujuan Li*, Yulin Deng*

The aim of current study was to investigate proteomic changes in liver of rats under short-term simulated microgravity using the Morey-Holton model. After 3 days, strong oxidative stress was observed through the accumulation of hydrogen peroxide and malonaldehyde in rats' liver. 215 proteins particularly those related to energy metabolism pathways were differentially regulated. Processes for oxidating nutriments, such as glycolysis, -oxidation and tricarboxylic acid cycle were greatly enhanced and thus glucose and non-ester fatty acid were heavily consumed. Mitochondrial oxidative phosphorylation was significantly disrupted and thereby, the vast electrons generated from oxygenolysis might not be fully transferred to dioxygen. The enhanced utilization of glucose and non-ester fatty acid coupled with impaired electron transfer chain might contribute to oxidative stress in rats 'liver under simulated microgravity. The proteomic changes support the usage of drugs regulating carbohydrate/lipid metabolism and anti-oxidant in manned space missions.

F5.2-0001-18 PSYCHOLOGICAL AND PSYCHIATRIC ASPECTS OF A MANNED MISSION TO MARS

Nick Kanas, nick.kanas@ucsf.edu

University of California San Francisco, Kentfield, California, United States

Introduction: Based on past studies of astronauts and cosmonauts participating in on-orbit space missions, much has been learned about important psychological, psychiatric, and interpersonal issues that affect crewmembers involved with near-Earth space activities. However, the extreme distances that will characterize a manned mission to Mars will introduce additional psychosocial stressors never before experienced. Methods: A review was made of psychosocial studies involving crewmembers who worked in on-orbit space missions, including the presenter's own work. Also included were studies in high-fidelity space simulation environments, such as the Mars 500 simulator in Russia. Results: Based on this review, a number of psychological, psychiatric, and interpersonal issues were identified and will be discussed. But a mission to Mars will involve unique stressors, such as increased crewmember autonomy, communication delays with the Earth, and the Earth-out-of-view phenomenon. Ideas will be presented for developing research that will help us deal with such issues. Conclusions: As we progress on to Mars, the lessons learned from on-orbit space missions will help up plan ways of dealing with new psychosocial stressors that will affect crewmembers. More research in the space environment is needed to better understand these stressors and to develop ways of coping with them to ensure the accomplishment of mission goals.

F5.2-0002-18 HUMAN NATURE IN LONG DURATION SPACE TRAVELS

Ayşe Ören, info@ayseoren.com Turkey

Introduction As we embark on a journey for new homes in the new worlds to lay solid foundations, we should consider not only the survival of frontiers but also well-being of those to live in zero gravity.

As a versatile science, architecture encompasses abstract human needs as well.

On our new different direction in the course of the Homo sapiens evolution, we can do this with designs addressing both our needs and senses. Well-being of humans can be achieved by creating environments supporting the cognitive and social stages in the evolution process.

Space stations are going through their own evolution process. Any step taken can serve as a reference for further attempts. When studying the history of architecture, window designing is discussed in a later phase, which is the case for building a spaceship as well.

We lean on the places we live both physically and metaphorically. The feeling of belonging is essential here, entailing trans-humanism, which is significant since the environment therein is like a dress comfortable enough to fit in, meeting needs without any burden.

Utilizing the advent of technology, we can create moods and atmospheres to regulate night and day cycles, thus we can turn claustrophobic places into cosy or dream-like places.

Senses provoke a psychological sensation going beyond cultural codes as they are rooted within consciousness, which allows designers to create a mood within a space that tells a story and evokes an emotional impact.

Colour, amount of light, sound and odour are not superficial. As much as intangible, they are real and powerful tools with a physical presence.

Tapping into induction, we can solve a whole system based on a part thereof. Therefore, fractal designs may not yield good results unless used correctly in terms of design although they are functional, which makes geometric arrangement critical.

F5.2-0003-18 NEW PROBIOTICS FOR ENHANCEMENT OF HUMAN COLONIAL RESISTANCE IN ARTIFICIAL ENVIRONMENT: ACHIEVEMENTS AND PROSPECTIVE

Institute for Biomedical Problems RAS, Moscow, Russia

Planned interplanetary missions require elaboration of sufficient means to enhance colonial resistance of space crew members. Previous studies reveal decrease of protection activity of indigenous microflora of cosmonauts, thus exogenous contamination could be dramatically easified. Today there are at least four main microbial risk factors 1. Risk of autoand cross infections 2. Risk of sapronose-like infection from alternative sources in confined habitat (e.g. contaminated surfaces and LSS elements) 3. Risk of microbial contamination from outer space during EVA 4. Risk of contamination by microbial community, formed on visiting planet. To avoid microbial risks reliable and fit prophylactic means should be elaborated. Among broad range of ecologically compatible means aimed to improve colonial resistance, autoprobiotics seem to be one of the most perspective groups. We have successfully tested several kinds of probiotics, based on autochthonous bifidobacteria, lactobacilli and enterococci strains in different experiments in long-term isolation, including "Mars-500". The tremendous advantage of autoprobiotics is that there is no problem for adhesion in the biotope, and that it has no allergic impact on human organism. The form of consumption is different: tablets, collagen stripes, ampoules, sour milk products, sprays. Other perspective group of probiotics are based on collection strains, which are well known as protective strains, but still never used as probiotic medicines. For example Corynebacterium pseudodyphteriticum for treatment of high respiratory tract, was tested in different dry immersion studies to decrease or to eradicate Staphtlococcus aureus, Veillonella parvula is a good antagonist versus periodontial pathogens. The third group of prospective means form combined preparates containing probiotics together with other substances. For example, simulator of nasal secretion, containing bacterial substance together with hyaluronic acid and lysozyme was successfully tested in dry immersion studies. The list of the these latter means will be expanded in our future studies.

F5.2-0004-18 EFFECTS OF A NUTRITIONAL COCKTAIL CONSISTING OF ANTI-OXIDANT AND ANTI-INFLAMMATORY SUPPLEMENTS TO PREVENT ECTOPIC FAT STORAGE AND CARBOHYDRATE AND LIPID METABOLISM ADAPTATIONS INDUCED BY 60 DAYS OF ANTIORTHOSTATIC BED REST.

PURPOSE: In the perspective of the foreseen space missions to Mars and Moon, space agencies aim to understand the mechanisms leading to space deconditioning and develop countermeasure programs. A recent observation during bed-rest studies is the general storage of fat in tissues not specialized in fat storage, i.e. muscle, bone, liver, and whose function is altered because of this lipid accumulation. This general ectopic fat storage is thought to contribute to the development of metabolic syndrome in astronauts, which would jeopardize their health over the long-run. Recent studies conducted in the general population showed several nutrients taken individually, i.e. resveratrol, quercitin, -3 fatty acids, vitamins and others, partially prevent the development of metabolic features associated with metabolic diseases. In a feasibility study, we showed that a cocktail of natural antioxidants XXS-2A (741mg), coupled with both omega-3 fatty acids (1g), vitamin E (168mg) and selenium (80µg) fully prevented the hypertriglyceridemia, the drop in fasting HDL and total fat oxidation as well as the increase in de novo lipogenesis induced by low levels of physical inactivity. The objective is to investigate whether this same nutritional supplementation helps to prevent and/or reduce the deleterious effects induced by simulated microgravity.

METHODS: Twenty healthy male volunteers were randomly assigned to dietary antioxidant cocktail countermeasure (n=10) or isocaloric control diet (n=10) during a 60-day bed rest. Before and at the end of the bed-rest, we measured body composition (DXA), ectopic fat storage (MRI), total energy expenditure and substrate oxidation (indirect calorimetry) and blood chemistry. Exogenous glucose oxidation and liver de novo lipogenesis (GC-MS) were measured by using a glucose tracer, (U-13C) glucose, mixed in standard meals. Analyses used linear mixed models taking into account repeated measures.

RESULTS: Data has been completed in December 2017 and samples and data are under analysis. We hypothesize that sixty days of antiorthostatic bed-rest induce an increased ectopic fat storage in both intra-muscular, intra-hepatic abdominal, abdominal, leg and belly subcutaneous fat based on MRI data. We also expect that physical inactivity trigger exogenous glucose oxidation. Bed-ridden enforced physical inactivity induces a hyperlipemia and a drop in total lipid oxidation. As well, the circulating anti-oxidant capacity could be altered by sixty days of bed rest. We hope to show that nutrition countermeasure can play a central role for the future space missions by counteracting metabolic alterations while not having adverse effects on other system, being easy to implement and inexpensive.

F5.2-0005-18 NEUROMUSCULAR AND CARDIOVASCULAR ALTERATIONS IN ORTHOSTATIC HYPOTENSION AND POSTURAL INSTABILITY INDUCED BY MICROGRAVITY

Alterations of postural and orthostatic tolerance are the constant consequence of space flights [Kakurin, 1972; Kozlovskaya et al., 1981; Charles, 1991; Paloski et al., 1992; Black et al., 1995;

Egorov, 1996; Buckey et al., 1996; Reschke et al., 1998, 2009; Convertino, 2002; Custaud et al., 2002; Fomina et al., 2007; Coupé et al., 2009; Jain et al., 2010; Saenko et al., 2011; Kotovskaya, 2013]. Muscle tone is considered as one of the mechanisms which play the important role in providing both orthostatic and postural tolerance. Decrease of muscle tone which is observed starting from the first minutes of exposure to weightlessness can contribute to development of both phenomena [Gevlich et al., 1984; Miller et al., 2010; Fomina et al., 2008; Kotovskaya, 2013]. In spite of the number of studies of cardiovascular and postural effects of microgravity the role of neuromuscular and vascular disorders in development of orthostatic and postural intolerance is not clear yet. The results of the study have shown that microgravity is followed by decrease of systolic arterial pressure and heart stroke volume, heart rate increase and deterioration of cardiac activity autonomic regulation during transition from supine position to vertical stance. Comparative analysis of cardiovascular parameters after 21-days of Bedrest and 3-days Dry Immersion has revealed the largest changes after Dry immersion. The changes observed after Bedrest have the same direction but less expressed. The deep alterations in postural control system such as multiple increase of amplitude and velocity of center of pressure fluctuations are observed during first hours after space flights accomplishment. The changes of these parameters after onground model experiments have the same direction but less evident. Support withdrawal is followed by postural muscles atonia. Results of our study revealed strong negative correlation between the changes of muscle tone and heart rate before and after Dry Immersion as well as correlation after exposure to Dry Immersion between parameters of postural stability and muscle tone which was not revealed under normal conditions. The study is supported by Russian Academy of Sciences, CNES and RFBR project 16-29-08320 ofim.

F5.2-0006-18 FAST TRACK MYOMETRIC ANALYSIS OF MUSCLE STATUS TO COMPLEMENT FUNCTIONAL NEUROMUSCULAR TESTS IN HUMAN ANALOG STUDIES AND SPACEFLIGHT

Dieter Blottner, dieter.blottner@charite.de

Charité Universitätsmedizin Berlin, Berlin, Germany Britt Schoenrock, britt.schoenrock@charite.de Charité Universitätsmedizin Berlin, Berlin, Germany Michele Salanova, michele.salanova@charite.de Charité Universitätsmedizin Berlin, Berlin, Germany Andreas Kramer, andreas.kramer@uni-konstanz.de Germany

Background | Neuromuscular tests are routinely used to document functional changes in skeletal muscle and tendon for example in human analog studies or during spaceflight missions. Due to the unique body positioning (usually supine in bed rest) or relaxed state of the free floating body in spaceflight, both training regimen and functional tests may not be always well tolerated due to the uncomfortable transition from relaxed state to maximal power output which is however required to maintain performance and health of astronauts in spaceflight. Thus, alternative tests for functional assessment are needed for monitoring muscle status and health under conditions of extended disuse and exercise on Earth and in Space. Hypotheses | Non-invasive myometry may be a reliable tool for monitoring of neuromuscular status in disuse and, for example, can be applied in bed rest without and with exercise (reactive jumps) as countermeasure (60 days RSL-study, DLR:envihab, Cologne, 2016). Methods | We used a hand-held MyotonPRO digital palpation device to collect biomechanical parameters, tone [Hz], stiffness [N/m], and viscoelastic properties, elasticity (log decrement) and relaxation time [ms] from surface soft tissue (muscle, tendon and fascia) at predefined body skin marks in two bed rest groups (control and exercise, n=8 each). Data collection included the shoulder/neck, back and legs of bed rest participants before (BDC-10), during (HDT+1 to HDT+58, approx.10 days increment), and after bed rest (R+10). Results | We defined a set of biomechanical property changes (vs. baseline) as key to negative bed rest effects, training effects in bed rest, and reconditioning effects (R+10 vs HDT+58) after bed rest (return to habitual activities). Functional neuromuscular tests (i.e., left leg hops linked to surface EMGs) before and after bed rest only showed trends in relevant muscular and myofascial structures of the leg. Discussion and Conclusion | The MyotonPRO technology turned out to be an easy and quick method for muscle status assessment in long-term bed rest. In thigh and calf muscle biomechanical and viscoelastic property changes preceded the functional changes. We propose non-invasive myometry as a fast track analysis protocol. It has the potential to serve as complementary assessment tool in cases where demanding neuromuscular tests may not be easily available, in field studies in extreme environments on Earth, and in long-term spaceflight. Sponsors | European Space Agency (ESA), DLR, Cologne, BMWI/DLR e.V., 50WB1421 to D.B.

F5.2-0007-18 INVESTIGATION OF PERIODONTAL TISSUES IN THE SIMULATION OF THE WEIGHTLESSNESS FACTOR

Viacheslav Ilyin, piton2004@bk.ru

Institute of Biomedical Problems, Moscow, Russia Marina Rykova, rykovamarina@yandex.ru Institute for Biomedical Problems RAS, Russia Evgenia Antropova, rykovamarina@yandex.ru Institute of Biomedical Problems, Moscow, Russia Zoya Soloviova, soloviova@imbp.ru

Institute for Biomedical Problems, RAS, Moscow, Russia Andrey Nosovsky, nam@imbp.ru

Institute for Biomedical Problems, RAS, Moscow, Russia Marina Skedina, skedina@imbp.ru

Russia

"Dry" immersion reproduces changes in physiological functions in the human body, as well as weightlessness. Investigations of periodontal tissues were carried out on the 1st day (background), on the 5th day of immersion (output) and on the 7th day after the end of the immersion. All investigations were performed on an empty stomach, before brushing your teeth. Six healthy male volunteers aged 19 to 26 participated in the investigation. Sampling was conducted locally from 8 points using standard sterile tampons. The concentration of immunoglobulins (sIgA, IgA, IgM) and cytokines (IL-6, IL-8, IL-1, INF, FNO, IL-4) in the oral fluid was determined by an enzyme immunoassay using the appropriate reagent kits of ZAO Vector-Best. For statistical processing of the results of the investigations, the scientific and statistical package "Statistica v6.0" was used. There is a tendency for sIgA to grow on the 5th day of immersion, and on the 7th day after the completion of the immersion, a significant increase in 2-fold IgA ($p < 0.05$) compared with the output. It can be assumed that an increase in sIgA is associated with the appearance of parodontopathogenic microflora in the oral cavity during the experiment. Pro-inflammatory cytokines (IL-8, IL-1, INF) make the main contribution to the total pool of cytokines, that is, a pro-inflammatory cytokine shift is observed. Concentration of IL-8 at the output is increased in comparison with the input in 3 times (p

<0.05). There is a tendency to increase the concentration of INF on the 5th day of immersion, and on the 7th day after the completion of the immersion it significantly increases by 2 times ($p < 0.05$) as compared with the output. Thus, the revealed changes in local immunity indicate a decrease in the protective mechanisms of periodontal tissues and the possibility of activation of inflammatory processes.

F5.2-0008-18 "AWAKENING" OF SUPPORT RECEPTORS IN LOCOMOTOR TRAINING DURING SPACE MISSIONS AS A FACTOR OF POST-FLIGHT CHANGES IN THE NEUROMUSCULAR SYSTEM

State Scientific Center of the Russian Federation Institute of Biomedical Problems of RAS, Moscow, Russia

The development of a fundamentally new approach in constructing a countermeasure system of the human body hypogravitational disorders has begun. It is based on the concept of the trigger role of reducing the intensity of sensory inflow from the support input in the development of the neuromuscular system changes in weightlessness. To assess the intensity of support receptors stimulation (as a result of physical training on the treadmill), the values of the vertical component of the ground reaction force with a sampling frequency of 100-120 Hz were recorded using strain gauges on the treadmill that is located on the International Space Station (ISS) and equipped with a vibration isolation system. A primary processing of the values of GRF was carried out using specially developed software that integrated the curve of ground reaction force with a given step (the integration step in this study was 5 kg). We calculated the relative exposure time of the entire spectrum of GRF values per day and individual segments of this spectrum: up to 32% of the cosmonaut body weight on the Earth, from 32% to 64% of body weight, more than 64% of body weight and more than body weight. The parameter of integral stimulation of support receptors was also calculated, by which we mean the product of the time of the support impact on the magnitude of GRF, that is, the area under the graph of GRF throughout the locomotor training. Twelve cosmonauts were participated in this study (age is 47±5 years, all men, weight is 81.8 kg ± 7.9 kg, duration of space flights is 163 ± 25 days). Based on the changes after the flight of the electromyographic cost of walking along a soft surface, two groups of cosmonauts were distinguished. In group A there was a decrease or a slight increase in the maximum amplitude of the m.soleus electromyogram, in group B there was a significant increase in this parameter after the flight. The results of the study show significant differences between the groups in the total exposure time on the support receptors. In group A it was 28.0 min per day, in group B it was 23.5 min (p 0,01). Moreover, the group A was surpassed in exposure time of ground reaction force in the segments from 32% to 64% of body weight, less than 64% of body weight and less than body weight (p 0,03). Both groups were equal in exposure time on the support receptors: with the intensity less than 32% of the body weight it was 4 minutes, and with the intensity higher than body weight it was 3 minutes. We also revealed differences between the groups and the parameter integral stimulation of support receptors. In group A it was 1499 min * kg per day of the flight and in group B it was 1209.8 min * kg per day of the flight (p 0,02). Thus, for the first time, we were able to compare the changes in the motor system after a long-term effect of weightlessness in connection with "awakening" of support receptors in locomotor training during space mission. The time and intensity of the support receptors stimulation during locomotion training are connected with a post-flight change in the electromyographic cost of walking along a soft surface. In the future we are going to analyze the connection between the intensity of the sensory inflow from the support input and the post-flight changes not only of the electromyographic cost of walking, but also of the muscles' speed-strength properties and the mineral density of bone. This work was supported by Russian Foundation for Basic Research grant № 17-04-01826.

F5.2-0009-18 A NUMERICAL PHYSIOLOGICAL ELECTRICAL-LIKE MODEL FOR PREDICTING THE HUMAN CARDIOVASCULAR DECONDITIONING. RESULTS FOR DIFFERENT SPACE MISSION SCENARIOS.

Antoni Perez-Poch, antoni.perez-poch@upc.edu Universitat Politecnica de Catalunya, Barcelona, Spain

We report on the results and validation of the model NELME (Numerical Emulation of LongTerm Microgravity Effect) across a wide variety of altered gravity scenarios. Computer simulations have become increasingly available for making predictions on the outcomes of complex physiological systems in extreme environments. However, technical limitations and difficulties of finding out opportunities to produce large series of experimental data to validate the models, have made accuracy difficul for these models. In recent years, this situation has changed as computer facilities have increased their power; and more experimental data from parabolic flights and other altered gravity platforms are available to researchers as well. Details on the development of NELME model are provided, a computer electrical-like physiological model which takes into account variables such as gender, weight, height and also environmental variables like temperature or exposure to gravity. From the model, we can retrieve output results related to the cardiovascular performance under stress and/or exposure to altered gravity. These measurements lead to an assessment of the deconditioning of the cardiovascular system in different scenarios. This is of interest, for example, in cases where it is unlikely that animal models or humans can be tested, such as long-term exposure to partial microgravity.The model has been validated through parabolic flights conducted at the Barcelona-Sabadell Airport using an aerobatic aircraft CAP10B. This aircraft provides up to 8 seconds of microgravity preceded and followed by peaks of around 2 seconds of hypergravity. The model, once validated, is applied to investigate on human exposure to different altered gravity scenarios.

Results are provided about different simulations for short, medium-term and long exposures to microgravity; along with different events embedded. These simulations may include simulation of physical aerobic exercise during a mission, EVAs, thermal stress or human exposure to altered gravity scenarios (centrifuges, Martian or Lunar gravity, rocket launch, etc.). Risks for human health that may put in jeopardy a manned space mission are evaluated and discussed. Results from the simulations account for a degree of impairment of human capabilities that may be of interest for designing future long-term human missions to Mars or others. Interestingly, a long-time exposure to less than 0.35g seems to be as hazardous as a zero g for missions longer than three months, while aerobic exposure does not fully counteract the risks.

F5.2-0010-18 BIOLOGICAL CLOCK SYNCHRONIZATION AND TIME PERCEPTION IN ISOLATED FROM SUNLIGHT HABITATS

Agata Kolodziejczyk, fichbio@gmail.com ESTEC, Noordwijk, Netherlands and M. Harasymczuk, A. Waśniowski

Nearly all living organisms evolved circadian rhythms as synchronization to rotational movement of the Earth. Lunares habitat is a biological clock laboratory established in 2017 in Poland. The facility is designed to investigate optimal for physiology and health lighting conditions for future Moon and Mars human space missions. Within two-week analog simulations astronaut crews, insects, plants and algae undergo multiple experiments in fully isolated from natural sunlight and UTC time environment. A prototype of physiological lighting administrated inside the habitat activates or inhibits multiple types of photoactive proteins responsible for homeostatic regulatory pathways including nervous, endocrine, digestive and immune systems in humans as well as growth and development processes in insects and plants. During three organized analog simulations in 2017, circadian rhythms of 6 analog astronauts with independent control groups were monitored for one month starting one week before the mission, during the mission and 1 week after the mission. During stay in the habitat, analog astronauts were exposed to 4 following circadian phases: first 3 days were 24h, next 4 days 26h (8h advance shift in total), next 4 days 22h (8h delay shift in total), and finally 3 days 24h before end of the mission. Jet lag effects were analyzed including levels of stress, water consumption, urine production and motivation. 12 analog astronauts and 13 control group (without time shifts) were exposed to time illusions through three different tools used by mission control center: specially adjusted scheduling with only two reference time points for briefings and debriefings, running the whole schedule on the lunar or martian clocks and light control in the habitat. After two days of the mission, astronauts completely lost perception of time. Jet lag was detected by analog astronauts at phase III. Astronauts stress and motivation levels were decreased at the Phase III and slightly recovered at Phase IV. Interestingly, water consumption and urination was changed with changing circadian phases. The second parameter analyzed during analog simulations was subjective time perception in astronauts and control groups. Data were collected using STPA software (www.astrotech.io/subjectivetimeperception). Subjects were performing the test twice a day just after waking up and just before going to sleep. During the mission subjects were able to see their results and based on them improve their performance. Effect of training was observed in both analog astronauts groups as well as in controls.

F5.2-0011-18 CHANGE OF AEROBIC CAPACITY AFTER LONG DURATION SPACE FLIGHT

Nataliya Lysova, cehbr@list.ru

State Scientific Center of the Russian Federation Institute of Biomedical Problems of RAS, Moscow, Russia

Elena Fomina, fomin-fomin@yandex.ru

State Scientific Center of the Russian Federation Institute of Biomedical Problems of RAS, Moscow, Russia

Swetlana Rezvanova, swetlanka-29@yandex.ru

State Scientific Center of the Russian Federation Institute of Biomedical Problems of RAS, Moscow, Russia

Change of aerobic capacity after long duration space flight The research of the mechanisms of physiological adaptation of a human to weightlessness and readaptation to the gravity is one of the problems of gravitational physiology that requires extending the knowledge when it comes to preparation for interplanetary missions. At the moment it is known that the maximum oxygen uptake decreases in comparison with the pre-flight level during exercise in microgravity; but the structural changes in the cardiovascular and respiratory systems that occurs during prolonged stay in weightlessness is only fragmentary studied. All the studies described in the literature were performed when testing metabolic change during the exercise with a cycle test. However, locomotions on the treadmill require maintaining the pose and incorporating more muscle mass into the work. Knowledge of metabolic changes in the performance of a locomotor test with a stepwise increasing load can expand the views of gravitational physiology about the change in the cardiovascular and respiratory systems after long-duration space flight (SF). Abovementioned was the purpose of our investigation. The study of post-flight changes in the cardiovascular and respiratory systems was carried out on the basis of ergospirometry data and heart rate from the locomotor test with stepwise increasing load. Three cosmonauts took part in the study (age 46 ± 1 years, weight 89.6 ± 3 kg, duration of the SF 162 ± 17 days). The gas exchange parameters were recorded when performing a test on a treadmill BD-2 with stepwise increasing load (from 3 to 15 km/h with a step 1 km/h every 30 s). The test was carried out before and on the 8th day after the SF. Due to the individual characteristics only one cosmonaut reached the maximum speed running - 15 km / h, the other two cosmonauts had a maximum running speed of 13 km/h and 12 km/h. On the day 8 after the SF a maximum running speeds were 12 km/h, 12 km/h and 10 km/h respectively. The stage of running at a speed of 10 km/h, performed by all cosmonauts before and after the SF, was chosen by us as a standard load for assessing the physiological cost of this work. It was shown that after the SF on the speed 10 km/h oxygen uptake increased on average by 15.7% (85.8 ml/min), carbon dioxide production - by 6.1% (292 ml/min), ventilation - by 18.4% (10.5 l/min). The cardiovascular response, calculated at the heart rate, increased by an average of 5.9% (bpm). The research showed that the long stay in the SF conditions leads to the changes in cardiovascular and respiratory systems, as evidenced by the dynamic of the changes in the oxygen uptake carbon dioxide production, ventilation and heart rate. The results evidence that the physiological cost of the load increases in microgravity and after landing. This work was supported by Russian Foundation for Basic Research grant № 17-04-01826.

F5.2-0012-18 HUMAN PHYSIOLOGY EXPERIMENTS IN AEROBATIC AIRCRAFT PARABOLIC FLIGHTS. EDUCATIONAL AND RESEARCH ACTIVITIES.

Antoni Perez-Poch, antoni.perez-poch@upc.edu Universitat Politecnica de Catalunya, Barcelona, Spain

We report on a variety of research and educational human physiology activities related to parabolic flights conducted in Barcelona (Spain), since 2008 (1). We use a single-engine aerobatic aircraft flying out of Sabadell Airport and operating in visual flight conditions providing up to 8 seconds of hypogravity for each parabola. Aside from biomedical experiments being conducted, different student teams have flown in parabolic flight under the international contest 'Barcelona Zero-G Challenge' framework, having published their results in relevant symposiums and scientific journals.

A large aircraft provides researchers with a microgravity environment during a short period of time of about 20 seconds. Specific training of skilled licensed aerobatic pilots from BarcelonaSabadell Aeroclub led to a new opportunity for students and researchers to conduct hands-on microgravity experiments with a different gravity profile than that achieved by larger aircraft. These small aerobatic aircraft are capable of providing short periods of hypogravity of up to 8 seconds, preceded and followed by a peak of hypergravity up to 3.2g's between 3 and 5 seconds. Residual acceleration levels in the hypogravity phase are typically in the order of 0.05 to 0.1g in the Z-axis (aircraft floor to ceiling direction), while accelerations along the aircraft X-axis (aft to front) and transversal Y-axis (right to left) are typically between 0.005g and 0.05g.

These parabolic flights are an excellent opportunity for university students to conduct real hands-on experiments on space science. Examples under the 'Barcelona Zero-G Challenge' framework, are given such as Reversible Images, studying the otholit impairement, which has also flown in the ISS; a study on the influence of mental calculus on the cardiovascular system, and a distance perception estimation experiment on board. Other parabolic flight research studies include validation of NELME, a numerical electrical-like model about the effects of microgravity exposure in cardiovascular deconditioning; and an analysis of brain biosignals under altered gravity loads. In conclusion, the platform can certainly be a good testbed for a proof-of-concept before accessing other microgravity platforms, and has proved to be excellent for motivational student campaigns.

CAS Institute of Mechanics, Beijing, China

Reorientation of liquid/gas free surface takes place when a partly filled storage tank experiences the step reduction of the gravity from the normal gravity. The reorientation behavior, such as the free surface shape, the moving of the apparent contact line, the frequency and damping of the oscillations of the free surface center point was investigated through the experiments in the Drop Tower facility at the National Microgravity Laboratory in Beijing, and corresponding numerical simulations were provided. The dependence of the reorientation behavior on the storage tank size and liquid fill ratio was discussed. This work is supported by the special project of The Chinese Academy of Sciences Strategic Guide TechnologyXDA15012700

G0.1-0002-18 EXPERIMENTAL RESEARCH ON THERMOCAPILLARY MIGRATION OF DROPS BY DIGITAL HOLOGRAPHIC INTERFEROMETRY

The investigation of thermocapillary flow is important for basic research, as well as for material sciences, chemical engineering, and space manufacturing. When the gravity effect is greatly reduced, the interfacial phenomenon becomes important. The motion of drops driven by temperature gradients is related to the thermocapillary Marangoni convection. The Marangoni effects are caused by interface tension changes, typically interface tension becoming decreased with increasing temperatures. Under different conditions, The Marangoni effects can cause a drop to move in the opposite direction. The thermocapillary migration of drops in a temperature gradient was studied in the present experiment by utilizing digital holographic interferometry. The temperature distribution around a drop, as well as on the interface of a drop, during migration in a vertical temperature gradient were visualized and provided quantitatively for the first time. The perturbed temperature distribution and the actual temperature distribution around the drop during the thermocapillary migration were obtained, and were discussed in detail in this study. The drop was colder than the continuous phase liquid, and a thermal wake existed behind the drop. The dimensionless interface temperature difference was a monotonically decreasing function of the Marangoni number for the three different temperature gradients. When the Marangoni number was increased, the dimensionless interface temperature difference was found to decrease, which was caused by the decrease of the enhanced convective transport results in the drop's thermocapillary migration velocity. With the increasing Marangoni numbers, the length of the thermal wake region increased, and the thermal wake region was extended.

G0.1-0003-18 DYNAMIC FREE SURFACE DEFORMATION OF HIGH-PRANDTL-NUMBER LIQUID BRIDGES WITH MARANGONI CONVECTION IN MICROGRAVITY

Temperature gradient-driven Marangoni convection is often appeared in the crystal growth process involving a liquid-gas interface (e.g., floating-zone method), and the physical understanding of this convection may lead to an improvement in crystal quality. The objective of the present study is the Marangoni convection in the liquid bridges of high-Prandtl-number (Pr) fluids. The silicone-oil liquid bridge of Pr = 67 or 112 is formed in the gap between two co-axial disks with different temperatures, and the temperature gradient along the liquid-gas interface generates the Marangoni convection because the surface tension of silicone oils depends negatively on the temperature. The convection exhibits an axisymmetric steady motion for small temperature difference between the disks, but the constancy of the flow and temperature fields are broken at the instability threshold. The characteristics of Marangoni convection depend on various factors, and the present study pays attention to the behaviors of the liquid bridge free surface. A series of microgravity experiments called "Dynamic Surf" have been carried out on the International Space Station (ISS) in order to elucidate the effects of the dynamic free surface deformation (DSD, hereafter) on the Marangoni convection. The microgravity environment on the ISS is superior in the following respects: (1) the pure Marangoni convection without buoyancy can be realized, and (2) the large-scale liquid bridges can be formed. The dynamic motions of the free surface are measured by an optical imaging technique for various experimental conditions. It is found that there are internal and external causes of the DSD in the present microgravity experiments: the former is the time-dependent flow structure inside the liquid bridge due to the Marangoni instability, and the latter is the residual acceleration of gravity called g-jitter on the ISS. The relations between the DSD and the instability of Marangoni convection as well as the resonance behavior of the liquid bridge will be discussed.

G0.1-0004-18 HEAT TRANSFER OF NUCLEATE POOL BOILING WITH LOW HEAT FLUX IN MICROGRAVITY

Ke Wu, wuke@imech.ac.cn China

Kai Li, likai@imech.ac.cn

Chinese Academy of Sciences, Beijing, China Peng Liu, liupeng173@mails.ucas.ac.cn China

Shu-Wen Yue, yueshuwen17@mails.ucas.ac.cn China

A series of space flight experiments on pool boiling heat transfer in microgravity have been performed aboard the Chinese recoverable satellite SJ-10. Heat transfer performance of nucleate pool boiling with low heat flux are analyzed and compared with those obtained in normal gravity, as well as those both in normal and microgravity reported in the literature. It is observed that the boiling curves in microgravity are approximately located in the lower extensions of those at the corresponding subcooling in normal gravity. A much lower critical heat flux (CHF), however, is observed in the present study, comparing with those in the literature. Influences of other factors are also discussed. This work is supported by the CAS-NSFC joint fund under the grant U1738105.

G0.1-0005-18 STABILITY AND CONTROL OF FLUIDS IN MICROGRAVITY WITH VIBRATIONS

Jeff Porter, jeff.porter@upm.es

Universidad Politécnica de Madrid, Madrid, Spain Ignacio Tinao Perez-Miravete, itinao@eusoc.upm.es Universidad Politécnica de Madrid, Madrid, Spain Jose Javier Fernandez Fraile, jfernandez@eusoc.upm.es Universidad Politécnica de Madrid, Madrid, Spain Pablo Salgado Sánchez, psalgado@eusoc.upm.es Universidad Politécnica de Madrid, Madrid, Spain Ana Laverón-Simavilla, ana.laveron@upm.es Universidad Politécnica de Madrid, Madrid, Spain

Vibrations can induce a range of different interfacial phenomena in fluid systems depending on the frequency and orientation of the forcing. With gravity, (large) interfaces are approximately flat and there is a qualitative difference between vertical and horizontal forcing. Sufficient vertical forcing produces subharmonic standing (Faraday) waves that extend over the entire interface. Horizontal forcing can excite both localized and extended interfacial phenomena. In the case where the interface separates two fluids of different density in, for example, a rectangular container, the mass transfer due to vertical motion near the endwalls requires a counterflow in the interior region that can cause a Kelvin-Helmholtz type instability and a "frozen wave" pattern. In microgravity, the dominance of surface forces favors non-flat equilibrium configurations and the distinction between vertical and horizontal applied forcing can be lost. Furthermore, the vibrational field contributes a dynamic pressure term that competes with surface tension to select the (time-averaged) shape of the surface. These modified (quasi-static) surface configurations, known as vibroequilibria, can differ substantially from the hydrostatic state. In fact, there is a tendency for the interface to orient perpendicular to the main vibrational axis, which can be considered as a type of artificial gravity. In some cases, a bulge or cavity is induced that leads to splitting (fluid separation). We investigate the interaction of these prominent interfacial instabilities in the absence of gravity, concentrating on harmonically vibrated rectangular containers of fluid. We compare vibroequilibria theory with direct numerical simulations and consider the effect of surfaces waves, which can excite sloshing motion of the vibroequilibria. A saddle-node bifurcation occurs with increasing forcing on the branch of symmetric singly-connected vibroequilibria solutions for sufficiently deep containers. The interaction of vibroequilibria and frozen waves is considered. Microgravity experimental results from the "Control of Fluids in Microgravity with Vibrations" (CFVib) experiment, which flew on the 65th ESA Parabolic Flight Campaign as part of the 2016 Fly Your Thesis! programme, are described as well. This experiment had cuboidal and cylindrical containers containing water/air, silicone oil/air or silicone oil/vacuum oil mixtures. Half of the containers were subjected to vibrations using a piezoelectric bender beam assembly that generated high-frequency vibrations from 50 Hz to 12 kHz. The primary objective was to observe the behaviour of vibrated liquids in a weightless environment and to investigate the extent to which vibrations could be used to influence and control this behaviour. Surface waves and large-

scale reorientation of the interface were observed, depending on the frequency. For cuboidal containers with water, particularly good agreement was found between the experimental data and the predictions of vibroequilibria simulations.

G0.1-0006-18 THE ROLE OF FLUID DYNAMICS IN SURFACTANT MONOLAYER EXPERIMENTS

María Higuera, maria.higuera@upm.es Technical University Madrid, Madrid, Spain Jose M. Perales, jose.m.perales@upm.es

Universidad Politécnica de Madrid, Madrid, Spain Jose Vega, josemanuel.vega@upm.es

Universidad Politécnica de Madrid, Madrid, Spain

Interfacial rheology has technological applications in the mechanical, chemical, and medical industries and is relevant in a variety of fields, such as colloid and interface science, biology, biochemistry, and biophysics. In particular, the interfacial dynamics are an important factor in understanding a variety of physical phenomena, including microfluidics, coating and drying processes, and the formation and dynamics of foams.

Interfacial rheological properties can be measured by directly changing the surfactant concentrations or by varying the interfacial area. On ground, this can be done, for example, by periodically modulating the surfactant concentration using two slightly immersed solid barriers that control the free surface area of a shallow liquid layer. Because such modulation is slow, most theoretical studies ignore fluid dynamics in the bulk. We present a long wave theory that also takes fluid dynamics coupled to the free surface. In particular we include two purely hydrodynamic effects that have been ignored and are related to each other.

The unsteady free surface deformation, whose analysis requires to also consider the fluid dynamics in the outer regions, outside the barriers. Let us anticipate that the surfactant concentration and free surface elevation at the center of the trough are in counterphase and thus reinforce each other in connection with the next item.

The dynamics of the menisci at Wilhelmy plate, which may promote several irreversible effects (including contact angle variations and contact line motion) that, in turn, could affect the surface tension measurements.

Results from this theory are discussed for various values of the parameters, which include both gravity and microgravity conditions. Specific predictions can be made for experiments, with the general conclusion that the fluid dynamics should not be ignored in the analysis of these devices.

G0.1-0007-18 SEPARATION OF WEAK MAGNETIC PARTICLES IN GENERAL THAT PROCEED BY A FIELD GRADIENT OF A PERMANENT MAGNET

Chiaki Uyeda, uyeda@ess.sci.osaka-u.ac.jp Osaka University, Osaka, Japan

Most solid particles, categorized as diamagnetic or weak paramagnetic (i.e. weak magnetic) materials, cannot attain strong magnetization; they are commonly believed to be magnetically inert. Strong magnetic field above the level of several Tesla were applied in the past to realize significant magnetic effects in these materials. A new principle to separate ensemble of heterogeneous particles was proposed by releasing them in an area of monotonically decreasing field under microgravity condition [1]. Furthermore, it was also expected that material of an unidentified particle could be determined from susceptibility obtained from the motion of particle. The practicability of the above two functions were experimentally confirmed within a short duration below 0.2 s; here the field distribution was supplied by a pair of small NdFeB plate [2]. The principle of separation was deduced as follows. A small magnetization is generally induced in a diamagnetic particle when it is placed in an area of external field B. The magnetization is proportional to three parameters; namely B, mass of particle m and intrinsic susceptibility assigned to material. The particle translates in the direction of monotonically decreasing field by a field gradient force, because direction of the magnetization is opposite to B. Considering an energy conservation rule, variance of terminal velocity of the particle at B = 0 area is uniquely determined by intrinsic of material [2], assuming that initial particle positions are identical. Accordingly, the particle ensemble released at a single position is separated into different groups of materials as the translation proceeds[1]. Using the above method, material abundance of a heterogeneous particle ensemble is determined in a simple manner without consuming sample. Such a pre-treatment is important in efficiently performing refined analysis on solid mixtures. In this sense, the significance of the proposed method may be comparable to the "chromatography" technique, which is a conventional method in separating and identifying mixture of organic molecules. Resource exploration of rare materials will become possible using the simple circuit from both natural and urban resources. That is, the explored particle can be simply collected by the apparatus after a "physical" crashing without any chemical treatment that may cause various hazard problems. In the present report, the validity of the proposed principle of separation is examined based on the numerical data obtained in the extending experiments, where the field gradient is considerably enhanced. In order to put the system to a practical use, the separation should be realized in two different materials that have small variance of values. [1] Hisayoshi, Uyeda Terada (2016) Sci Reps, 6, 38431. G0.1-0008-18 THE EXPERIMENTAL FURNACE FOR MATERIAL PROCESSING IN CHINESE SJ-10 RECOVERABLE SATELLITE

Haiqin Wen, hqwen@mail.sic.ac.cn

Shanghai Institute of Ceramics, CAS, Shanghai, China Xiuhong Pan, xhpan@mail.sic.ac.cn

Shanghai Institute of Ceramics, CAS, Shanghai, China Fei Ai, aifei@mail.sic.ac.cn

Shanghai Institute of Ceramics, CAS, Shanghai, China

The experimental facility named "multifunctional materials processing furnace" has been developed for material experiments in space microgravity. It was designed for materials processing by Bridgman method. It's made up of four units: vacuum chamber unit, heating furnace unit, sample management unit, and drive control unit. The total weight of the facility is less than 19kg and the maximum power input is less than 140W. The double-zone heating structure is one of its main features. Based on this feature, the temperature field distribution can be adjusted to adapt the materials processing demands. This facility can be heated to 950C under vacuum level of less than 1×10-1Pa. The maximum axial temperature gradient is 75C/cm. There are 6 sample cartridges of 16mm×231mm in this furnace, and they can be exchanged automatically and accurately by the sample management mechanism. The maximum sample processing length is 80mm, and the moving speed range is from 0.5 to 120mm/hr. This facility served successfully in Chinese SJ-10 recoverable satellite in April 2016.

G0.1-0009-18 THERMOPHYSICAL PROPERTY MEASUREMENTS OF MOLTEN OXIDES BY THE ELECTROSTATIC LEVITATION FURNACE ONBOARD THE INTERNATIONAL SPACE STATION

Chihiro Koyama, koyama.chihiro@jaxa.jp JAXA, Tsukuba, Japan

Haruka Tamaru, tamaru.haruka@jaxa.jp JAXA, Tsukuba, Japan

Takehiko Ishikawa, ishikawa.takehiko@jaxa.jp

Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, Tsukuba, Japan

The electrostatic levitation method is a containerless technique that levitates a charged sample by Coulomb force between the sample and the surrounding electrodes. Since the technique doesn't utilize container, high temperature liquids can be handled without contamination under wide temperature range including undercooling range. Therefore, the technique has been utilized for precise measurements of thermophysical properties as a function of temperature, which are necessary for improvement of materials processing and investigation of liquid structure. Originally the technique was developed by Rhim et al. 1 at the Jet Propulsion Laboratory (JPL). On the basis of their knowledge, the Japan Aerospace Exploration Agency (JAXA) has been developing the technique for more than 20 years2. As a result, JAXA succeeded in measuring thermophysical properties of molten metals with high melting temperature such as W, Re and Ta on the ground. However, the measurements of molten oxides were scarcely performed on the ground, because oxides are difficult to charge and then do not levitate. In order to resolve this problem and measure physical properties of oxides, JAXA designed and fabricated the Electrostatic Levitation Furnace onboard the International Space Station (ISS-ELF) 3which enables to levitate oxides with small charge due to an effect of microgravity. First, to measure molten density, one of the fundamental thermophysical properties, the capabilities of levitation and heating were checked by using alumina (Al_2O_3). As a result, each sample was succeeded in levitating and melting fully in dry air by four semiconductor lasers. When the sample was fully molten, all lasers were powered off to cool it. During cooling, the temperature was measured by a pyrometer. The sample images were recorded by using CCD camera and UV-light. From the image and weight after the measurement, the density was calculated. The density as a function of temperature shows good agreement with that obtained by Langstaff et al. (2013)4 using aerodynamic levitator. It also shows about 2 % lower than our earlier results obtained by using electrostatic levitator on the ground in high vacuum condition (Paradis et al. 2004)5. This result proves the validity of the density measurement with the ISS-ELF. The functional check for the surface tension and viscosity measurement is being currently conducted, and detailed results will be reported later.

G0.1-0010-18 A TWO-ZONE HEATER FOR MATERIAL EXPERIMENTS IN MICROGRAVITY

Xiuhong Pan, xhpan@mail.sic.ac.cn

Shanghai Institute of Ceramics, CAS, Shanghai, China Fei Ai, aifei@mail.sic.ac.cn

Shanghai Institute of Ceramics, CAS, Shanghai, China Haiqin Wen, hqwen@mail.sic.ac.cn

Shanghai Institute of Ceramics, CAS, Shanghai, China

Heating furnace is one important material processing facility in microgravity, since most kinds of materials, such metal alloys, semiconductors, oxide crystals, ceramics, are fabricated generally under high temperature. Here we introduce one kind of two-zone heater for materials experiments in microgravity. The core of this heater is two individual resistance coils which are enwound spirally into one tube. This tube is composed by several circular alumina pans whose symmetrical axis are in the same line. The inner diameter of the tube is 18mm and its length is 82mm. Two S-type of thermocouples are designed for temperature control. The electrical current of the two resistance coils can be controlled separately to achieve various temperature profiles along the axes in accordance with each special experimental requirement. The resistance coils as well as the tube are enclosed by some ceramic felt and five columnar radiation shields, which have the ability to severely decrease the heat transfer. The maximum of the axial temperature can get up to 950 centigrade. This kind of heaters were used to perform high temperature material experiments in Chinese Tiangong 2 space laboratory and Chinese SJ-10 recoverable satellite in 2016. Up to now, totally more than 20 experiments have been carried out in microgravity in such heaters.

G0.1-0011-18 PHOTOELECTROCATALYSIS: SOLAR-ASSISTED HYDROGEN PRODUCTION IN MICROGRAVITY ENVIRONMENTS

Katharina Brinkert, brinkert@caltech.edu

California Institute of Technology, Pasadena, California, United States Photoelectrocatalysis

Katharina Brinkert, Matthias Richter, Slobodan Mitrovic, Hisayoshi Matsushima, Yasuhiro Fukunaka, Hans Joachim Lewerenz

Artificial photosynthesis systems, which follow the concept of the Z-scheme of natural photosynthesis, are presently being realized as catalyst-functionalized photovoltaic tandem devices for the photoelectrochemical oxidation of water and the simultaneous generation of hydrogen as a so-called “solar fuel”. The successful implementation of an efficient photoelectrochemical (PEC) water splitting cell is not only a highly desirable approach to solving the energy challenge on earth: an effective air revitalization system generating a constant flux of O2 while simultaneously recycling CO2 and providing a sustainable fuel supply is also essential for the International Space Station and long-term space missions, where a regular resupply from earth is not possible. Here, we present the photoelectrochemical production of hydrogen in microgravity environments on p-type indium phosphide electrodes with deposited rhodium electrocatalysts. Our findings indicate that microgravity has a significant impact on the gas bubble evolution behaviour and the mass transfer rate of the evolved hydrogen gas on the electrode surface. Furthermore, microgravity influences the current-voltage characteristics and the overall solar-to-hydrogen efficiency of the catalyst functionalized semiconductor-based half-cell. Further experiments with nanostructured rhodium catalysts fabricated by shadow nanosphere lithography on the InP surface suggest that the structure of the electrode surface plays a significant role for the gas bubble evolution behaviour and for the further the development of efficient prototypes for solar-assisted water splitting and hydrogen production that operate in microand hypergravity environments.

G0.1-0012-18 STUDY OF ELECTROSTATIC LEVITATION FURNACE BASED ON DUAL HIGH SPEED CAMERA DETECTORS

Qingyuan Guo, guoqingyuan@csu.ac.cn

Chinese Academy of Sciences, CSU, Beijing, China Wenbo Dong, wbdong@csu.ac.cn

Chinese Academy of Sciences, CSU, Beijing, China Jianding Yu, yujianding@mail.sic.ac.cn

Shanghai Institute of Ceramics, CAS, Shanghai, China Chaoyue Wang, cywang@mail.sic.ac.cn

Shanghai Institute of Ceramics, CAS, Shanghai, China

The containerless electrostatic levitation technology is an important research direction in the development of space materials science. The materials can obtain a large degree of supercooling, thus forming new materials or research on solidification. Electrostatic levitation technology does not generate additional interference factors in the process of material solidification. And it is easy to combine with other non-contact measuring equipment to realize the thermal measurement of materials, which is more suitable for the scientific experiment of space materials. The optical path and other factors in the electrostatic levitation furnace, cause unpredicted error interference for the position detection of Position Sensitive detector. At the same time, during the processing of the material, the high temperature and brightness of the laser heating samples have a great influence on the Position Sensitive detector. Therefore, two high-speed cameras are used to detect the three-dimensional position of the sample. The electric field analysis of high voltage electrode in electrostatic levitation position control system is carried out. And the model of the control system is theorized. The position information of the sample is obtained by the image and optical acquisition system, which helps to control the potential of the high voltage electrode. By adjusting the position of the sample using the closed-loop feedback algorithm, the stable suspension of the charged samples is realized, which lays a foundation for further space free processing experiments in the future.

G0.1-0013-18 BASIC FLOWS AND HYDROTHERMAL WAVE INSTABILITY IN THERMOCAPILLARY DRIVEN FLOW IN A THIN LIQUID FILM WITH LONG SPANWISE LENGTH

Ryohei Wada, 7514143@ed.tus.ac.jp Tokyo University of Science, Chiba, Japan Yosuke Kowata, 7512048@alumni.tus.ac.jp Tokyo University of Science, Chiba, Japan

Toshiki Watanabe, cattleya1232000@gmail.com Tokyo University of Science, Chiba, Japan Toshihiro Kaneko, tkaneko@rs.tus.ac.jp

Tokyo University of Science, Chiba, Japan Ichiro Ueno, ich@rs.tus.ac.jp

Tokyo University of Science, Noda, Chiba, Japan

We target the thermocapillary-driven flow in a free liquid film which has two gas-liquid interfaces. We performed a series of experiments employing silicone oil of 6 cSt (Pr = 83.5) as the test fluid in rectangular geometry. We also use gold-coated acrylic particles of 15 µm in diameter as the tracers of flow in the film. By exposing the film to designated temperature difference between the end walls, two types of basic flows occur in the film; 'single-layered flow' and 'double-layered flow.' In the 'single-layered flow,' the cellular flow is realized over free surfaces. Increasing the span-wise length of the film, the number of the cells increases. We evaluate the cell number against the horizontal aspect ratio; the horizontal aspect ratio is defined as the ratio of the span-wise length per the length in the temperature gradient direction. In the 'double-layered flow,' one-directional flow emerges over the free surface, and then return in the inner region of the film toward the hot-end wall. Increasing the temperature difference, the two-dimensional basic flow exhibits the transition to the three-dimensional oscillatory flow. Increasing the temperature difference, thermal waves over free surfaces induced by hydrothermal wave (HTW) instability are observed by the infrared (IR) camera, and those waves steadily propagate from the cold-end wall to the hot-end wall. It is indicated that there are two types of propagation forms of thermal waves induced by HTW instability in the free liquid film; 'planar waves' and 'radial waves,' as indicated in the case of the liquid layer with a single free surface. Especially, in the film with long span-wise length, thermal waves change their propagation form near the side walls. Moreover, increasing the temperature difference, uneven distribution of tracer particles is exhibited in the film. We investigate the correlation between the surface temperature variation and the flow field observed in the top and cross-sectional views of the film with long span-wise length.

G0.1-0014-18 EFFECT OF AMBIENT-GAS FORCED FLOW ON OSCILLATORY THERMOCAPILLARY CONVECTIONS IN A HALF-ZONE LIQUID BRIDGE OF HIGH ASPECT RATIO

Yuya Fukuda, 7514107@ed.tus.ac.jp Tokyo University of Science, Noda, Japan

Toru Ogasawara, 7513018@alumni.tus.ac.jp Tokyo University of Science, Chiba, Japan Toshihiro Kaneko, tkaneko@rs.tus.ac.jp Tokyo University of Science, Chiba, Japan Ichiro Ueno, ich@rs.tus.ac.jp

Tokyo University of Science, Noda, Chiba, Japan

A series of fluid physics microgravity experiments were performed in the Japanese Experiment Module, "KIBO." aboard the International Space Station. Among the experiments, it was examined that the transition to chaos of the thermocapillary convection in a half-zone liquid bridge of silicone oil with a Prandtl number of 112. It was detected by the infrared (IR) camera that 'X' shaped cold temperature regions composed with a pair of thin cold temperature 'band'- like structure emerged over the free surface of the liquid bridge. In other words, a pair of cold lines propagated in the opposite direction with the same velocity over the free surface. This flow was realized in pulsating-wave oscillation. From numerical analysis, the effect of heat transfer between the ambient gas and the liquid bridge on realizing such flows was indicated as one of causes. We focus on such effect in the terrestrial experiment on the thermocapillary convection in the half-zone liquid bridge of high Prandtl number fluid and high aspect ratio ($\Gamma = 2.0$, where Γ is defined as the ratio of the height to the radius of the bridge). The working fluid is 2-cSt ($Pr = 28$) silicone oil for the liquid bridge, and the air for the ambient gas. The liquid bridge is suspended in a gap between the upper heating rod and the lower cooling rod. Whole of the liquid bridge is settled in a coaxial cylindrical external shield in which upward forced flow of the ambient gas is added. Heat transfer between the liquid bridge and the ambient gas through the free surface is evaluated using the Biot number by measuring the temperature distribution in the ambient region. Reynolds number of forced flow is defined as Reamb. We investigate the thermal-convection field as functions of the Marangoni number (Ma) and Reamb as the parameters. We visualize the flow field by suspending tiny particles as the tracers. We indicate the surface-temperature variations over the free surface and their Fourier spectrum to make comparisons with the results of the space experiments.

G0.1-0015-18 THE FUNDAMENTAL CALCULUS AND TEMPERATURE DRIFT PROBLEM OF THE ELECTROMAGNETIC INDUCTIVE PRESSURE SENSOR

China Academy of Launch Vehicle Technology, Beijing, China

The pressure sensor is an object that transfers the pressure signals to electrical information, and it is widely used in the industry and national defense area. Especially, the electromagnetic inductive pressure sensor, which shows high reliability and high environmental adaptability, is employed in the aircraft and aerospace area. This paper describes the mechanical principle and circuit principle of the inductive pressure sensor, and provides the mathematical model with the main influence parameters. Similarly, the signal of pressure sensor in the zero state is calculated, and the precautions of the designing are provided. Meanwhile, the temperature drifts performance and failure modes of the pressure sensors are discussed and analyzed, the structural asymmetry or magnetic materials defects can both lead to the failure, thus the improving methods for solving the temperature drift problem are also proposed. Besides, the electromagnetic inductive pressure sensor samples are designed and fabricated, the performance of the products have been verified by the tests, the results of which are close to the expectations. This research offers guidance and reference for electromagnetic inductive pressure sensors designing and manufacturing in future.

G0.2-0001-18 DESIGN AND EVALUATION OF AN AIRBAG DECELERATION SYSTEM FOR A DROP TOWER FACILITY

Nikhil Vijayakumar Valsalakumari, nikhilzerog@gmail.com IIT Madras, Chennai, India

Presenting author: Abhilash Nair, abhilash.nair295@gmail.com IIT Madras, Chennai, India

The design of a proper deceleration system is one of the major challenges in the development of a drop tower facility. One of the major systems that are used for decelerating drop capsules is the airbag. An airbag offers a controlled deceleration for a wide range of masses impacting at different velocities by having a controlled air venting arrangement. In the drop tower facility at Indian Institute of Technology Madras, a deflatable airbag system is used as the deceleration mechanism. The paper here describes the design of the airbag system and the method to predict the systemic variations of the airbag and the outlet control valves using the equations that govern their motion. The different control parameters viz. inflation pressure, the initial opening area and the delay time for valve closing for the airbag system are varied to obtain the desired deceleration levels. The required variation of the vent area during the deceleration process is achieved using a combination of spring valves, gate valves and electromagnet controlled openings.

G0.2-0002-18 THE GRAVITOWER BREMEN - PROTOTYPE: A NOVEL ACTIVELY DRIVEN DROP TOWER SYSTEM

Thorben Könemann, thorben.koenemann@zarm.uni-bremen.de ZARM Fab mbH, Bremen, Germany

Andreas Gierse, andreas.gierse@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany

Ulrich Kaczmarczik, ulrich.kaczmarczik@zarm.uni-bremen.de ZARM Fab mbH, Bremen, Germany

Christian Eigenbrod, christian.eigenbrod@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany

Peter Von Kampen, peter.vonkampen@zarm.uni-bremen.de ZARM Fab mbH, Bremen, Germany

Claus Laemmerzahl, claus.laemmerzahl@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany

Marc Avila, directorate@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany

The Center of Applied Space Technology and Microgravity (ZARM) founded in 1985 is part of the Department of Production Engineering at the University of Bremen, Germany. ZARM is mainly concentrated on fundamental investigations of gravitational and space-related phenomena under conditions of weightlessness as well as questions and developments related to technologies for space and their applications on Earth. At ZARM about 100 scientists, engineers, and administrative staff as well as many students from different disciplines are employed. Today, ZARM is one of the largest and most important research center for space sciences and technologies in Europe.

With a height of 146 m the Bremen Drop Tower is the predominant facility of ZARM and also the only drop tower of its kind in Europe. ZARM's ground-based laboratory offers the opportunity for daily short-term experiments under conditions of high-quality weightlessness at a level of 10(-6) g - microgravity. Scientists may choose up to three times a day between a drop experiment with 4.74 s or an experiment in ZARM's worldwide unique catapult system with 9.3 s in free fall. Since the start of operation of the drop tower facility in 1990, over 8000 drops or catapult launches of more than 200 different experiment types from various scientific fields like fundamental physics, combustion, fluid dynamics, planetary formation / astrophysics, biology and material sciences have been accomplished so far. In addition, more and more technology tests have been conducted under microgravity conditions at the Bremen Drop Tower in order to prepare appropriate space missions in advance.

Beside an introduction about ZARM and its various activities like ZARM's contributions to interesting programs/opportunities for Bachelor, Master and/or PhD students - (i) Drop Your Thesis!" by the European Space Agency (ESA), (ii) DropTES" (Drop Tower Experiment Series) by the United Nations Office for Outer Space Affairs (UNOOSA) and the German Aerospace Center (DLR), and (iii) the GermanSwedish Student Program REXUS / BEXUS" (Rocket / Balloon Experiments for University Students) by DLR and the Swedish National Space Board (SNSB) - a comprehensive insight into the technology and the development of the GraviTower Bremen - Prototype (GTB-Pro) will be presented. The GTB-Pro represents a novel class of drop tower system, which is actively driven being capable to perform over 100 microgravity experiments per day.

G0.2-0003-18 ALONG THE G-CONTINUUM: SUBORBITAL FLIGHTS ON BLUE ORIGIN'S NEW SHEPARD VEHICLE

Erika Wagner, ewagner@blueorigin.com

Blue Origin, KENT, Washington, United States

With the emergence of a vibrant commercial space industry, researchers now have more options than ever for conducting research along the continuum of microgravity exposure. Blue Origin's New Shepard reusable spacecraft offers a large-format crew capsule, capable of carrying a wide range of payloads above the Karman Line (100 km), where they can experience approximately three minutes in a high-quality microgravity environment before returning for a soft landing. In collaboration with drop tower facilities worldwide, investigators can advance their science, technology, and education payloads stepwise towards longer exposure times and higher Technology Readiness Levels. This talk will introduce the standard interfaces, environments, and operations for payloads within the New Shepard capsule, which began payload flights in 2016. We will discuss specific microgravity use cases already being demonstrated on the platform, including fluid physics, particle interactions, materials science, acute biological responses, and technology demonstrations. And we will highlight collaborations with the ZARM Drop Tower in advancing such payloads from concept to flight.

G0.2-0004-18 STUDY ON FLUID TRANSPORTATION AND INTERFACE BEHAVIOR IN PLATE SURFACE TENSION TANK

Qi Kang, kq@imech.ac.cn

Institute of Mechanics, Chinese Academy of Sciences, Beijing, China

Surface tension tank which is applied on fluid transportation and gas-liquid separation by surface tension and provides the engine or propeller with non-gas pure propellant is the most widely used satellite propellant tank in the world. The plate surface tension tank has the advantages of simple structure, easy processing and high reliability. In this paper, experiment and numerical calculation for fluid transportation and interface behavior of plate tank are conducted. Based on the national microgravity drop tower, the experiments of a plate low temperature tank with different acceleration vector and different liquid filling are conducted independently. In all cases, except for 5% and 20% filling in reverse acceleration, the fluid outlet of tank can be covered by liquid. And the suggestion that baffles must be installed in inner ring is put forward to meet the satisfaction. The capillary climbcaused by the surface tension generated by the eccentric of inner ring is greater than that caused by inertia force in the internal sphere. And the velocity of the climb increases as the gap of inner ring reduces. In the same acceleration vector, the relocation time of tank will decrease along with the decrease of liquid filling. The VOF method and the global hexahedral structured grid are used to simulate the static balance of the 20L-plate tank. The surface tension of the 20L tank is larger in the corner formed by baffle and the wall and the velocity of the liquid climbing is faster along the baffle, which proves that the baffle has good transportation. The liquid sloshing amplitude of liquid, the impact force and impact torque loading on the tank drop significantly with the application of anti-sloshing vane under harmonic excitation. During acceleration period, PMD can effectively reduce the shaking effect. After acceleration, PMD can succeedin collecting the liquid covering the fluid outlet in the tankto ensure the next supplement.

KEY WORDS: plate surface tension tank, microgravity drop tower, VOF, interface behavior, fluid transportation

G0.2-0005-18 CAPILLARY FLUIDICS: DISCOVERY VIA DROP TOWER

Karl Cardin, kcardin@pdx.edu

Portland State University, Portland, Oregon, United States Mark Weislogel, mmw@cecs.pdx.edu

Portland State University, Portland, Oregon, United States

The Dryden Drop Tower is a safe, low-cost, high-rate drop tower located in the atrium of the engineering building at Portland State University. The unique combination of these features serves to lessen the burdens of scientific discovery, creating a low-g access point for commercial entities as well as students of all levels. In this presentation we share drop tower experiment test footage for a variety of large length scale capillary fluidic phenomena. The first drop test investigating a specific phenomena is often preformed on a whim, as will be apparent from the select video clips we present, where unearthly phenomena of 'giant' liquid volumes interacting with non-wetting surfaces are as enjoyable as they are good applied science. We discuss in detail a subset of such phenomena that warranted further investigation including large jet rebounds, spontaneous particle ejections, and spontaneous ejection of non-oscillatory droplets from super-hydrophobic wedges.

G0.2-0006-18 FERROFLUID DYNAMICS IN MICROGRAVITY CONDITIONS

Álvaro Romero Calvo, alvaro.romero.calvo@gmail.com Universidad de Sevilla, Sevilla, Spain

Lidia Parrilla Benítez, lidiaparrilla22@gmail.com Universidad de Sevilla, Sevilla, Spain

Tim H.J. Hermans, timthjhermans@gmail.com

Delft University of Technology, CD Delft, Netherlands Miguel Ángel Herrada Gutiérrez, herrada@us.es Universidad de Sevilla, Sevilla, Spain

Elena Castro-Hernández, elenacastro@us.es Universidad de Sevilla, Sevilla, Spain

Ferrofluids are colloidal suspensions of magnetic nanoparticles in a carrier liquid. It is beneficial, for both fundamental research and future applications of ferrofluids in space, to obtain reliable measurements of the dynamics of ferrofluids in microgravity. This field remains unexplored since experiments in microgravity are expensive and the access to associated facilities is limited. In this work, the free surface displacement of a ferrofluid solution is measured in microgravity conditions in the ZARM Drop Tower in Bremen as part of the Drop Your Thesis! 2017 educational programme run by ESA Education. The ferromagnetic solution is subjected to a controlled magnetic field while an initial percussion is imposed.

The ferrofluid solution was produced with a commercial water-based ferrofluid. The solution filled two Plexiglas containers up to a quarter of their height. A copper coil was placed around each container and imposed a constant magnetic field on the ferrofluid solution. A monoscopic fringe reflectometry detection system and a complementary lateral visualization were employed to measure the position of the free ferrofluid surface. The complete set-up was given an initial percussion which produced a vertical acceleration profile. This experiment was launched five times in the ZARM Drop Tower in Bremen with different magnetic field intensities.

From the video data, a 3D representation of the free surface of the ferrofluid and relevant dynamical parameters are extracted. Simultaneous acceleration, temperature and current intensity measurements are employed to generate a CFD simulation, which is compared with the measurements of the real free surface. The validated CFD model leads to more reliable simulations of the dynamics of ferrofluids in microgravity, with multiple applications in fields like ferrofluid sloshing control or magnetothermal convection in Space.

G0.2-0007-18 EXPERIMENTAL EVALUATION OF LIQUID SLOSHING OSCILLATION IN A SPHERICAL TANK UNDER LOW GRAVITY

Mitsuhisa Baba, baba.mitsuhisa@jaxa.jp

Japan Aerospace Exploration Agency (JAXA), Kanagawa, Japan Masatsugu Otsuki, otsuki.masatsugu@jaxa.jp

Japan Aerospace Exploration Agency, Sagamihara-shi, Japan Takane Imada, imada.takane@jaxa.jp

Japan Aerospace Exploration Agency, Ibaraki, Japan Takehiro Himeno, himeno@aero.t.u-tokyo.ac.jp University of Tokyo, Tokyo, Japan

The science missions around low gravity planet will be more valuable if a planetary lander can stay and observe on the planetary surface. In order to cruise between planets, the planetary lander has to carry a large amount of propellant which can be heavier than the dry mass of the probe. The acceleration to the tank when the lander touches down on the surface under the low gravity can evolve the sloshing of the liquid in the tank and might cause to fail the landing. In addition, the residual shaking of sloshing in the low gravity environment has a long period in the bare tank without the damping device and it is difficult to damp the fluctuation. Accordingly, it can affect the probe dynamics even though the probe successfully lands on the surface under the micro-gravitational celestial body. Therefore, basic investigation to identify the influence of sloshing is important for a spacecraft landing and staying the environment. However, it is difficult to continuously find analytical solutions since the most of propellant tanks used for satellites and probes are spherical. Furthermore, the surface tension of the liquid cannot be ignored compared to the low gravity. Thus, to evaluate the period on the ground is difficult. In this study, liquid behavior under 1/200 gravity environment is observed using parabolic flight by aircraft. The behavior of colored water which is filled with 75% or 45% in a transparent container simulating a spherical tank of the probe was visualized. The period of the primary sloshing observed in the container filled with water at 75% was roughly consistent with the assumption of a mechanical model to evaluate its eigenfrequency. However, liquid behaviors that surface tension is not negligible based on the observation even if the number of bonds in this container were greater than 1.

G0.2-0008-18 ADVANCEMENTS IN THE QUANTIFICATION OF THE CRYSTAL STRUCTURE OF ZNS MATERIAL PRODUCED IN VARIABLE GRAVITY

Martin Castillo, martin.castillo@zarm.uni-bremen.de University of Bremen, Bremen, Germany

Magdalena Thode, magdalena.thode@zarm.uni-bremen.de University of Bremen, Bremen, Germany

Julia Tielke, julia.tielke@zarm.uni-bremen.de University of Bremen, Bremen, Germany

Screens and displays consume tremendous amounts of power. Global trends to significantly consume less power and increase battery life have led to the reinvestigation of electroluminescent materials. The state of the art in ZnS materials has not been furthered in the past 30 years and there is much potential in improving electroluminescent properties of these materials with advanced processing techniques. Self-propagating high temperature synthesis (SHS) utilizes a rapid exothermic process involving high energy and nonlinearity coupled with a high cooling rate to produce materials formed outside of normal equilibrium boundaries thus possessing unique properties. The elimination of gravity during this process allows capillary forces to dominate mixing of the reactants which results in a superior and enhanced homogeneity in the product materials. ZnS type materials have been previously conducted in reduced gravity and normal gravity. It has been claimed in literature that a near perfect phases of ZnS wurtzite was produced. Although, the SHS of this material is possible at high pressures, there has been no quantitative information on the actual crystal structures and lattice parameters that were produced in this work. Utilizing this process with ZnS doped with Cu, Mn, or rare earth metals such as Eu and Pr leads to electroluminescence properties, thus making this an attractive electroluminescent material. The work described here will revisit the synthesis of ZnS via high pressure SHS and will re-examine the work performed in both normal gravity and in reduced gravity within the ZARM drop tower facility. Quantifications in the lattice parameters, crystal structures, and phases produced will be presented to further explore the unique structure-property performance relationships produced from the SHS of ZnS materials.

G0.2-0009-18 COOLING OF GRANULAR GASES

Torsten Trittel, torsten.trittel@ovgu.de

Otto von Guericke University, Magdeburg, Magdeburg, Germany

Granular gases represent one of the simplest systems for investigations of non-equilibrium statistical physics. They are dilute ensembles of macroscopic grains, which move erratically and interact through inelastic collisions. This statistical system is easy to picture, but still insufficiently understood. There are various theoretical treatments on this system, especially for spherical particles under periodic boundary conditions, including numerical simulations and analytical predictions. Experiments on such systems have been performed mainly in two dimensional (2D) systems. An experimental realization of a 3D granular gas requires strong external forces or microgravity. Potential microgravity platforms for such experiments are sounding rockets, drop towers or satellites. Often experiments are dominated by wall particle interactions. Recently we determined translational and rotational velocity distributions under permanent excitation in a stationary state, during a sounding rocket ight. The use of elongated grains allows the realization of a 3D granular gas beyond the Knudsen regime. Here, we provide novel results on granular cooling (energy dissipation after stopped excitation) in a 3D granular gas. We focus on the evolution of kinetic and rotational energy during cooling in drop tower experiments and compare our results to Haff's law and recent numerical studies.

G0.2-0010-18 FLUFFING AND RISING OF GRANULAR MEDIA IN TRANSITION TO LOW GRAVITY ENVIRONMENT

In Japan, we are planning landing exploration missions such as OMOTENASHI, SLIM, Martian Moons Exploration (MMX) and Solar Sail within the next 10 years. In these missions, asteroids, Earth moon and Mars moon are target objects, and in order to safely landing on them, it is necessary to design a landing gear on the basis of the mechanical characteristics of the planetary surface. For verification of the design, interaction between the gear and the surface is generally confirmed by using a drop tower or an aircraft under a low gravity environment. In the low gravity environmental test using simulated regolith covering the planetary surface, it is essential to properly arrange regolith's initial conditions, but there are various issues. One of the issues is a phenomenon in which the gas trapped in the regolith is blown up in a vacuum environment. It is a supposed solution to leave the regolith for a long time while stirring it in a vacuum environment in advance. Next, the surface of the regolith fluffs or rises up when transitioning from the Earth's gravity or the high gravity environment to the low gravity environment. Regarding the latter, similar behaviour of the regolith is observed not only by the experiment using the drop tower and the aircraft, but also by numerical calculation using a DEM software. As a tendency of the experiment and simulation results, it has been confirmed that more amount of particles flight as the size of the particles increases, and particles that fly at higher speed appeared as particles become smaller. In ground tests, it is difficult to leave regolith in a low gravity environment for a sufficient time; hence, in order to prevent the regolith particles fluff and rise up, it is a solution to utilize fine natural sands or install a device to put a covered sheet on the sand and open it just before the test.

G0.2-0011-18 MECHANICAL FEATURES ANALYSIS OF THE NITINOL ALLOY UNDER MICROGRAVITY CONDITIONS

Jhon Abel Ordoñez Ingali, ja.ordonez@acad.ucb.edu.bo Universidad Católica Boliviana "San Pablo", La Paz, Bolivia Universidad Católica Boliviana "San Pablo"

Fabio Díaz Palacios Gabriel Rojas Silva Maritza Irahola Zalles Diego Rojas Arancibia

Mechanical qualities of the alloy known as Nitinol(Nickel and Titanium) were analized to determine their changes by means of two experiments executed under microgravity conditions (10-6g) compared to those of Earth gravity. The first experiment is to analize the angular velocity throughout the reconfiguration process of the material. Additionally, a second experiment was carried out to analyze the elasticity coefficient and rupture force capacity of the same material. The experiments outcomes were gathered at the ZARM institute in the Drop Tower facility.

G0.2-0012-18 SEPARATION AND IDENTIFICATION OF VOLATILE DIAMAGNETIC PARTICLES REALIZED BY A FIELD GRADIENT OF A NIOBIUM MAGNET

Chiaki Uyeda, uyeda@ess.sci.osaka-u.ac.jp Osaka University, Osaka, Japan

Many of the solid materials that exist in nature (including outer space) are composed of diamagnetic volatile materials which do not exhibit saturated magnetization; these materials are generally believed to be magnetically inert. An apparatus to separate various volatile and refractory particles, using a monotonically decreasing field, was newly designed and experimentally examined; the setup was based on an apparatus that was recently operated in a micro-gravity condition [1]. Using the new system, magnetic separation was realized for the first time on an ensemble of heterogeneous particles that included solid H2O and CO2; the former setup could conduct the experiment only at room temperature. Furthermore, the material of an unidentified particle can be estimated from the value of magnetic susceptibility that is obtained from the velocity of the translating particle. It is expected from the above results that the material abundances of heterogeneous solid particles that exist in the low temperature regions in the outer solar system are speedily determined without consuming sample, as it is necessary to survey the material distribution of volatile particles over a wide region. The mechanism of the separation is explained as follows.When an external field B is applied on a diamagnetic particle, a small magnetization (i.e. diamagnetic magnetization) is generally induced in a direction opposite to the field; this magnetization is proportional to B, mass of particle m and an intrinsic magnetic susceptibility (per unit mass) assigned to a material. Accordingly, terminal velocity of the translating particle outside the field does not depend on m; it is uniquely determined by the intrinsic susceptibility of the material.It is expected from the above properties that an ensemble of heterogeneous diamagnetic particles can be separated into different groups of materials as translation proceeds [1]. In the experiment, the NdFeB plates were fixed in an insulating container together with the homogeneous particles. Then the container was filled with dry ice blocks to maintain temperature at T=198 K, and was installed inside a compact drop box. A hi-vision camera was set to observe the translation, and susceptibility is calculated by obtained terminal velocity [1]. Micro-gravity condition is produced inside the drop box as it dropped through a short shaft Based on the numerical data obtained in the experiment, the validity of the separation principle is examined, and the possibility of applying the system in a remote sensing mission is discussed. The prototype machine developed in the present study has a rigid and compact structure, and is operated by a simple principle that is easy to examined; its power consumption is small, and finally, analysis is completed without consuming sample.

So far, the spec of the apparatus is suitable for a remote a sensing mission. [1] Hisayoshi, Uyeda Terada (2016) Sci Reps 6 38431.

G0.2-0013-18 READINESS OF SURFACE EXPLORATION ROVER MINERVA-II IN HAYABUSA2 ASTEROID MISSION THROUGH POST-LAUNCH VERIFICATION EXPERIMENTS USING A DROP TOWER

Introduction

Hayabusa2 spacecraft launched in 2014 makes a round-trip travel to one of the small solar system bodies named "Ryugu." It will arrive at the target this year and make a proximity stay around the asteroid for one and a half years in order to make scientific remote observations as well as to land onto the surface for sample acquisition. The obtained samples are brought back to the Earth in 2020.

The authors developed a tiny rover package for Hayabusa2 mission. The package consists of two rover containers, a relay module and an antenna to communicate with the rovers. Three rovers are included in the two containers. Two of them installed together in one container are the responsibilities of the authors. Another one in the secondary container came from domestic university members. All the rovers were developed without the official budget from the mission to seek for technology-driven challenges on the surface of the target asteroid.

This paper addresses the results of the microgravity experiments of the rovers. The microgravity experiments included the deployment mechanism of the rovers as well as the hopping mobile system of the rover. The results of the experiments are reflected in the deployment operation scheduled to make in 2018 – 2019 when the spacecraft stays in the vicinity of the asteroid.

Post-launch verification using a drop tower

After the launch of the spacecraft, we made two ground-based microgravity experiments needed for the proximity operation. The experiments were made at the drop tower at ZARM, Bremen, Germany, in which 4.7 seconds of microgravity was provided inside the capsule falling for more than 100 meters from the top of the tower.

The rovers are pushed by the springs to be ejected outside from the container when the wire to tightly hold the rover is cut. The microgravity experiments of the deployment mechanism were made for evaluating the deployment direction and speed of the rovers accommodated together in one container.

The deployment speed of the rover from the container highly affects the altitude from the asteroid surface when the rovers are ejected. Deployment from high altitude will accelerate the rover during the fall onto the asteroid and the rover speed might exceed over the escape velocity from the surface.

We used the backup model of the rover container and two aluminum rigid masses whose weights are identical to the ones of the flight models of two rovers.

The evaluation of the hoppping mobile system of the rovers were also accomodated together in a long capsule to conduct two experiments simultaneously in one drop. The speed and direction of the rovers during the fall were measured by the image processing.

We will adjust the torquer acceleration in the autonomous navigation software used on the asteroid surface because the maximum hopping speed of the rover must not be larger than the escape velocity from the surface.

Rover operation

The spacecraft makes remote sensing observation from the distance of 20 kilometers for a couple of month after the arrival. The observation results are used to make a three-dimensinal shape model of the asteroid, and to derive the physical parameters of the asteroid such as gravity, rotational period, and so on.

After the characterization of the asteroid is finished, the spacecraft makes some descent operations including rover deployments and sample acquisitions. Rover deployment may be done around September – October 2018 when the spacecraft descends to the altitude of 50 meters.

After arriving at the asteroid, the rovers move autonomously over the microgravity environment of the surface by hopping with use of a torquer installed inside the body. The rovers are powered by the solar cells, activating the onboard computer and the communication module. The extra power is charged into the capacitors, which assist additional power demand such as hopping by the torquer or image shooting by cameras. The obtained data by the rovers are transmitted to the relay component of the mother spacecraft by radio. The rover operation continues as long as the radio link from the rovers retains.

Acknowledgement

The opportunities of the microgravity experiments at ZARM were granted by the agreement between DLR and JAXA about Hayabusa2 project. The authors are deeply grateful for the technical and operational supports from ZARM.

G0.2-0014-18 PARABOLIC FLIGHT EXPERIMENT FOR MEASURING LANDING IMPACT ON SMALL GRAVITY ENVIRONMENT AND APPLICATION TO LANDER DYNAMIC SIMULATOR

Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, Kanagawa, Japan

For the small body landing exploration, it becomes important to know the feature of the contact dynamics between the landing gear of the spacecraft and the celestial soil. It is difficult to know the feature of the celestial soil under the small gravity environment on Earth. We conducted a parabolic flight experiment with a vacuum chamber and a Martian regolith simulant. The projectile was shot into the Martian regolith simulant by a compressed spring. The contact acceleration and sinkage were measured on board. Based on this result, the difference of the force and sinkage under the Earth gravity and small gravity were discussed. Then, the result was applied to the dynamical landing simulator. The landing on the Martian Moon Phobos which is assumed for Martian Moons Exploration (MMX) mission in Japan is verified by the result of the experiment and this simulator.

G0.2-0015-18 DEPLOYMENT TESTS OF PW-SAT2 DEORBIT SAIL IN MICROGRAVITY CONDITIONS DURING FREE-FALL AT DROP TOWER IN BREMEN

Dominika Rafalo, dominika.rafalo@gmail.com

Warsaw University of Technology, Poland, Warsaw, Poland PW-Sat2

P. Brunne, K. Ciechowska, K. Gajc, K. Gawin, M. Gawin, M. Kania, P. Kuligowski, Z. Kusznierewicz, D. Paczkowska, F. Perczynski, K. Pilarski, D. Rafalo, E. Ryszawa, M. Sobiecki, I. Uwarowa

Testing space technology devices, especially deployable ones, is always the most time-consuming and complex activity during the space-related projects. This was experienced by young engineers from Warsaw University of Technology in Poland working on the PW-Sat2 CubeSat. The satellite is going to be launched by SpaceX Company in the third quarter of 2018. The primary objective of PW-Sat2 is to test the deorbit sail system as well to verify its effectiveness.

Deorbit system designed by PW-Sat2 team takes the form of a square sail (2 m side) stretched across four flat springs, coiled around a specially shaped center core. Sail deployment system requires low power for a very short period of time i.e. less than 2 W of power for less than 1 minute. The deployment of the sail is driven completely by the energy stored in folded flat C-shaped springs, that release and unfold the structure of the sail. Therefore, the deployment process is very dynamic, lasts less than 0.7 s and strongly varies depending on environmental factors like gravity, the friction of surfaces or moment of inertia of the mechanism. Due to the sail dimensions, the gravity influence on the sail deployment is significant while testing on the ground. Gravitational forces acting on all parts of the sail cause drag between the ground and the sail material when testing in two dimensions. This does not allow to observe the effects of the sail deployment that may occur in weightlessness conditions. About 25 exact sail models have been built for testing purpose on the ground, but none of these tests provided a sufficient microgravity imitation. Hence, the team was looking for an opportunity to fully simulate sail deployment in a 3D environment without constraints.

The PW-Sat2 team finally has been qualified to DropTES Program organized by ZARM in collaboration with UNOOSA and DLR. Students had a chance to perform 4 sail deployment tests in the high-quality microgravity conditions under low pressure during the free-fall in Drop Tower in Bremen, Germany. In order to get reliable results, a real size dummy mass model of the satellite was prepared, that contained the sail deployment system in the final configuration. Due to the large size of the sail, the experiment had to be dropped from the height of 8 meters in the Drop Tower deceleration chamber. This resulted in about 1.2 s of free-fall. It was enough to observe 4 full deployments of the deorbit sail and to record the process using high-speed cameras. The experiment successfully conducted at Drop Tower in November 2017 proved the reliability of the PW-Sat2 sail's deployment system. Moreover, the readouts of accelerators mounted on satellite's model and footage gathered during the experiment series allowed to fully understand the influence of the sail deployment process on the satellite. The team is going to build a reliable and correct model of sail deployment, which is going to be used to investigate the PW-Sat2 sail scalability and the possibility to be used on larger satellites.

As PW-Sat2 deorbit sail system passed deployment test in microgravity conditions, the effectiveness of the deorbit sail will be verified on the orbit. These tests will make the sail viable to be used onboard other satellite missions and could help prevent the Earth's orbit from space debris in the future.

G0.2-0016-18 QUANTUS-2 - A MOBILE HIGH-FLUX BEC SOURCE IN MICROGRAVITY

Merle Cornelius, merle.cornelius@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany Tammo Sternke, tammo.sternke@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany Sven Herrmann, sven.herrmann@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany

Claus Laemmerzahl, claus.laemmerzahl@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany QUANTUS Team

ZARM, Universität Bremen; Institut für Quantenoptik, Leibniz Universität Hannover; Institut für Physik, Humboldt-Universität zu Berlin; Institut für Physik, Johannes Gutenberg Universität Mainz; Institut für Quantenphysik, Universität Ulm; Institut für angewandte Physik, TU Darmstadt

Matter-wave interferometry allows to realize highly sensitive quantum sensors for applications in inertial sensing as well as for tests of fundamental physics. The sensitivity of such measurements thereby greatly benefits from extended free fall times on the order of several seconds. Thus, the operating of matter-wave interferometers in microgravity, ideally in space is currently pursued by research groups worldwide.

To implement such complex experiments on a space-based platform, a validation of the stringent requirements concerning compactness and robustness is needed. Thus, the mobile high-flux BEC source QUANTUS-2 [1] was developed as a pathfinder experiment to perform measurements in microgravity at the ZARM drop tower in Bremen, Germany. The payload is integrated into a catapult capsule and can be launched in a parabolic flight inside a 110m high vacuum tube, providing 9.3s microgravity time.

Here we report on the preparation of a Rubidium-87 BEC to provide an ideal input source for a matter-wave interferometer, where ultra-low residual expansion rates are crucial to reach long interferometer times. We use magnetic lensing (delta-kick collimation) to narrow the momentum distribution of the atomic ensemble and demonstrate expansion rates of 100µm/s, which corresponds to a three-dimensional effective temperature below 100pK. This enables the observation of the ensemble after 2s of free evolution time with a high signal to noise ratio. With this results we are able to provide an ideal input state for a highly sensitive matter-wave interferometer and verify the technical readiness for future space missions.

Claus Laemmerzahl, claus.laemmerzahl@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany

Dennis Schlippert, schlippert@iqo.uni-hannover.de Leibniz Universität Hannover, Hannover, Germany Henning Albers, albers@iqo.uni-hannover.de Leibniz Universität Hannover, Hannover, Germany Ernst Maria Rasel, rasel@iqo.uni-hannover.de Leibniz Universität Hannover, Hannover, Germany

PRIMUS is a drop tower experiment set up to explore the potential of matterwave interferometry in microgravity to realize quantum sensors with increased sensitivity and to enable future space-based fundamental physics tests in particular. To exploit the benefit of extend free fall times in such interferometers, the atoms need to be cooled to the low nK regime, possibly to quantum degeneracy by evaporative cooling. While most cold atom experiments in microgravity rely on magnetic trapping with atom chips for subsequent evaporative cooling, we employ an optical dipole trap instead. This offers several advantages such as improved harmonicity, trapping of all magnetic substates and the possibility to apply Feshbach resonances to control atomic interactions. However, while dipole traps are well established in ground based experiments, their application in a microgravity environment is significantly more demanding.

In this talk, we will present our drop capsule setup and show first results of trapping and cooling atoms in an optical trap in the drop tower. To our knowledge this is the first time an optical dipole trap has been operated in a microgravity environment. We will also outline the next steps to cool the atoms further to ultra-cold temperatures e.g. by applying spatial modulation of the trapping beam to decouple the trapping volume from trapping frequency thus significantly accelerating the evaporative cooling process.

G0.2-0018-18 WHAT IS SO SPECIAL ABOUT QUANTUM TECHNOLOGIES?

Claus Laemmerzahl, claus.laemmerzahl@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany

Quantum technologies are becoming more and more important. There is, for example, a European Research flagship on Quantum Technologies, one is building quantum computers for solving real problems for the first time in the near future, one plans to use quantum cryptography having the advantage that it cannot be decoded, there was a Chinese mission which realized the entanglement of quantum states on a satellite with states on the Earth, one is building quantum sensors for geodesy, positioning, and navigation, and one now will base the international system of physical units, the SI system, on quantum realizations replacing analogue units like the Paris kilogram prototype which still is in use today. Why there are so many activities in the direction of quantum technology?

The speciality of quantum systems lies in the fact that they are unique in the sense that they can be uniquely characterized by a finite number of rational numbers. As a consequence, by giving some rational numbers, everybody in the universe can single out a particular type of atoms and extract a particular frequency which then may serve as universal time standard. And from that, e.g. by defining natural constants like the velocity of light and the Planck, Avogadro, and Helmholtz constants, one can define the units of metre, kilogram, mol, and temperature. For that additional quantum effects like the Josephson effect or the quantum Hall effect are needed. Furthermore, quantum systems are given by nature. They cannot and need not to be machined. They are are same everywhere, they are uniquely and unchangeably given. The "only" work left for physicists is to read out the characteristic frequencies or other unique effects or properties of the given quantum systems.

This uniqueness, complemented by the special features of the measurement process and the linear evolution of the quantum systems, then makes such systems perfect for all the purposes described above. In this talk we will describe these unique features, their fundamental consquences, as well as their practical applications. We also will mention the role of fundamental physical symmetries in this context, that is, in which sense the use of quantum technologies depends on the validity of Special and General Relativity.

G0.3-0001-18 ANALYSIS OF DATA FROM ATOMIC OXYGEN MONITOR SYSTEM ONBOARD TSUBAME/SLATS SATELLITE

Yugo Kimoto, kimoto.yugo@jaxa.jp

Japan Aerospace Exploration Agency (JAXA), 305-8505, Japan

JAXA has proposed a brand-new concept for satellites in Low Earth Orbit (LEO). The Super Low Altitude Test Satellite (SLATS) also known as Tsubame is the first Earth observation satellite to adopt a "super low orbit" at an altitude lower than 300 km. Higher resolution optical observation and the reduced emission power of such active sensors as radar are expected in Earth observations from super low altitude orbits in the future. Launched on December 23, 2017 from the Tanegashima Space Center, Tsubame (SLATS) successfully completed its critical operation phase. The Atomic oxygen MOnitor (AMO) is one of the mission sensors of Tsubame. The AMO consists of two mission sensors-the Atomic Oxygen Fluence Sensor (AOFS) and the Materials Degradation Monitor (MDM). The AOFS will obtain AO environment data in Tsubame's orbit. It consists of eight sensor heads (AOFS-Hs) and one readout electronics. For AO measurement, six Thermoelectric Quartz Crystal Microbalances (TQCMs) with polyimide sensors (AOFS-Hs) were mounted at several positions of the satellite. Two non-coated TQCM sensors were also mounted next to the AO sensors for measuring contamination background. Two AOFS-Hs have shutter mechanisms that control incident AO fluence on the front of the AOFS-Hs. The MDM will observe the degradation of candidate materials selected for future use in super low altitude satellites. It consists of a sample control unit (MDM-S) and a CCD camera unit (MDM-C). Thirteen temperature-controlled samples were fixed at MDM-S. The samples are thermal control films, power cables, and an AO monitor material. MDM-C will take an image once a week with LED lights that illuminate from the front and back of the material surface. Such AMO data will be used for a design standard and material usage guidance on future super low altitude orbit satellites. The initial verification of AOFS and MDM functions began on January 4, 2018. The status and functions of both sensors pose no problem. This final paper presents the initial observation data from both the AOFS and MDM.

G0.3-0002-18 SPACECRAFT CHARGING MATERIAL DATABASE (SCMD) IN THE FREE SPACE ENVIRONMENT

Linda Parker, lparker@usra.edu

USRA/NASA MSFC, Huntsville, Alabama, United States Joseph Minow, joseph.i.minow@nasa.gov

NASA Langley Research Center, Huntsville, Alabama, United States

Materials exposed to the free space environment will charge to a net potential due to differential collection of ion and electron currents from the space radiation and plasma environment. The magnitude of the electric fields generated by an excess charge density on (or in) a material is an important consideration for space system design and operations. Accumulation of significant charge can lead to electric fields which exceed the electrostatic breakdown strengths of materials, resulting in electrostatic discharges which are responsible for a number of detrimental effects including material degradation, electromagnetic interference, and even catastrophic failure of electronic components in extreme cases.

We will first provide an introduction to the physics of surface and internal charging processes and identify the relevant material properties required to model charging in each case. We then will describe the Spacecraft Charging Materials Database (SMDC) under development by NASA. This new database of material properties will collect information on the material properties required for conducting charging analyses. Examples of relevant material parameters are volume and surface conductivity, dielectric constant, secondary electron and backscatter yields, photoelectric current density, and material density. We intend for the database to be open to the international community. The goal is to provide a resource for the exchange of information on electrical properties of materials available to both contributors providing fundamental measurements of electrical properties of materials and the analysis community conducting quantitative modelling studies of spacecraft charging. The Spacecraft Charging Material Database will be an archive for ground based testing to support the community's understanding of materials in the free environment.

G0.3-0003-18 HAS THE PLASMA ENVIRONMENT INFLUENCE ON SPACECRAFT INSTRUMENTS?

Anja Schlicht, schlicht@bv.tum.de

Institute for Astronomical Physical Geodesy, Technical University Munich, Munich, Germany Karl-Heinz Glassmeier, kh.glassmeier@tu-bs.de

Technical University of Braunschweig, Braunschweig, Germany

Electromagnetic waves in a plasma have a unique propagation behavior as the free electrons and ions react on the electric field of the wave. In the dispersion relation distinct resonances and cut-off frequencies occur depending on the magnetic field strength and plasma density. We focus in our discussion on very low frequencies below 10 kHz which propagate in the so called whistler mode. These frequencies can excite coherent phonons which transport the electric field through the metal. We compare this hypotheses with already performed experiments and the literature of coherent phonons. We will discuss why these frequencies cannot be shielded by metals and how this can affect space instruments. We found this disturbances on accelerometers flying in the ionosphere. We review the disturbances which can be seen on the GRACE and GOCE gravity field missions, like impulsive disturbances due to different switching processes and twangs and continuous disturbances detected on the gravity gradients of the GOCE mission. The relation to very low frequencies excitations in a plasma is given, as well as an explanation why accelerometers are extremely sensitive to these disturbances. The accelerometers suffers from the electromagnetic incompatibility but other instruments may be more disturbed by mechanical interactions. As an outlook we show observations on the Swarm accelerometers where a coupling of mechanical and electrical influences occur.

G0.3-0004-18 CHARACTERISTICS OF THE FREE SPACE ENVIRONMENT AND MATERIAL PROPERTIES CONTROLLING THE DEVELOPMENT OF AURORAL CHARGING

Joseph Minow, joseph.i.minow@nasa.gov

NASA Langley Research Center, Huntsville, Alabama, United States

Spacecraft materials charge to significant negative potentials relative to the ambient space environment when an incoming electron current to a surface exceeds the incoming ion and outgoing secondary electron and photoemission currents. Materials on spacecraft surfaces may charge to potentials of a few hundred volts to a few thousand volts in low Earth orbit when exposed to the electron currents responsible for producing discrete auroral features at high latitudes. These large negative potentials are a concern to spacecraft designers and operators since they can result in electrostatic discharges that damage materials or spacecraft components. While discrete aurora generated by both inverted-V and Alfenic type electron spectra can exhibit strong electron currents, charging to large negative potentials only occurs when spacecraft pass through the inverted-V type electron environments. This paper will summarize the characteristics of the electrons and ions in the free space environment and electrical properties of materials including the secondary electron yield and photoemission yields of importance in controlling the charging process. We will first provide a background on the physics of surface charging. Next, we will describe the characteristics of the secondary electron yield and photoemission yield properties of materials that are important to the charging process. Finally, we will provide examples of charging due to both inverted-V and Alfenic type electron spectra using records from the space environment sensors on the Defense Meteorological Satellite Program spacecraft.

G0.3-0005-18 ADDITIVE LAYER MANUFACTURING FOR CUBESAT MISSION TO STUDY THE BEHAVIOR AND PERFORMANCE ON STRUCTURAL MATERIAL IN THE SPACE ENVIRONMENT

Muhammad Shadab Khan, shadab_khan@msn.com IMT Mines Albi, Albi, France

CubeSats are a class of nano-satellites that use a standard size and form factor. The standard CubeSat size uses a “one unit” or “1U” measuring 10x10x10 cms and is extendable to larger sizes; 1.5, 2, 3, 6, and even 12U. The concept was originally developed in 1999 by California Polytechnic State University at San Luis Obispo (Cal Poly) and Stanford University to provide a platform for education and space exploration. CubeSat has a several systems and subsystems, among one of them is the primary mechanical structure which supports all the subsystems including the Solar Panel and Antenna. The prospective to develop and launch a 1-Unit CubeSat “AlbiSat” for Institut Clement Ader, Albi proposes the concept of utilization of Additive Layer Manufacturing (ALM) process to develop the primary Mechanical structure. Traditionally the mechanical structure in present time for the CubeSat is built using machining and other manufacturing processes. The application of Additive Layer Manufacturing to design and manufacture the primary mechanical structure for the CubeSat as a novel mission concept to study the behavior and performance of the structural material in space conditions as a prospective preparation towards understanding the effects of the space environment on the material performance and structural health can help us in utilizing the Additive Layer Manufacturing Process for future applications in space exploration. Aluminum 7075 and 6061, alloys which are the only two materials permitted by the CubeSat specifications so only these two materials can be used to prepare the powder to use in the ALM process. By utilizing the ALM process to manufacture the mechanical structure which has several advantages over conventional manufacturing process like moving parts such as hinges which support the solar panel deployment can be printed in metal directly into the product, which can significantly reduce the part numbers as well as several other advantages like whatever we design in the CAD software we can create easily and only the material that is needed is used, there is very little (if any) material wasted. Considering our future perspective of space exploration,future spacecrafts and objective to build base camps on Moon and Mars, ALM process to design and manufacture them can reduce the manufacturing costs. It costs less to print a complex part instead of a simple cube of the same size. The more complex (or, the less solid the object is), the faster and cheaper it can be made through additive manufacturing. In this regard the development of the Mechanical structure for the AlbiSat CubeSat project utilizing the ALM process can help us to better understand the behavior and performance of the material and the overall mechanical structure in the condition in Low Earth Orbit at a low cost to simulate and analyse both Mechanical and Thermal behaviour, to find out the feasibility of utilising ALM process in space environment which can help us to do further research and utilize the concept of ALM in minimizing the manufacturing cost and time in building future spacecrafts.

G0.3-0006-18 QUANTIFICATION OF NIOBIUM ALLOY C-103 SUBLIMATION IN EXTREME SPACE ENVIRONMENTS

Christopher Stiles, christopher.stiles@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Andrew Lennon, andrew.lennon@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Michelle Donegan, michelle.donegan@jhuapl.edu

NASA/Glenn Research Center, Cleveland, Ohio, United States

Late in the Parker Solar Probe (PSP) development, high temperature emissivity testing uncovered a possible risk related to sublimation of niobium alloy C-103. Although the experiment inadvertently demonstrated that sublimation of the alloying elements of C-103 could occur at high temperatures and vacuum conditions, determining the risk to the spacecraft and its components required an estimate of the amount of material that would sublimate over the mission lifetime. In order to quantify this, the rate limiting mechanisms of sublimation need to been well understood for the C-103 alloy. From there one can construct a mathematical model for the behavior of the material and predict what species will sublimate, when the sublimation will occur, and how much material is sublimated. The major hurdle in the approach lies with the very limited information available for C-103 in this environment, and for the major alloying component hafnium in particular. Since time for defining the risk to PSP was limited, an engineering approach was devised to acquire estimates for the missing information, mainly diffusion rates and sublimation rates at the surface of the C-103 alloy.

Through the use of high temperature vacuum ovens at Oak Ridge National Laboratory, JHUAPL, and NASA Glenn Research Center (including vacuum thermogravimetric analysis), C-103

coupons were exposed to temperatures up to 1800 °C at pressures as low as 10−5 Torr. From the mass losses observed and concentration gradients of hafnium and titanium across the thickness of the coupon, improved transport properties have been obtained.

Within two months of discovering that there was a fundamental physics problem with the potential to affect everything on the spacecraft, the scope of the problem was narrowed down to two instruments based on the predicted sublimation rates and ray tracing analysis.

G0.3-0007-18 MODELING THE INFLUENCES OF ELECTROSTATIC DISCHARGE IN MATERIALS ON A FAILURES OF ONBOARD ELECTRONIC EQUIPMENT IN UNDER MICROGRAVITY

Valentina Grichshenko, gri@gzi.kz

National Center of Space Researches and Technologies, JSC, Almaty, Kazakhstan Zhumabek Zhantayev, gri@gzi.kz

Kazakhstan

Acemhan Mukushev, gri@gzi.kz Kazakhstan

It is known, that during SV exploitation failures of automated systems happens as the result of complex influence of Space leading to SV's shorter life span, sometimes to their lose. All of the SV, functioning in the near-Earth Space (NES), subjected to influence of different Space factors. Causes and character of failure onboard equipment are different. Many researchers think that failures of onboard electronics connected to changing solar activity level. However, by the numerous onboard experiments established that even in the absence of solar burst in magnetostatic days there are registered failures of onboard electronics. In this paper discussed the results of modeling the impact of electrostatic discharge (ESD), occurring in the materials, on a failures of electronic onboard equipment in microgravity. The paper discusses the conditions of formation and influence of electrostatic discharge in microgravity on the elements of the onboard electronics in Space. Developed technique using circuit simulation in ISIS Proteus environment is discussed. Developed the recommendations for noise immunity of on-board equipment from ESD in Space. The results are used to predict the failure rate on-board electronics with the long term of space mission.

G0.3-0008-18 INFLUENCE OF SPACE FACTORS ON PHYSICAL PROCESSES, TAKING PLACE IN MATERIALS AND ON-BOARD ELECTRONICS IN SPACE

Valentina Grichshenko, gri@gzi.kz

National Center of Space Researches and Technologies, JSC, Almaty, Kazakhstan Zhumabek Zhantayev, gri@gzi.kz

Kazakhstan

It is known that during flights of manned and unmanned spacecraft failures of on-board electronic equipment occur which are related to physical processes in functional materials. It is accepted that these failures are caused by charged high-energy particles that are of solar and galactic cosmic rays (SCR, GCR). In real conditions, there are other factors SF, which must be taken into account in the design and planning of missions of various spacecraft. Therefore, it is very important to study the complex influence of space factors (KP) on the degradation of materials and on-board electronic equipment in the space. In this paper we analyze the results of ground modeling studies and space experiments to study the physical properties of materials exposed in the space. Criteria of reliability of on-board electronic equipment and material degradation are developed and discussed. Criteria include the factors of space, including: radiation exposure, thermal shock, microgravity, electrostatic discharge, vacuum; factors of technological and functional purpose. The mechanism of material degradation in conditions in the space and microgravity is discussed. Practical recommendations are discussed to increase the reliability of functional materials, as well as on-board electronic equipment.

G0.3-0009-18 STUDY ON THE THERMAL-MECHANICS COUPLING CHARACTERISTICS OF COMPOSITE ENVELOPE STRUCTURE OF HIGH ALTITUDE STRATOSPHERIC AIRSHIP

Haibo Luo, bobo@aoe.ac.cn

China Academy of Science, Beijing, China Xiangqiang Zhang, xiangqiangzhang@aoe.ac.cn Chinese Academy of Sciences,AOE, BEIJING, China Taihua Zhang, zth@aoe.ac.cn

Academy of Opto-electronics, Chinese Academy of Sciences, Beijing, China

A thermodynamic coupling model of the high latitude stratospheric airship envelope structure is established in this study based on the damage theory of laminated composite. Based on the flight test data, the mechanics response of composite envelope is revealed under different flight altitudes, different pressure difference conditions and different temperature conditions. The mechanical characteristics of the different structural parts of the airship under the same temperature and pressure difference are discussed in depth. The results show that the thermal stress of the composite envelope is small under low temperature and low pressure, and the influence on the envelope material damage is almost negligible. The in-plane shear thermal stress (S12) distribution along the longitudinal axis direction (from head to tail) of the airship gradually increases when the temperature is lower and the pressure difference is smaller, but the thermal stress (S12) along the circumferential central axis direction of the airship almost no change; The in-plane thermal stress (S11) between the two ends of is larger along the longitudinal axis direction of the airship, while the thermal stress (S11) along the circumferential central axis direction of the airship is smaller in the middle. The difference is that the circumferential thermal stress is greater overall than the axial thermal stress. Through the analysis also found that the mechanical properties of composite envelope structure are stable, and almost no damage is observed under low temperature and low pressure thermal-mechanics coupling conditions. Keywords: Thermal-mechanics coupling, Stratospheric airship, Composite envelope, Thermal stress, Damage theory

G0.3-0010-18 PARTICLE RADIATION EFFECTS REPRESENTING GCR AND SPE SPACE RADIATION ON SPACECRAFT AND SPACESUIT MATERIALS-OF-CONSTRUCTION

Jess Waller, jess.m.waller@nasa.gov

NASA/Johnson Space Center, Las Cruces, New Mexico, United States Kristina Rojdev, kristina.rojdev-1@nasa.gov

NASA, Houston, Texas, United States Benjamin Peters, benjamin.j.peters@nasa.gov

NASA/Johnson Space Center, Houston, United States Khadijah Shariff, khadijah.i.shariff@nasa.gov

NASA/Johnson Space Center, Houston, Texas, United States Douglas Litteken, douglas.litteken@nasa.gov

NASA-Johnson Space Center, Houston, Texas, United States Charles Nichols, charles.nichols@nasa.gov

NASA-JSC White Sands Test Facility, Las Cruces, New Mexico, United States

The effect of particle radiation on materials-of-construction used in inflatable habitat, composite habitat, and space suits was investigated. The materials irradiated are lightweight candidates having a variety of applications such as permeation barriers, micrometeoroid and orbital debris (MMOD) protective layers, and restraint layers. The types of particle radiation used were chosen to be representative of the species and energies present in galactic cosmic ray (GCR) and solar particle event (SPE) space radiation. For example, low-Z (proton) and high-Z (iron) 1- GeV particle beams were used to bracket GCR ionization and displacement effects. Intermediate energy (ca. 20 to 40-MeV) protons were used to simulate ionization effects due to exposure to SPE radiation. The amount of damage caused by either form of radiation was quantified by determining changes in relevant mechanical and physical properties. Although lower and higher dose effects were ascertained in the study, materials were generally irradiated to doses representing up to a 50-hear exposure to deep space radiation (approximately 700 and 10,000 cGy for GCR and SPE dosese, respectively). The test logic was, therefore, to qualify materials out to 50-years, rather than to determine terminal doses leading to catastrophic property loss.

In most cases, little or no significant property change was observed after exposing materials to particle radiation representing a 50-year GCR or SPE dose. However, in certain cases, moderate property changes were observed. For example, a 325-denier Spectra® space suit restraint layer exhibited a 20.6 percent drop in the initial puncture extension after receiving a 10,300-cGy proton dose simulating a worst case 50-year exposure to SPE radiation. Similarly, significant drops in the initial puncture extension were also noted for 325-denier Spectra® after receiving a 400 to 709 cGy

1-GeV 26Fe dose emulating an exposure to high-Z GCR radiation. The largest mechanical property changes noted in this study were 133 to 205 percent increases in the room temperature ultimate tensile strength (UTS) for a bladder materials reinforced with 210-denier Spectra® receiving 709 and 10,300 cGy doses emulating 50 year GCR and SPE exposures, respectively. Other commercially available bladder materials (Cadpak® HD200 and Armorflex® ST10) exhibited small but reproducible increases in the UTS, consistent with predominant cross-linking. Thermogravimetric analysis (TGA) of selected bladder materials suggested the occurrence of some cross-linking of high molecular weight polymeric species, with some increase in liberation of low molecular weight (non-polymeric) species; however, the changes noted were small. Permeation results for an Armorflex® ST10 bladder material revealed an initial drop in the permeation resistance after irradiation, which recovered to acceptable levels after repeated pressure cycling. Deterioration in ballistic performance was noted after exposure of inflatable habitat MMOD protective layers receiving doses equivalent to a 50- year high-Z GCR exposure. Results on filled and unfilled sandwich core constructions showed that panels with filled honeycomb core are significantly strengthened after iron proton 1-GeV particle exposures. Last, the combined effects of radiation exposure and thermal aging on high density polyethylene (HDPE, similar make-up to Spectra®) were demonstrated, suggesting that physical aging may exacerbate radiation degradation processes occurring in spacecraft and space suit materials used in long term applications in space radiation environments.

While catastrophic end-of-life material failure indicative of a terminal dose was not observed for any material investigated, the potentially antagonistic (accelerative) degradation by simultaneous radiation exposure and physical aging was. The relevance of the current findings to NASA's missions is discussed and recommendations for future testing are made. Corroboration of current data with available scientific literature is also discussed.

G0.3-0011-18 MATERIALS INTERNATIONAL SPACE STATION EXPERIMENT-9 (MISSE9) POLYMERS AND COMPOSITES EXPERIMENT

Kim De Groh, kim.k.degroh@nasa.gov

NASA Glenn Research Center, Cleveland, Ohio, United States Bruce Banks, bruce.a.banks@nasa.gov

NASA Glenn Research Center, Cleveland, Ohio, United States Loredana Santo, loredana.santo@uniroma2.it

University of Rome Tor Vergata, Rome, Italy

Spacecraft in low Earth orbit (LEO) are subjected to harsh environmental conditions, including radiation (cosmic rays, ultraviolet, x-ray, and charged particle radiation), micrometeoroids and orbital debris, temperature extremes, thermal cycling, and atomic oxygen (AO). These environmental exposures can result in erosion, embrittlement and optical property degradation, threatening spacecraft performance and durability. To increase our understanding of effects such as AO erosion and radiation induced embrittlement of spacecraft materials, NASA Glenn has developed a series of experiments flown as part of the Materials International Space Station Experiment (MISSE) missions on the exterior of the International Space Station (ISS). These experiments have provided critical LEO space environment durability data such as AO erosion data for many materials and mechanical properties changes after long term space exposure. In continuing these studies, a new experiment called the Polymers and Composites Experiment has been selected for flight on the MISSE-Flight Facility (MISSE-FF). The Polymers and Composites Experiment will be flown as part of the MISSE-9 mission, the inaugural mission of MISSE-FF manifested on SpaceX-14. This experiment includes 138 samples being flown in ram, wake or zenith orientations for space environmental durability assessment. The primary objective is to determine the LEO AO erosion yield, Ey (the volume loss per incident oxygen atom (cm3/atom)), of polymers, composites, and coated samples, as a function of solar irradiation and AO fluence. In addition, epoxy samples with varying levels of ZnO powder are included to study the effect of filler quantity on AO erosion. An AO Scattering Chamber is included to help improve the understanding of AO scattering mechanisms for improved AO undercutting modeling. Indium tin oxide (ITO) coated samples are included to validate the durability of ITO conductive coatings in LEO. Tensile samples of Teflon fluorinated ethylene propylene (FEP) of varying thicknesses and back-surface coatings will be flown in wake and zenith orientations to study radiation embrittlement versus thickness, and the effect of heating on FEP embrittlement. Finally, shape memory composite and cosmic ray shielding samples will be flown for LEO durability assessment. This paper presents an overview of the MISSE-9

Polymers and Composites Experiment.

G0.3-0012-18 LARGE CONSTRUCTIONS FOR FUTURE SPACE EXPLOITATION

Alexey Kondyurin, kond@mailcity.com University of Sydney, Sydney, Australia

Future space exploitation requires large space structures. A sufficient large volume of pressurized modules for crew, passengers, space processing equipment, etc are required. However the size and mass of modern space ship and stations is limited by possibilities of a launch vehicle. It limits our future in exploitation of space by human crew and makes space industry projects non-profitable. Large-size space construction can be made with using of the curing technology of the fibers-filled composites and a reactionable matrix applied directly in free space. For curing the fabric impregnated with a liquid matrix (prepreg) is prepared in terrestrial conditions and shipped in a container to an orbit. In due time the prepreg is unfolded by inflating. After curing reaction, the durable construction can be fitted out with air, apparatus and life support systems. Our experiments of the curing processes directly in the free space environment showed that the curing of composite in orbit is possible. The large-size space construction can be created in Earth orbit. Large size space station, Moon base, Mars base, mining station, interplanet space ship, telecommunication station, space observatory, space factory, antenna dish, radiation shield, solar sail are proposed. The study was supported by Humboldt Foundation, ESA (contract 17083/03/NL/SFe), NASA program of the stratospheric balloons and RFBR grants (05-08-18277, 12-08-00970 and 14-08-96011).

G0.3-0013-18 STUDY OF MASS LOSS OF POLYMERIC COMPOSITES IN VACUUM UNDER SPACE RADIATIONS

Rashid Khasanshin, rhkhas@mail.ru JSC "Kompozit", Korolev,, Russia

Polymeric materials find ever-widening application in space technique. This is tied with the simplicity of producing the polymeric-based composites with the predetermined set of properties. However, these materials in space become the sources of volatile products that increase density of spacecraft outer atmosphere that undermines on serviceability of the on-board equipment. Therefore, study of mass loss of spacecraft materials in service conditions is a vital task. Polymeric composites are often used as thermal control coatings (TCC), which are subjected to maximum radiation exposure in service. It is known that irradiation of a PC is accompanied by intense gas formation but evolution of volatile products (VP) through the material-vacuum surface is limited by diffusion. Well-developed surface together with little thickness of a TCC film facilitate migration of radiolysis products to free coating surface. In this case outgassing and destruction of material augment permeability of the film, accelerate migration processes and make them easier. This work is devoted to studying action of separate (electron, proton, and electromagnetic), paired, and the whole set of radiations on mass loss of a pattern material in vacuum. The primary focus was on studying and interpretation of synergistic effects appearing in the course of mass loss of the pattern materials EKOM-1 and EKOM-2 polymeric composites, the widely used spacecraft TCC. Irradiation was made by 20-40-keV electrons and protons and electromagnetic radiation in vacuum chamber of the UV-1/2 test facility. It was found that parameters characterizing the synergistic effects of mass loss of the material for fixed conditions of electron-proton and combined radiations are the functions of irradiation time. To interpret the experimental data, a physical-mathematical model of mass loss of polymeric materials in vacuum was proposed. The obtained data can be explained by diffusion fluxes associated with the gradient of concentration of radiolysis products and increase of gas permeability of a material under radiation.

G0.3-0014-18 ELECTROSTATIC DISCHARGES UNDER SEPARATE AND COMBINED RADIATION OF SPACECRAFT SOLAR ARRAY PROTECTIVE GLASSES BY ELECTRONS AND PROTONS

Rashid Khasanshin, rhkhas@mail.ru JSC "Kompozit", Korolev,, Russia Lev Novikov, novikov@sinp.msu.ru

Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia

It is known that irradiation of low-conductive dielectric by charged particles which track lengths do not excess the sample dimensions results in formation of areas with high density charge. The field induced by the accumulated charge can initiate the electrostatic discharge between the charge location area and surface of the dielectric. The study of electrostatic discharges in low conductive dielectrics under radiation is essential both from a scientific point of view and for the solution of applied problems. In particular, interaction of a spacecraft with ambient plasma causes accumulation of electric charges on its surface producing, as a consequence, electric potential between the spacecraft surface and the plasma. Initiation conditions and features of evolution of electrostatic discharges on surface of K-208 and CMG glass used as the protective covering of spacecraft solar arrays, under combined irradiation by electrons and protons in vacuum were studied in this work. Energies of electrons and protons were 20- 40 keV and 20 keV respectively. The particles beam current was varied within 1.5 -200 nA. Surfaces of irradiated samples were studied by AFM methods. It was shown that changes of sample morphology due to radiation are determined by radiation annealing of defects in the near-surface layer of the glass, mass transfer processes accompanying by forming various structures on its surface and electrostatic discharges, surface modification having depended on radiation type and intensity. It was ascertained that microprotrusions either presenting on glass surface due to the process of its fabrication or appeared at the early stage of irradiation promotes discharge development. Changes of glass surface morphology due to radiation, as was shown, are stipulated both radiation annealing and electrostatic discharges, surface modification having depended on radiation type and intensity. The observed differences in the development of discharges in the K-208 and CMG glass are attributed to the fact that the latter has a magnesium fluoride coating and exhibits a higher conductivity and a lower concentration of defects and dislocations that the former.

G0.3-0015-18 SIMULATION OF COSMIC RADIATION DOSE OF A SOLAR CELL AND A LI-ION BATTERY FOR A LOW EARTH ORBIT (LEO) SATELLITE WITH GEANT4 AND COMPARISON FOR TWO DIFFERENT ORBITS

Merve Yiğitoğlu, merve.yigitoglu@cern.ch

Middle East Technical University, Ankara, Turkey

Space radiation environment consists of high energy particles, mostly electrons and protons and devices that operate in space are exposed to these cosmic rays during their operation. This radiation may cause damage to the solid structure of devices and result in operational failure. Therefore the amount of absorbed radiation for each component should be calculated carefully before the production and qualification. Components can be sensitive to the total ionizing dose as well as the single event effects and displacement damage. Solar panels which provide power are one of the most vital parts of a satellite and consist of solar cells which are semiconductor devices and are very sensitive to radiation. Even a short term power cut may result in a total failure of the satellite. Similarly, Li-Ion batteries have a vital importance for satellites because of the energy storage requirements. Radiation can cause a Li-Ion battery to lose storage capacity dramatically. As a result, the operational lifetime or performance of a satellite can be reduced.

In this study, the trapped proton and electrons fluxes and some solar ions fluences from the Space Environment Information System (SPENVIS) program for Sun-synchronous LEO orbits with two different altitudes have been compared. The solar cell and the Li-Ion battery of a specific LEO satellite were analyzed layer by layer for these two different altitudes. The data output from SPENVIS is used as input to a GEANT4 simulation which calculates the energy deposition in the layers of the solar cell and the Li-Ion battery. The results obtained from this simulation are considered in determining the amount of radiation hardness needed for the cells and the batteries and to improve their designs after future testing.

G0.3-0016-18 PACKING AND DEPLOYMENT OF LARGE-SIZE SHELL CONSTRUCTIONS FOR USE IN SPACE ORBIT

Alexey Kondyurin, kond@mailcity.com University of Sydney, Sydney, Australia Sergey Rusakov, rusakov@psu.ru

Perm State University, Perm, Russia Valery Pestrenin, pestreninvm@mail.ru Perm State University, 614000, Russia Irena Pestrenina, ipestrenina@gmail.com Perm State University, Perm, Russia

The raising in Earth orbits of large-size working modules may be used for biological, technological, logistic and other purposes is driven by the exploitation of near-Earth space [1-3]. In the report a possibility of using modules such as large-sized shell structures is considered. It is assumed that the shell is delivered into orbit in the folded state in the spaceship container. Packaging of large-sized compound shell structures (corrugated, cylinder and truncated cone) and their deployment by internal pressure loading are considered. It is believed that the middle surfaces of the composite elements of the shells have a sweep, with which these surfaces coincide in a packed state. The constituent elements of the corrugation are rings, and the cylinder and cone have trapezoidal plates. The considered structural elements, in contrast to pneumatic products made from soft materials (fabric, film), take bending loads. When the structure is deploying (bringing into working shape by internal pressure), resistance to stretching strain and also bending strain, is taken into account. The composite elements are made of carbon fiber with orthotropic or transversely isotropic elastic properties and are stitched together by seams that do not perceive resistance to rotation around the tangent to the seam line. The minimum internal pressure required to deploy a large-size shell structure is determined. Geometrically nonlinear problems of the deformable solid mechanics are solved using the ANSYS engineering software. The dependence of the pressures unfolding the shell to the working shape, on the shell thickness, and the constituent elements number is considered. It is shown that the deployment pressure of large-sized casings is commensurate with the excess pressures of pneumatic structures made of soft materials. It is revealed that the stresses in the shells unfolding into the corrugation can reach critical values, while the stresses in cylinder and the truncated cone are insignificant. The formulation and solution of the problem of the thermodynamic state of the injected gas is given for quasi static shell loading by internal pressure. It is established that at the beginning of the deployment the gas is cooled depending on the composition at 50-80

° C, subsequently its temperature grows to the injection temperature. The results show the possibility of manufacturing large-size pneumatic structures for space exploitation. The study is supported by the grants RFFI 16-48-590844, 17-41-590649, and subsidy (grant) of Perm Krai (Agreement C-26/793 of December 21, 2017).

Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia

The spacecraft charging is an important factor which gives rise to anomalies in the operation of on-board electronic equipment and damages spacecraft dielectric materials. Two types of spacecraft charging can be considered separately: surface charging, which is caused by hot magnetosphere plasma with electron and proton energy of E 0.1-50 keV, and internal charging of dielectrics due to the influence of electrons of the Earth's radiation belts with energy of E 1- 10 MeV. In general, the main consequence of spacecraft charging are electrostatic discharges that create electromagnetic noise leading to malfunction of on-board electronics and damage spacecraft materials. To study processes of spacecraft charging, computer modeling as well as ground-based and in-flight experiments are carried out.

This paper discusses methods of mathematical modeling of spacecraft charging and laboratory experiments to study surface and internal charging, including investigations of electrostatic discharges, and presents the information related to in-flight observations of charging effects on Russian spacecraft in the low-Earth orbits (LEO) and the geostationary orbit (GEO). The Russian spacecraft charging model, COULOMB 2, which was developed in SINP MSU to study surface charging in LEO and GEO, is described, and some calculated electric potential distributions over spacecraft surfaces of GEO and LEO spacecraft under different space conditions are given. The main directions of further research in this field are outlined.

G0.3-0018-18 EFFECTS OF COMBINED IRRADIATION OF 500 KEV PROTONS AND ATOMIC OXYGEN ON POLYIMIDE FILMS

Lev Novikov, novikov@sinp.msu.ru

Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia Ekaterina Voronina, voroninaen@nsrd.sinp.msu.ru

Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia

Polyimide films are widely used on the external surface of spacecraft. The space ionizing radiation can alter the mechanical, optical and electrical properties of polyimide. For example, it is well known that 20-100 keV proton irradiation causes breaking of chemical bonds and destruction of the surface layer in polyimide, deterioration of its optical properties, etc. In lowEarth orbits serious danger for polymeric materials is atomic oxygen of the upper atmosphere of the Earth, which is the main component in the range of heights of 200-800 km. Due to the orbital spacecraft velocity, the collision energy of oxygen atoms with the surface (5 eV) enhances their reactivity and opens additional pathways of their reaction with near-surface layers of materials. Hyperthermal O atom flow causes erosion of the polyimide surface by breaking chemical bonds and forming of volatiles products (primarily, CO and CO2), which leads to mass losses and degradation of material properties.

Combined effect of protons and oxygen plasma is expected to enhance the destruction of polyimide surface layers. This paper describes experimental investigation of polyimide films sequential irradiation by protons and atomic oxygen. The samples were irradiated by 500 keV protons at fluences of 1014-1016 cm−2 produced with SINP cascade generator KG-500 and 5-20

eV neutral oxygen atoms at fluence of 1020 cm-2 generated by SINP magnetoplasmodynamics accelerator. The comparative analysis of polyimide optical transmission spectra, Raman and XPS spectra obtained at different stages of the sample irradiation, data on mass loss due to polyimide erosion by atomic oxygen are given. The report also presents the results of computer simulation of protons and oxygen atoms interaction with polyimide, and a comparison of the experimental and calculated data.

G0.3-0019-18 COMPUTER SIMULATION OF REACTIONS OF HYPERTHERMAL O ATOMS WITH POLYIMIDE

Ekaterina Voronina, voroninaen@nsrd.sinp.msu.ru

Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia Lev Novikov, novikov@sinp.msu.ru

Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia

Atomic oxygen (AO) of the upper Earth's atmosphere is one of the most important space factors that can cause degradation of materials on the external surface spacecraft in the low-Earth orbits. AO impact leading to erosion and mass losses of materials is well studied experimentally for most spacecraft materials, however, elementary physical and chemical processes occurring in polymers under AO attack are not completely understood. This paper presents some results of computer simulation of chemical reactions between hyperthermal O atoms and polyimide chains, carried out with ab initio density functional theory (DFT) and semi-empirical density functional based tight-binding (DFTB) methods on Lomonosov supercomputer of MSU. The study focuses on reactions with formation of volatile products like 2, ,. The computer simulation demonstrated that the probability of volatile species elimination depends on sites of O atom attacks. For reactions with CO2 and CO formation that give the main contribution to mass losses of polymers the highest probability is obtained for the cases when an incident O atom trajectory goes in the vicinity of an imide group. The characteristic time of direct reactions of hyperthermal O atoms with polyimide is 20-500 fs. The results of the mathematical simulation are in good agreement with the available experimental data and can be used to evaluate the polyimide durability to atomic oxygen effects of in near-Earth space.

The MICROSCOPE space mission tests the Weak Equivalence Principle (WEP), which states that the acceleration of a test object falling in an external gravitational field is independent of its mass and internal composition. The Equivalence Principle is at the basis of General Relativity, which has passed all experimental tests, including on-ground WEP tests whose record accuracy, reached in 2012 with torsion-balance experiments, is a few 10^{-13}. However, General Relativity does not allow the unification of the gravitation with the three other fundamental interactions.

Most alternative theories for the unification predict an apparent violation of the WEP. The accuracy of the on-ground tests of the WEP is limited by the numerous perturbations in the terrestrial environment. Being performed in space, the MICROSCOPE experiment overcomes these limitations and aims to test the WEP with an accuracy of 10^{-15} never reached before.

The MICROSCOPE drag-free microsatellite, developed by CNES, was launched in April 2016 and is currently quasi-circularly orbiting the Earth at a mean altitude of 710 km. It embarks a differential electrostatic accelerometer developed by ONERA and composed of two cylindrical test masses in electrostatic levitation made of different materials. Control loops with electrostatic actuation keep the two masses concentric, so that they both are submitted to the same gravitational field. The drag-free system compensates for external non-gravitational perturbations, thus allowing the satellite to follow the free-fall motion of the masses.

The electrostatic acceleration applied to the masses to maintain them relatively motionless are measured and will demonstrate a violation of the WEP if found unequal.

MICROSCOPE first results, based on only 1/15th of the scientific data collected during the mission, have already improved by one order of magnitude the accuracy of the previous test of the WEP. They are being completed and analyzed.

After a brief presentation of the MICROSCOPE mission and its payload, the presentation will focus on the data analysis method leading to this result as well as the determination of the systematic and stochastic error. The measurement is indeed impacted by systematic environmental and instrumental errors, which are calibrated in-orbit during dedicated sessions. Other perturbations must be considered during the data analysis: in the case of missing data, spectral leakage effects increase the noise of the measurement. Specific methods have thus been adapted and developed in order to extract the Equivalence Principle violation parameter with minimal numerical perturbations. The on-going process to further improve the accuracy and tend toward the mission objective will be presented: the systematic error should be reduced by a better knowledge of the instrument in order to correct the systematics, while the random error can be reduced by cumulating data.

H0.1-0005-18 SPACE BORNE BOSE-EINSTEIN CONDENSATION FOR PRECISION INTERFEROMETRY

Wolfgang Ertmer, ertmer@iqo.uni-hannover.de Leibniz Universität Hannover, Hannover, Germany QUANTUS-MAIUS Team

QUANTUS-MAIUS Team

On January 23rd 2017 the first Bose-Einstein Condensate (BEC) in Space has been created onboard the sounding rocket mission MAIUS-1. The successful operation of the atom-chip based BEC source marks a major advancement in the effort of performing matter wave interferometry in weightless in space vehicles. Thanks to the high-flux source, experiments could be performed during the microgravity phase of the flight, which lasted six minutes. The experiments served to characterize the creation and features of the space BECs: the transition between a thermal ensemble and a BEC, the free evolution of BECs, their coherence and state preparation. In addition the creation of cold atomic clouds in highly dynamic environments was observed during the launch and ascend of the rocket. There will be two follow-up missions planned which will include dual-species atom interferometry using Rubidium-87 and Potassium-41. Thus, MAIUS-1 opens a new path towards space born inertial sensing employing atom interferometers with high accuracy and unprecedented sensitivity. In the recent past several missions have been proposed ranging from a test of the universality of free fall using a dual-species atom interferometer for earth observation. Due to their small initial size and low expansion rates BECs are the ideal source for such an interferometric measurement in space. This research has been funded by the German Space Agency DLR under grant number DLR 50WP1435.

H0.1-0007-18 ON THE INTERFACE OF QUANTUM AND GRAVITY

Wolfgang Schleich, wolfgang.schleich@uni-ulm.de Universität Ulm, Ulm, Germany

Quantum mechanics and general relativity constitute two major pillars of modern physics. Although their predictions have been tested in numerous experiments we still have not been able to completely crasp their consequences nor put to use their subtleties to the fullest extent. Indeed, even today the measurement problem, the application of entanglement to technology and the unification of the two theories illustrate in a striking way this fact by representing active fields of research.

In the present lecture we focus on the last issue and discuss three questions located on the interface between quantum and gravity: (i) inertial and gravitational mass in quantum mechanics, (ii) proper time in atom interferometry, and (iii) quantum clocks. We argue that the answers to these questions will shine some light on why general relativity and quantum mechanics still resist their unification. Moreover, the recent experiments with cold atoms in space in the framework of the MAIUS-rocket mission provide an excellent testing ground for these ideas.

H0.1-0009-18 EARTH OBSERVATION BASED ON QUANTUM OPTICS AND RELATIVITY

Jürgen Müller, mueller@ife.uni-hannover.de University of Hannover, Hannover, Germany

Novel developments in quantum physics can excellently be used for geodetic applications, where new technologies and concepts lead to enhanced capabilities for satellite geodesy and terrestrial gravity sensing. We will focus on two new concepts: one applies atom interferometry for (satellite) gravimetry, the other uses clock networks for determining potential differences at the Earth surface. In the first case, gravity anomalies are obtained by observing free-falling atoms (quantum gravimetry), such technique can also be applied for future gradiometric measurements in space. In the second case according to Einstein's theory of general relativity, frequency comparisons of highly precise optical clocks connected by fibres give access to differences of the gravity potential (relativistic geodesy). In addition, laser interferometry between test masses in space with nanometer accuracy belongs to these novel concepts. For the latter, technology developed for gravitational wave detection and successfully tested in the LISA/pathfinder mission is being prepared for geodetic measurements. Those concepts are recently elaborated in close cooperation between physicists and geodesists at the University of Hannover under the umbrella of the Collaborative Research Center SFB 1128 "Relativistic geodesy and gravimetry with quantum sensors (geo-Q)". We will illustrate where geodesy will potentially benefit from these novel developments and show future perspectives. Examples are the direct determination of physical height differences over large distances and the unification of height systems. We will also underline the strengths of the new methods for Earth observation, where local and global mass variations can be observed with unforeseen accuracy and resolution, for a multitude of geoscience applications.

H0.1-0010-18 ESA'S STUDIES OF NEXT GENERATION GRAVITY MISSION CONCEPTS

Olivier Carraz, olivier.carraz@esa.int ESA ESTEC, Noordwijk, Netherlands

Christian Siemes, christian.siemes@esa.int ESA-ESTEC, Noordwijk, Netherlands Luca Massotti, luca.massotti@esa.int ESA-ESTEC, Noordwijk, Netherlands

Roger Haagmans, roger.haagmans@esa.int ESA, Noordwijk, Netherlands

Pierluigi Silvestrin, pierluigi.silvestrin@esa.int ESA-ESTEC, Noordwijk, Netherlands

The presentation addresses the preparatory studies of future ESA mission concepts devoted to improve our understanding of the Earth's mass transport phenomena causing temporal variations in the gravity field, at different temporal and spatial scales, due to ice mass changes of ice sheets and glaciers, continental water cycles, ocean masses dynamics and solid-earth deformations.

The ESA initiatives started in 2003 with a study on observation techniques for solid Earth missions and continued through several studies focussing on the satellite system, technology development for propulsion and distance metrology, preferred mission concepts, the attitude and orbit control system, as well as the optimization of the satellite constellation. These activities received precious inputs from the GOCE, GRACE and GRACE-FO missions.

The latest results concerning the preferred satellite architectures and constellations, payload design and estimated science performance will be presented as well as remaining open issues for future concepts.

H0.1-0011-18 THE GERMAN MICROGRAVITY PROGRAM IN PHYSICAL SCIENCES

Thomas Driebe, thomas.driebe@dlr.de

DLR - German Aerospace Center, Bonn, Germany

As German Space Agency, the DLR Space Administration manages the German Space Program. This program integrates the German participation in the ESA programs, the activities in the National Program as well as the RD activities of the DLR research institutes. One core element of the German space activities is called Research under Space Conditions. This program covers life and physical sciences experiments utilizing space conditions such as weightlessness and space radiation and is based on the provision of microgravity platforms, the development of flight hardware, and the preparation, execution, and analysis of experiments in microgravity.

The German Physical Sciences Program deals with gravity-dependent effects on physical and chemical processes and covers the research disciplines material sciences, fundamental physics, soft matter, and the physics of fluids and combustion processes. The main program goal is to gain scientific knowledge by addressing fundamental questions in physics, to foster new technological developments and to reveal new application potentials by both fundamental as well as application-oriented research.

In this talk, major German research topics and on-going facility developments for the ISS and other microgravity platforms such as sounding rockets, parabolic flights and the Bremen drop tower will be presented, and the important role of international co-operations will be outlined. Results of some microgravity experiments and the status of the program implementation will be discussed.

H0.1-0012-18 SHADOW SIZES AROUND BLACK HOLES AS POSSIBLE SIGNATURES OF HORNDESKI GRAVITY

Silesian University in Opava, Opava, Czech Republic

The classical general relativity (GR) is remarkably confirmed in different astronomical tests. Recently, gravitational waves have been detected from binary black holes and binary neutron star systems. Moreover, constraints on alternative theories of gravity have been obtained, so that graviton mass bounds have been found such as mg < 7.7 $10^{-}2^{3}$ eV. It means that theories of massive gravity, if they are realized in nature, have to be very close to GR. In spite of a great progress of GR now there exist a number of alternative theories of gravity, such as f (R) theories, theories of massive gravity, scalar-tensor theories etc. Scalar-tensor theories proposed by Hordeski are among popular alternatives for classical general relativity (GR). There are no-hair theorems in such a theory, however, there exist hairy black hole solutions under some assumptions. for instantce, Babichev et al. (2017) constructed a set of hairy static black hole solutions (for quartic Hordeski Lagrangian of scalar-tensor theory of gravity). We show that analytical expressions for shadow size obtained for Reissner – Nordström metric (with electric and tidal charges) may be used to compare theoretical predictions and observations for asymptotically flat black holes with a scalar hair which mimics an electric charge. We present analytical expressions for shadow size for static black hole solutions with de-Sitter and antide-Sitter asymptotics. The relations could be used for comparison of the theoretical models with observational data obtained with the Event Horizon Telescope for the black hole at the Galactic Center or in galaxy M87.

H0.1-0013-18 AN OVERVIEW OF THE COLD ATOM LAB MISSION

Robert Thompson, robert.j.thompson@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States

Microgravity offers a wealth of advantages for studies of ultra-cold atomic gases and their applications. These include the ability to achieve exceptionally low temperatures via expansion into very weak traps, which don't need to be supported against gravity and the ability to achieve very long interaction times with samples that have been released from traps. The Cold Atom Laboratory (CAL) will be a flexible, multi-user ultra-cold atom facility that will enable the precise study of quantum gases at effective temperatures well below the coldest achievable on Earth. CAL will launch to the International Space Station in May 2018, giving scientists a unique window into the quantum world.

CAL is supported by SLPS and ISS-PO. Jet Propulsion Laboratory, California Institute of Technology

We will present recent developments in the context of the mission proposal MAQRO and a potential future space platform for testing quantum physics with massive objects. In 2017, the European Space Agency (ESA) selected tests of the quantum to classical transition and quantum decoherence as a topic of interest in the context of its call for New Science Ideas. During the first half of 2018, ESA will perform a study of this topic at its Concurrent Design Facility (CDF). In this presentation, we will present the results from this CDF study and provide an overview of on-going and future efforts towards realizing MAQRO or similar missions for tests of macrosopic quantum physics in space, to develop enabling technology, and to perform proof-of-principle experiments towards that goal.

H0.1-0015-18 NANOHERTZ-FREQUENCY GRAVITATIONAL WAVE ASTROPHYSICS WITH PULSAR TIMING ARRAYS

Stephen Taylor, srtaylor@caltech.edu

California Institute of Technology, Pasadena, California, United States

The gravitational wave (GW) landscape is expansive and ripe for discovery, offering unparalleled insights into a plethora of astrophysical systems. While the present and future successes of LIGO-Virgo and LISA rely on precision control of mechanical systems, Pulsar Timing Arrays (PTAs) are GW detectors that are themselves forged out of extreme astrophysical objects. PTAs exploit the exquisite rotational stability of millisecond pulsars to establish a Galactic network of clocks, capable of registering the correlated influence of passing extragalactic GWs. At nanohertz frequencies (where PTAs are sensitive) the most promising target is the ensemble signal of many inspiraling supermassive black-hole (SMBH) binary systems throughout the Universe. A detection of this signal (or even a stringent constraint) can teach us much about the merger history of massive galaxies, the dynamical environments of galactic cores, and the scaling relationships between massive black holes and their host galaxies. I will review the latest methodological and technological advances toward GW detection in the nanohertz band, whose rogues gallery of signals includes stochastic backgrounds of astrophysical (and potentially cosmological) origin, bright resolvable SMBH binaries, and memory bursts. I will also discuss the unique science accessible to PTAs beyond GWs, including new insights into Solar System dynamics as a by-product of PTA searches, and detailed characterization of the ionized interstellar medium.

H0.1-0016-18 GROUND-BASED GRAVITATIONAL WAVE DETECTORS AND THE SYNERGY WITH LISA

David Shoemaker, dhs@mit.edu

Massachusetts Institute of Technology, Cambridge, MA, USA, Wyoming, United States

Ground-based gravitational-wave observatories have just recently succeeded in detecting gravitationalwave sources from astrophysical events. In particular, the realization of multi-messenger astronomy including gravitational waves via the GW170817 neutron-star merger, observed with many electromagnetic observatories, has demonstrated the potential for this field. Groundbased instruments will be evolving in the coming years, and the instruments operating simultaneously with LISA will have capabilities to see further, and with higher signal-to-noise, many gravitational-wave sources. The is the high likelihood of multi-band detections - binaries seen first in LISA and then years later in ground-based detectors and EM observatories allowing unprecedented detailed characterization of these systems. A brief introduction to present instruments and results, followed by our roadmap for the future of the ground-based gravitational-wave observatories, will be given.

H0.2-0002-18 DETECTION OF CHAMELEON DARK ENERGY IN SPACE

Sheng-wey Chiow, chiow@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Nan Yu, nan.yu@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Dark energy constitutes 70% of the universe, which explains the observed accelerated expansion of the universe. While little is known about the nature of dark energy, it is conjectured that it is a new scalar field that interacts normal matter at the cosmological scale. Due to the lack of any evidence of a violation from general relativity in the solar system so far, screening mechanisms are implemented in all dark energy scalar field models. Possible scalar fields are described in the forms of chameleon, symmetron, and galileon models. Recently, cold atom experiments in laboratory have contributed significantly on the constraints of chameleon and symmetron parameters. These experiments are currently limited by the knowledge of the Newtonian gravity of the test masses, and eventually by the uncertainty of the gravitational constant G.

In this talk, we will describe an experimental concept of using atom interferometry in microgravity to improve the sensitivity to chameleon and symmetron by orders of magnitude than the state-of-the-art, without relying on future precision measurements of G. In this scheme, spatially modulated chameleon forces will be induced at a specific frequency with a periodic geometry of the local mass distribution. Gravitational forces of the mass structure will be minimized at the spatial frequency using trim masses. Multiloop atom interferometers will measure the periodic acceleration while largely reject forces at other spatial frequencies. We will present the dark energy force calculation and design analysis, and will show that regions of interest of the chameleon parameters will be tested at high confidence levels, and all systematics will be below the anticipated signal size.

This research was carried out at the Jet Propulsion Laboratory, California Institute of Technology, under a contract with the National Aeronautics and Space Administration.

H0.2-0003-18 ELECTROMAGNETIC CASCADE MASQUERADE: ASTROPHYSICAL BACKGROUNDS FOR GAMMA-ALP OSCILLATION SEARCHES USING EXTREME TEV BLAZAR SPECTRA

Timur Dzhatdoev, timur1606@gmail.com

Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia

Extreme TeV blazars are active galactic nuclei with spectral energy distribution peaked at an energy of 1 TeV or above. These sources, while still rare in currently available surveys of space and ground-based gamma-ray telescopes, nevertheless play an extraordinary important role in extragalactic gamma-ray propagation studies. Some works report the existence of the "pair-production anomaly", an apparent excess of observed gamma-rays in the highest energy bins, where the optical depth of the γγ pair production process exceeds unity. This anomaly is frequently interpreted as an evidence for gamma-axion-like particle (ALP) oscillations. We inquire whether such an anomaly may be explained by any conventional astrophysical process. We show that the development of electromagnetic (EM) cascades in the intergalactic volume may potentially provide a strong source of background for gamma-ALP searches in extreme TeV blazar spectra. We provide detailed fits for a number of extreme TeV blazar spectra that were measured by atmospheric Cherenkov telescopes in the past, and make detailed predictions that will allow to verify/falsify the proposed model (see Sect. 4 of [AA, 603, A59 (2017)] for more details).

H0.2-0004-18 EXCAVATING BLACK HOLE CONTINUUM SPECTRUM: POSSIBLE SIGNATURES OF SCALAR HAIRS AND OF HIGHER DIMENSIONS

Indrani Banerjee, tpib@iacs.res.in

Indian Association for the Cultivation of Science, Kolkata, India
Sumanta Chakraborty, tpsc@iacs.res.in

Indian Association for the Cultivation of Science, Kolkata, India
Soumitra SenGupta, tpssg@iacs.res.in

Indian Association for the Cultivation of Science, Kolkata, India

Continuum spectrum from black hole accretion disc holds enormous information regarding the strong gravity regime around the black hole and hence about the nature of gravitational interaction in extreme situations. Since in such strong gravity regime the dynamics of gravity should be modified from the Einstein-Hilbert one, its effect should be imprinted on the continuum spectrum originating from the black hole accretion. To explore the effects of these alternative theories on the black hole continuum spectrum in an explicit manner, we have discussed three alternative gravitational models having their origin in three distinct paradigms-(a) higher dimensions, (b) higher curvature gravity, and (c) generalized Horndeski theories. All of them can have signatures sculptured on the black hole continuum spectrum, distinct from the standard general relativistic scenario. Interestingly all these models exhibit black hole solutions with tidal charge parameter which in these alternative gravity scenarios can become negative, in sharp contrast with the Reissner-Nordström black hole. Using the observational data of optical luminosity for eighty Palomar Green quasars we have illustrated that the difference between the theoretical estimates and the observational results gets minimized for negative values of the tidal charge parameter. As a quantitative estimate of this result we concentrate on several error estimators, including reduced $\chi2$, Nash-Sutcliffe efficiency, index of agreement etc. Remarkably, all of them indicates a negative value of the tidal charge parameter, signaling the possibility of higher dimensions as well as scalar charge at play in those high gravity regimes.

H0.2-0005-18 DETECTING THE ANGULAR MOMENTUM OF THE GALACTIC DARK HALO

Angelo Tartaglia, angelo.tartaglia@polito.it Politecnico di Torino, Torino, Italy

David Lucchesi, david.lucchesi@iaps.inaf.it IAPS/INAF, Tor Vergata - Roma, Italy Enrico C. Lorenzini, enrico.lorenzini@unipd.it Universita' di Padova, Padova, Italy

Giuseppe Pucacco, giuseppe.pucacco@roma2.infn.it Università di Tor Vergata, Roma, Italy

Matteo Luca Ruggiero, matteo.ruggiero@polito.it Politecnico di Torino, Torino, Italy

It is well known that general relativity predicts the presence of a gravito-magnetic component of the gravitational interaction induced by a rotating mass. Such contribution has been verified for the angular momentum of the earth. Here we present a proposal to measure the gravitomagnetism of the sun and possibly of the dark galactic halo currently assumed to incorporate our galaxy (as well as the others). The experimental approach is based on the fully relativistic version of the Sagnac effect. When an electromagnetic signal is led to travel along a spacely closed path and the material device with which the beam interacts rotates with respect to the "fixed stars", the time of flight for a complete turn depends on the direction of rotation. The same happens when the loop is immersed in a gravito-magnetic field, even if it is not rotating: this is the typical Lense-Thirring drag. In this case the asymmetry in the time of flight is proportional to the projection of the angular momentum of the main body onto an axis perpendicular to the plane of the loop. This behavior is the basis of measurements using ringlasers. Going to space and having the sun and its angular momentum as a target, the implementation of a "Sagnac" approach is still possible but the size of the closed circuit must be at the scale of the orbit of the earth. Furthermore the geometry of the loop needs be reasonably stable. The solution we propose is to exploit the Lagrange points of the sun-earth system. The configuration of the Lagrange points is indeed stable (if not strictly rigid) and moves around together with the earth. Considering as an example the triangle L2-L_4-L_5 (according to the standard enumeration of the points) the expected time of flight asymmetry due to the angular momentum of the sun is approximately 4x10−13 s. Other combinations of the L-points are of course possible, but the order of magnitude of the effect is more or less the same. In this case the technique cannot be the same as for ringlasers, rather a local measurement of the proper time interval between the arrivals of "right" and "left" signals is required. The same approach lends also an interesting opportunity to verify the presence or absence of an effect originating from the dark halo of our galaxy. In fact if the halo is there and it interacts gravitationally with the visible matter of the Milky Way, it has also to rotate with the same peripheral speed as the stars. If, then, the halo is much more massive than the baryonic matter its angular momentum too has to be large and, if general relativity is true, it must produce a gravito-magnetic field. To work out numbers requires the knowledge or reasonable guesses about the mass distribution of the dark matter, but the very nature of that matter is unimportant and the scale of the halo and its total mass tell us that the effect could be non-negligible. An advantage of the Sagnac-like approach, worth mentioning, is that it neutralizes the dominant effect of the gravito-electric component of the field, since the latter has no chiral symmetry.

H0.2-0006-18 DARK MATTER SEARCHES WITH HAWC

Tolga Yapici, tyapici@ur.rochester.edu

University of Rochester, Rochester, New York, United States

The High Altitude Water Cherenkov (HAWC) Observatory is an extensive air shower array sensitive to gamma rays between 500 GeV - 100 TeV. TeV photons provide unique tests of fundamental physics phenomena, such as dark matter annihilation and decay. HAWC is capable of performing indirect dark matter searches in a mass range that is inaccessible to most other experiments. For such searches, one promising class of objects are dwarf spheroidal galaxies, which are expected to have few astrophysical gamma rays but large dark matter content. In addition, we consider the Milky Way halo, the M31 galaxy and the Virgo Cluster, because of the expected flux boost due to the substructure of the main dark matter halo. We present limits on the dark matter annihilation cross-section and decay lifetime from 15 dwarf spheroidal galaxies within the HAWC field of view, the Milky Way halo, the M31 galaxy and the Virgo Cluster.

H0.2-0008-18 SECOND-ORDER COSMOLOGICAL PERTURBATIONS ENGENDERED BY POINT-LIKE MASSES

Maxim Eingorn, maxim.eingorn@gmail.com

North Carolina Central University, Durham, North Carolina, United States Ruslan Brilenkov, ruslan.brilenkov@gmail.com

University of Rome Tor Vergata, Rome, Italy

In the ΛCDM framework, presenting nonrelativistic matter inhomogeneities as discrete massive particles, we develop the second-order cosmological perturbation theory. Our approach relies on the weak gravitational field limit. The derived equations for the second-order scalar, vector and tensor metric corrections are suitable at arbitrary distances including regions with nonlinear contrasts of the matter density. We thoroughly verify fulfilment of all Einstein equations as well as self-consistency of order assignments. In addition, we achieve logical positive results in the Minkowski background limit. Feasible investigations of the cosmological backreaction manifestations by means of relativistic simulations are also outlined.

H0.2-0010-18 DARK MATTER PRODUCTION MECHANISMS AND THE DARK COUPLING

Popa Lucia Aurelia, lpopa@spacescience.ro Institute for Space Sciences, 09887123, Romania

Understanding the nature of Dark Matter (DM) and Dark Energy (DE) are the most important problems in modern cosmology, with profound implications for astronomy, high-energy physics and general relativity, that demands ambitious programs at both theoretical and observational level. In particular, the Euclid mission, an ESA scientific mission selected to be launched at the end of 2020, is conceived to probe the physical origin of the DE and DM by using two independent probes, the redshift clustering and the weak lensing tomography of about a billion of galaxies. In this paper we investigate the possibility of the DE coupling with different matter components introducing a new force, the fifth force, mediated by the DE.

We consider the possibility that DE can interact with a fraction of DM particles in the form of sterile neutrinos produced by two complementary mechanisms: neutrino oscillations in a leptonasymmetric Universe and scalar decays interacting with Standard Model particles. The presence of the fifth force changes the stress-energy tensor for all components in the expanding Universe (general covariance requires that the sum of stress-energy tensor components is conserved) modifying the background and perturbations evolution. We will evolve the perturbed Einstein's equations in the expanding Universe and compute the matter and radiation power spectra. Then we will employ a Monte Carlo technique to place constraints on DM particle masses and couplings, the DE properties and the main cosmological parameters, by using the mock Euclid datasets for both spectroscopic and weak lensing surveys, complemented with Planck and other existing cosmological astrophysical observations.

H0.2-0011-18 COSMOLOGICAL CONSTANT CONSTRAINTS FROM OBSERVATION-DERIVED ENERGY CONDITION BOUNDS AND THEIR APPLICATION TO BIMETRIC MASSIVE GRAVITY

Marcio E.S. Alves, alvesmes@gmail.com

UNESP – Univ Estadual Paulista, São José Dos Campos, Brazil Fabio C. Carvalho, fabiocabral@uern.br

Universite catolique de Louvain, Louvain-la-Neuve, Belgium

Among the various possibilities to probe the theory behind the recent accelerated expansion of the universe, the energy conditions (ECs) are of particular interest, since it is possible to confront and constrain the many models, including different theories of gravity, with observational data. In this context, we use the ECs to probe any alternative theory whose extra term acts as a cosmological constant. For this purpose, we apply a model-independent approach to reconstruct the recent expansion of the universe. Using Type Ia supernova, baryon acoustic oscillations and cosmic-chronometer data, we perform a Markov Chain Monte Carlo analysis to put constraints on the effective cosmological constant Ω^0. By imposing that the cosmological constant is the only component that possibly violates the ECs, we derive lower and upper bounds for its value. For instance, we obtain that 0.59 $< \Omega^0$

< 0.91 and $0.40 < \Omega^0$

< 0.93

within, respectively, 1σ and 3σ confidence levels. In addition, about 30% of the posterior distribution is incompatible with a cosmological constant, showing that this method can potentially rule it out as a mechanism for the accelerated expansion. We also study the consequence of these constraints for two particular formulations of the bimetric massive gravity. Namely, we consider the Visser's theory and the Hassan and Roses's massive gravity by choosing a background metric such that both theories mimic General Relativity with a cosmological constant.

Using the Ω^0 observational bounds along with the upper bounds on the graviton mass we obtain constraints on the parameter spaces of both theories.

H0.2-0012-18 CONSTRAINING A COSMOLOGICAL CONSTANT-TYPE PARAMETER WITH PULSAR TIMING IN THE GALACTIC CENTER: PERSPECTIVES

Lorenzo Iorio, lorenzo.iorio@libero.it MIUR-Istruzione, Bari, Italy

Independent tests aiming to constrain the value of the cosmological constant Λ are usually difficult because of its extreme smallness (Λ 1 10^{-5}2 m−2). Bounds on it from Solar System orbital motions determined with spacecraft tracking are currently at the 10^{-43} 10^{-44} m−2

level, but they may turn out to be somewhat optimistic since Λ has not yet been explicitly modeled in the planetary data reductions. Accurate $\sigma\tau p$ 1 10 s timing of expected pulsars orbiting the Black Hole at the Galactic Center, preferably along highly eccentric and wide orbits, might, at least in principle, improve the planetary constraints by several orders of magnitude. By assuming for such a hypothetical pulsar the orbit of, say, the very far star S85, characterized by an eccentricity as large as e = 0.78 and an orbital period as long as Pb = 3580 2550 yr, the cosmological constant would induce an instantaneous timing orbital shift $\Delta\delta\tau\ {}^{\Lambda}E$ as large as just ~ 1 − 10 s for some given values of its eccentric anomaly *E* at different epochs. By looking at the average time shift per orbit $\Delta\delta\tau$ of closer pulsars, a S2-like orbital configuration with e = 0.8839, = 16 yr would allow to obtain an upper bound as little as $|\Lambda|$ 9 × 10^{-47} m−2. Our results can be easily extended to modified models of gravity using Λ−type parameters.

H0.2-0013-18 DARK ENERGY BEYOND Z GREATER THAN 1 WITH SUPERNOVAE

Pilar Ruiz-Lapuente, pilar@icc.ub.edu

IFF (CSIC) and ICCUB, Barcelona, Spain

We will review the status of dark energy determinationa at z > 1 with the ongoing very high redshift supernova projects. We will present results obtained and the prospects of using new methods involving supernovae to track the behavior of dark energy at z 20. The role of the new generation of telescopes and new methods will be outlined. We will discuss *Lambda* versus modified gravity as dark energy in view of the evidence so far available.

H0.2-0014-18 EXPECTATIONS FOR GRAVITON MASS CONSTRAINT IMPROVEMENTS WITH FUTURE OBSERVATIONS OF APOCENTER SHIFTS FOR BRIGHT STARS AT THE GALACTIC CENTER

Alexander Zakharov, zakharov@itep.ru

Institute of Theoretical and Experimental Physics, Moscow, Russia Predrag Jovanovic, pjovanovic@aob.rs

Astronomical Observatory Belgrade, Belgrade, Serbia Dusko Borka, dusborka@vinca.rs

Vinca Institute of Nuclear Sciences, University of Belgrade, P.O. Box 522, Belgrade, Serbia Vesna Borka Jovanovic, vborka@vinca.rs

Vinca Institute of Nuclear Sciences, University of Belgrade, P.O. Box 522, Belgrade, Serbia

We analyze a potential to reduce upper bounds for graviton mass with future observational data on trajectories of bright stars near the Galactic Center. Since gravitational potentials are different for these Yukawa gravity and GR, expressions for relativistic advance for these theories potential are different functions on eccentricity and semimajor axis, it gives an opportunity to improve current estimates of graviton mass with future observational facilities. In our considerations of an improvement potential for a graviton mass estimate we adopt a conservative strategy and assume trajectories of bright stars and their apocenter advance will be described with general relativity expressions and it gives opportunities to improve graviton mass constraints. We express expectations to improve current constraints for graviton mass, assuming the GR predictions about apocenter shifts will be confirmed with future observations. We concluded that if future observations of bright star orbits during around fifty years will confirm GR predictions about apocenter shifts of bright star orbits it give an opportunity to constrain a graviton mass at a level around 5 10^{-2^3} eV or slightly better than current estimates obtained with LIGO observations.

H0.2-0015-18 PACZY'NSKI-WITTA POTENTIAL FORM OF SCALARIZED NEUTRON STAR

Partha Pratim Pradhan, pppradhan77@gmail.com

Hiralal Mazumdar Memorial College For Women, Kolkata, India

We present a detailed study of the circular geodesic motion of neutral test particles on the equatorial plane of a spherically symmetric scalarized neutron star (NS). We also examined the stability criteria for massive and massless particles for the said NS by computing the effective potential. We compute the radii of innermost stable circular orbit (ISCO), marginally bound circular orbit (MBCO) and circular photon orbit (CPO). We also derive the Paczyński-Witta potential which is so called the pseudo-Newtonian potential which is very crucial to analyze the accretion disk properties. By analyzing the null circular geodesics we compute the Lyapunov exponent for the scalarized NS. Moreover, we show that in the eikonal limit, the real and imaginary parts of the quasi normal modes (QNM) of the scalarized NS could be determined in terms of the frequency of the NS and instability time scale of the unstable circular photon geodesics.

H0.2-0016-18 THE HIGH RELIABLE CONTROL LOGIC FOR PLASTIC SCINTILLATOR ARRAY DETECTOR OF DARK MATTER PARTICLE EXPLORER

Zhao Hongyun, 627405172@qq.com

Chinese Academy of Sciences, Institute of Modern Physics, LANZHOU, China Hong Su, suhong@impcas.ac.cn

Chinese Academy of Sciences, Institute of Modern Physics, LanZhou, China Jie Liu, j.liu@impcas.ac.cn

Chinese Academy of Sciences, Institute of Modern Physics, LANZHOU, China Jie Kong, kongjie@impcas.ac.cn

Institute of Modern physics, Chinese Academy of Sciences, Lanzhou, China Qian Yi, qianyi@impcas.ac.cn

Chinese Academy of Sciences, Institute of Modern Physics, Lanzhou, China Haibo Yang, yanghaibo@impcas.ac.cn

Chinese Academy of Sciences, Institute of Modern Physics, LANZHOU, China

As one of the payloads of the Dark Matter Particle Explorer (DAMPE) satellite, the new type of plastic scintillator array detector developed by Institute of Modern Physics, Chinese Academy of Sciences (CAS) has two main tasks: first one is to distinguish high energy photons and electrons in near-earth space, second one is to measures the charge of high energy particles with the charge number of 1 26. All these functions are implemented by four front end readout circuit boards, each board contains one FPGA which is configured a set of high reliable control logic developed by us. The control logic is not only used to control multiple ASIC, ADC, DAC chips on front end readout circuit boards to achieve the operations of signal sampling, processing, data caching, and data transmission with upper payload manager which is inspired by valid triggers from trigger generator system, but also to configure, self-calibrate and monitor the whole detector system when received commands from earth. In order to acquire mass reliable particle information with detector in complex electromagnetic radiation environment for a long time, many effective error checking and correcting methods such as odd parity check, accumulate check, CRC check, double backup for the key modules are applied in the control logic. Especially, we design a new TMR error correct solution for RAM to recover some error key parameters from single event upset. When reading key parameters from three backed up RAMs to every raw data processing, the control logic compares three same address bytes at the same time, if it checks out that the value in one byte is different from other two bytes, control logic will update the byte with other two byte's value and then rewrite them to three RAMs using the same address. The satellite was launched at the end of 2015, it has been discriminated over 2.8 billion high-energy particles and completed the energy spectrum of particles with the atomic number of 1 26 in space up to now. It still works well.

H0.2-0017-18 PHENOMENA OF TRANSFER AND THEIR ROLE IN THE UNIVERSE

Evgeny Tsvetkov, tsvetkov@izmiran.ru IZMIRAN, Moscow, Troitsk, Russia Yury Tsvetkov, yurtsvetkov@ya.ru

Pushkov Institute of Terrestrial Magnetism, Ionosphere and Radio wave propagation of Russian Academy of Sciences, Troitsk-Moscow, Russia

Dark matter-IZMIRAN

Evgeny Tsvetkov, Yury Tsvetkov

Neutrinos are postulated as particles of space, whereas quarks are postulated as particles of action. The mechanism of transfer of isospin vectors and time in quark-neutrino interactions is obtained. Overcoming of the separating barrier at the expense of combined symmetry leads to the occurrence of linear spaces and masses of particles, volume and its surface. The role of surface consists in the synchronization of quark-neutrino processes and energy release in the volume, which leads to the Big bang. The channel in which the intermediate complex Zw is dark matter, is proposed for the synthesis of hydrogen. The intrinsic chaos in the complex, responsible for its undetectability, is caused by the absence of the Coulomb field. The mechanisms of origination of the gravitational and Coulomb fields are presented. The asymmetry of matter and antimatter in the universe, as well as its extension, is explained by different directivities of the vectors of isospin and time in matter and antimatter.

H0.2-0020-18 DARK MATTER AND DARK ENERGY AS REMNANTS OF FORMATION OF LARGE SCALE-STRUCTURE IN COSMOLOGICAL MODELS

Abd El Fady Morcos, fadymorcos@hotmail.com

National Research Institute of Astronomy and Geophysics (NRIAG), Cairo, Egypt

The accelerated expansion of our universe needs consistent theoretical models to explain the origin of this acceleration. The cosmological equations describing the formation of large scale structures in a homogeneous and isotropic universe are systems of ordinary differential equations. The formations of large scale structures depend of the cosmological model and the frame work of the theory in which the model has been formed. It is assumed, in this work, that the remnants after the formation of large scale structures (visible universe) represent the dark matter and dark energy. Different cosmological models have been used as Saez and de Juan model, The self-consistent model and the standard model. It is found that the description of dark matter and dark energies as remnants of visible matter depends on a parameter which depends on the model itself.

H0.2-0021-18 TIMELIKE GEODESICS AND THEIR FLOWS AROUND A CHARGED BLACK HOLE SURROUNDED BY QUINTESSENCE

Hemwati Nandan, hnandan@associates.iucaa.in

Gurukula Kangri Vishwavidyalaya, Haridwar, India, Haridwar, India
H Nandan

Hemwati Nandan and Rashmi Uniyal

Quintessence is one among the several candidates to represent the presence of mysterious dark energy in our universe. It would therefore be quite interesting to study the geodesics and their deformations/flows in the background of a Black Hole spacetime surrounded by quintessence to see the effect of dark energy, if any, on the universe locally. We investigate the motion of timelike geodesics in the spacetime of a charged Black Hole surrounded by quintessence. The nature of effective potential along with the structure of the possible orbits for test particles in view of the different values of equation of state parameter for quintessence is discussed. The evolution of timelike geodesic congruences in the background of such black hole spacetime is investigated by solving the Raychaudhuri equations numerically for three kinematical quantities namely the expansion scalar, shear and rotation (or ESR variables) along the geodesic flows. Both the weak and the strong energy conditions for the focusing of timelike geodesic congruences are also analysed. The effect of all the concerned parameters on the evolution of the expansion scalar of geodesic congruences is discussed in the presence and absence of an initial shear and rotation. In general, it is observed that there always exists a critical value of the initial expansion below which we have focusing with smaller values of the normalisation constant and equation of state parameter.

H0.2-0022-18 DARK ENERGY'S ROLE IN GRAVITY

Scott Gordon, sgkiss@aol.com Florida, United States

Gravity had been expressed mathematically by Newton and subsequently modified by Einstein where Newton's Equation represents a special case within General Relativity. So far General Relativity has successfully withstood every experimental test to date but yet this theory of gravity cannot be reconciled with the other known forces of nature.

When Newton first tackled gravity, he left us to solve the question of how two objects seemingly separated by nothing can develop forces on each other. While Einstein answered this question by showing us that objects exist in spacetime, in doing so he left us with two even more puzzling questions:

1) What is the mechanism by which mass bends spacetime? 2) If spacetime has the property of bending, then what is spacetime composed of such that it can bend?

This presentation proposes a solution to these questions by revealing the role dark energy plays in gravity and spacetime.

H0.2-0023-18 ABOUT STABLE, PLAIN, NON-COMPACT MATTER STRUCTURES IN SPACE, AND POSSIBLE REMNANTS IN GALAXIES

Daniel Berdichevsky, dbberdi@yahoo.com Maryland, United States

Daniel Berdichevsky, dbberdi@yahoo.com Maryland, United States

A solution of tenuous matter and magnetic field with its gravitational and magnetic stresses in equilibrium for a simple fully toroidal solution is discussed. (A specific constitutive nature of a steady state of magneto - matter is assumed 1).) This solution, if correct, would contain the fundamentals of nebula structures commonly observed to undergo negligible change in time. See the local molecular cloud currently explored in-situ by VOYAGER 1 with an extension of several kilo-parsecs. This nebula is the first one explored in-situ. From current observations2), it appears to possess the strong presence of an ordered magnetic field, with a mean value <|B|>

= 0.42 nT and a matter density of about 1 - 2 neutrals per cm3 as well as solely one tenth of that in its ionized state. We point out that it is most likely that this state of matter and magnetic field, if located further away, could hide from our observational capabilities, thereby constituting a non-negligible amount of matter and field literally too dark for our abilities to record, i.e. an amount of mass common in nature but dark to our observational skills. 1) Berdichevsky, D., B., On fields and mass constraints for the uniform propagation of magnetic-flux-ropes undergoing isotropic expansion, Solar Phys., 284, 245-259, DOI; 10.1007/s11207-012-0176-5, 2013; Berdichevsky, D., B., and K. Schefers, On the thermodynamics and other constitutive properties of a class of strongly magnetized matter observed in astrophysics, Astrophysical J., 805, 70, 2015. 2)Private communication, Professor D. Gurnnett, (a mean value at the Sun orbit (R 8.5 kpc, and at that orbit for a width of 1 kpc) the presence of 0.98 hadrons per cm3, of which about 80

H0.2-0024-18 UNIFIED COSMOLOGICAL EVOLUTION: WILL THE UNIVERSE DECELERATE IN FUTURE?

Vijay Singh, gtrcosmo@gmail.com

University of Zululand S Africa, Kwa Dlangezwa, South Africa

We propose a new scalar factor for the description of unified cosmological evolution (early inflation, deceleration and present acceleration) for a spatially flat homogeneous and isotropic model in Einstein general relativity. The scale factor leads to the variable equation of state of effective matter that serves all matter (quintessence, relativistic and non-relativistic baryonic matter, stiff matter and cosmological constant) exactly in same manner as it is required for governing the whole cosmological evolution. We depict the statefinder parameters to know the geometrical behaviour of the model. The proposed scalar factor predicts a decelerated epoch of the universe in near future.

H0.3-0001-18 A TEST OF THE RELATIVISTIC GRAVITATIONAL REDHSHIFT WITH GALILEO SATELLITES IN ECCENTRIC ORBITS

Claus Laemmerzahl, claus.laemmerzahl@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany

The European GNSS satellites Galileo 5 and 6 launched in August 2014 have not reached their targeted circular orbit. Instead they have been accidentally injected into an eccentric orbit, due to a failure of the Fregat upper stage. After a series of correction maneuvers their orbits now possess an eccentricity of 0.16 corresponding to a periodic variation of altitude of about 8000 km. While this is of some disadvantage for navigation purposes it offers a unique possibility to perform a precise test of the gravitational redshift as predicted by Einstein's theory of General Relativity.

Thus, with support from the European and German space agencies ESA and DLR we have conducted an analysis of the clock and orbit data from these two satellites. Both satellites are equipped with passive hydrogen maser clocks and Rubidium atomic frequency standards. The modulation that these clocks' frequencies undergo due to the gravitational redshift is approximately $\Delta\nu = 5 \times 10^{-11}$. Here we show that with the clocks onboard of these satellites a test of this general relativistic effect competitive to the most accurate such test, as obtained by the Gravity Probe A (GPA) experiment in 1976, can be achieved. We present an analysis of the available data so far covering approximately 3 years and discuss the main systematic effects we have identified. We finally give a combined statistical and systematic uncertainty and compare our result to that of GPA.

BOOST is a mission that aims at testing the foundations of Special Relativity. The centre piece of BOOST are two frequency references mounted on a satellite. It is dedicated to test the validity of Lorentz invariance by comparing a length reference (i.e. a highly stable optical resonator) with a molecular frequency reference. Similar experiments have been performed on Earth. The current best Earth-bound test has been performed by Tobar et al. [1] in 2010, being able to determine the Kennedy-Thorndike coefficient with an accuracy of 4 10^{-8}. By operating a state-of-the-art Res experimental setup in space for aduration of two years that accuracy could theoretically be improved to 1 10^{-10}. With the restrictions induced by the choice of orbit and the achievable stability of the in-build clocks an improvement of the accuracy in the order of two orders of magnitude is targeted. In addition, BOOST could be employed to observe Lorentz violations These violations are described by the standard model extension (SME) by introducing new terms to the according Lagrangians [2]. The accuracy of some of the associated standard model extension coefficients could be improved by a two orders of magnitude in the fermion sector by executing BOOST.

In addition to the expected scientific outcome, BOOST offers substantial technological progress with impact on other space-based missions, such as LISA, NGGM, STE-QUEST, and future GNSS namely:

Operating optical clocks with unprecedented frequency stability in orbit

High performance thermal stabilization of the optical resonator

Space-qualification for state of the art diode laser technologies

Efficient, space qualified electronics

BOOST is a phase 0 study funded by DLR that is planned to be constructed in a combined effort by participants from the University of Bremen, DLR, the University of Hannover, the Humboldt University Berlin, and Airbus Defence and Space.

A unique test of a cornerstone of general relativity, the gravitational redshift effect, was conducted with the space radio telescope RadioAstron, which has been in a highly eccentric orbit around the Earth since 2011. We probed the flow of time on board, which varies while RadioAstron passes through the varying gravitational potential of the Earth, by recording the spacecraft's downlink signal, which is synchronized to its ultra-stable on-board H-maser, at the ground radio telescopes. The experiment requires us to extract the tiny gravitational redshift signal from the mixture of a number of much larger effects, including those of the nonrelativistic Doppler frequency shift, signal propagation through the Earth's troposphere and ionosphere, higher-order kinematic effects of special relativity, Earth tides, and various instrumental effects. A total of 17 successful experiments were performed while the on-board H-maser was operational. Preliminary data analysis of the data from two experiments gives us a fractional accuracy of the gravitational redshift test of at least 2 10^{-4}, which is comparable to that obtained by Gravity Probe A. We present arguments in favour of the experiment uncertainty currently being dominated by that of the ionospheric frequency shift and discuss prospects for improving the achieved accuracy further.

H0.3-0004-18 TEST MASS CHARGE CONTROL FOR FUNDAMENTAL PHYSICS MISSIONS: PAST, PRESENT AND FUTURE

Peter Wass, pwass@ufl.edu

University of Florida, Gainesville, Florida, United States University of Florida LISA GRS Team

Peter Wass, Stephen Apple, Simon Barke, Andrew Chilton, Myles Clarke, John Conklin, Ben Letson, Guido Mueller, Taiwo Olatunde, Samantha Parry.

Fundamental physics experiments in space often rely on free falling test masses as the reference for gravitational measurements. Electrostatic charge control is a crucial factor in maximizing the sensitivity of these experiments. At the University of Florida we are developing a testmass charge control system as part of a NASA contribution to the LISA gravitational wave observatory. We present the lessons learned from the successful LISA Pathfinder technology demonstration mission, the developments that will improve the robustness of the system for LISA taking advantage of new, semiconductor UV LED light sources and the torsion pendulum facility that provides a ground-based test-bed for new gravitational reference sensor technology and discharging methods.

H0.3-0005-18 SATELLITE-BASED FREE SPACE QUANTUM COMMUNICATION

Jian-Wei Pan, pan@ustc.edu.cn

University of Science and Technology of China, Hefei, China

Quantum information science and technology are emerging and fascinating technologies formed by combining coherent manipulating of individual quantum systems and information technology, which enables secure quantum cryptography (quantum communication), super-fast quantum computing, revealing laws of complex physical systems (quantum simulation), and improving measurement precision (quantum metrology) etc., to beat classical limits. This presentation will highlight a few of our progress along quantum communication, quantum computing, quantum simulation and quantum metrology, based on photons and atoms. For fundamental aspect, one is led to the conception of quantum entanglement when apply quantum superposition principle to multi-party system. The appeared 'spooky action at a distance' phenomena referred by Einstein, is often explained by seemingly reasonable assumptions of "local realism". The inequalities proposed by John Bell and others provide immediate tests for correctness of quantum mechanics. Many efforts are addressing loophole-free tests of Bell inequalities, which tries to close various loopholes, in which some of loopholes are still needed to be addressed including freedom of choice loophole, the collapse locality loophole. Well, the final test is ongoing, many developed ground-breaking technologies for coherent manipulation of quantum systems offers elegant and feasible solutions for satisfying increasing needs of computational power and information security. Based on state-of-the-art fiber technology and rich fiber resources, we have managed to achieve prevailing quantum communication with realistic devices in real-life situation. This constitutes demonstrations by developing decoy state scheme over 100km firerextending its employment in the metropolitan area network, as well as maintaining Measurement Device Independent QKD (MDI-QKD) over 400km. At the meantime, we are also developing practically useful quantum repeaters that combine entanglement swapping, entanglement purification, efficient and long-lived quantum memory for the ultra-long distance quantum communication. Another complementing route is to attain global quantum communication based on satellite. We have spent the past decade in performing systematic ground tests for satellite-based quantum communications. Our efforts finally ensure a successful launch of the Micius satellite. Three major scientific missions have been finished, which includes achieving QKD between satellite and ground station at thousand kilometer scale, achieving satellite-based entanglement distribution between two ground stations separated by a distance of 1200 km, achieving quantum teleportation from ground to satellite over 1400 km. Very recently, using Micius satellite as a trustful relay, the intercontinental QKD between Beijing and Vienna over a distance of 7600 km has also been realized. Future Prospects include building a global quantum communication infrastructure with satellite and fiber networks, quantum computing by employing manipulating coherently more

than 50 qubits to exceed the simulating power of the current best supercomputers and reaching "quantum supremacy", Bell-test experiment with human-observer at a distance on the order of one light-second.

H0.3-0006-18 ISLAND: THE INVERSE SQUARE LAW AND NEWTONIAN DYNAMICS SPACE EXPLORER

Joel Berge, joel.berge@onera.fr ONERA, Chatillon, France

Bruno Christophe, bruno.christophe@onera.fr ONERA, Chatillon, France

Bernard Foulon, bernard.foulon@onera.fr ONERA, Chatillon, France

Emilie Hardy, emilie.hardy@onera.fr ONERA, Châtillon, France

Martin Pernot-Borras, martin.pernot_borras@onera.fr ONERA, Chatillon, France

The Inverse Square Law And Newtonian Dynamics Space Explorer (ISLAND) is a new science concept developed by ONERA and collaborators to test the gravitation inverse square law at small scales and at the largest scales reachable in the Solar System. Its instruments are based on the same (tested and proven) technology as that of missions like LISA Pathfinder and MICROSCOPE.

The small scale experiment will rely on measuring the torque exerted by a massive plate onto an electrostatic pendulum put at the center of gravity of the spacecraft. A gradiometer surrounding it will allow us to finely measure and correct for any gravity gradient in the pendulum's environment; moreover, a drag-free system will ensure that the experiment is done in an optimal gravitational environment.

The large scale experiment will rely on the accurate and precise measurement of the orbit of the spacecraft on its outbound cruise in the Solar System, to the giant planets and beyond, together with the model-independent measurement of non-gravitational accelerations with onboard accelerometers. This will allow us to make sure that we consider only purely gravitational effects when constraining the parameters of modified gravity theories.

Using a Yukawa parameterization to quantify deviations from the Inverse Square Law, we expect ISLAND to improve the current constraints by two orders of magnitude at scales smaller than 100 microns and at scales larger than 6 AU (beyond Jupiter's orbit).

In this talk, I will present and motivate the science case for ISLAND, and show how we can meet the aforementioned improvement of constraints on Yukawa-type deviations from Newton's gravity. The first goal can be reached by using existing concepts of torsion pendulums, that must nevertheless be adapted for the micro-gravity environment. This adaptation can be readily done with, for example, ONERA's experience in ultrasensitive electrostatic accelerometry. The second goal can be reached by using accurate absolute accelerometers, which are able to measure absolute accelerations of 1 pm/s2. Such accelerometers are developed at ONERA: they add a bias rejection system to the more common accelerometers that have flown in GOCE and LISA Pathfinder.

Scientific project GAMMA-400 (Gamma-Astronomy Multifunction Modules Apparatus) relates to the new generation of space observatories intended to perform a search for signatures of dark matter in the cosmic gamma-emission, measurements of characteristics of diffuse gamma-ray emission and gamma-rays from the Sun during periods of solar activity, gamma-ray bursts, extended and point gamma-ray sources, electron/positron and cosmic-ray nuclei fluxes up to TeV energy region by means of GAMMA-400 gamma-telescope represents the core of the scientific complex. For gamma-rays with energy >100 GeV expected energy and angular resolution are 1% and 0.01° respectively and electron/protons rejection factor is 5 10^5. The GAMMA-400 space observatory will be launched at the middle of the next decade on the Navigator service platform designed by Lavochkin Association on the elliptical orbit with following initial parameters: an apogee 300000, a perigee 500 km, a rotation period 7 days and inclination of 51.4°. The GAMMA-400 observatory is expected to operate more than 5 years, reaching an unprecedented sensitivity in the indirect search of dark matter signatures and in the study of the unresolved and unidentified gamma-ray sources.

We present the structure, logic of operation and distinctive features of the system of triggers formation of GAMMA-400 gamma-telescope in the main aperture constitutes the processor system which collects data from the gamma-telescope subsystems and produces summary information used in forming the trigger decision for each event. The system's design is based on the use of state-of-the-art recongurable logic devices and fast data links.

The properties of a prototype of time-of-ight detector of gamma-telescope constitutes of BC-408 scintillator bars of 128 cm long with a cross-section of 10x1 cm^2, viewed from opposite ends by matrixes of silicon photomultipliers SensL MicroFC-60035-SMT were studied using 100- 300 MeV/c positron beam at the test beam of synchrotron "PAKHRA" of Lebedev Physical Institute (Russia). The test results in different configurations show that the time resolution better than 500 ps was reached.

H0.3-0008-18 HIGH PRECISION MODELLING WITH APPLICATION TO THE MICROSCOPE MISSION: NON-GRAVITATIONAL FORCES AND AERONOMY

Benny Rievers, benny.rievers@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany Stefanie Bremer, stefanie.bremer@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany Meike List, meike.list@zarm.uni-bremen.de

ZARM, University of Bremen, Bremen, Germany Hanns Selig, hanns.selig@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany

Claus Laemmerzahl, claus.laemmerzahl@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany

After more than 15 years of planning, developing, building, and testing, the french MICROSCOPE satellite was finally launched on 25th of April 2016. It is the first satellite in a low Earth orbit using a drag-free attitude control system. The payload comprises two differential accelerometers, each containing two test masses. Due to the drag-free system non-gravitational disturbances are canceled thus allowing the test masses to follow a pure gravitational orbit. The goal of the mission is the test of the validity of the weak equivalence principle to an accuracy of 10−15. An initial evaluation of the first science data has already led to an improvement of the Eötvös parameter characterizing the relative difference in test mass free-fall acceleration by one order of magnitude compared to the best values achieved by torsion balance experiments.

However, for calibration purposes and as a means to identify residual couplings between test mass motion and external perturbations simulations of the satellite system and the mission are necessary. We present our approach for a high precision analysis of the non-gravitational perturbations acting on MICROSCOPE by means of the High Performance Satellite Dynamics Simulator (HPS), which is being developed by the Center of Applied Space Technology and Microgravity (ZARM), at the university of Bremen, Germany in cooperation with the Institute of space systems (DLR-IRS) of the German Aerospace Center. Here the calculation of the non-gravitational effects include the specifics of spacecraft geometry and illumination condition thus allowing for highest modeling accuracy.

Furthermore we introduce an application for MICROSCOPE which can be used for any spacecraft employing high performance accelerometers to conduct aeronomy experiments. By accurately modeling all non-gravitational effects we achieve subsequent estimates of all accelerations acting on the craft. When the satellite is operated in non-drag free mode and other dynamical effects derived from the rotational behavior are known, we can subtract these estimated values from the accelerometer signal. By means of a fit of the atmospheric density parameter in the drag model with respect to the residual acceleration we can get an improved estimate on the thermospheric density. We show details of the procedure as well as an application for the MICROSCOPE satellite after its primary science phase.

H0.3-0009-18 THE SOFT MATTER DYNAMICS EXPERIMENT FOR THE ISS

Robert Sütterlin, robert.suetterlin@airbus.com Airbus Defence and Space, Immenstaad, Germany

Soft Matter Dynamics is an experiment platform developped under ESA contract to enable a variety of soft matter experiments with extended micro gravity time from August 2018.

Soft matter are materials that are "supramolecular, exhibit macroscopic softness, have metastable states and a sensitivity of their equilibrium to external conditions" [de Gennes], for example colloidal suspensions, emulsions, foams and granular media. On the one hand these materials are used in many industrial processes, are well understood empirically and have interesting future potential, for instance as design materials. On the other hand Soft Matters are primary research candidates for investigations on non-equilibrium thermodynamics, phenomena at the critical point or rheology, like jamming and glass transitions. Fundamental research under gravity conditions is generally limited by the macroscopic softness of these materials, i.e., most of the internal processes are completely hidden by gravity induced dynamics and stresses.

The Soft Matter Dynamics experiment platform provides optical microscope, single and multi specke diffusing wave spectroscopy, supporting also time resolved correlations, to investigate primarily dynamics on the surface of and inside opaque but translucent materials. The experiment platform can be extended with on-orbit replaceable science cartridges. These so called sample cell units not only allow the extension of the mission by adding additional material samples. These are smart inserts that can include their own custom agitation mechanisms, sensorics, thermalization and thereby expand the science goals of the mission. The initial research are non-equilibrium dynamics in dense granular media and coarsening of wet foams. Potential future experiments include for instance coarsening of emulsions and rheology of foams.

The experiment will be launched with Space-X 15 and is scheduled for commisioning in August 2018. The mission, instrument, its mayor design elements, performance and limits will be presented.

H0.3-0010-18 HYDRODYNAMICS OF DROPLET LATTICES IN QUASI-2D FREE-STANDING LIQUID FILMS

Christoph Klopp, christoph.klopp@ovgu.de

Institute of Experimental Physics, Otto von Guericke University Magdeburg, Magdeburg, Germany

Torsten Trittel, torsten.trittel@ovgu.de

Institute of Experimental Physics, Otto von Guericke University Magdeburg, Magdeburg, Germany

Ralf Stannarius, ralf.stannarius@ovgu.de

Otto von Guericke University, Magdeburg, Magdeburg, Germany

The layered molecular structure in smectic A and smectic C phases allows the preparation of stable thin and homogeneous films with huge aspect ratios, quasi as two-dimensional fluids. One can prepare them even in spherical geometry, as macroscopic bubbles. In an experiment on the ISS, we created such bubbles with centimeter-size radii to study the hydrodynamics of inclusions in these quasi 2D systems [1]. Here, we present the study of nearly regular triangular lattices of micron-sized inclusions in the free-standing films, to investigate inclusion mobilities and interactions in such lattices. We record the trajectories and derive their diffusion characteristics. The experiments are compared to numerical simulations of inclusion arrangements, assuming specific repulsive interaction potentials. The temporal evolution of the mean-square displacement of the inclusions reveals mobilities within the lattice and the strength of the repulsive interaction potential.

The study was supported by NASA, DFG and DLR and a fellowship of Sachsen-Anhalt.

H0.3-0011-18 METRIC: A DEDICATED EARTH-ORBITING SPACECRAFT FOR FUNDAMENTAL PHYSICS TESTS AND GEOPHYSICS

Roberto Peron, roberto.peron@iaps.inaf.it IAPS/INAF, Roma, Italy

Enrico C. Lorenzini, enrico.lorenzini@unipd.it Universita' di Padova, Padova, Italy

A dedicated mission in low Earth orbit — called METRIC — is proposed to test selected predictions of theories for the gravitational interaction and to directly measure the atmospheric density in the covered altitude range, at the same time providing a metrological platform able to perform a tie between different space geodesy techniques. The core of the mission would be a rather simple spacecraft placed in a highly eccentric orbit between 450 and 1200 km; it should be tracked from ground with high precision, and an on-board accelerometer would measure the non-gravitational accelerations acting on it. A precise orbit determination is expected to provide estimates of fundamental physics and geophysical parameters, while the accelerometer data are fundamental in constraining the atmospheric density along the orbit. Together with the mission scientific objectives, a possible baseline for spacecraft configuration, including a typical payload complement, and for data analysis is described and discussed.

H0.3-0012-18 TESTING GRAVITATION IN THE SOLAR SYSTEM: A BRIEF REVIEW

Roberto Peron, roberto.peron@iaps.inaf.it IAPS/INAF, Roma, Italy

In this talk our current knowledge of the gravitational interaction is discussed in the context of the Solar System dynamics. Thus far, general relativity theory appears to be the best description of this interaction. The most important predictions of the theory are briefly discussed in the post-Newtonian approximation, which provides a way of describing also an important set of alternative theories, the so-called metric ones. The Solar System indeed remains a privileged arena for performing precise tests of gravitation, and these tests are often strictly related to the exploration of Solar System itself. A selection of past, ongoing and future tests of the theory and its foundations is presented, giving emphasis on main results and technological requirements, and with an outlook to the near future.

Cryptography via Quantum Key Distribution (QKD) is one of the most promising applications of quantum optics. Unlike current classical cryptography methods such as RSA, quantum cryptography does not rely on the assumption that a mathematical function is too hard for an adversary to invert. The fundamental laws of quantum physics therefore allow for unconditionally secure communication schemes.

Generating a secure key via QKD is most conveniently achieved by exploiting the quantum properties of single photons. However, unavoidable losses restrict glass fiber based QKD to

<400 km. The most efficient alternative is to establish quantum optical free-space links to satellites. In this talk we will demonstrate the feasibility of a QKD scheme that can be carried out with a 3U CubeSat of only 4 kg, using commercial off-the-shelf components. So far, QKD in space has only been shown by a much larger 600 kg satellite mission. Our approach is to establish an uplink to the satellite rather than a downlink. This allows for the more complex sending apparatus to stay on ground, therefore relaxing the requirements for the CubeSat. A comprehensive link budget was generated to calculate the key rates and tolerable losses in detail. The study includes considerations about orbit and ground station choice, pointing, tracking, the CubeSat's field of view, varying weather conditions and the implementation of different protocols as well as a size, weight and power analysis. We discuss design choices and trade-offs to maximize the key rate while minimizing the cost and development needed. Thus, show that up to 13 Mbit of secure key per year could be acquired with the low-cost satellite of our design.

H0.3-0014-18 DETERMINING THE SPIN AXIS ORIENTATION OF THE ECHOSTAR-2 INACTIVE GEOSYNCHRONOUS SATELLITE

Michael Earl, mie263@mail.usask.ca

University of Saskatchewan, Saskatoon, Canada

For the first time, the spin axis orientation of an inactive geosynchronous satellite has been determined using ground-based optical photometric observations. The light curves that resulted from high-frequency Echostar-2 observations conducted in 2012 contained very bright specular sunlight reflections having a period of one half the satellite's inferred spin period. These regularly observed reflections suggested two highly reflective surfaces with surface normals separated by approximately 180 degrees on the satellite body. A geometrical method, based on these observed reflections, was used to determine the late-2012 spin axis orientation coordinates of the Echostar-2 satellite.

H0.3-0015-18 CONSTRAINING EXTENDED GRAVITY BY SOLAR SYSTEM EXPERIMENTS

Salvatore Capozziello, capozziello@unina.it Università "Federico II", Napoli, Italy

We consider Extended Theories of Gravity and in particular, models containing scalar-tensor and higher-order curvature terms, as well as models derived from some fundamental theories. In the weak-field approximation, we take into account the geodesic and Lense-Thirring processions, deriving constraints on the free parameters by the experimental data of Gravity Probe B (GPB) and Laser Relativity Satellite (LARES). The main result of this research is that constraints on fundamental theories of gravity can be achieved at Solar System level.

H0.3-0016-18 AN ASSESSMENT OF LISA PATHFINDER MISSION EXTENSION TO THE SUN-EARTH SADDLE POINT. A MISSED OPPORTUNITY?

Diogene Alessandro Dei Tos, diogenealessandro.deitos@polimi.it Politecnico di Milano, Milan, Italy

Francesco Topputo, francesco.topputo@polimi.it Politecnico di Milano, Milano, Italy

Mirco Rasotto, rasotto@dinamicatech.com Dinamica Srl, Milan, Italy

Florian Renk, florian.renk@esa.int ESA/ESOC, Darmstadt, Germany

Methodologies for the design, navigation, and guidance of potential transfer trajectories to the Sun-Earth gravitational Saddle Point are presented. In particular, this work investigates the feasibility of transferring LISA Pathfinder from its Sun–Earth L_1 Lissajous orbit to the Saddle Point. Unlike the Lagrange points where the gravitational potential has to cancel out the centrifugal acceleration, the Saddle Points are regions of arbitrarily small gravitational force residing in a finite domain. They are, therefore, ideal locations for undertaking tests of the ultra-weak gravitational force and where possible deviations from General Relativity can be tested. Hitting the Saddle Point with precision presents a major orbital mechanics and flight dynamics challenge.

Many optimal trajectories that fly through the Sun–Earth gravitational Saddle Point are found with a series of impulsive maneuvers imparted to LISA Pathfinder, assumed to have thrust-tomass ratio of 0.2-2 µN/kg and Δv levels of 1-2 m/s. An efficient algorithm is then demonstrated that converts each impulsive maneuver into a finite thrust arc by solving a pseudo-rendezvous problem. The impulsive-to-finite burn conversion shows versatility and robustness when applied to a wide variety of transfers. Orbit determination and navigation analysis are simulated by modeling both the space and ground segments. The capability to navigate platforms with ultra-limited control authority is strongly limited by the frequency of ground station passes, the accuracy of the radiometric data from ground stations, the accuracy of the orbit determination and propagation, the frequency of the orbit determination and orbit correction cycle, and the accuracy of the Δv correction. Evidence is here provided on the feasibility to accurately navigate LISA Pathfinder by the Sun–Earth Saddle Point.

Gamma-telescope GAMMA-400 (Gamma Astronomical Multifunctional Modular Apparatus) consists of the converter-tracker (C), time-of-flight system TOF (2 sections S1 and S2), top (ACtop) and lateral (AClat) sections of anticoincidence system, position-sensitive calorimeter CC1 makes of 2 strips layers and 2 layers of CsI(Tl) detectors, electromagnetic calorimeter CC2 composed of CsI(Tl) crystals, scintillation detectors of the calorimeter (S3 and S4). Installation of lateral detectors of the calorimeter (LD) required for particles registration from lateral directions. All detector systems ACtop, AClat, S1-S4, LD consist of two BC-408 based sensitive layers of 1 cm thickness each. The thickness of CC1 and CC2 is ~ $2X_0$ (~ $0.1\Lambda_0$) and

~ $20X_0$ (~ $0.9\Lambda_0$) respectively (where Λ_0 is nuclear interaction length). The total calorimeter thickness is $22X_0$ ($1.0\Lambda_0$) for vertical incident particles registration and $56X_0$ ($2.5\Lambda_0$) for laterally incident ones.

Three apertures provide events registration both from upper and lateral directions. Gammatelescope GAMMA-400 is optimized for the γ-quanta and charged particles with energy 100 GeV detection with the best parameters in the main aperture. Other apertures used for studying of transient events do not require best angular resolution as solar flares and gamma-ray bursts. The main aperture created firstly due to converter-tracker (C): gammas converted in tungsten conversion foils are registered. Triggers in the main aperture will be formed using information about particle direction provided by TOF system and about presence of charged particle or backsplash obtained from ACtop and AClat anticoincidence detectors in energy band 20 MeV

1.0 TeV for gammas and E > 100 MeV for electrons. Additional aperture allows to registered particles from upper directions which don't interact with converter-tracker and don't formed TOF signal. Particles detection in additional aperture starts with signal of CC1 fast discriminators in anticoincidence with TOF. Energy band for gammas registration in this aperture is similar to the main one. In the lateral aperture low energy (0.2 - 100 MeV) photons classified by using simple anticoincidence signals from the individual detectors of LD and CC2. Higher energies γ-quanta (E > 100 MeV) recognized using energy deposition analysis in the individual detectors of S3, S4, LD and CC2.

High-energy γ-quanta registered in scintillator mostly after formation of electron-positron pairs. Thus electron and positron beams also used to gamma-detectors calibration. The positron beam with energies 100-300 MeV was used for calibrations of prototypes of GAMMA-400 detectors on synchrotron "PAKHRA". GAMMA-400 prototype of additional aperture functioning consist of two detectors. One of them is BC-408 based with dimensions of 128 10 1 cm3 (AC/LD prototype) and other composed of CsI(Tl) crystal with dimensions of 33 5 2 cm3 (CC1 prototype).

A fractal analysis often used for investigation of time series corresponding to transitive events (solar flares, gamma-ray bursts and so on). The fractal dimensions must be different for the temporal profiles of events caused by different physical processes. It has some features that allow it to be used to study sets with characteristics varying over a wide range: scaling (two events with similar temporal profiles but with different durations have a similar fractal dimension) and the possibility to process simultaneously the fractal dimension distributions obtained by using data from different detectors if the background fractal dimensions for these detectors are the same. Thus background fractal dimension is useful characteristic of detector. We calculate fractal dimension of AC/LD and CC1 prototypes temporal profiles measured during calibrations and obtain preliminary results of 1.50 0.05 and 1.48 0.08 correspondingly. This is similar to Poisson statistics with coefficient of error in counting up to 10. Analogous results were previously obtained for other detectors used for GRBs registration such as BATSE/CGRO and Swift/BAT.

H0.3-0018-18 SUN GRAVITATIONAL LENS MISSION TO 550 AU

Claudio Maccone, clmaccon@libero.it

International Academy of Astronautics, Torino, Italy

It is well-known that the Sun Gravitational Lens (SGL) would provide magnified radio pictures of whatever lies on the other side of the Sun with respect to the probe position, if the probe can get to 550 AU and beyond.

See, for instance, the popular video https://www.youtube.com/watch?v=Hjaj-Ig9jBs This space mission could be used for two different goals:

Imaging exoplanets possibly hosting Life (Astrobiology) or even Alien Civilizations (SETI).

Enabling radio communications across interstellar distances by virtue of relay probes sent to 550 AU and beyond.

In his book "Deep Space Flight ad Telecommunications" (2009) this author studied extensively the above goal 2), while, in recent years, a NASA Team based at both JPL and Marshall Space Flight Center studied extensively the above goal 1).

In this presentation we give the state-of-the-art of this space mission to 550 AU and beyond. We will point out that this innovative space mission would open up unprecedented prospects for the exploration of space beyond the Solar System. For instance, traveling to the nearest stars (Breakthrough StarShot) and getting in touch with Alien Civilizations (Breakthrough Listen SETI).

H0.3-0019-18 RIEMMANN PENDULUM (AND OSCILLATOR) IN FREE FALL SYSTEM

Daniele Fargion, daniele.fargion@roma1.infn.it

Physics Department, Rome University 1, INFN Rome 1,, Rome, Italy

The possible detection in space and in different free fall systems of the tidal effects, via metric deviations, occurring in Riemann oscillators or in pendulum systems in orbit space, is considered in detail. The possibility to perform such an experiment for educational purpouse and General Relativity test, by a Moire' or Holographic double exposure detection, is described. The International Space Station may obtain high quality test for complex 3D anisotropic Riemann pendulum patterns in a simple set up.

H0.3-0020-18 INTEGRATION AND TESTING ACTIVITIES DEDICATED TO LISA SPACE INSTRUMENT

Olivier Grosjean, olivier.grosjean@cnes.fr

Centre National d'Etudes Spatiales, TOULOUSE, France Yves André, yves.andre@cnes.fr

Centre National d'Etudes Spatiales, Toulouse, France Nicoleta Dinu-Jaeger, nicoleta.dinu-jaeger@oca.eu ARTEMIS/OCA, Nice, France

Halloin Hubert, hubert.halloin@apc.univ-paris7.fr APC AstroParticle & Cosmology, Paris, France Joseph Martino, martino@apc.in2p3.fr

APC AstroParticle & Cosmology, Paris, France

LISA is an ESA project dedicated to space gravitational waves observation in the very low frequency range from 10−1 to 10−4 Hz, opening a window on massive black hole binaries which are not observable from ground based interferometers. The LISA space observatory consists of three satellites planned to be launched in 2034 by Ariane 6.4 launcher. The three satellites will be positioned on their final orbits in a triangular shape constellation with an arm of 2.5 million of km, orbiting around the Sun at 1 AU and following the Earth at a distance of 50 to 65 million of km. The gravitational waves detection is based on laser interferometric measurement of very tiny distance variations (i.e. several tens of picometers) between pairs of free falling test masses (TM), core elements of the two instrument terminal units mounted in each satellite at the end of each triangle arm. One instrument terminal unit consists of a telescope, an optical bench, a gravitational reference sensor (including free falling TM) and a support structure, this entity being called MOSA (Movable Optical Sub-Assembly). An assembly of two MOSA's together with various electronics sub-systems (e.g. Phasemeter, Laser, Payload Commanding and Processing) forms the instrumental payload or the LISA Core Assembly (LCA) of every LISA satellite. Each MOSA emits a laser beam towards its associated MOSA receiver based on the opposite satellite and, reciprocally, it receives the beam emitted by the distant MOSA. These dual links form one of the three interferometric arms of the triangular LISA satellites constellation. The interferometric measurement accuracy, expressed in optical path length has to present a single pathlength stability of 10 pm/*sqrtHz* above 3 mHz, also implying a beam pointing stability of 10 nanoradians/*sqrtHz* in the same frequency range. These performances have to be verified (by measurements or modeling) at MOSA level and therefore require a very sophisticated testing and verification process. France will contribute to this project with the development of the data processing center and the achievement of integration and testing (AIV/T activities) for the six MOSA flight models. The presentation describes the integration and testing steps, the verification tests principle with associated specifications, and the ground support equipment's that are required for the MOSA AIV/T activities. The MOSA assembly activities will be performed in a clean controlled environment and they will consist of µm precision alignment of the telescope relatively to the optical bench by mechanical adjustments on the MOSA support ring structure, followed by the assembly of the gravitational sensor (GRS). At the end of the assembly process, the size of a MOSA will be of 1 meter length and

0.6 meter diameter, with a mass of 75 Kg. Once the assembly of various sub-assemblies and their mechanical alignment step was achieved, the MOSA optical testing will be carried out inside a vacuum chamber, in order to comply with high precision requirement for optical path length (OPL) measurement. A vacuum pressure below 10-5 mb is required to provide a very stable and homogeneous thermal environment and consequently a limited thermal expansion. Moreover, stable low pressure below 10-5 mb avoids also refraction disturbances on the laser beam path. A pressure of 10-5 mb induces an optical path elongation of several picometers. The aimed accuracy is about 1 picometer stability over 30 seconds' time span in order to verify the intrinsic optical length path stability inside MOSA. Slow and slight thermal drifts will be performed to quantify the thermal effects affecting optical path length and wavefront quality for each MOSA. A major test equipment, called far-field optical simulator, is required to simulate the distant satellite laser beam. Its mechanical stability must comply with OPL accuracy requirement and the wave front of the emitted beam has to verify a flatness of Lambda/30. The simulator must also respect pointing stability and strict polarization requirements. The verification of the beam pointing angle requires a measurement stability of one nano-rad over a 30 seconds time span. This far field simulator is fixed on a cradle also bearing the MOSA during testing under vacuum. The material of the cradle must have a very low coefficient of thermal expansion (CTE) and it can be the same material as the telescope one (e.g. Zerodur ceramics). Moreover, three interferometers will measure the relative far-field simulator displacements in order to compensate them for the OPL measurement intrinsic to MOSA. The full MOSA performance verification is based on interferometric measurement involving the main MOSA elements, but also two additional major LISA sub-systems: the Phasemeter and the Laser source. Moreover, the full test of gravitational reference sensor (GRS), of which principle is based on a free falling test mass, cannot be implemented on ground, under gravity. Therefore, an optical sensor simulating the flight movements of the TM inside of its enclosure will be used as GRS substitute. Cleanliness is of paramount importance since a single 10 µm size dust is able to generate interference pattern by scattering laser light that could impair the detection sensitivity or jam gravitational events detection. Drastic precautionary measures will be defined and taken to avoid particle contamination during assembly and testing.

H0.3-0021-18 IN QUEST OF AXIONIC HAIRS IN QUASARS

Indrani Banerjee, tpib@iacs.res.in

Indian Association for the Cultivation of Science, Kolkata, India Bhaswati Mandal, tpbm3@iacs.res.in

Indian Association for the Cultivation of Science, Kolkata, India Soumitra SenGupta, tpssg@iacs.res.in

Indian Association for the Cultivation of Science, Kolkata, India

The presence of axionic field can provide plausible resolutions to several long standing problems like dark matter, dark energy etc. The pseudo-scalar axion whose derivative corresponds to the Hodge dual of the Kalb-Ramond field strength in four dimensions plays crucial roles in explaining several astrophysical and cosmological observations. Therefore, the detection of axionic hairs/Kalb-Ramond field which appears as closed string excitations in the heterotic string spectrum may provide a profound insight to our understanding of the current universe. The current level of precision achieved in solar-system based tests employed to test general relativity, is not sufficient to detect the presence of axion. However, the near horizon regime of quasars where the curvature effects are maximum seems to be a natural laboratory to probe such additions to the matter sector. The continuum spectrum emitted from the accretion disk around quasars encapsulates the imprints of the background spacetime and hence acts as a storehouse of information regarding the nature of gravitational interaction in extreme situations. The surfeit of data available in the electromagnetic domain provides a further motivation to explore such systems. Using the optical data for eighty Palomar Green quasars we demonstrate that the theoretical estimates of optical luminosity explain the observations best when the axionic field is assumed to be absent. However, axion which violates the energy condition seems to be favored by observations which has several interesting consequences. Error estimators, including reduced $\chi 2$, Nash-Sutcliffe efficiency, index of agreement etc. are used to solidify our conclusion and the implications of our result are discussed.

H0.3-0022-18 ASSESSMENT OF DEDICATED MISSIONS TO SUN-EARTH SADDLE POINT

Carmine Giordano, carmine.giordano@polimi.it Politecnico di Milano, Milano, Italy

Francesco Topputo, francesco.topputo@polimi.it Politecnico di Milano, Milano, Italy

Christian Trenkel, christian.trenkel@astrium.eads.net Astrium UK, Stevenage, United Kingdom

Saddle points are peculiar regions of space where the net gravitational acceleration is null. The interest in exploring those locations is increasing in the scientific community. Close-tozero background acceleration environments allow to perform experiments in order to quantify possible deviations from General Relativity and test alternative theories of gravitation in a very weak field region. Multiple passages through the saddle point are needed to collect relevant data. Highly non-linear orbits can be exploited in order to accomplish this aim.

In this paper, periodic orbits through the Sun–Earth Saddle Point are sought. A systematic approach is designed, exploiting the hierarchical structure of astrodynamical models. The periodic orbits survey is firstly addressed in the circular restricted three-body problem with the Sun and the Earth as main bodies: first attempt trajectories are sought through a grid search and then refined using a simple shooting, differential correction scheme. Stability is evaluated and a classification is made. Restricted four body problem adding the Moon is used as middle complexity model in order to find quasi-periodic orbits. These are refined in a full ephemeris high-fidelity n-body model.

Preliminary results show different possible solutions with diverse characteristics and properties.

H0.3-0023-18 TRAJECTORY ANOMALIES IN INTERPLANETARY SPACECRAFT

Frederico Francisco, frederico.francisco@fc.up.pt

Universidade do Porto, Porto, Portugal

For almost two decades after its detection, the Pioneer Anomaly stood as a possible breach in the experimental record of General Relativity (GR), allowing for the formulation of a number of alternative theories. This trajectory anomaly was ultimately found to be caused by the radiative heat dissipation from the spacecraft itself. A similar phenomenon was observed during a specific experiment designed to test GR on the Cassini mission. The non-gravitational acceleration was accounted for using a method that employs techniques originally developed for computer graphics and video games. One examines the surprising role that a shading algorithm from the !970's played in solving these riddles. The prediction made for a similar effect on the New Horizons probe is also presented, as well as the overarching implications for the study of gravity in the solar system.

H0.4-0001-18 MEASURING FEMTO-G ACCELERATION NOISE DOWN TO 20 MUHZ: LISA PATHFINDER RESULTS

The LISA Pathfinder ESA probe mission has measured the residual acceleration between two free falling reference test masses orbiting in the same apparatus at femto-m/s2Hz^1/2 level and performed sub 100f m/Hz^1/2 interfero metric measurements of their relative distance, during its one year and half lifetime frequency science potential of the next–coming LISA mission for gravitational waves observation in space.

H0.4-0002-18 SUCCESSFUL INTERMITTENT CONTROL CONFIRMS THE LISA PATHFINDER PERFORMANCE: THE FREE-FALL EXPERIMENT RESULTS

Roberta Giusteri, roberta.giusteri@unitn.it University of Trento, Trento, Italy

Giuliana Russano, giuliana.russano@unitn.it University of Trento, Trento, Italy

LISA Pathfinder Collaboration

M Armano, H Audley, J Baird, P Binetruy, M Born, D Bortoluzzi, E Castelli, A Cavalleri, A Cesarini, A M Cruise, K Danzmann, M de Deus Silva, I Diepholz, G Dixon, R Dolesi, L Ferraioli, V Ferroni, E D Fitzsimons, M Freschi, L Gesa, F Gibert, D Giardini, R Giusteri, C Grimani, J Grzymisch, I Harrison, G Heinzel, M Hewitson, D Hollington, D Hoyland, M Hueller, H Inchauspe, O Jennrich, P Jetzer, N Karnesis, B Kaune, N Korsakova, C J Killow, J A Lobo, I Lloro, L Liu, J P Lopez-Zaragoza, R Maarschalkerweerd, D Mance, N Meshksar, V Martn, L Martin-Polo, J Martino, F Martin-Porqueras, I Mateos, PW McNamara, J Mendes, L Mendes, M Nofrarias, S Paczkowski, M Perreur-Lloyd, A Petiteau, P Pivato, E Plagnol, J Ramos-Castro, J Reiche, DI Robertson, F Rivas, G Russano, J Slutsky, CF Sopuerta, T Sumner, D Texier, J I Thorpe, D Vetrugno, S Vitale, G Wanner, H Ward, P Wass, WJ Weber, L Wissel, A Wittchen, and P Zweifel

The continuous compensation of the gravitational imbalance between the two free-falling test masses (TMs) that has been achieved in flight by LISA Pathfinder ESA probe mission in standard operations control loop, can be also performed with intermittent control, by forcing electrostatically one of them with brief periodic impulses, with TMs free to move in between two “kicks”. The actuation-free motion is then analysed for the remaining sources of acceleration noise below the repetition frequency of the experiment (3 mHz). This alternative control method allows to test a LISA-like actuation configuration, free from the actuator noise and its calibration and obtains a measurement of the residual acceleration at subfemto-m s–2 Hz–1/2

level in the frequencies below 1 mHz, in agreement with that achieved with continuous control.

H0.4-0003-18 THE GRACE FOLLOW-ON LASER RANGING INTERFEROMETER: MAKING HERITAGE FOR LISA

Brent Ware, brent.ware@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Robert Spero, spero@jpl.nasa.gov

JPL, Pasadena, California, United States William Klipstein, klipstein@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Kirk McKenzie, kirk.mckenzie@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

By measuring the distance between two satellites orbiting the earth with microwaves, the Gravity Recovery and Climate Experiment (GRACE) mission has successfully monitored the gravity profile of the Earth for over a decade. GRACE observed the Earth’s environment due to shifting water masses, giving insight into global climate change over long time scales. GRACE has now reached the end of its lifetime. Its replacement, GRACE Follow-On (GFO) will launch in the spring of 2018. The GRACE Follow-On microwave instrument is a build-to-blueprint replacement of GRACE. In addition, a nanometer-precision laser interferometer demonstration instrument has been incorporated to demonstrate a much finer precision measurement.

A partnership between NASA and Germany, the Laser Ranging Interferometer (LRI) on GRACE Follow-On is based on technology originally developed for gravitational wave detection for the Laser Interferometer Space Antenna (LISA). The LRI implements one arm of the three-arm LISA observatory at a distance of hundreds of kilometers. Between the ESA LISA Pathfinder mission and the GFO LRI, many of the elements of a picometer-sensitivity space-based gravitational wave detector will be demonstrated in space.

H0.4-0004-18 LISA SCIENCE BEFORE LISA: DETECTION OF ULTRA-COMPACT BINARIES WITH THE ZWICKY TRANSIENT FACILITY

Thomas Prince, prince@caltech.edu

California Institute of Technology, Pasadena, California, United States Kevin Burdge, kburdge@caltech.edu

California Institute of Technology, Pasadena, United States Thomas Kupfer, tkupfer@caltech.edu

California Institute of Technology, Pasadena, California, United States

Ultra-compact galactic white dwarf binaries will be the most numerous astrophysical sources detectable by LISA. These binary systems are the result of evolutionary pathways that involve a rich collection of astrophysical phenomena including episodes of common envelope evolution, gravitational wave emission, tidal interaction and mass transfer. Several LISA-detectable binaries are already known through optical observations. These are ultra-compact white dwarf binaries with orbital periods, masses, and distances such that they should be detected by LISA.

The Zwicky Transient Facility (ZTF) is a new ground-based large-area optical survey instrument that saw first light in October 2017 and is now performing science surveys. ZTF has a 47 square degree field of view and acquires an image every 45 seconds with a median limiting magnitude of R=20.3. ZTF will be carrying out variability surveys of the Galactic Plane at both moderate and high cadence. We expect that ZTF will more than double or triple the number of known LISA-detectable sources, as well as identify numerous other ultra-compact binaries that will provide better understanding of the many potential evolutionary pathways for the binaries that LISA will detect.

We will describe ZTF and discuss preliminary results from some of its observations. We will also discuss recent results from the Palomar Transient Factory (PTF), a smaller prototype survey to ZTF. These include detection of AM CVn systems, compact He star systems, and one new LISA-detectable “verification binary”.

H0.4-0005-18 SUPERMASSIVE BLACK HOLE BINARIES AND LOW-FREQUENCY GRAVITATIONAL WAVES

Maria Charisi, mcharisi@caltech.edu

California Institute of Technology, Pasadena, California, United States

Compact Supermassive Black Hole Binaries (SMBHBs) are the most promising sources of lowfrequency gravitational waves, and are expected to be detected in the near-future by Pulsar Timing Arrays, such as the North American Nanohertz Observatory for Gravitational Waves. Such systems should form frequently in galactic nuclei as a result of galaxy mergers. Despite their expected ubiquity, the observational evidence for systems at small (sub-parsec separations) remains elusive. I will summarize ongoing multi-wavelength efforts to identify sub-parsec SMBHBs from their electromagnetic signatures (e.g., quasars with periodic variability, Doppler shifted spectra, etc.). I will also discuss the astrophysical implications of the detection of the gravitational wave background from a population of merging SMBHBs and the prospects of multi-messenger astronomy in the low-frequency part of the gravitational wave spectrum.

H0.4-0006-18 RUNAWAYS: RECOILING BLACK HOLES AND THEIR GRAVITATIONALWAVE SIGNATURES

Davide Gerosa, dgerosa@caltech.edu

California Institute of Technology, Pasadena, California, United States

Binary black holes radiate linear momentum in gravitational waves as they merge. Recoils imparted to the black-hole remnant can reach thousands of km/s, thus ejecting black holes from their astrophysical hosts with deep consequences for both spaceand ground-based gravitationalwave observatories. In this talk, we present some advances in modeling recoiling black holes. In particular, (i) we show how waveform approximants able to model higher harmonics provide an innovative way to estimate black-hole recoils without relying on fitting formulae, and (ii) we exploit the Doppler shift induced by the recoil on the emitted signal to show how future detectors have the potential directly detect these "runaways".

H0.4-0007-18 SCOPING OUT THE LISA CATALOG

Curt Cutler, cjcutler@jpl.nasa.gov

JPL, Pasade A, California, United States

A conventional astronomical catalog contains a list of detected sources, along with their best-fit parameters and (ideally) the error bars for those parameters. There are several reasons why this structure would be far from optimal for LISA: different sources may often have strongly correlated errors; fits with different numbers of sources will have comparable posterior probability; and even for many individual sources, the posterior probability distributions of source parameters may often have many local maxima of comparable probability. Furthermore, the great majority of sources will be very long-lived, with most detectable signals emerging gradually out of the noise, so the catalog will need to be updated very frequently throughout the mission. In this talk, we explain these and related problems that arise as we plan for the creation and dissemination of useful LISA data products. We will describe what we understand already, but this talk will contain more questions than answers.

H0.4-0008-18 STRUCTURED DOCTORAL PROGRAMMES FOR THE NEXT GENERATION OF GRAVITATIONAL SCIENTISTS IN HANNOVER

Fumiko Kawazoe, fumiko.kawazoe@aei.mpg.de

Uni Hannover/AEI Hannover, Hannover, Germany the IMPRS on Gravitational Wave Astronomy has become major resource for education in the field of gravitational wave physics. We have also set up a new programme called the the geo-Q Research Training Group. It aims to study relativistic geodesy and gravimetry with quantum sensors. The two programme started to provide substantial synergy to members of both programmes by our strong cross disciplinary approach. Our effort to create a joint programme has received excellent feedback from our scientists and various external committee members. Building on this successful establishment of a joint programme, we aim to expand globally, and to create a joint programme among international institutions. This will help to further foster collaborations among researchers all over the world in the field of gravitational wave physics and astronomy.

H0.4-0009-18 CAN ACCRETION DISKS AROUND BLACK HOLES AFFECT THE GRAVITATION WAVE SIGNALS?

Sandip Kumar Chakrabarti, chakraba@bose.res.in

S.N. Bose National Centre for Basic Sciences, Kolkata, India

Recent observations of LIGO has opened up a new window to the Universe, a window which is likely to be very very noisy, because every celestial body emits this wave. Simplest templates which are created using two point like objects are wishful thinking and enforcing data to fit such templates could give rise to wrong parameter extraction. There is one good candidate to cause significant perturbation of the signal and it is the accretion disks drag on the binary companion which is on its way to coalesce with the central object. A merger would most certainly be accompanied by electro-magnetic waves due to the presence of the disk, a fact which is impossible for point like mergers. I present results obtained in this intriguing topic of effects of disks drag on the signal variation, especially when extreme mass ratio is considered (in order to see major effects). I discuss the statistics of such objects and argue about their observability.

H0.5-0001-18 TESTING THE EQUIVALENCE PRINCIPLE IN SPACE AFTER MICROSCOPE

Anna M. Nobili, anna.nobili@unipi.it Università di Pisa, Pisa, Italy

Tests of the weak equivalence principle can reveal a new force of nature or disprove many models of new physics. The rst such test in space is successfully carried out by the MICROSCOPE satellite in low Earth orbit. Early results show no violation from the Earth for PT and Ti test cylinders with random errors (after about 8 days of integration time) of about 1 part in 1014, and similar systematic errors. The improvement over the best ground tests with rotating torsion balances is by about 10 times in spite of a 70 times worse sensitivity to dierential accelerations thanks to the much stronger driving signal in orbit. The potential of space for orders-of-magnitude improvements is demonstrated. Many lessons can be learned from the success and the limiting factors of MICROSCOPE. We analyze random and systematic errors, show how they compare with their expected values and discuss the key lessons to learn for testing the equivalence principle in space to higher precision.

H0.5-0002-18 FUNDAMENTAL PHYSICS MEASUREMENTS WITH LASER-RANGED SATELLITES

Carmen Pardini, carmen.pardini@isti.cnr.it ISTI/CNR, Pisa, Italy

Roberto Peron, roberto.peron@iaps.inaf.it IAPS/INAF, Roma, Italy

Giuseppe Pucacco, giuseppe.pucacco@roma2.infn.it Università di Tor Vergata, Roma, Italy

Ruggero Stanga, stanga@arcetri.astro.it Universita' degli Studi di Firenze, Firenze, Italy Massimo Visco, massimo.visco@iaps.inaf.it IAPS/INAF, Italy

The key role that laser-ranged satellites - such as the two LAGEOS (LAser GEOdynamic Satellite) - have had in the fields of space geodesy and fundamental physics is well known. They provided a wealth of significant applications and results in geophysics, as well as in the measurements of tiny relativistic effects in the weak-field and slow-motion (WFSM) limit of Einstein's theory of general relativity (GR). In this regard, these achievements have been reached thanks to two very important ingredients: i) the quality of the tracking observations of the orbit of the satellites, guaranteed by the powerful Satellite Laser Ranging (SLR) technique, and ii) the quality of their overall dynamical model implemented in a software code. Moreover, today GR has to be considered a fundamental pillar of space geodesy and of geophysics in general: the use of atomic clocks on-board a navigation satellite or on-ground, are just two important examples, among many. Indeed, terms like "relativistic metrology", "relativistic geodesy" and "relativistic celestial mechanics" are very frequent in the literature; in fact they are pertinent and represent bridges among fields wrongly considered separated in the past. SLR is one of the techniques that constitute the Global Geodetic Observing System (GGOS). In the near future it is expected, within the GGOS activities, an improvement of one order of magnitude in global accuracies in the observational as well as the theoretical components of space geodesy. This implies improvements in measuring accuracies, in reference frames realization, in modelling, in the stations network geometry and, consequently, into the accuracies involved in fundamental physics measurements using space geodesy techniques. However, in order to reach these ambitious objectives with a fruitful contribution from the existing satellites, as the two LAGEOS and the more recently launched LARES, several improvements are necessary in their precise orbit determination (POD). For instance, under this point of view, an hot topic is constituted by the knowledge of the so-called center-of-mass correction for these satellites, that directly impact the range determination of the satellites, i.e. the precision of their normal points, and correlates with the so-called range bias of the Earth-bound tracking stations. One more very important aspect that deeply affects the POD of the satellites is represented by a reliable modelling of the subtle thermal effects produced by the visible solar radiation and the infrared radiation emitted by the Earth's surface. These are the Sun Yarkovsky-Schach effect and the Earth-Yarkovsky effect. Their complexity arises from two main aspects: i) the knowledge of the temperature distribution on the satellite surface, and ii) the knowledge of the satellite attitude, i.e of its spin vector evolution.

In this talk, the main activities of the LAser Ranged Satellites Experiment (LARASE) will be described. The LARASE research program is funded by the Italian National Institute for Nuclear Physics (INFN) and it is a collaboration between different institutions. The main goal of LARASE is to provide accurate measurements for the gravitational interaction in the WFSM limit of GR by means of the very precise laser tracking of geodetic satellites orbiting around the Earth. In particular, LARASE aims to improve the dynamical model of the current best laser-ranged satellites in order to perform a refined POD of their orbit. This represents a first step towards new refined tests and measurements of GR in the field of the Earth and of a most profitable use of the orbit analysis of the considered satellites for space geodesy and geophysics. The current results of LARASE in terms of development of new models for the non-gravitational perturbations acting on the two LAGEOS and LARES satellites, their POD and new measurements of relativistic effects on their orbit will be shown, together with an accurate evaluation of the error budget due to the main systematic sources of error.

H0.5-0003-18 GALILEO FOR SCIENCE PROJECT (G4S): ECCENTRIC GALILEO SATELLITES FOR GENERAL RELATIVISTIC INVESTIGATIONS.

Francesco Vespe, francesco.vespe@asi.it ASI Italian Space Agency, Matera, Italy G4S team

On August 22nd 2014, Galileo satellites 205 and 206 were launched on wrong orbits. If the injection of the two satellites on wrong highly eccentric orbits (e=0.256 then reduced after recovery maneuvers to 0.156) jeopardized the full operation of two satellites for navigation civilian purposes; on the other hand it provided the unique opportunity to have satellites fully suitable for scientific investigations. Satellites with so eccentric orbits can be exploited indeed for investigations in the field of General Relativity and Gravitation. Gravitational red-shift (GRS), Schwarschild perigee precession (Schw) and Lense-Thirring gravitomagnetic drag (L-T) are the main General Relativistic effects that could be measured with unprecedented accuracy today thanks to the twin satellites. The project GALILEO for Science (G4S) is a joint ESA and ASI effort, which has the primary goal to measure such GR effects. Furthermore, the satellites can be the first space facility for the establishment of a pure Relativistic Positioning System (RPS). Finally bounds on alternative theories of gravity can be settled exploiting the observations of the twin satellites. For the measurements of the above mentioned GR effects we do need to construct a very refined surface model of the GALILEO satellites and conceive proper effective analysis strategy just to minimize the systematic uncertainties due to their very long periodic perturbations. For what regards the analysis strategy we plan to use both Lmicrowaves and Laser Ranging observations. Regarding this last technique, we propose a tailored periodic scheduling of the campaigns which will help us to single out the contributions of each Non Gravitational perturbation (NGP): Sun radiation pressure,thermal thrust and Earth's Albedo.

H0.5-0004-18 DIRECT MULTIPIXEL IMAGING AND SPECTROSCOPY OF AN EXO-EARTH WITH A SOLAR GRAVITATIONAL LENS TELESCOPE

Slava Turyshev, turyshev@jpl.nasa.gov

NASA Jet Propulsion Lab / California Institute of Technology, Pasadena, California, United States

Michael Shao, michael.shao@jpl.nasa.gov

NASA Jet Propulsion Lab / California Institute of Technology, Pasadena, United States

Nature has presented us with a very powerful “instrument” that we have yet to explore and learn to use. This instrument is the Solar Gravitational Lens (SGL), which results from the ability of the gravity field of the Sun to focus light from faint, distant targets. In the near future, a modest telescope could operate on the focal line of the SGL and, using the enormous magnification power of the Lens, could provide high-resolution images and spectroscopy of a habitable exoplanet. We present the imaging properties of the SGL, when the image occupies many pixels in the region near the optical axis. We discuss a mission to the SGL focal region that could provide us with direct, multi-pixel, high-resolution images and spectroscopy of a potentially habitable Earth-like exoplanet. Based on our initial studies, we find that such a mission could produce (1,000×1,000) pixels images of “Earth 2.0” at distances up to 100 light years with spatial resolution of 10 km on its surface, enough to see its surface features. The same instrument would be able to conduct a very high-resolution spectroscopy. We address some aspects of mission design and spacecraft requirements, as well as capabilities needed to fly this mission in the next two decades.

H0.5-0005-18 MOONLIGHT'S AND INRRI'S FOR LUNAR AND MARTIAN MISSIONS

Luca Porcelli, luca.porcelli@lnf.infn.it INFN-LNF, Frascati, Italy

INFN-ASI Team for COSPAR 2018

L. Porcelli (1,*), S. Dell'Agnello (1), D. G. Currie (2), G. Delle Monache (1), S. Contessa (1), O. Luongo (1), C. Mondaini (1), M. Muccino (1), L. Salvatori (1), M. Tibuzzi (1), M. Maiello (1),

R. Vittori (3,1), G. Bianco (4,1), (1) Istituto Nazionale di Fisica Nucleare - Laboratori Nazionali di Frascati (INFN-LNF), Frascati, Italy (corresponding author: luca.porcelli@lnf.infn.it),

University of Maryland (UMD), MD, USA, (3) Aeronautica Militare Italiana (AMI), Rome, Italy, (4) Agenzia Spaziale Italiana - Centro di Geodesia Spaziale "Giuseppe Colombo" (ASICGS), Matera, Italy.

Since its foundation, dating back to 2003, one of the most important objective of the INFN's SCF_Lab has been the development, design, manufacturing, and qualification for space flight of an 'innovative' LRA (laser retroreflector array) of CCRs (cube corner retroreflectors) especially intended for laser ranging operations in the Earth-Moon system; in fact, the innovation is the use of a single, large retroreflector for lunar laser ranging from MLRO (Matera Laser Ranging Observatory) for precision tests of general relativity. The SCF_Lab Team, with support by ASI, is reaching the aforementioned goal, and is going to fly to the Moon two LRAs, namely MoonLIGHT (Moon Laser Instrumentation for General relativity High-accuracy Tests) and INRRI (INstrument for landing-Roving laser Retroreflector Investigation). MoonLIGHT is a LRA, which makes use of a single CCR; it has got a unique and original design, aimed at compensating for the detrimental effect of lunar librations on the precision of lunar laser ranging to the Moon. INRRI is the microreflector array developed by INFN for laser ranging interrogations, from an orbiting laser down to the surface of any suitable planet, satellite, or minor body of the solar system; it has already got space heritage, and it was space qualified for the needs of interplanetary martian missions of two Agencies: ESA's ExoMars EDM 2016 and NASA's InSight 2018. This paper describes INFN's unprecedented payloads, their range of possible uses, and their space qualification process for TeamIndus and Moon Express 1 missions to the Moon, which are both scheduled for 2018/2019. The microreflector may in fact be used also for martian applications, which will be commented, following integration of LaRRI (Laser RetroReflector for InSight) on board the NASA InSight Mars lander. The use of MoonLIGHT for precision tests of General Relativity will be also commented, given its next deployment on our natural satellite.

H0.5-0006-18 UPDATES FROM INPOP EPHEMERIS: FROM FUNDAMENTAL PHYSICS TESTS TO LUNAR INTERIOR PROBE

We present here, our published results obtained with the latest version of the Planetary and Lunar ephemeris - INPOP17a [1]. The lunar part of this solution is fitted to LLR data (1969- 2017) with constraints imposed on the lunar gravity field coefficients using estimates derived from the GRAIL mission [2]. The post-fit residuals obtained with INPOP17a reach 1.15cm for the recent and most accurate LLR datasets. We take advantage of this accurate model by performing tests of the Universality of Free Fall (UFF) of the Earth-Moon system in the gravitational field of the Sun, in an attempt to find signatures arising from a differential acceleration of the test bodies. We compare our estimates with other LLR analysis groups and show no violation at the $(3.8 \pm 7.1) \times 1014$ [3]. Additional results to be presented include, sensitivity of the UFF violation estimates to various fluid core sizes and the sensitivity of lunar dynamical model parameters to the principal axis PA rotation of the GRAIL solution. The latter as a first attempt to account for incompatibilities found between GRAIL-derived gravity field solutions and LLR estimates [4,5]. Furthermore, new estimates are presented that includes recent 6 months of high accuracy IR LLR data set from Grasse station [6] obtained in 2018.

H0.5-0007-18 THE SOLAR LENSE-THIRRING EFFECT ON MERCURY AND THE PERSPECTIVES OF MEASURING IT WITH BEPICOLOMBO

Lorenzo Iorio, lorenzo.iorio@libero.it MIUR-Istruzione, Bari, Italy

We analytically calculate the time series for the perturbations $\Delta\rho$ (t), $\Delta\dot{\rho}$ (t) induced by a general disturbing acceleration A on the mutual range ρ and range-rate $\dot{\rho}$ of two test particles A, B orbiting the same spinning body of mass M, angular momentum S, equatorial radius and oblateness J2. We apply it to the general relativistic Lense-Thirring effect, due to the primary's spin S, and the classical perturbation arising from its quadrupole mass moment

J2 for arbitrary orbital geometries and orientation of the source's symmetry axis $\hat{S}$. The

Earth-Mercury range and range-rate are nominally affected by the Sun's gravitomagnetic field to the 10 m, 10^{-3} cm s–1 level, respectively, during the extended phase (2026-2028) of the forthcoming BepiColombo mission to Mercury whose expected tracking accuracy is of the order of ~ 0.1 m, 2×10^{-4} cm s–1. The competing signatures due to the solar quadrupole J20, if modelled at the σJ0 10^{-9} level of the latest determinations based on the MESSENGER data analyses, are nearly 10 times smaller than the relativistic gravitomagnetic effects.

H0.5-0008-18 REALISTIC DETECTION OF GRAVITATIONAL EFFECTS VIA OPTICALLY DRIVEN DISPERSION FORCE PARAMETRIC AMPLIFIERS

Fabrizio Pinto, fabrizio.pinto@ieu.edu.tr Izmir university of economics, Izmir, Turkey

The measurement of lengths and times of the unprecedented accuracy anticipated in next generation relativistic metrology experiments naturally indicates the possibility to access regimes in which "gravitation and quantum electrodynamics are both central to the outcome." [1, 2] This prospect has already led to suggestions that highly sensitive measurements of dispersion forces,

[3] such as the Casimir force [4, 5] or the Casimir-Polder force, [6, 7] will yield information about the effects of spacetime curvature on the quantum vacuum. Although both predictions of this type, including via proposed "Gravity Probe-C"-like missions, [8] have yet to be verified, attention has also been focused, in more recent times, on identifying possible effects on dispersion forces due to the existence of spacetime fluctuations. Direct observation of a gravitational Casimir effect in the laboratory would require demonstration of gravitational wave reflectors, which remains a theoretical speculation. [9] The author has proposed investigating fluctuations of the standard electrodynamical Casimir effect due to gravitational waves. [10] In this case, estimates based on already demonstrated approaches for Lifshitz-Casimir dispersion force detection in real materials suggest that optical parametric amplification strategies might succeed in the detection of astrophysical and cosmological stochastic gravitational wave backgrounds. [11, 12] In this presentation, we shall briefly review the fundamentals of Casimir force physics as it applies to this particular application, propose possible future space-based experimentation, and present an epistemological and ontological framework for the interpretation of possible results regarding the ultimate structure of spacetime. [13] Finally, nanotechnology application of Casimir force cavities to gravitational field measurements in space will be discussed.

H0.5-0009-18 XHPS: A MODULAR APPROACH FOR THE HIGH PRECISION MODELING OF SATELLITE FORMATIONS FOR GEODETIC AND FUNDAMENTAL PHYSICS APPLICATIONS

Benny Rievers, benny.rievers@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany Takahiro Kato, takahiro.kato@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany Meike List, meike.list@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany

Florian Wöske, florian.woeske@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany

Within the scope of the German collaborative research center "Geo-Q", merging on-ground and space-based geodesy, the need for a high precision simulation tool for the investigation of performance analysis for different kinds of space-based geodesy missions has been identified. A generic tool is beneficial for upcoming and operational missions as it allows for flexibility in the implemented mission scenario. Here the generation of mock data can be used a) to optimize and verify data evaluation procedures and b) to analyze and identify error sources within the science signals. However, in order to realize a sensible agreement between the implementation and a real satellite in orbit, thorough details have to be implemented such that all aspects influencing the real satellite operations are covered. In terms of the modeling, this implies not only a considerably realistic and complete implementation of the gravitational field and all non-gravitational disturbance effects (such as Solar, infrared, Albedo and thermal radiation pressures, atmospheric drag etc.) but also precise modeling of the satellite system, the sensors and the actuators, and their couplings. This includes a model of the satellite shape, noise and coupling models for the sensors, thermal flow models as well as a detailed approach on the implementation of the attitude control.

Besides the obvious relevance for existing mission concepts, such a tool is also crucial for the evaluation of the performance of future mission concepts. By generating a "virtual satellite" (or several at the same time) in virtual space, any mission scenario can be analyzed with respect to the chosen science goal and optimized with respect to orbit, formation, a number of spacecraft and sensor requirements.

Originated from HPS, an orbit propagator developed by the Center of Applied Space Technology and Microgravity (ZARM) at the University of Bremen in Germany in cooperation with the Institute of space systems (DLR-IRS) of the German Aerospace Center, the eXtended High Performance satellite dynamics Simulator (XHPS) has been developed during the first phase of Geo-Q from 2015 - 2018. The tool combines high precision data types with accurate implementation of the satellite system and sensor characteristics. The involved methods have strong generic characteristics and are applicable to a broad range of satellite geodesy and fundamental physics mission layouts. In particular multi-satellite scenarios including the interaction between different spacecraft can be simulated. As an example, we show the reproduction of GRACE Level 1B data using XHPS, namely the dynamic state of the satellite and sensor readouts. Furthermore, we introduce the upcoming work towards the implementation of GRACE-FO including the laser ranging interferometer and the analysis of next-generation geodesy mission scenarios.

The high-precision catalog that will be available from the Gaia mission opens the opportunity to improve on the astrometric tracking and orbit determination of different types of artificial satellites. Such technique has been explored for at least some 25 years with performances ranging from $\sim$ 100 m to tenths of meters, depending on the approach and observing conditions.

A novel implementation of the technique, relying on large angle, high precision astrometry from ground applied to geostationary satellites and other near-Earth space objects observed from two or more telescopes, would allow an accuracy of a few $10^{-}2$ m with 1-meter-class telescopes and a field of view of some arcminutes. The potential benefits for satellite orbit control and navigation systems depend on the number and position of the contributing telescopes, as well as on the target sample.

This idea, although based on proven technologies, represents a novel measurement concept on a planet-wide scale. We discuss the possible applications of a permanent network of automated telescopes for satellite orbit tracking to astrophysics (direct link between Terrestrial and Celestial Reference Frames) and Fundamental Physics.

H0.5-0011-18 THE RELATIVISTIC GEOID: DEFINITION AND APPLICATION

Dennis Philipp, dennis.philipp@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany Volker Perlick, volker.perlick@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany Dirk Puetzfeld, dirk.puetzfeld@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany Eva Hackmann, eva.hackmann@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany

Claus Laemmerzahl, claus.laemmerzahl@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany

One of the fundamental tasks of geodesy is to determine the Earth's geoid from gravity field measurements. Within a Newtonian framework, the definition of the geoid combines the Newtonian gravitational potential and the potential related to centrifugal forces that act on the rotating Earth. Modern relativistic geodesy needs to incorporate a relativistic theory of gravity to fully exploit the technological capabilities and for an undoubtedly correct interpretation of specific high-precision measurements.

We present a definition of the geoid that is based on the formalism of general relativity without approximations; i.e., it allows for arbitrarily strong gravitational fields. For this reason, it applies not only to the Earth and other planets but also to very compact objects. We define the geoid as a level surface of a time-independent redshift potential. Our definition is operational because the level surfaces of a redshift potential can be realized with the help of standard clocks, which may be connected by optical fibers. Therefore, these surfaces are also called "isochronometric surfaces." We deliberately base our definition of a relativistic geoid on the use of clocks since we believe that chronometric geodesy offers the best methods for probing gravitational fields with highest precision in the future. However, we also point out that our definition is mathematically equivalent to a definition in terms of an acceleration potential, i.e., that our geoid may also be viewed as a level surface orthogonal to plumb lines.

We comment on the quantitative and qualitative differences between the conventional and relativistic concept. For particular spacetimes, we illustrate the application of our definition and show how conventions and the arbitrariness left in the comparison of respective notions influence the results.

H0.5-0012-18 LARGE SCALE ATOM INTERFEROMETERS FOR GROUND AND SPACE RELATIVISTIC METROLOGY

Philippe Bouyer, philippe.bouyer@institutoptique.fr Institut d'Optique, TALENCE CEDEX, France

The past decades has seen dramatic progress in our ability to manipulate and coherently control the motion of atoms. This exquisite control offers the prospect of a new generation of force sensors of unprecedented sensitivity and accuracy, from applications in navigation and geophysics, to tests of general relativity or study of highly-entangled quantum states. The spectacular sensitivity or matter-wave interferometers can be used for very precise measurements. It is for example possible to measure the acceleration of gravity with an accuracy of 1 part per billion, the rotation of the Earth with an accuracy better than 1 millidegree per hour and detect minute changes in gravity caused by mass displacements. These devices are so precise that they are used today as reference for fundamental constants (mass, gravity), and are powerful candidates to test general relativity on ground, underground or in space.

The future of matter-wave inertial sensors goes far beyond lab-based inertial sensors. While these experiments are typically quite large, require a dedicated laboratory, and are designed to operate well only in environments where the temperature, humidity, acoustic noise is tightly constrained, many efforts have been put in designing compact, robust and mobile sensors. The development of this technology lead to a new generation of atomic sensors that have been operated in airplanes and rockets, that are commercially available and could be the next generation of navigation unit.

This paper will review the recent experimental results with free-fall dual species interferometer, where two atomic species, 39K and 87Rb, are used to verify that two massive bodies undergo the same gravitational acceleration regardless of their mass or composition. We will present the recent progress in measuring the Eotvos parameter which compared the gravitational acceleration measured by two atomic species, and discuss how precision atom interferometry can be used to perform long-term, drift-free integration even in the harsh environment of a plane or a satellite, and thus provide a new tool for precision measurement and navigation. We will also review, large-scale differential gravitational measurement is using an array of Atom Interferometers (AIs) configured to differentiate Newtonian Noise, geodetic signal and GW detection. In this gravitation antenna, each of the AIs measures the local gradient of gravitational acceleration and the correlation between distant sensors enables to cancel out fluctuations of the terrestrial gravitational forces. With the foreseen cold atom technology developments in the next decade, strain sensitivities down to 10-19 in the 0.1-10 Hz band are within reach, offering interesting complementary observations to optical GW detectors operating at other frequencies.

H0.5-0013-18 AN APPROACH FOR THE GLOBAL-WISE ONE-STEP TIME AND FREQUENCY TRANSFER

Junping Chen, junping@shao.ac.cn

Shanghai Astronomical Observatory, Chinese Academy of Sciences, Shanghai, China

GNSS geodetic techniques have been widely used for time and frequency transfer. Among different approaches, they could be grouped into two types: pseudo-range based and carrierphase based. Pseudo-range approaches are implement for real-time applications but with low accuracy due to big Pseudo-range noise, and carrier-phase approaches have much higer accuracy but are normally realized in post-processing with a latency from several hours to weeks. In this paper, we proposed an algorithm based on GNSS network solution, which uses high accuracy carrier-phase data and can be implement for real-time data analysis. We applied this method using regional and global GPS networks for time and frequency transfer. We also demonstrate the benefits of this new approach for the one-step process for global-wise time and frequency tranfer, where all timing laboratories could be connected and combined.

H0.5-0014-18 PERSPECTIVES FOR ATOM INTERFEROMETERS IN SPACE

Christian Schubert, schubert@iqo.uni-hannover.de Leibniz Universität Hannover, Hannover, Germany Waldemar Herr, herr@iqo.uni-hannover.de

Institute for Quantum Optics, Leibniz Universität Hannover, Hannover, Germany Naceur Gaaloul, gaaloul@iqo.uni-hannover.de

Institute for Quantum Optics, Leibniz Universität Hannover, Hannover, Germany Wolfgang Ertmer, ertmer@iqo.uni-hannover.de

Leibniz Universität Hannover, Hannover, Germany Ernst Maria Rasel, rasel@iqo.uni-hannover.de Leibniz Universität Hannover, Hannover, Germany

Atom interferometry can be utilized for the measurement of rotations, accelerations and for tests of fundamental physics. In these devices, typically three laser light pulses separated by a free fall time coherently manipulate the matter waves which resembles the Mach-Zehnder geometry in optics. Atom gravimeters demonstrated an uncertainty of few 10^{-8} m/s2, atom gradiometers showed a noise floor of 5 10^{-9} $s^{-}2$ $Hz^{-1/}2$, and dual atom gravimeters tested the universality of free fall to parts in 10^{8}.

Further improvements of atom interferometers are anticipated by the integration of novel source concepts providing condensed and collimated atomic ensembles, which enables an extension of the free fall time and enhanced techniques for coherent manipulation. The QUANTUS collaboration pioneered these techniques and exploited the unique features of microgravity in drop tower experiments and in a sounding rocket mission. The latter demonstrated the first Bose-Einstein condensate in space. All these activities serve as pathfinders for applications in space.

This contribution will outline capabilities of atom interferometers, anticipated improvements, and the perspective for future space missions as tests of the universality of free fall and gradiometry for earth observation based on atom interferometery.

This work is supported by the German Space Agency (DLR) with funds provided by the Federal Ministry for Economic Affairs and Energy (BMWi) due to an enactment of the German Bundestag under grant numbers DLR 50WM1551-1558, 50WP1431, 50WP1700, by the Deutsche Forschungsgemeinschaft in the framework of the SFB 1128 geo-Q, and by “Niedersächsisches Vorab” through the “Quantumand Nano-Metrology (QUANOMET)” initiative within the project QT3.

H0.5-0015-18 GENERAL RELATIVISTIC GEODESY - BENEFIT AND CHALLENGES

Claus Laemmerzahl, claus.laemmerzahl@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany

Owing to the ever increasing precision of new instruments for practical geodesy like atom interferometers, clocks, and lasers, it is possible to measure the gravitational field with a precision never achieved, also on a global scale. This goes along with the necessity to employ General Relativity in the theoretical modelling of the measurements and of the gravitational field of the Earth.

In this talk, after first reminding at the basic tasks of geodesy, the new instruments will be described and it will be explained how they are of use for geodetic purposes and how they complement the existing instruments. Due to the inclusion of General Relativity the framework of geodesy has to be adapted accordingly. Therefore, in the second part of the talk the corresponding new general relativistic notions for geodesy like the geoid, height, leveling, elipsoid, etc. are described and compared with the usual notions in the traditional Newtonian framework. The third part of the talk then concentrates on the remaining challenges in setting up a fully relativistc framework for practical geodesy. The challenges to be addressed are, among others, the definition of the geoid in a time-dependent environment, the procedure of levelling in the framework of General Relativity, how one can measure the geoid with satellites, what is the full general relativistic gravitational field of the Earth, what kinf of measurements with satellites can tell us about the complete gravitational field of the Earth, how the measured gravitational field is related to the mass distribution of the Earth, or what is the relativistic ellipsoid. It will finally be pointed out that such precision measurements may also be used for improved tests if General Relativity.

H0.5-0016-18 CLOCKS IN SATELLITE NAVIGATION

Urs Hugentobler, urs.hugentobler@bv.tu-muenchen.de Technische Universitaet Muenchen, Munich, Germany Inga Selmke, inga.selmke@tum.de

Technische Universitaet Muenchen, Munich, Germany Anja Schlicht, schlicht@bv.tum.de

Institute for Astronomical Physical Geodesy, Technical University Munich, Munich, Germany Erik Schoenemann, erik.schoenemann@esa.int

European Space Operations Centre (ESOC), Darmstadt, Germany

Clocks play a fundamental role in satellite positioning, based on GNSS. The basic measured quantity is the travel time of light from the satellites to the receivers requiring clocks at both ends. The ingenious concept of global satellite navigation however allows the epoch-wise synchronization of all clocks which leads to the paradoxical situation that, although GNSS bases of precise travel time measurements, no ultra-stable clocks are required. For geodetic applications of GNSS today either all satellite and receiver clock offsets are estimated epoch-wise with re- spect to an arbitrary reference clock or clock parameters are eliminated by double-differencing of observations which is equivalent. Driven by navigation the satellite clocks get more and more stable. The hydrogen masers onboard Galileo satellites and the Rubidium clocks onboard GPS Block IIF satellites show an excellent performance, offering the potential for further exploita- tion of this stability. As an example the presentation will demonstrate the impact of clock modelling on precise GNSS orbit determination and discusses further applications.

With their supreme accuracy and precision, optical clocks are highly interesting as tools to sense gravity or for precision test of fundamental physics on ground and in space.

The first aspect is related to chronometric levelling, where the difference frequency between two clocks measured via e.g. an optical fibre link is related by the relativistic redshift to the potential difference between both clocks. This opens-up a new tool for geodesy that provides high special resolution and avoids accumulation of measurement errors, as in classical levelling. Here, transportable optical clocks will provide the flexibility required by geodesy to choose measurement sites. We will present the

evaluation of a transportable strontium-87 lattice clock that is installed in an air-conditioned car trailer for operation in field campaigns. With this clock, we have reached a fractional frequency uncertainty of 2×10−17, which corresponds to a height resolution of 10 cm. This resolution is achieved after 8000 s of averaging. The application of this clock for field campaigns will be discussed.

The second apparatus we will discuss originates from the Space Optical Clock consortium, which has the goal to prepare a space mission with a Sr optical lattice clock. The setup is optimized for compactness and low power consumption to provide design guidelines for spaceworthy constructions. Presently, the clock is operated with the boson 88Sr. By comparison against PTB's 87Sr laboratory clock, we have measured the isotope shift between 88Sr and 87Sr with an uncertainty of about 12 mHz.

This work is supported by DFG (CRC 1128), EU-FP7 (Marie Curie ITN FACT) and the ESA-funded project iSOC.

H0.5-0018-18 SPACE-BORNE GRAVIMETRY WITH CLOCKS

Pieter N.A.M. Visser, p.n.a.m.visser@tudelft.nl Delft University of Technology, Delft, Netherlands Dominic Dirkx, d.dirkx@tudelft.nl

Faculty of Aerospace Engineering, Delft University, Delft, Netherlands

The US/German GRACE and European Space Agency GOCE satellite missions have shown the importance of sustained space-borne gravimetry for observing and understanding mass transport in the Earth system, which can be considered an essential climate variable. For the near future, i.e. the 2017-2022 time frame, continued observation is foreseen by the Grace Follow-On mission. For the more remote future, i.e. after 2022, GRACE-II and a Next Generation Gravity Mission are under study and/or proposed by the US and the European Space Agency. All these missions rely on the very precise observation of the inter-satellite distance, referred to as low-low satellite-to-satellite tracking (ll-SST). For the very long term, i.e. beyond 2030, additional observation concepts are being considered, including satellite gravity gradient cold-atom interferometry and the use of ultra-precise atomic clocks. This paper revisits the fundamental equations for atomic clocks in relation to among others gravity. Moreover, an assessment is made of the feasibility of using ultra-precise space-borne atomic clocks for observing Earth's time variable gravity field by means of an efficient error propagation tool. It is shown that very strict and challenging requirements need to be met for using clocks for space-borne observation of the local potential height. Especially the velocity of the space-borne clock needs to be known with extreme high precision. High precision knowledge about the velocity of the satellite provides more accurate information on the gravity field than the use or orbiting clocks. However, clocks with high long-period stability may be advantageous in orbit determination, as the behavior of the clock can be estimated over a longer arc than its translational state.

H0.5-0019-18 VLBI NETWORKS AND FIBER OPTIC LINKS USED TO COMPARE REMOTE ATOMIC CLOCKS

Roberto Ricci, ricci@ira.inaf.it

Istituto di Radioastronomia, Istituto Nazionale di Astrofisica, Bologna, Italy

Very Long Baseline Interferometry experiments require an extremely precise synchronization between the atomic clocks keeping the time and frequency standards at radiotelescope observatories. Recently the availability of fiber optic links from the a few radio observatories and their national metrological institutes has made possible the streaming of extremely stable frequency standards via optical atomic clocks (even two order of magnitudes better than Rubidium or Hydrogen maser standards). In this talk I will present the infrastructure of the Italian Link for Frequency and Time (LIFT) and a few results of the MetGesp project obtained as part of the efforts to create a common clock between two of the antennas of the VLBI Italian Network. Finally I will describe how the VLBI technique can be used to accurately compare atomic clocks located at very distant (a few hundred km) sites as a valid and competitive alternative to satellite-based techniques such as GPS or Two-way Satellite Frequency and Time Transfer.

H0.5-0020-18 ABOUT THE RESULTS OF TESTING MODERN GLOBAL GEOPOTENTIAL MODELS BY COMPARING THE MODEL DATA AGAINST INDEPENDENT GROUND DATA ON THE TERRAIN OF THE WESTERN SIBERIA

Siberian State University of Geosystems and Technologies (SSUGT), Novosibirsk, Russia Nikolay S. Kosarev, kaf.astronomy@ssga.ru

Siberian State University of Geosystems and Technologies (SSUGT), Novosibirsk, Russia

Results of our study of modern global models of Earth's gravitational field, obtained from observations of space gravimetric missions CHAMP, GRACE and GOCE, are briefly outlined. Spectral analysis using the harmonic coefficients of modern global geopotential models is performed. As a result, estimates of resolution and accuracy of the investigated models were obtained. Testing of accuracy of modern global geopotential models is performed by comparing the model data against independent ground-based determinations of quasigeoid heights along with gravimetric measurements conducted on the territory of Novosibirsk region. The results of our study allow us to conclude that the standard methods employed to improve the resolving power and accuracy of Earth's gravitational field models, have reached their own limitations in both technical and methodological aspects of their applications. Therefore, development of new technological approaches and methodological principles is required for further improvement of Earth's gravitational field approximation. This implies creation of new concepts and techniques in studying gravitational field of the Earth. Keywords: CHAMP, GRACE, GOCE, ground gravity data

H0.5-0021-18 GEO-Q - RELATIVISTIC GEODESY AND GRAVIMETRY WITH QUANTUM SENSORS

Matthias Weigelt, weigelt@ife.uni-hannover.de

The Collaborative Research Center (CRC) 1128 "Relativistic Geodesy and Gravimetry with Quantum Sensors" - or short geo-Q - studies and uses modern quantum physics to develop and utilize innovative experimental devices and measurement techniques, and to develop new theoretical and modeling methods for high precision recovery of the Earth's gravitational field in the next decade and beyond. It focuses on the development of atomic gravity sensors, laser interferometry for satellite gravimetry and optical clocks. The contribution will give an overview about the fundamental research conducted within geo-Q and its applications in geodesy.

H0.5-0022-18 COLD ATOM INTERFEROMETERS USED IN SPACE (CAIUS) FOR MEASURING THE EARTH'S GRAVITY FIELD AND PREPARATORY LABORATORY ACTIVITIES

Olivier Carraz, olivier.carraz@esa.int ESA ESTEC, Noordwijk, Netherlands Luca Massotti, luca.massotti@esa.int ESA-ESTEC, Noordwijk, Netherlands

Christian Siemes, christian.siemes@esa.int ESA-ESTEC, Noordwijk, Netherlands Tania Casal, tania.casal@esa.int European Space Agency, Netherlands Roger Haagmans, roger.haagmans@esa.int ESA, Noordwijk, Netherlands

Pierluigi Silvestrin, pierluigi.silvestrin@esa.int ESA-ESTEC, Noordwijk, Netherlands

In the past decades, it has been shown that atomic quantum sensors are a newly emerging technology that can be used for measuring the Earth's gravity field. Whereas classical accelerometers typically suffer from high noise at low frequencies, cold atom interferometers are highly accurate over the entire frequency range.

The first airborne gravity survey during the ESA Cryovex/KAREN 2017 campaign using this technology was conducted by DTU and ONERA. The survey started with a return flight along a profile from Akureyri to Snæfellsnes, for which the reproducibility of the instrument's measurements was better than 4.5 mGal in terms of standard deviation. A gravity survey over the glacier Vatnajokull was then realized during three days flying. The measurements did not show any drift and their accuracy was found to be a few mGal, leading to the conclusion that the world's first airborne campaign using an absolute CAI gravimeter was a full success.

In space, there are two ways of using that technology for measuring Earth's gravity field. The first is a gravity gradiometer concept that has a high common mode rejection, which greatly relaxes the drag-free control requirements compared to the GOCE mission. The second is to deploy quantum accelerometers for correcting low frequency errors of electrostatic accelerometers that are used in a low-low satellite-to-satellite ranging concept for measuring non-gravitational accelerations. We will present for both concepts the expected improvement in measurement accuracy and the expected improvement of Earth gravity field models, taking into account the different types of measurement (e.g. single axis vs. three axes, integration time, etc.) and different mission parameters such as attitude control, altitude of the satellite, lifetime of the mission, etc.

Additionally, we outline the planned mission preparatory laboratory activities that aim at exploiting synergies between fundamental physics missions (week equivalent principle, gravitational redshift), planetary exploration and Earth observation missions.

H0.6-0001-18 INERTIAL ULTRA-COLD ATOM SENSORS IN WEIGHTLESSNESS

Baptiste Battelier, baptiste.battelier@gmail.com Institut d'Optique Graduate School, FRANCE, France Gabriel Condon, gabriel.condon@institutoptique.fr Institut d'Optique Graduate School, Talence, France Martin Rabault, martin.rabault@institutoptique.fr Institut d'Optique Graduate School, Talence, France Brynle Barrett, brynle.barrett@ixblue.com iXBlue, Saint-Germain-en-Laye, France Arnaud Landragin, arnaud.landragin@obspm.fr Observatoire de Paris, PARIS, France

Philippe Bouyer, philippe.bouyer@institutoptique.fr Institut d'Optique, TALENCE CEDEX, France

Quantum technology based on cold-atom interferometers is showing great promise for fields such as inertial sensing and fundamental physics. However, the best precision achievable on Earth is limited by the free-fall time of the atoms, and their full potential can only be realized in Space where interrogation times of many seconds will lead to unprecedented sensitivity. Various mission scenarios are presently being pursued, which plan to implement matter-waves inertial sensors to detect gravitational waves, to measure the Earth gravity field or to test fundamental physics such as the Equivalence Principle.

We developed a cold atom sensor experiment adapted to microgravity platforms, especially the ZERO-G plane. To achieve a test of the Universality of Free Fall, we realize the first onboard operation of simultaneous 87Rb -39K interferometers in the weightlessness environment produced during parabolic flight. The large vibration levels (10−2 g/Hz1/2), acceleration range and rotation rates (5 deg/s) during flight present significant technical challenges for atom interferometers. By hybridizing each atomic sensor with a common mechanical accelerometer, we achieve a sensitivity of 3.4 10−5 g per shot-more than 1600 times below the ambient vibration level onboard the aircraft. We demonstrate the capability of our dual-quantum sensor by measuring the Eötvös parameter with systematic-limited uncertainties of 3.0 10−4 during microgravity. This constitutes the first quantum test of the equivalence principle in a free falling vehicle. Our results can be extended to the trajectory of a satellite for future Space missions. We also achieved a simultaneous 87Rb-39K interferometer on ground with a long term stability on the differential acceleration measurement around 5 10−8g, limited by the fall of the atom clouds. To increase the interrogation time and the sensitivity, a ZERO-G simulator has been installed in our laboratory and allows our experiment to be in free fall during 500 ms every 12 seconds, to achieve highly repeatable measurements in microgravity. We expect to increase our short-term sensitivity by two orders of magnitude, and consequently reach a long-term measurement of the Eötvös parameter at the level of 10−11.

To benefit from the free fall of the experiment completely, it is necessary to produce atoms clouds with a reduced velocity dispersion. To reach this goal, we put 87Rb atoms in an optical

dipole trap supplied by a compact fiber laser compliant with onboard applications and decrease the optical power on a very controlled way to obtain evaporative cooling. Preliminary results of ultra-fast evaporative cooling (less than a few seconds) onboard the ZERO-G plane allowed us to reach a regime of temperature compliant with an interrogation time of the order of one second. This method and technology will be tested on the ZERO-G simulator as well.

H0.6-0002-18 COMPACT COLD ATOM SYSTEMS - PROSPECTS FOR SPACE APPLICATIONS

Erling Riis, e.riis@strath.ac.uk

University of Strathclyde, Glasgow, United Kingdom Paul Griffin, paul.griffin@strath.ac.uk

University of Strathclyde, Glasgow, United Kingdom Aidan Arnold, aidan.arnold@strath.ac.uk

University of Strathclyde, Glasgow, United Kingdom

The magneto-optic trap (MOT) is the workhorse behind virtually all cold neutral atom experiments. It is based on the viscous damping obtained from laser cooling and a restoring force guiding atoms towards the zero-point of a magnetic field. This constitutes a trap for neutral atoms and they are held there at a temperature typically of order 1 mK. A sufficient number of atoms can be collected from a thermal vapour to form the basis for a large number of experiments including precision measurements such as atomic clocks and atom interferometry. The potential has been recognised for extending the use of these cold atom sources to space-based applications such as space-qualified atomic clocks and timing devices (incl. GNSS), remote sensing (incl. gravity measurements), deep-space navigation and tests of fundamental principles of physics. A key requirement for this would be the development of robust technologies to support extended and autonomous operation of what has so far mainly been complex and labour intensive laboratory-based experiments. This includes lasers and optical technologies as well as associated vacuum systems and signal processing and control electronics. The magneto-optical trap that is presently in use in hundreds of experiments across the world is essentially the same as that used in the first demonstration more than 30 years ago. While being remarkably robust the standard system remains bulky and requires alignment of multiple laser beams. Here we report on a programme that is developing microfabricated diffraction gratings as core elements for simplifying the MOT setup [1]. This enables single-beam laser cooling free of regular alignment and is a key step in reducing the size and weight of cold-atom systems. Additionally, this approach opens avenues for realising compact vacuum systems, which offers further reductions in the overall power requirements. We demonstrate how this technique provides performance in terms of atom number and temperature comparable to that of the conventional MOT configuration. The system has been realised both in a single and a double-chamber setup. In the case of the latter a microfabricated diffraction grating optimised for a 2D MOT configuration was used to inject atoms into an adjacent chamber equipped with a grating for a 3D MOT. This forms the starting point for ongoing work on rapid creation of a BEC for space applications. By rapidly switching off the MOT magnetic field the grating setup has been demonstrated to produce atomic ensembles at 3μK [2]. We report on the use of such samples in a compact atomic microwave clock based on coherent population trapping.

H0.6-0003-18 BECCAL - QUANTUM OPTICS WITH BOSE-EINSTEIN CONDENSATES AND MIXTURES ABOARD THE ISS

Waldemar Herr, herr@iqo.uni-hannover.de

Institute for Quantum Optics, Leibniz Universität Hannover, Hannover, Germany BECCAL the NASA-DLR funded BECCAL cooperation

The joint NASA-DLR Bose-Einstein Condensate and Cold Atom Laboratory (BECCAL) will be a multi-user, multi-purpose facility aboard the International Space Station (ISS). BECCAL is designed to be a versatile toolbox for a multitude of experiments with ultra-cold Rb and K atoms, and their mixtures in regimes and timescales inaccessible on ground. The absence of gravitational sag and the method of matter-wave lensing enable experiments on ultra-long time-scales and unreached fidelity.

The system will be based on the design of drop tower and sounding rocket experiments QUANTUS and MAIUS including an atom chip for efficient evaporation and excellent control of the quantum degenerate atomic clouds. The setup will provide an abundance of time-dependent potentials including magnetic, RF-dressed as well as redand blue-detuned optical potentials. This will serve as a platform to realize experiments in matter-wave optics, physics of quantum degenerate gases, their mixtures, and atom interferometry to test fundamental principles of physics, e. g. to test Einstein's Equivalence Principle.

We present an insight on possible experiments and their expected performance in BECCAL.

This talk presents work of the NASA-DLR funded BECCAL cooperation. The BECCAL project is a collaboration of LU Hannover, U Ulm, HU Berlin, FBH Berlin, JGU Mainz, DLR Institute of Space Systems Bremen and ZARM at U Bremen. It is supported by the German Space Agency DLR with funds provided by the Federal Ministry of Economics and Technology (BMWi) under the grant numbers 50WP1431 and 50WP1700.

Atom interferometry is now proven to be a very efficient technique to achieve highly sensitive and absolute inertial sensors. As a matter of fact gyroscopes or gravimeters based on this technique by using cold atoms have already been developed reaching state-of-the-art performances. This kind of instruments should allow significant advances in fields such as navigation, geophysics or fundamental physics and appear also very promising candidates for future satellite missions for gravity field mapping or testing the Einstein's general relativity (Equivalence Principle, Lense-Thirring effect).

Our work focuses in particular on the development of cold atom instruments for onboard applications dedicated to gravity field measurements from mobile platforms such as boats, aircrafts or satellites. We will present ongoing developments at ONERA in this context and in particular recent results obtained in collaboration with DGA, SHOM and DTU concerning the elaboration of a gravity map from a ship and an aircraft using an absolute cold atom gravimeter. The presentation will show also the first steps we take toward a future space geodesy mission, conducted in collaboration with TUM and ESA, aiming to hybridize a cold atom instrument with a state-of-the-art space electrostatic accelerometer.

H0.6-0005-18 MATURING SPACE-BASED PRECISION METROLOGY WITH QUANTUM GAS STUDIES ABOARD THE ISS

Jason Williams, jrwillia@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Precision atom interferometers (AI) in space are expected to become an enabling technology for future fundamental physics research, with proposals including unprecedented tests of the validity of the weak equivalence principle, measurements of the fine structure and gravitational constants, and detection of gravity waves and dark matter/dark energy. We will discuss our preparation at JPL to use NASA's Cold Atom Lab facility (CAL) to mature the technology of precision, space-based, AIs. The focus of our flight project is three-fold: a) study the controlled dynamics of heteronuclear Feshbach molecules, at temperatures of nano-Kelvins or below, as a means to overcome uncontrolled density-profile-dependent shifts in differential AIs, demonstrate unprecedented atom-photon coherence times with spatially constrained AIs, use the imaging capabilities of CAL to detect and analyze spatial fringe patterns written onto the clouds after AI and thereby measure the rotational noise of the ISS. The impact from this work, and potential for follow-on studies, will also be reviewed in the context of future space-based fundamental physics missions.

This research was carried out at the Jet Propulsion Laboratory, California Institute of Technology, under a contract with the National Aeronautics and Space Administration.

H0.6-0006-18 POINT SOURCE ATOM INTERFEROMETRY FOR INERTIAL NAVIGATION AND PRECISION MEASUREMENTS

Elizabeth Donley, elizabeth.donley@nist.gov

National Institute of Standards and Technology, Boulder, Colorado, United States

Atom interferometers are being developed for applications like navigation and geodesy as well as for testing fundamental physics, where they may help answer important outstanding questions. Most of these applications will ultimately require portable instruments, and balancing performance and simplicity is an ongoing challenge. As a potential path forward, we evaluate the technique of point source atom interferometry (PSI) [1]. With PSI, the Raman $\pi/2$ π $\pi/2$ pulse sequence is applied to a ballistically expanding cloud of cold atoms. Because of the correlation between final position and atom velocity, a spatial sinusoidal fringe pattern arising from rotations is imprinted on the atom population at the end of the pulse sequence. By imaging the fringe pattern, the PSI technique simultaneously measures acceleration in the propagation direction of the Raman lasers and rotation in the plane perpendicular to that direction. This simple experimental geometry makes the technique promising for miniaturization and hence portable applications. We have previously demonstrated a PSI gyroscope, which used a vacuum volume of 1 cm3 [2]. We will present our ongoing work on optimizing and characterizing the system.

H0.6-0007-18 THE SPACE ATOM LASER - A CAL FLIGHT EXPERIMENT

Matthias Meister, matthias.meister@uni-ulm.de Universität Ulm, Ulm, Germany

Up to now atom-laser experiments have been performed in earth-bound laboratories, where the dominant force acting on the outcoupled atoms is gravity, which results in a directed and accelerated beam of atoms leaving the condensate. Here we propose to enter a completely new regime for the atom laser by taking advantage of NASA's Cold Atom Laboratory (CAL): thanks to the microgravity conditions on the ISS it is possible to create a unique shell-like atom laser which slowly expands away from the initial BEC driven only by the repulsive interaction between the atoms. This phenomenon can be exploited to establish a nearly isotropic source for ultra-cold atoms in microgravity.

We present a scheme based on radio-frequency outcoupling that enables the generation of a slowly expanding shell of atoms featuring an isotropic momentum distribution even if the initial BEC was trapped in an elongated anisotropic trap. This output is achieved by resonantly outcoupling at the very edge of the BEC with relatively small coupling strength in order to establish a spatially well-localized and state-selective outcoupling process.

In order to prepare for the CAL flight campaign, we report on our recent progress towards a realistic modeling of atom-laser experiments in microgravity taking into account higher-order contributions to the Zeeman effect and fluctuations of the number of particles and the Rabi frequency as well as varying magnetic fields. In this way we identify a promising parameter regime for a successful realization of the space atom laser with CAL.

H0.6-0008-18 AN ULTRA-HIGH VACUUM SYSTEM FOR THE MAIUS-2/3 ATOM INTERFEROMETER ON A SOUNDING ROCKET

DLR - Institute of Space Systems, Bremen, Germany MAIUS-Team

MAIUS-Team

During the two sounding rocket missions MAIUS-2 and MAIUS-3, it is planned to perform sequential and simultaneous dual-species atom interferometry with Bose-Einstein condensates of

Potassium-41 and Rubidium-87. The microgravity environment offers experiments on timescales that are not possible on ground. To perform long lifetimes of the BEC, a pressure 5·10−10

mbar needs to be reached and maintained in the vacuum chamber. During ascent of the rocket, vibrational loads of 1.8 g RMS in the frequency range of 20-2000 Hz and accelerations of up to 13 g are applied to the vacuum system and the payload. During re-entry and landing static loads can reach a level of up to 50 g. The ultra-high vacuum system presented in this talk is designed to withstand these loads while maintaining the vacuum quality. Sealing technologies and pumping concepts as well as used commercial parts, needed to be tested and qualified. This talk presents the ultra-high vacuum system of the MAIUS-2/3 payload and its vibration and qualification tests at the shaker test facility at the Center of Applied Space Technology and Microgravity (ZARM) in Bremen.

H0.6-0009-18 ACCELEROMETERS FOR FUNDAMENTAL PHYSICS AND SOLAR SYSTEM EXPLORATION

Francesco Santoli, francesco.santoli@ifsi-roma.inaf.it IFSI-INAF, Roma, Italy

In the last decades the role of space-qualified high-sensitivity accelerometers — devices which measure tiny accelerations acting on spacecraft due to non-gravitational forces — has increased considerably. Today their use is a first-choice option in all the cases — as fundamental physics

— where small dynamical effects must be accounted for a good outcome of the mission. In this talk the accelerometers developed by the Experimental Gravitation Group of IAPS-INAF are presented, focusing on their concept, design, performance verification and calibration strategies. Their main applications in fundamental physics tests, as well as in the exploration of the Solar System, are discussed, with an outlook to the near-future.

H0.6-0010-18 LISA TECHNOLOGIES FOR OTHER PURPOSES: ONGOING DEVELOPMENT OF EXTREMELY PRECISE AND STABLE OPTICAL SYSTEMS

Daniel Hillsberry, danielhillsberry@ufl.edu

University of Florida, Gainesville, Florida, United States Andrew Chilton, chilton@phys.ufl.edu

University of Florida, Gainesville, Florida, United States Guido Mueller, mueller@phys.ufl.edu

University of Florida, Gainesville, Florida, United States John Conklin, jwconklin@ufl.edu

University of Florida, Gainesville, Florida, United States

The Laser Interferometer Space Antenna (LISA) mission has pushed the state of the art of high precision and stability optics further than ever before. Some of the concepts and technologies can be re-purposed to the benefit of other industries and science endeavors. A modular and integrable optics system built from conventional engineering materials has been in development and is steadily moving ever closer to LISA like stability levels. This system will be capable of interferometry, metrology, optical communication and will include: monolithic piezo actuated steerable optic mounts, optical bench, and a metal-to-glass structural interface. Further experiments are planned to demonstrate nano-meter angular resolution of the steering mirror and pico-meter optical path stability in the 0.1 Hz to 1 Hz LISA band. A compact and lowcost shaker table for space-flight qualification tests of experimental LISA technology has also been in development. This hardware could bring preliminary flight testing in-house to save time and money compared to off sight evaluation. The shaker table will give other institutions the opportunity to enjoy more cost effective and partially in-house flight qualification of their experiments or even small satellites. Motivated by space science metrology needs the optical system is designed to be compact, low cost, and highly configurable which makes it relevant to a diverse range of applications beyond LISA which may require such scientific instrumentation.

H0.6-0011-18 DESIGN OF A CUBESAT PAYLOAD TO TEST A MAGNETIC MEASUREMENT SYSTEM FOR SPACE-BORNE GRAVITATIONAL-WAVE DETECTORS

Ignacio Mateos, mateos@uca.es Universidad de Cádiz, Cádiz, Spain

Space observatories for gravitational radiation such as LISA are equipped with dedicated onboard instrumentation capable of measuring magnetic fields with low-noise conditions at millihertz frequencies. The reason is that the core scientific payload can only operate successfully if the magnetic environment meets certain strict low-frequency requirements. With this purpose, a simplified version of the proposed magnetic measurement system for LISA has been developed for a six-unit CubeSat, which will make it possible to improve the technology readiness level (TRL) of the instrument. The special feature of the experiment is that the magnetic sensors integrated in the payload are magnetically shielded to low-frequency fluctuations by using a small cylindrical permalloy enclosure. This will allow the in-flight noise characterization of the system under the CubeSat orbit environment. Therefore, a CubeSat platform will offer the opportunity to measure the capability of the instrument and will guide the progress towards the improved magnetic measurement system for LISA. This talk describes the principal characteristics and implementation of the CubeSat payload.

H0.6-0012-18 OPTICAL IODINE FREQUENCY REFERENCES FOR SPACE

Markus Oswald, oswald@zarm.uni-bremen.de

Claus Braxmaier, claus.braxmaier@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany

Highly stable frequency references are an essential component for several space experiments and missions in the field of global navigation satellite systems (GNSS), Earth observation and geodesy as well as for tests of fundamental physics e.g. gravitational waves detection and special relativity. Here we present our latest efforts in development and qualification of absolute optical frequency references based on Doppler-free saturation spectroscopy of molecular iodine, where a laser is stabilized onto one of the hyperfine transitions near 532 nm using modulation transfer spectroscopy. This wavelength can be conveniently obtained by frequency doubling a 1064 nm laser source which is baseline e.g. for LISA and GRACE-FO missions. In conjunction with their high long-term stability and low complexity, optical iodine clocks are a promising candidate for use on future space missions. In collaboration with the Humboldt-University of Berlin and the Laboratory of Enabling Technology at Airbus Defence and Space GmbH in Friedrichshafen, three spectroscopy units have been realized with emphasis towards space compatibility. A setup on elegant breadboard level (EBB) using a 30 cm long iodine cell in triple pass configuration has been integrated on a thermally and mechanically stable 55 x 25 cm^2 glass ceramic base plate [1], as well as a more compact setup on engineering model level (EM) realized on a 38 x 18 cm^2 fused silica base plate, where a squared iodine cell in 9-pass configuration is used to reduce overall dimensions while preserving absorption length [2]. Similar frequency instabilities in the 10–15 domain at integration times between 10 s and 1000 s could be shown with both of the setups, whereas the EM unit was

additionally subjected to thermal cycling and vibrations. As a major step towards space, a spectroscopy unit for use on a sounding rocket mission scheduled in May 2018 has been developed and realized [3]. Optimized in terms of compactness and ruggedness, a 15 cm long tube cell in double pass configuration and all necessary optical components have been integrated on a 24.6 x 14.5 cm^2 fused silica base plate.

The BepiColombo Italian Spring Accelerometer (ISA) is a component of the dedicated suite of instruments which will perform the so-called Radio Science Experiments in order to study gravitational field, internal structure and rotational state of the planet Mercury, and to verify important predictions of the general theory of relativity. Its main role is the measurement of non-gravitational accelerations acting on the surface of the Mercury Planetary Orbiter spacecraft, thereby enabling to work on a virtually drag-free satellite. In this talk the concept, design and development of the instrument are reviewed, along with its main scientific products. The development and testing of the data processing procedures, as well as the definition of the instrument operations for the various mission phases, are also presented.

H0.6-0014-18 PERFORMANCE OF THE DAMPE IMAGING CALORIMETER IN SPACE

Yunlong Zhang, ylzhang@ustc.edu.cn

University of Science and Technology of China, Hefei, China

The Dark Matter Particle Explorer, primarily designed to directly measure high energy electrons (positrons, gamma rays) in cosmic radiation, was launched successfully on Dec 17th, 2015, and, since then, it is in continuous data taking. The calorimeter of the DAMPE apparatus has been designed to measure the energy of incident particles and identify electrons (positrons) from protons (antiprotons) with high efficiency and rejection power. It is a total absorption 3D BGO imaging calorimeter, which comprises 308 BGO crystal logs. In this work we present the on orbit performance of the calorimeter, including the measured energy reconstruction and identification capabilities. The calorimeter provides a proton rejection factor of 105 while keeping a high efficiency in selecting electrons and positrons. We also show that, after two years operation in space, the calorimeter is still performing nominally.

H0.6-0015-18 A NOVEL APPROACH FOR TRACKING PARTICLES IN SPACE

Ester Ricci, ester.ricci@unitn.it University of Trento, Povo (TN), Italy Roberto Iuppa, roberto.iuppa@unitn.it University of Trento, Trento, Italy

Benedetto Di Ruzza, benedetto.diruzza@gmail.com INFN-TIFPA, Trento, Italy

Giuseppe Masciantonio, giuseppe.masciantonio@roma2.infn.it INFN and University of Rome Tor Vergata, Rome, Italy

In the last decades new silicon detector technologies were developed for and applied to particle tracking in different research fields, namely high energy physics, nuclear physics, radiation physics, dosimetry and medical physics. Nonetheless, tracking high energy particles in space continues exploiting microstrip detectors, based on a concept of late 80s. An important problem is rising, since future space applications will require better performances, e.g. lower thickness and sub µm spatial resolution tracking over O(100)m2 areas. Monolithic Active Pixel Sensors, based on commercially-available CMOS technology, offer an interesting solution for this scenario. They are O(µm) sized pixel with integrated readout, allowing on-chip zero suppression and being at the same time suitably radiation hard and cost-effective. Studies on MAPS suitability for space applications are presented, taking as a reference the case of ALPIDE, developed at CERN for the ALICE Inner Tracking System Upgrade, and proposed for the High Energy Particle Detector of the Second China Seismic Electromagnetic Satellite.

H0.6-0016-18 RESEARCH ABOUT TEMPERATURE CONTROL SYSTEM FOR THE CABIN OF THE SCIENTIFIC BALLOON

Jingjing Cai, caijingjing@aoe.ac.cn

Chinese Academy of Sciences,AOE, BEIJING, China Yanchu Yang, yangyanchu@aoe.ac.cn

Chinese Academy of Sciences,AOE, BEIJING, China Qiang Liu, liuqiang1001@aoe.ac.cn

Academy of Opto-electronics, Chinese Academy of Sciences, Beijing, China Taihua Zhang, zth@aoe.ac.cn

Academy of Opto-electronics, Chinese Academy of Sciences, Beijing, China

Currently, the scientific balloon has achieved good development and applied in a wide range, especially for scientific exploration in extreme regions. However, the payload requires very limited environment. Too high or too low temperature is not good for the normal operation of the equipment. Too high temperature may even cause equipment failure. Therefore, the temperature control inside the cabin is essential. This article studies temperature control for the cabin of a scientific balloon by statistics the heating power of the payload and designing a set of control scheme to ensure that the temperature was within the required range. The comprehensive performance of the heating power of the payload, the heating equipment and the cooling fan were simulated by software ANSYS. Through the analysis of the distribution of temperature field and velocity field on different cross section, the pattern of the gas flow and heat transfer in the cabin are obtained. Based on the simulation results, the design of the cabin and the location of the thermal payload can be further optimized. Finally, we also tested the analysis results on a scientific balloon, the test results and analysis of the results are basically the same, indicating that the control scheme is feasible. The work provides a practical reference for the temperature control of cabin for scientific balloon and stratospheric airship.

H0.6-0017-18 THE EPD INSTRUMENT CONTROL UNIT

Sebastián Sánchez Prieto, sebastian.sanchez@uah.es Universidad de Alcalá, Alcalá De Henares, Spain Oscar Rodriguez Polo, opolo@aut.uah.es Universidad de Alcalá, Alcalá De Henares, Spain Antonio Da Silva, antonio.dasilva@upm.es Universidad Politécnica de Madrid, Madrid, Spain Pablo Parra Espada, pablo.parra@uah.es Universidad de Alcalá, Alcalá De Henares, Spain Agustín Martínez Hellín, agustin.martinez@uah.es Universidad de Alcalá, Alcala De Henares, Spain Manuel Prieto, manuel.prieto@uah.es

Universidad de Alcalá, Alcalá De Henares, Spain Javier Rodríguez-Pacheco, fsrodriguez@uah.es Universidad de Alcalá, Alcalá De Henares, Spain Daniel Meziat, daniel.meziat@uah.es Universidad de Alcalá, Alcalá De Henares, Spain

The EPD experiment aims to measure the composition, spectra, timing and distribution functions of suprathermal and energetic particles. The main scientific topics to be addressed include the sources, acceleration mechanisms, and transport processes of these particles. This experiment is an instrument suite consisting of several sensors measuring electrons, protons and ions over a broad energy interval (2 keV to 15 MeV for electrons, 3 keV to 100 MeV for protons and few tens of keV/nuc to 450 MeV/nuc for ions), that is part of the Solar Orbiter payload. Solar Orbiter is the first medium-class mission of ESA's Cosmic Vision 2015-2025 Programme. All operations of the instrument are handled by the EPD Instrument Control Unit (ICU), which is composed of a Common Data Processing Unit (CDPU) and a LVPS (Low Voltage Power Supply). The CPU of the experiment is based on a LEON2 architecture (a SPARC V8 implementation) running the RTEMS real time operating system. The main purpose of the ICU is to control and communicate the sensors (EPT, HET, SIS and STEP) with the spacecraft. Communications between EPD and the satellite are performed via a SpaceWire links. Data acquisition from the sensors is performed via a UART/LVDS 115200 bps interface. In this work, we describe the ICU of the experiment and the general software scheme.

H0.6-0018-18 A NOVEL THEORETICAL MODEL FOR THE FAMOUS QUANTUM PHYSICS PARTICLE - WAVE DUALITY EXPERIMENT AND GENERALIZATION OF THE SCHRODINGER EQUATION: IMPLICATIONS FOR SPACE EXPLORATION.

Natalia Duxbury, nduxbury@gmu.edu

George Mason University, 4400 University Drive MSN 3F3, Fairfax, Virginia, United States

A novel theoretical model for the famous quantum physics particle - wave duality experiment: implications for space exploration.

The famous Thomas Young double -slit diffraction experiment for light, proving the wave nature of light, was performed in 1803, far before the advent of quantum physics in the 20th century. Nonetheless, this old experiment remains at the heart of understanding quantum mechanics, as was noted by Richard Feynman. It introduces such unusual concepts as non-locality of a particle in a micro world and a dualism of particle-wave nature.

There were many attempts undertaken to elucidate the results of this experiment. Some were even based on the “wavy” structure of space itself, and on the concept that the particles are influenced by that “wavy” nature of the ambient environment. Other interesting interpretation is a multi-universe model. But there are many arguments against this multiverse theory. Despite the wide usage of the quantum mechanical effects, to-date there is still no consistent, complete explanation of this most famous experiment in quantum physics.

An absolutely novel approach and corresponding consistent theoretical model will be presented to explain the results of this important quantum physical double-slit experiment in its entirety. The model is non-linear, time-dependent and multi-phase. For this particular case, a particle wave duality will be elucidated using an experiment with an electron /electron gun. Nevertheless, the results are applicable to other plasma particles, also to photons, atoms, sub-atomic and other particles of the micro world. The results of my theoretical model are also consistent with the results of the Delayed Choice Quantum Eraser Experiment (1999). This experiment can be considered a modified initial double-slit experiment.

The famous long-standing Schrodinger equation will be generalized by a novel boundary value problem. This new mathematical approach will help to better describe and elucidate the reality of a micro world.

The ramifications for the space exploration will be be discussed as well.

H0.6-0019-18 THERMAL DESIGN OF A QUANTUM OPTICS EXPERIMENT ABOARD THE ISS

Marvin Warner, marvin.warner@dlr.de

ZARM, University of Bremen, Bremen, Germany Jens Grosse, jens.grosse@dlr.de

ZARM, University of Bremen, Bremen, Germany Lisa Wörner, lisa.woerner@zarm.uni-bremen.de ZARM, University of Bremen, Bremen, Germany Ernst Maria Rasel, rasel@iqo.uni-hannover.de Leibniz Universität Hannover, Hannover, Germany Wolfgang Schleich, wolfgang.schleich@uni-ulm.de Universität Ulm, Ulm, Germany

Claus Braxmaier, claus.braxmaier@dlr.de

DLR - Institute of Space Systems, Bremen, Germany BECCAL-Team

Bose-Einstein Condensate - Cold Atom Laboratory

Bose-Einstein Condensate - Cold Atom Laboratory (BECCAL) is a high precision quantum optics experiment about to fly on the International Space Station (ISS). BECCAL is a bilateral collaboration established between NASA and DLR. The facility shall satisfy the needs of both the American and German scientific community concerning cold atoms physic.

Proper thermal stabilization of any high precision experiment is crucial to its operation. Here, the requirements are further complicated by having to fit the constraints of the ISS. This contribution will cover a summary of the occurring thermal loads and present a concept of the Thermal Control System (TCS).

The predecessors to BECCAL are the sounding rocket campaigns MAIUS (MAteriewellen Interferometrie Unter Schwerelosigkeit - Matter wave interferometry in microgravity). MAIUS was developed by a German consortium and produced the first BEC in space. Consequently BECCAL inherits many systems and components from MAIUS with planned novel features. BECCAL shall be housed in a quad locker and a single locker inside an EXPRESS (Expedite the PRocessing of Experiments to Space Station) rack on the ISS. For this reason the payloads structure and the TCS have to be adapted.

BECCAL consists of three main systems: The laser system, the control electronics and the physics package. Especially the electronic components and the laser induce high thermal loads to the structure. In addition, most of the electronic and laser components require a narrow temperature range and a limited temperature gradient during operations. The lasers, for instance, require a frequency and power stabilization during operation to allow for an ideal performance. Therefore, the TCS has to stabilize the micro optical bench of the lasers to ± 0.1 K. Considering the high electrical powers averaging 850 W with a peak power of up to 1.13 kW in close proximity to the lasers, thermal stabilization has to be designed carefully to meet the payloads requirements.

The ISS provides multiple options for thermalizing installed payloads. Two of which are considered for BECCAL: A water cooling cycle in a Moderate Temperature Loop (MTL) and a ducted air cooling via the Avionic Air Assembly (AAA). The Rack provides two interfaces to the MTL with quick connectors. A maximum of 500 W cooling is possible with one interface. The AAA allows up to 200 W cooling for each payload position.

Within this contribution, these restrictions and the challenging thermal requirements of the experiments subsystems will be discussed and the current design of the TCS presented.

H0.6-0020-18 MEMORY LAYOUT FAULT TOLERANCE TESTING OF APPLICATION SOFTWARE ON-BOARD EPD INSTRUMENT CONTROL UNIT

Antonio Da Silva, antonio.dasilva@upm.es Universidad Politécnica de Madrid, Madrid, Spain Pablo Parra Espada, pablo.parra@uah.es Universidad de Alcalá, Alcalá De Henares, Spain Oscar Rodriguez Polo, opolo@aut.uah.es Universidad de Alcalá, Alcalá De Henares, Spain Sebastián Sánchez Prieto, sebastian.sanchez@uah.es Universidad de Alcalá, Alcalá De Henares, Spain Agustín Martínez Hellín, agustin.martinez@uah.es Universidad de Alcalá, Alcala De Henares, Spain

The Space Research Group (SRG) of the University of Alcalá is in charge of the development of the Instrument Control Unit (ICU) for the Energetic Particle Detector (EPD) on-board Solar Orbiter along with the corresponding boot (BOOTSW) and application software (ASW). Because of the proximity of the Sun, from the Solar Orbiter perspective, it is mandatory to look out for permanent memory errors resulting from a Single Event Latch-up (SEL) failures in application binaries stored in EEPROM and its SDRAM deployment areas. In order to better manage this process when a SEL happens, each one of the two ASW images stored in EEPROM is internally organized in a particular memory layout described by descriptors and a set of code/patch segments. This paper describes the EEPROM ASW binaries organization and the exhaustive runtime testing procedure in order to ensure that all possible fault pair in ASW binaries; memory location and faulty bits, is tested. This exhaustive verification has been accomplished by the use of a LEON2 Virtual Platform (Leon2ViP) with fault injection capabilities developed by the Space Research Group (SRG). Leon2ViP has been boosted with external scripting capabilities. This batch mode allow the definition of very complex fault injection scenarios and is especially useful in order to integrate the virtual platform in a continuous development and testing environment to achieve a complete test run automation. Thus, it has been possible to carry out a complete assessment of the effectiveness of the EEPROM memory layout fault tolerance mechanism stated in the system specification and to get feedback for their enhancement and correction.

H0.6-0021-18 ELECTRODE BREAKDOWN ANALYSIS IN NEAR SPACE

Xuwei Wang, wangxuwei@aoe.ac.cn

Academy of Opto-electronics, Chinese Academy of Sciences, Beijing, China Li Zhaojie, lizhaojie@aoe.ac.cn

Academy of Opto-electronics, Chinese Academy of Sciences, Beijing, China Zhang Yanlei, zhangyanlei@aoe.ac.cn

China Academy of Science, Beijing, China

In recent years, research on near space has drawn increasing attention and enterprises and research institutions from various countries have invested a great deal of manpower and resources into this field. Due to the special environment in near space, the electrode breakdown phenomenon of the electronic and electrical equipment in near space is different from those of ground, aviation and aerospace. Corresponding standards have been set to limit the electrode distances in situations of ground, aviation and aerospace. But in near space, the standards are not very clear. Electrode breakdown phenomenon refers to that the current it created between the positive and negative poles in the circuit due to the breakdown of particles in the air. The key to explaining electrode breakdown is Paschen's Law, which is related to the pressure, voltage, electrode distance and temperature. This article studies the electrode distance limitation in near space, including the electrode distance limitation of solar cells and high voltage battery packs under different conditions of high temperature, high voltage and low pressure, and verifies it with ground tests. The research in this article is of great significance by providing basis for the design and manufacture of near space electronic and electrical equipment in the near future.

H0.6-0022-18 STUDY ON THE SYSTEM PLAN OF INTELLIGENT RECONSTRUCTION BASED ON CARRIER ROCKET

Jingkun Zhan, jackie_zhan@163.com

China Academy of Launch Vehicle Technology, Beijing, China

Abstract:the technology of intelligent reconstruction of carrier rocket is self-repair and intelligent regeneration according to the system state, which does not rely on manual intervention, does not rely on hardware disassembly. It independently identifies the system state, which completes the rebirth of the inherent functions and regeneration of new functions. The reasons of system reconstruction include passive reconstruction based on changes in the inner state and active reconstruction based on changes in the external environment. The technology of reconfiguration that covering a complete technology ecological chain, relates to the testing, fault mode recognition, fault diagnosis, fault management, software architecture, reconfiguration decision making technology etc. According to the characteristics of rocket system, this paper put forward the plan of reconstruction scheme of launch vehicle system with hierarchical fault processing and reconstruction. Key words:carrier rocket,fault management,intelligent reconstruction.

LR.1-0001-18 GRAVITATIONAL WAVES AND ASSOCIATED EMISSIONS

Alessandra Corsi, alessandra.corsi@ttu.edu

Texas Tech University, Lubbock, Texas, United States

On 2017 August 17 the dazzling discovery of GW170817, a binary neutron star merger with an electromagnetic (EM) counterpart, marked the start of a new era in multi-messenger astronomy.

In this talk I will review what we have learned from GW170817, starting from the prompt detection of an associated gamma-ray burst by Fermi and Integral. I will then emphasize the key role of the massive space- and ground-based follow-up effort that unveiled the properties of GW170817 in all bands of the EM spectrum. Finally, I will discuss what questions remain open after GW170817, and highlight future prospects for joint gravitational wave and EM observations of the transient sky.

LR.1-0002-18 DAMPE AND ITS LATEST RESULTS

Jin Chang, chang@pmo.ac.cn

Purple Mountain Observatory, Chinese Academy of Sciences, NanJing, China

Dark Matter Particle Explorer (DAMPE), the first Chinese astronomical satellite, was launched into a Sun-synchronous orbit at an altitude of about 500 km on 17 December 2015. DAMPE is a high-energy particle detector optimized for observations of cosmic ray electrons and gammarays up to about 10 TeV. In this talk I'll introduce the on-orbit performance of the detector, the calibration, and the latest results on cosmic rays and gamma-rays of DAMPE.

Ogohara10, J. Peralta8, T. M. Sato8, T. Satoh8, M. Takagi11, S. Watanabe12, M. Yamada13, A. Yamazaki8, and E. F. Young14 *: presenting, Takeshi Horinouchi, horinout@ees.hokudai.ac.jp, 1: Hokkaido University, Japan, 2: AIST, 3: Rikkyo Univ., 4: Univ. Tokyo, 5: Kobe Univ., 6: Univ. Wisconsin-Maddison, 7: Univ. Colorado, 8: JAXA/ISAS, 9: Kyushu Univ., 10: Univ. Shiga Prefecture, 11: Kyoto Sangyou Univ., 12: Hokkaido Information Univ., 13: Chiba Inst. Tech., 14: Southwest Research Inst.

Since its orbit insertion in December 2015, Akatsuki has been providing new discoveries on the Venusian atmosphere, which is known for thick clouds and the super-rotation with angular speeds up to several tens of times as the solid planet. This talk will focus on dynamical aspects revealed from imaging at multiple wavelengths. Venus is covered with clouds that extend from about 45 to 70 km altitude. Images at the near-infrared "atmospheric window" wavelengths visualize the silhouette of lower-to-middle layer clouds. From Akatsuki's near-infrared images, it was found that a jet-like feature emerged and lasted over several months near the equator, which had never been observed previously. Also found are large-scale vortices presumably due to dynamical instability. These results suggest that winds in the lower and middle cloud layers are much more variable than have been thought. Ultraviolet imaging has long been used to observe winds at the cloud top. However, with novel two-wavelength imaging and cloud tracking with high accuracy, major advances have been provided from Akatsuki. We have succeeded in evaluating angular momentum budget regarding the super-rotation for the first time. Also found are hemispheric asymmetry that developed for a period of time and the existence of long-lasting overall vertical shear at the cloud top. Akatsuki's midinfrared imaging revealed that huge interhemispheric stationary gravity-wave signatures appear around the cloud top over low-latitude highlands when they are in local afternoon. This finding provided an unexpected probe of near-surface atmospheric conditions, since its formation depends on near-surface winds and static stability. It will provide a useful constraint for the study of the persistency of super-rotation. Long-term monitoring at UV from 2006 to 2017, including Venus Express observations, exhibits significant decadal variations of solar energy depositions at the cloud top level, which should affect atmospheric circulation. In fact, cloud-top super-rotation rate varied consistently. In combination with general circulation modelling and theoretical works, Akatsuki is expected to renew our understanding of the atmosphere of Venus.

LR.1-0004-18 A 25-YEAR RECORD OF GLOBAL MEAN SEA LEVEL CHANGE: WHAT HAVE WE LEARNED?

Steve Nerem, nerem@colorado.edu

University of Colorado, Boulder, Colorado, United States

A 25 Year Record

R. S. Nerem, B. D. Beckley, A. Cazenave, J. Church, J. Fasullo, B. Hamlington, B. Meyssignac,

G. T. Mitchum, and J. Willis

The 25-year record of global sea level change from satellite altimetry is one of our most valuable climate data records of how the Earth is responding to anthropogenic warming. But what have we learned from this record? This presentation will summarize our current understanding of sea level change based on the satellite altimeter record. One important fact we have learned from these observations is that the 25-year altimeter record occurs during a remarkably unusual time in the 100+ year sea level record. As a result, we must ask ourselves how this affects our interpretation of the altimeter record - are the changes we are observing short term or long term? Sorting out the natural and anthropogenic climate signals is a continuing challenge as we move in.

COSPAR CAPACITY BUILDING INITIATIVE: A REVIEW OF THE LAST 15 YEARS AND HOW TO FACE THE NEXT 10 (PCB.1)

PCB.1-0001-18 THE LAST 8 YEARS OF THE COSPAR CAPACITY BUILDING

Mariano Mendez, mariano@astro.rug.nl University of Groningen, Groningen, Netherlands

In this talk I will describe the purpose of this COSPAR initiative, and I will summarise the activities that the Panel on Capacity Building carried out in the last 8 years, the period during which I acted as chairperson. In particular, I will describe the expansion of the programme, both through a significant increase of the number of workshops we organised and the number of fellowships we awarded per year, and the involvement of new areas within the COSPAR remit.

PCB.1-0002-18 CROSS-DISCIPLINARY CAPACITY BUILDING IN SPACE WEATHER

Alexi Glover, alexi.glover@esa.int

Institute of Cosmophysical Research and Radiowave Propagation, FEB RAS, Paratunka, Russia

Raffaella D'Amicis, raffaella.damicis@ifsi-roma.inaf.it

INAF - Istituto di Fisica dello Spazio Interplanetario, Rome, Italy Fabio Becker-Guedes, fabio(at)dae.inpe.br

Instituto Nacional de Pesquisas Espaciais - INPE, Sao Jose Dos Campos, Brazil Dibyendu Nandi, dnandi@iiserkol.ac.in

Center of Excellence in Space Sciences India, IISER Kolkata, Mohanpur, India

Over the last 4 years, a series of Capacity Building Workshops in the cross-disciplinary subject of Space Weather has been initiated in the framework of COSPAR's Panel on Capacity Building. The first workshop took place in 2016 in Kamchatka, Russia led by IKIR RAS and the second will take place later in 2018 in Sao Jose dos Campos, Brazil led by INPE's Embrace Programme. This presentation will describe efforts undertaken to date in order to develop a format which combines scientific excellence with operational awareness and practices. Current experience will be presented along with possible future directions. Opportunities presented by increasingly available web technologies to reach a wider audience, while maintaining the integrity and quality of the courses themselves, will be discussed.

PCB.1-0003-18 IRI CAPACITY BUILDING WORKSHOP - AN ORGANIZER AND STUDENT PERSPECTIVE

Dieter Bilitza, dbilitza@gmu.edu

George Mason University, Fairfax, Virginia and NASA, GSFC, Greenbelt, Maryland, United States

Chinmaya Nayak, physics642@gmail.com

George Mason University, Fairfax, Virginia, United States

The International Reference Ionosphere (IRI) is a joint project of the Committee on Space Research (COSPAR) and the International Union of Radio Science (URSI) with the goal of developing and improving an international standard for Earth's ionosphere. IRI is well established and widely used and in 2014 was elected as the ISO standard for ionosphere (ISO

= International Standardization Organization). Good performance, easy use, and open accessibility have made IRI a catalyst for ionospheric science in many developing countries and an excellent topic for COSPAR's Capacity Building Workshops (CCBW). IRI already had a long tradition of bi-annual workshop with 60-100 participating experts. Combining this expert meeting with a training program for students has turned out very beneficial for students and experts. The students get a full week of lectures and hands-on study followed by, in many cases, their first participation and presentation at an international science meeting. This, on the other hand, also makes it easier to find good lecturers because they were planning to come to the IRI Workshop anyway. Lecturers and participants in the expert meeting may find good candidates for open graduate and post-doc opportunities to work on their science projects. During the first week training the students will work in groups of 4 or 5 on a specific ionospheric modelling problem and present their results during the second week expert meeting. They are encouraged to continue their collaboration after the workshop and are invited to publish their results in a special issues of Advances in Space Research dedicated to ionospheric modelling and data assimilation. We will present experiences from the 2015 and 2017 IRI CCBWs from the organizer and student perspective.

PCB.1-0004-18 COMMENT ABOUT CAPACITY BUILDING WORKSHOP "CRYSTALLOGRAPHY FOR SPACE SCIENCES" CO-ORGANIZED BY IUCR-COSPAR-IAU IN PUEBLA, MEXICO, 2016

Hanna Dabkowska, dabkoh@mcmaster.ca

IUCr, International Union of Crystallography, Hamilton, Canada Juan M. Garcia-Ruiz, juanma.garciaruiz@gmail.com

University of Granada,, Granada, Spain Mariano Mendez, mariano@astro.rug.nl

University of Groningen, Groningen, Netherlands Maria Eugena Mendoza, emendoza@ifuap.buap.mx UAP, Puebla, Mexico

Guillermo Tenorio-Tagle, gtt@inaoep.mx iNAOE, Puebla, Mexico

COSPAR, the International Union of Crystallography and the International Astronomical Union together organized a very successful International School/Workshop on Crystallography for Space Sciences, within the frame of COSPAR Capacity Building Workshop (CBW). It was held in Puebla, Mexico in April 17-29 2016. The aim of the Workshop was to prepare a selected number of participants for the next generation of projects in search of a deeper knowledge and understanding of extraterrestrial minerals and rocks, either large solid bodies or interstellar dust particles, using in-situ and remote analytical techniques. The workshop hosted about 30 PhD students, postdocs and young staff members from Central and South America. They were trained in modern crystallographic techniques in the fields of diffraction, imaging, spectroscopy and remote sensing. They learned from the world class experts about the formation of mineral growth patterns in the early Earth, our Moon, Mars and other planets and moons, meteorites and interstellar dust, as well as relevance of crystals with origin of life and detection of primitive life forms. During the workshop, the students analyzed and discussed data from the missions Discovery and Curiosity as well as the forthcoming Exomars mission. Portable difractometers and spectrophotometers designed for these missions were used during field trips for remote analysis of volcanic rocks. Possibilities of organizing similar CBW on other continents will be discussed

PCB.1-0005-18 THE COSPAR CAPACITY BUILDING WORKSHOP AT MEKELLE UNIVERSITY IN ETHIOPIA

Nat Gopalswamy, nat.gopalswamy@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States

This talk summarizes the experience in organizing the COSPAR Capacity-Building Workshop "Coronal and Interplanetary Shocks: Analysis of Data from SOHO, Wind, and e-CALLISTO" in Mekelle University, Ethiopia. The main objective of the COSPAR Capacity-Building Workshops is to encourage the scientific use of space data by scientists in developing countries. In particular, in view of the large number of extensive archives of data from past and current space missions, and the ready access to these and the associated analysis software via the internet, the typical workshop aims to provide a highly practical training in the use of one or more of these, based on current missions. In line with this objective, a two-week workshop introduces data analysis of space-based white-light coronagraph observations and radio spectral observations from space and ground to study shocks driven by coronal mass ejections. In particular, the wealth of data accumulated at the CDAW Data Center at NASA Goddard Space Flight Center from the ESA/NASA Solar and Heliospheric Observatory (SOHO) mission, NASA's Solar Terrestrial Relations Observatory (STEREO), NASA's Wind and Advanced Composition Explorer (ACE) missions are used. In addition, ground based radio data from the e-CALLISTO network and the Radio Solar Telescope Network (RSTN) around the globe are used for the study. Context information from NOAA's GOES mission and NASA's Solar Dynamics Observatory (SDO) missions are also used. This workshop enables scientists and students in developing countries where the eCALLISTO instruments are deployed to use their data in conjunction with space data to study Earthaffecting solar transient phenomena.

PCB.1-0006-18 EXPERIMENTAL TRAINING AND CAPACITY BUILDING: EUROMOONMARS WORKSHOPS AND FIELD SIMULATIONS 2016-2018

Bernard H. Foing, bernard.foing@esa.int ESA/ESTEC, Noordwijk, Netherlands EuroMoonMars Team (2016-2018)

B.H. Foing (1,2,3), G.A. van der Sanden (1,2,3), E. Clavé (1,2,3), H.C. Vos (1,2,3), L.C. Dubois (1,2,4), J.Vago (1), M. Grulich (1,2,6). J. Lousada (6), S. Hettrich (2,6), C. Jonglez (1,2,4),

A. Lillo (1,2,4), A. Kołodziejczyk (5), C. Heinicke (2,3,7), M. Harasymczuk (5), M. Krainski (1), A. Zaklynsky (2,8), A. Sitnikova (2,8), A. Izotova (2,8), A. Neklesa (2), J. Preusterink (2,9) & ILEWG EuroMoonMars 2016, 2017 & 2018 support teams, 1)ESA/ESTEC, Postbus 299, 2200 AG Noordwijk, NL, 2)ILEWG, 3)Vrije Universiteit Amsterdam, 4)ISAE Supaero, 5)LunAres Space Garden, Poland, 6) SGAC, 7)ZARM, 8)ArtScience Interfaculty The Hague, 9)Kopernicus Observatory

The ILEWG/COSPAR EuroMoonMars programme conducted in 2016-2018 a series of workshops and field analogue missions where students and professionals all over the world became one space crew. Young professionals joined the team as scientists, engineers or as education/outreach experts in process of simulating real life and work on the MoonMars ExoHab and ExoLab laboratories, and in order to develop experience, training and capacity building.

Goals: The EuroMoonMars mission simulations in ESTEC 2017 and 2018 set a few key goals:

First of all the participants had been developing and testing equipments, experiments, investigations, and procedures.

Secondly they developed their own communication protocol between the Mission Control Center, the ExoLab and the ExoHab from both technical and verbal sides aimed to standardize and facilitate the communication.

Thirdly, they performed evaluation of ergonomics of all units and the equipment needed to complete the mission.

And finally, samples were collected from the surface for analysis in the MoonMars labs.

All above was the subject of a training program in the process of learning astronaut's daily performance.

PCB.1-0007-18 COSPAR CBP: GOOD, BETTER, BEST - NEVER LET IT REST

Carlos Gabriel, carlos.gabriel@sciops.esa.int ESA/ESAC, Villanueva De La Cañada, Spain

The Capacity Building Programme is considered today one of the flagships of COSPAR activities. It started in 2001 as a tentative project to widening expertise in space science and promoting the use of data archives from space missions in developing countries. A first period of settling down went on for 8-9 years, led by Prof. Willmore, in which the initial concepts were refined, the usefulness of the workshops confirmed and an associated Fellowship created. A second period, marked by a continuous expansion followed, this time with a Panel heading the Programme, in which the different main space science disciplines were represented. This year is perhaps a good moment to reflect on what can be done better, what is still missing in the Programme, and how we can use the impending Panel reorganisation to renew and expand our objectives, and so maybe initiate a new era of the CBP. Under these premises, I would like to present and discuss some ideas concerning: a) ways to better evaluate the impact of the Programme, b) a larger interaction between the diverse space disciplines represented in it, and c) an extension of the Programme with the aim of motivating younger students to move in the direction of space sciences in developing countries.

PCB.1-0008-18 A STUDENT'S VIEW OF THE COSPAR WORKSHOPS

Mariano Mendez, mariano@astro.rug.nl University of Groningen, Groningen, Netherlands

This slot is reserved for short talks by former participants to COSPAR Capacity Building Workshops who attend the Assembly.

PE.2-0001-18 SPACE GENERATION EDUCATION PROFILE

Rosa Doran, rosa.doran@nuclio.pt

NUCLIO - Núcleo Interactivo de Astronomia, Sao Domingos De Rana, Portugal

Discussions on best practices for education are trending topics in all generations. How can we better prepare future generations? But the 21st century is bringing opportunities and challenges that are shifting towards a more demanding and deep change in our educational systems. Discussions about how to rebuild educational systems are taking place all around the world and space exploration, data handling, digital skills are some of the keywords helping steer the wheel towards the skills for the future. Space Exploration is a very rich topic that gracefully accommodates several concepts from different disciplines and is at the same time interesting and motivating for students. Space can also be the trigger to a more open schooling where discussions among local community stakeholders become part of the education process of their young members, preparing them to become critical thinkers and literate decision makers. In this presentation we intend to share with the audience some best practices taking place in Europe that are helping reshape how we collaborate with schools and how Space is having a major role.

PE.2-0002-18 ROBOTICS PROGRAMMING COMPETITION SPHERES, RUSSIAN PART. FIVE YEARS EXPERIENCE

Andrei Sadovski, asadovsk@rssi.ru

Space Research Institute (IKI), Russian Academy of Sciences, Moscow, Russia Natalia Biryukova, biryukovans@tsniimash.ru

Central Research Institute for Machine Building (TsNIIMash), Korolev, Moscow Region, Russia

“Spheres” such name was done to Russian part of the Zero Robotics project which is a student competition devoted to programming of SPHERES (SPHERES-Synchronized Position Hold Engage and Reorient Experimental Satellites are the experimental robotics devices which are capable of rotation and translation in all directions, http://ssl.mit.edu/spheres/), which perform different operations on the board of International Space Station. Competition takes place online on http://zerorobotics.mit.edu. The main goal is to develop a program for SPHERES to solve an annual challenge. The end of the tournament is the real competition in microgravity on the board of ISS with a live broadcast. The Russian part of the tournament has already five years history for high school students and two years for middle school but the problems, organization and specific are useful for the other educational projects especially for the international ones. We introduce the history of the competition, its scientific and educational goals in Russia and describe the participation of Russian teams in 2014-2018 tournaments. Also we discuss the organizational problems.

PE.2-0003-18 HOW TO TEACH ASTRONOMY TO ILLETERATE KIDS

Fatoumata Kebe, fatoumata.kebe@gmail.com IMCCE, CNRS, Observatoire de Paris, Paris, France

We founded the association Ephemerides 4 years ago. Its first goal was to teach astronomy to people living in marginalized places in the Paris region. In 2018 we started to organize astronomy activities in Mali, a West African country where only 23.1% of teenage girls go to secondary school. In our presentation we will share our experience and the different challenges we faced.

PE.2-0004-18 ASTRONOMY AND SPACE SCIENCE ON THE SCHOOL - AN OUTREACH PROJECT FOR ELEMENTARY AND HIGH SCHOOL STUDENTS OF BRASILIA

Jose Leonardo Ferreira, leo@fis.unb.br Universidade de Brasília UnB, Brasilia DF, Brazil Rodrigo Miranda, rmiranda@unb.br

University of Brasilia, 70910-900, Brazil Ivan Ferreira, ivansoaresf@gmail.com University of Brasilia, 70910-900, Brazil Cassio Laranjeiras, claranjeiras@gmail.com

Universidade de Brasília UnB, Brasília, Brazil

This project aims to develop interdisciplinary actions, articulated and convergence in the field of education, dissemination and popularization of science and technology in Brasilia-DF, the Federal District of Brazil. These actions are also been carried out at DF surroundings areas. Since 2015 linked convergent actions are focused on the development of space science and astronomy teaching with hands on experimental activities. Workshops, short basic astronomy courses, expositions and planetarium show are been carried out by a team of professors, graduate and under graduate students from University of BrasiliaUnB. At the same time upgrade actions are been done in order to modernize The Luiz Cruls Astronomical Observatory located at the far campus of UnB, named Fazenda Água Limpa. It is now a Center for research and space science dissemination and popularization not only for students but also for the whole community of Brasilia. Working toghether with the Physics Institute of UnB we have the recently created a Museum of Science and Technology of Brasilia, temporarily located at the UnB campus. The Museum is responsible for contac with schools and Brasilia community and for the organization of the activities of the Science on the School Project.

Science on the School is an educational, scientific and cultural proposal was approved and financed by the brazillian national research council (CNPq) and by the Science and Technology Reseach Foundation of Brasilia. Besides science dissemination for the brazillian society the project is also developing theoretical and experimental research in the area of Space Science and Astronomy. The project also aim to transform the Museum in a strong Science Education Center for the Brazil central region population, It is going to be a cultural environment and leisure for the Federal District and surrounding areas of Brasilia.

In this work we will describe the coordinate actions of the Astronomical Observatory and of the Museum destinated to public communication of up to date advances of science and technology.

In their facilities will be possible to conceive, plan, develop, encourage and support scientific activities (playful and interactive) in schools and communities of Brasilia and surrounding areas, focusing on different aspects of space science and astronomy and their relationship with society through investigative practices involving, particularly students and teachers of basic education and the community in General. The project is acting even in the promotion of events, courses, workshops and scientific-cultural experiences, production of radio and TV programs aimed at promoting initiation into Science and environmental awareness on basic education.

PE.2-0005-18 THE ARGUMENT FOR USING QUALITY SCIENTIFIC LEVEL EQUIPMENT IN PRIMARY SCHOOLS FOR AUTHENTIC ASTRONOMY ACTIVITIES TO INCREASE KNOWLEDGE OF AND IMPROVE ATTITUDE TOWARDS SCIENCE.

Auriol Heary, auriol.heary@iinet.net.au

University of Western Australia, Western Australia, Australia David Blair, david.blair@uwa.edu.au

University of Western Australia, Western Australia, Australia Grady Venville, grady.venville@uwa.edu.au

University of Western Australia, Australia David Coward, coward@physics.uwa.edu.au

University of Western Australia, Perth, Australia

This presentation reports on the ability of primary school students to use scientific level telescopes efficiently. It outlines impact that participation in authentic science activities can have on student knowledge of and attitude towards science.

Modern, relatively cheap automated telescopes and imaging software has made transient object searches a valuable addition to research based activities conducted by professional astronomers. This provided an opportunity to use transient object searches as a tool for authentic science in the classroom. The students located and imaged astronomical transient objects, such as near Earth asteroids. It is an exciting field of modern research where discoveries can have real life implications, such as discovering potentially hazardous near Earth asteroids.

The ability of primary school students to understand complex concepts is generally underestimated. This activity followed ten and eleven year old students from a primary school classroom in Western Australian as they successfully used three different research level telescopes. Each telescope had a different system of operation, yet the students were able to locate known asteroids and plan and execute a search for ones yet to be discovered.

PE.2-0006-18 NEW METHODS OF TEACHING ASTRONOMY AND SPACE SCIENCE IN NEPAL

Jeevan Lamsal, jvnlamsal@gmail.com

Pokhara Astronomical Society (PAS), Pokhara, Nepal

Pokhara Astronomical Society (PAS) has introduced new techniques in teaching astronomy and space science in Nepal with more practical approach since 2012. We are helping students to construct refracting telescopes from PVC pipes and using it to observe the night sky which is contributing to bring remarkable interest in studying astronomy in middle school. Similarly in high schools we have organized series of webinars with renowned scientist from different parts of the world. We have screened documentaries of space activities; and are helping students to use online robotic telescopes by using internet. This eventually is creating more interest in students to study science and particularly astronomy and space science in their higher studies. The use of mobile apps and different satellite tracking website have helped students to determine the location of space objects and has generated curiosity in students for the detailed study of them. Students are learning practical methods of weather forecasting. New generations of students are now learning the uses and benefits of space based technology also from outside of the curriculum. We have organized numerous talk show programs to spread the awareness of space education in the different parts of the country. We are now reaching thousands of students with different proceedings to popularize astronomy and generating interest to pursue higher education in this subject. As well as creating the scientific awareness and understanding among others who are not choosing science in their higher studies. This paper highlights the means of advanced and practical approaches of teaching astronomy and space science over traditional approach.

PE.2-0007-18 ASTRONOMY EDUCATIONAL OUTREACH PROGRAM IN NEPAL.

Suman Gautam, frenzsuman@gmail.com Tribhuvan University, 9846142632, Nepal

Education of basic space science and astronomy is nominal in Nepalese society. Institutionalization's of it providing space science education are few in number. No space agency is in existence till. Yet, the development in space science and technology is very much essential in raising our living standard.

The coverage of astronomy education to students and public is very less. Only 20%, 25% and 30% of the entire course contains the few topics on astronomy on secondary, undergraduates and graduates level. However some research works on astronomy are carried out by Tribhuvan University at central and state level. The gap in the astronomy education are fulfilled by some existing astronomy clubs like PAS by conducting educational outreach programs like, Night sky observation and hands on activities through constellation models, Solar motion, Star clock whereas for the public conducting by the series of night sky observation as well as the awareness programs on several astronomical phenomenon like eclipses. These types of activities create a lot of interests to the school students and reduce the superstition beliefs prevailing in the society. So this paper discussed the major beliefs prevailing in the society and the major steps taken by clubs to eliminate the beliefs. In addition importance of the educational outreach conducted outside the program to enhance the astronomy education will be highlighted.

Key Words: Educational Outreach, Hands on Activities, Public

PE.2-0008-18 THE NASA/IPAC TEACHER ARCHIVE RESEARCH PROGRAM (NITARP): 12 YEARS OF WORKING WITH HIGH SCHOOL TEACHERS

Luisa Rebull, rebull@ipac.caltech.edu

California Institute of Technology, Pasadena, California, United States Varoujan Gorjian, varoujan.gorjian@jpl.nasa.gov

NASA, United States

Gordon Squires, squires@ipac.caltech.edu California, United States

NITARP, the NASA/IPAC Teacher Archive Research Program, gets teachers involved in authentic astronomical research. We partner small groups of educators with a professional astronomer mentor for a year-long original research project. The teams echo the entire research process, from writing a proposal, to doing the research, to presenting the results at an American Astronomical Society (AAS) meeting. The program runs from January through January. Applications are available annually in May and are due in September. The educators' experiences color their teaching for years to come, influencing hundreds of students per teacher. This submission will review the NITARP program, including lessons learned.

PE.2-0009-18 ATTEMPTS TO BRING TRAINED TEACHERS IN THE SCHOOLS OF NEPAL

Jeevan Lamsal, jvnlamsal@gmail.com

Pokhara Astronomical Society (PAS), Pokhara, Nepal

To develop space activities and to industrialize astronomy, base of space education in the high schools must be very effective. This paper highlights the present scenario of space education and discusses the syllabus of astronomy in the different education level of Nepal. Astronomy is included in the curriculum of science book of middle school and high school which contains very few contents of solar system, constellations, galaxy, black holes and formation of stars. There are no any degrees for higher studies in astronomy as a separate department in any universities of Nepal. This paper also highlights the space activities and national level programs conducting in Nepal to support astronomy education. With the rise of many astronomical clubs and societies in the different regions of Nepal, astronomy education has been more effective in the recent time. Galileo Teacher's Training Program is being organized in the different parts of Nepal since 2011 by Global Hands on Universe in cooperation with local astronomy clubs. The attempts to bring more trained and skilled teachers in the classroom by the government and non-government agencies are now gradually increasing. The competition of private schools and their capacity building workshops to their teachers to attract more students is also playing active role to shape the school education effective. The challenges, prospects and the practice of effective astronomy education prevailing in Nepal will be discuss.

PE.2-0010-18 EDUCATIONAL OUTREACH ACTIVITIES OF TEAM PULI SPACE TECHNOLOGIES IN INDIA

Muhammad Shadab Khan, shadab_khan@msn.com IMT Mines Albi, Albi, France

Educational Outreach activities have an important role to play in our quest for Space exploration in not only inspiring the youths and students to choose space science as a career but also to educate the general public to make them aware about the mysteries of the Universe and the efforts being taken by the humans in bringing the applications of space technology in various daily life on Earth. Team Puli Space Technologies, an Ex-Google Lunar X-Prize Competitor Company from Hungary has marked its presence in India during several occasions at Educational Outreach events. The company motto to Moon and beyond is flagship sentence to inspire the young kids. The connection of the word "Puli" with India is not new. In 2015 an Indian movie named "Puli" was released much before Team Puli Space Technologies got to make its presence in India with the Educational Outreach events. The word Puli is from Tamil language which means Tiger. Most recently in the month of September, a Water Rocket Launch event was conducted in India where Team Puli Space Technologies got its presence with the Team Puli Logo marked on the Water Rocket. The successful launch of the water Rocket with team Puli Logo on it signifies that the Team Puli Space Technologies will have journeys to the outer space in the coming time with its ongoing project Puli Rover will become an additional source of inspiration to lift off in quest for exploration of Moon,Mars and beyond. The Educational outreach activities have not only helped in making people aware about the works of Puli Space Technologies in India particularly school and college students but also encouraged and motivated the young students to participate in space science activities during the events and inspired them to look up space technology as a career perspective. Before Team Puli Space actually starts its trip to Moon and beyond such educational outreach events will definitely help the Team Puli Space to make presence in different parts of the world through the various and establish the presence of the Hungarian flag as one of the forefront leader in the quest for Space exploration for the benefit of mankind on Earth.

PE.2-0011-18 SPACE RESEARCH INSTITUTE (IKI) EXHIBITION AS AN EDUCATIONAL PROJECT

Andrei Sadovski, asadovsk@rssi.ru

Space Research Institute (IKI), Russian Academy of Sciences, Moscow, Russia Elena Antonenko, antonenko@iki.rssi.ru

Space Research Institute (IKI), Russian Academy of Sciences; Moscow Institute of Physics and Technology, Moscow, Russia

The Exhibition “Space Science: Part and Future” in Space Research Institute (IKI) was opened in 2007 in commemoration of the 50th anniversary of the first man-made satellite launch. It covers the latest and the most important findings in space research, shows instruments which are used in space exploration, and presents past, current, and future Russian science missions. Prototypes of space instruments developed by Russian specialists and mockups of spacecraft and spaceships flown to space are displayed, together with information posters, describing space missions, their purposes and results. The Exhibition takes a great part in school space education. Its stuff actively works with schoolchildren, undergraduate students and also makes a great contribution in popularization of space researches. Moreover the possibility to learn about scientific space researches first-hand is priceless. We describe the main parts of the Exhibition and forms of it work and also describe the collaboration with other museums and educational organizations.

PE.2-0012-18 31ST JANUARY LUNAR ECLIPSE, HYDERABAD - A REPORT OF NS ASTROCLUB SPONSORED EVENT

Sumit Ghosh, dr_sumitghosh@yahoo.com

Andhra Vidyalaya College, Osmania University, Hyderabad, India Naveen Chary, gnaveenchary@rediffmail.com

India

The lunar trifecta, combination of a super moon, a total lunar eclipse and a blue moon watching event was organised by the NS Astroclub. The club has been organising such celestial and sky gazing events from time to time. Such a rare celestial wonder in India was one of its kind. A report of the event is presented.

The first glimpse of eclipse was visible from 18:10, 72 degrees ENE onwards till the eclipse ended at 21:39. Total duration was 3hours, 29 min approx. Necessary preparations were planned and put in place for the D-Day - Telescope with tripod, Astro binoculars, Astro Camera, stop watch, flash lights.

Students were prior informed of the event and the response was enthusiastic. It was heartening to see the onlookers who for the first time let go of their traditional beliefs and watched this mega event. This time even the weather gods supported us with clear skies, although it was a very chilly night. Beforehand, a short ppt presentation was made by our subject expert on the fundamentals and the process of observing the event, the different phases of the eclipse. This proved a lot informative as the students were made to realise what they would be seeing and the interpretations. High tea was arranged. Further necessary precautions in observations were emphasised.

The students and others gazers circled up and started to observe the celestial event as it unfolded first time in 35 years where a blue moon had synched up with a supermoon and a total lunar eclipse. All students were bubbling with euphoria when they sighted the blood red moon during the peak of the eclipse and awed at the various shades of red, followed later on with the different phases of eclipses. Using the astro cam, pictures of the event were shot. After the totality the partial eclipse was witnessed by the audience. The session ended with the culmination of the penumbral eclipse and the crowd was mesmerised, most of them witnessing this event for the first time, a timeless moment inscribed permanently in the mind.

PE.2-0013-18 ATTEMPTS TO BRING TRAINED TEACHERS IN THE SCHOOLS OF NEPAL

Jeevan Lamsal, jvnlamsal@gmail.com

Pokhara Astronomical Society (PAS), Pokhara, Nepal

To develop space activities and to industrialize astronomy, base of space education in the high schools must be very effective. PE.2-0014-18 SEEKING AN INTEGRATIVE VISION OF THE PLANET AND MAN IN BRAZILIAN BASIC EDUCATION THROUGH THE TEACHING OF SPACE SCIENCE IN SCHOOLS AND NON-FORMAL SPACES

Paulo Guimarães, pauloguimaraes28@gmail.com PUC-MG, Belo Horizonte, Brazil

Peter Leroy, leroy@pucminas.br

PUC-MG, BELO HORIZONTE, Brazil

Brazilian education is governed by the National Curricular Parameters (PCNs). These, in principle, favor an integrative view among several areas of knowledge. However, they are not always fully developed, partly due to deficiencies in teachers training, among other problems.

The group of Astronomy and Astrophysics (GAIA) of PUC Minas develops activities of teaching and dissemination of science, in the Museum of Natural Sciences of PUC and in other spaces.

Through teaching materials prepared by the Brazilian Space Agency (AEB), the group proposes activities to instigate students' interest in space science as a way to solidify the experience of scientific literacy, reinforcing the implementation of the PCNs. These activities include space science training courses for teachers, courses and lectures for students, hands on experiments and workshops, observation of the sky, planetarium sessions, and rocket launching competition between schools. All this aims to give an integrative vision of the planet and civilization in order to create a more conscious, egalitarian and just society. An idea of a planetary civilization.

PEDAS.1-0001-18 WISE IR OBSERVATIONS OF BREEZE-M ROCKET BODIES AT GEO

Chris Lee, chjlee1996@gmail.com

University of Michigan, Ann Arbor, Michigan, United States Joshua Fitzmaurice, joshua.fitzmaurice@rmc.ca

California Institute of Technology, Pasadena, California, United States Jeremy Murray-Krezan, jeremy.murray-krezan@us.af.mil

Air Force Research Laboratory, Albuquerque, New Mexico, United States Thomas Schildknecht, thomas.schildknecht@aiub.unibe.ch

Astronomical Institute, University of Bern, Bern, Switzerland

In 2010, NASA's Wide-field Infrared Survey Explorer (WISE) observed the entire sky from low Earth orbit in four infrared (IR) bands simultaneously (3.4, 4.6, 12, 22 microns). Although WISE was originally launched to investigate more distant astronomical sources, its orbit and scanning strategy serendipitously allowed for a large number of resident space objects (RSOs) to be detected in its images. The WISE IR bands measure reflected sunlight and thermal emission from RSOs, and the simultaneous four-band observations allow us to correlate RSO reflective and thermal properties. We investigate different populations of objects in the geosynchronous orbit (GEO) regime. Calibrated IR colors and magnitudes of ILS Proton Breeze-M rocket bodies are presented along with those of Titan rocket bodies and debris as well as active geostationary satellites. Preliminary results show that Breeze-M rocket bodies appear photometrically distinct from Titan rocket bodies but similar to cylindrical geostationary satellites. We discuss possible reasons for these differences.

PEDAS.1-0002-18 LIGHT CURVE ANALYSIS OF NON-OPERATIONAL GLONASS SATELLITES

Abdul Rachman, abdul.rachman@aiub.unibe.ch

Astronomical Institute, University of Bern, Bern, Switzerland Alessandro Vananti, alessandro.vananti@aiub.unibe.ch Astronomical Institute, University of Bern, Bern, Switzerland Thomas Schildknecht, thomas.schildknecht@aiub.unibe.ch Astronomical Institute, University of Bern, Bern, Switzerland

Knowledge of attitude dynamic of debris objects is crucial concerning the foreseen active debris removal missions. It also allows researchers to better understand the natural forces that govern the attitude motion of the objects. In this regard, 70 non-operational GLONASS satellites have been observed by the Astronomical Institute of the University of Bern (AIUB) for several years. Non-resolving optical observations of these objects was performed using the 1-meter telescope ZIMLAT located at Swiss Optical Ground Station and Geodynamics Observatory Zimmerwald in Switzerland. The resulting light curves were analyzed to obtain the apparent rotation periods and phase diagrams. Here we discuss our analysis of the temporal evolution of the rotation rates and of the signatures in the light curves.

PEDAS.1-0003-18 PROJECT LEDSAT: USING LEDS TO IMPROVE ORBITS AND ATTITUDE DETERMINATION OF LEO SATELLITES

Project LEDsat is an international effort to investigate the use of Light Emitting Diodes (LEDs) for applications on satellites in Low Earth Orbit (LEO). These applications include improved orbit determination by making the satellite visible even in Earth shadow, distinguishing satellites by using different flash patterns on satellites in simultaneous launches of multiple satellites, attitude determination, and telemetry.

Optical observations are often used for determining the orbit of uncooperative spacecraft and space debris and they provide the possibility to significantly improve the Two-Line Elements (TLE) orbital parameters estimation with a small set of optical data. However, a comparison between optical and other positioning data is not easily available for the uncooperative nature of the observed objects. LEDSAT will offer a unique opportunity to compare the optical orbit determination results to the on-board Global Positioning System (GPS) receiver data and to the laser ranging measurements allowed by on-board retro-reflectors, hence providing the chance to verify, improve and cross-correlate the optical stand-alone orbit determination techniques for space debris.

An Italian student team from Sapienza Space Systems and Space Surveillance Laboratory (S5Lab) at Sapienza - University of Rome

is developing the 1-Unit Cubesat LEDSAT. The satellite project is realized within the European Space Agency Fly Your Satellite! Programme, that will offer a satellite launch opportunity for the International Space Station in late 2019, in addition to technical support for the satellite development process. The satellite mission consists in testing a Light Emitting Diodes (LED) -based payload as calibration target for the current methodologies and techniques for optical-based orbit determination of space objects.

A student team from the University of Michigan is developing a 3U CubeSat LED mission called PHAROS. Initial efforts here are centered on a balloon payload to test visibility of LEDs, trajectory information from LEDs and other sources, and attitude determination of the payload. The primary goal is to verify the optical link budget used for future spacecraft missions.

We will review the current status of both of these missions, and how lessons learned will benefit knowledge of the increasingly congested LEO environment.

PEDAS.1-0004-18 HIGH ALTITUDE BALLOON DEMONSTRATION OF OPTICAL TRACKING AND ATTITUDE DETERMINATION FOR SATELLITES

University of Michigan, Ann Arbor, Michigan, United States

Here we present one part of an international effort to investigate the use of light emitting diodes (LEDs) for orbit determination and spacecraft identification by flight testing the concept on a high altitude balloon payload (HAB). The increasing number of spacecraft being launched into low Earth orbit (LEO) calls for new techniques for tracking, orbit determination and spacecraft identification.

The Michigan eXploration Laboratory (MXL) is a research laboratory run out of the University of Michigan Aerospace Engineering Department. MXL has flown 7 CubeSats and 29 HABs as technology demonstrations and science missions in collaboration with organizations such as NASA-JPL, NSF and SRI International. MXL will demonstrate the combined use of LEDs and a network of optical and radio ground stations to augment current LEO tracking abilities while still maintaining low cost through the use of existing ground station infrastructure and inexpensive hardware. This autonomous and robust tracking capability could enhance on-orbit satellite conjunction prevention and space situational awareness. Here, we describe a high altitude balloon flight mission to verify these concepts.

There are three facets to the demonstration: an LED balloon payload, an optical ground station network, and a radio ground station network. The LED balloon payload has been designed via an optical link budget that accounts for losses through links in the onboard battery of the communications system, the LEDs themselves, as well as the atmosphere and the ground telescope. The purpose of this mission is to prove the validity of our optical link budget in a real flight scenario, which derives the intensity of

the signal obtained given a specific telescope's parameters and LED input power. The radio ground station receives GPS telemetry data via APRS beacons that will provide feedback for a remote telescope that we will use to track the balloon payload. Once we are able to obtain stable tracking of the payload, we will use the optical ground station to detect and receive payload telemetry such as brightness and rotation rate. This telemetry will be post-processed to derive two closely interlinked datasets: attitude and light intensity, which will be compared to truth data collected on-board with gyroscopic sensors. This data and analysis is critical for the design of an optical tracking and attitude determination CubeSat mission.

PEDAS.1-0006-18 ALGORITHMS FOR AUTOMATED ANORMALY DETECTION OF GEO OBJECTS USING SPACE-BASED NON-RESOLVED OPTICAL OBSERVATIONS

Rong Xu, xurong@aoe.ac.cn

Chinese Academy of Sciences,AOE, Beijing, China Qingbo Gan, qbo.gan@aoe.ac.cn

Chinese Academy of Sciences,AOE, Beijing, China Fei Zhao, zhaofei@aoe.ac.cn

Chinese Academy of Sciences,AOE, Beijing, China

Ground-based non-resolved optical observations have been known to provide researchers with valuable information about satellite status. In order to cover all the objects in the GEO belt, at least three observatories are needed across the world. Instead of building overseas sites, one alternative option is to launch a space-based detector for characterization, which can also get rid of atmospheric effects. To reduce data transmission, we are designing algorithms that automate the process of rapidly characterizing objects from non-resolved optical data. Simulation tests have shown that our algorithms can achieve automated object identification and photometry. Via in-situ data processing of the lightcurves, unnormal status of the objects, including tumble rates, error pointing and miss tracking, can be detected and reported to ground sites, impelling the satellite manager to conduct a fine tracking of the concerned targets. Such algorithms, while deployed in future intelligent detectors, may become a great addition to the current capacity of debris measurements.

PEDAS.1-0007-18 PASSIVE OPTICAL SYSTEM FOR SPACE DEBRIS SURVEILLANCE AT NRIAG

- EGYPT

National Research Institute of Astronomy and Geophysics (NRIAG), Cairo, Egypt

As the number of space debris growths with time around the Earth, the collision probability between space debris and active satellites increases. In order to avoid a collision, it is necessary to monitor space debris. In the absence of an optical monitoring system in the Middle East and North Africa, National Research Institute of Astronomy and Geophysics (NRIAG) has been established the passive optical system for space debris surveillance which consists of an optical telescope attached with a highly sensitive camera with a field of view in the range of (3.4 x 2.3). According to this system, we can detect objects with a diameter about 10 cm which can cause major damage to active satellites. The primary goal of the optical system is to obtain and preserve physical and orbital information of space debris by purely optical means. To overcome the limits of optical observation, we have included in the International Scientific Optical Network (ISON) through scientific cooperation. The NRIAG team started a test operation in September 2017. A group of LEO space debris and satellites such as FENGYUN 1C DEB, CFESAT and COSMOS 2251 have been successfully observed using its NORAD Two-Line Element Sets (TLEs).

PEDAS.1-0009-18 LABORATORY SIMULATION OF MULTI-SITE SPECTRAL MEASUREMENTS OF A THREE-AXIS STABILIZED GEO SATELLITE

Fei Zhao, zhaofei@aoe.ac.cn

Chinese Academy of Sciences,AOE, Beijing, China Rong Xu, xurong@aoe.ac.cn

Chinese Academy of Sciences,AOE, Beijing, China

Spectral analysis has been playing a significant role in revealing the material composition of space objects. Compared to observations from a single site, simultaneous multi-site observations are supposed to provide more convincing results. This paper introduces a six degrees of freedom platform used for parallel physical simulating the actual lighting and observing geometry of space objects. Spectral measurements and analysis of a three-axis stabilized GEO satellite model, observed from three ground sites, are presented and yield two significant outcomes. First, spectral data collected by sites of adjacent latitudes share similar way of variation related to time, indicating an analogous combination of illuminated surfaces. Second, by examining the specific spectral features' appearing time during different observations, the attitudes of the satellite's body and panel can be roughly estimated. Such evidence implies the great potential of multi-site spectral measurements in determining the attitudes of space objects.

PEDAS.1-0010-18 VALIDATION OF THE MASTER MODEL

TU Braunschweig, Braunschweig, Germany

The Institute of Space Systems of the TU Braunschweig is currently developing the latest version of the European MASTER model. MASTER is the European reference model for the description of the space debris environment. It allows the calculation of a high-resolution particle flux on oriented satellite surfaces on Earth orbits. The model is based on the simulation of a large number of historical single events that released space debris. The descriptions of the release and the debris properties are based on statistical models. The orbital debris distribution is based on the higher orbit mechanics. There have been important improvements in this source modeling. The resulting populations must be validated with historical and current measurements. This validation is a very elaborate process in the development of the model. On the one hand, it is about the validation of the object population in the large size regime by observational data. For this the software PROOF is used. It compares the detections of simulated observations with actual measurement campaigns. Both, optical and radar measurements can be simulated. On the other hand, it is about the validation of the small sized particle population using impact data on retrieved satellite hardware. Here, the simulated particle flux is compared with the actually measured number of impacts. This paper shows examples of validating the new version of the MASTER model. The process of validation will be explained. The procedure is identical to the validations of previous versions of the MASTER model. The revised historical population will be re-validated. New results are presented taking into account data from current measurement campaigns. It will be illustrated with selected examples how the simulated results match the measured data.

PEDAS.1-0011-18 ENVIRONMENTAL ESTIMATION ON SUB-MILLIMETER-SIZE DEBRIS UTILIZING IN-SITU MEASUREMENT DATA

Masahiro Furumoto, f.masa@aero.kyushu-u.ac.jp Kyushu University, Fukuoka, Japan

Toshiya Hanada, hanada.toshiya.293@m.kyushu-u.ac.jp Kyushu University, Fukuoka, Japan

Space debris smaller than 2 mm, which cannot be tracked nor detected by ground-based observations, may cause a fatal damage on a spacecraft. To understand the environment of such sub-millimeter-size debris sufficiently, in-situ measurements and modeling should be conducted. Therefore, IDEA the project for In-situ Debris Environmental Awareness, which aims to detect sub-millimeter-size debris using a group of micro satellites, has been initiated at Kyushu University. To estimate the debris environment based on in-situ measurements from the project, this paper proposes an environmental model that estimates the population of sub-millimetersize debris utilizing the date, time and location at impact on a measurement satellite. The proposed environmental estimation is based on an algorithm of a particle filter, considering the natures of orbits on which debris can be detected by the in-situ measurement satellite. This paper also evaluates the proposed model with a simulation using MASTER-2009, which is the environmental model developed at European Space Agency. Comparison between the debris population predicted by MASTER-2009 and the simulated estimation verifies that the proposed model can estimate the debris environment. Collision flux estimated by the proposed model is also evaluated to predict the impact rate into the measurement satellite. It is concluded, therefore, that the estimation model proposed and evaluated in this paper can provide a better definition of sub-millimeter-size debris environment with in-situ measurements.

PEDAS.1-0012-18 UNCONTROLLED RE-ENTRIES OF SIZABLE SPACECRAFT AND ROCKET BODIES: A POTENTIAL THREAT IN THE AIRSPACE AND ON THE GROUND

Carmen Pardini, carmen.pardini@isti.cnr.it ISTI/CNR, Pisa, Italy

Luciano Anselmo, luciano.anselmo@isti.cnr.it ISTI/CNR, Pisa, Italy

More than 24,000 cataloged orbiting objects have re-entered so far into the Earth's atmosphere since the beginning of the space age. The associated returning mass, close to 30,000 metric tons, was mainly concentrated in intact objects, i.e. spacecraft, platforms and spent upper stages, accounting for nearly 29% of the re-entered objects. Over the last ten years, from 2008 to 2017, almost 440 large intact objects (80 spacecraft and 360 rocket bodies) have re-entered without control, with a total mass of about 900 metric tons (150 and 750 metric tons for spacecraft and spent upper stages, respectively). Therefore, approximately 90 metric tons belonging to large intact objects would have, on average, re-entered the Earth's atmosphere each year, and a mass fraction between 5% (4500 kg) and 15% (13,500 kg) might have crossed the airspace and hit the ground. In spite of a not negligible amount of mass suspected to have survived re-entry, and of at least fifteen events, from 2008 to 2017, in which spacecraft and rocket bodies components were retrieved, trivial damages to property occurred and no case of personal injury was confirmed. However, even if the risk related to the re-entry of manmade space objects is still extremely low, it cannot be commonly accepted as being inevitable. Moreover, it cannot be excluded that uncontrolled re-entries of sizable space objects might become of greater concern in the future, as a consequence of the increased use of space and growing population density on the ground.

After an overview of the most critical historic re-entries events, the attention will be focused on the re-entries of massive objects occurred without control during the last decade, highlighting:

1) the relative relevance of spacecraft versus rocket bodies (typically, the re-entry of large spacecraft catches more media and people attention than the re-entry of an equally, or even more massive, upper stage); 2) the re-entry frequency; 3) the distribution in inclination; 4) the potential risk due to a large returning mass (such as the NASA's Upper Atmosphere Research Satellite, the Russian cargo ship Progress M-27M, the Russian-Ukrainian second stage of the Zenit-3 launcher), or the presence on board of a significant amount of highly toxic propellants (as was the case of the Phobos-Grunt probe). For a number of re-entry events eyewitnesses sightings were reported and/or pieces of debris were recovered (as for debris from the RussianUkrainian Zenit-3 second stage 2015-074C, landed in Vietnam at the beginning of January 2016, or the Composite Overwrapped Pressure Vessel of the Vega's upper stage AVUM 2012-006K, recovered near Oddanchatram, India, in November 2016).

Hence, lessons learned from past uncontrolled re-entries of enough massive bodies suggest that, even if still small compared to other commonly accepted risks related to the lifestyle, or workplace and household safety, the risk for aircraft, or people and property on the ground, of being hit by falling orbital debris cannot be absolutely neglected. Moreover, it should not be ignored that also space vehicles intended for a controlled re-entry at the end of their mission may sometimes suffer failures, compromising the success of the planned de-orbiting strategy. This is, for instance, the case of the Chinese space station Tiangong-1. There are also large upper stages, with masses of about 4 metric tons or more, which still mostly re-enter without control.

PEDAS.1-0013-18 DETERMINATION OF HARMFUL SPACE DEBRIS USING TWO COLLISION CALCULATION ALGORITHMS

Keita Owatashi, 2te17929w@s.kyushu-u.ac.jp Kyushu University, Nishiku, Fukuoka, Japan, Japan Melissa Zemoura, melissa.zemoura@gmail.com Ariane Group, Limeil-Brevannes, France

Toshiya Hanada, hanada.toshiya.293@m.kyushu-u.ac.jp Kyushu University, Fukuoka, Japan

This paper investigates which debris are highly dangerous to exacerbate the future orbital environment based on the outcomes of an orbital debris evolutionary model with two different algorithms of collision risk assessment. One is "Two-Sphere Overwrap" collision risk assessment, which focuses on the geometrical relation between the orbits of the two colliding objects, calculates the collision risk on the assumption that the objects are closest to each other at the intersections of the orbital planes at an interval of one year. The other is "Cube" collision risk assessment, which focuses on the relative positions of the two colliding objects, calculates the collision risk when both objects are inside a cube with a side of 10 km at an interval of 5 days. The previous study by the second author (Dr. Zemoura) identified harmful debris to be removed based on the outcome of an orbital debris evolutionary model with the "Two-Sphere Overwrap" collision risk assessment. As a result, it was found that there are removal debris with short-term environmental improvement effect and removal debris with long-term environmental improvement effect. This paper identifies harmful debris to be removed based on the outcome of the same orbital debris evolutionary model but with the "Cube" collision risk assessment. Finally, this paper compares harmful debris to be removed between the previous and present outcomes and investigate how the harmful debris to be removed change as the collision risk assessment changes.

PEDAS.1-0014-18 DESIGN OF A BAU SCENARIO INCLUDING CURRENT TRENDS IN THE SPACE MARKET

Kerstin Soggeberg, k.soggeberg@tu-braunschweig.de TU Braunschweig, Braunschweig, Germany

Jonas Radtke, j.radtke@tu-braunschweig.de

Institute of Aerospace Systems, TU Braunschweig, Braunschweig, Germany Carsten Wiedemann, c.wiedemann@tu-bs.de

Institute of Space Systems, TU Braunschweig, Braunschweig, Germany Enrico Stoll, e.stoll@tu-braunschweig.de

TU Braunschweig, Braunschweig, Germany

Since the beginning of space exploration, the amount of space objects and especially space debris in Earth orbits has almost steadily increased. Consequences are a rise up of collisions (e.g. Sentinel 1-A in 2016) and collision avoidance maneuvers, and satellite protection requirements. Thus, a stabilization of the space debris environment is desirable. For this purpose it is necessary to know which parameters influence the space debris environment and their importance.

To gain insight into the possible evolution of the space debris environment, long-term projections can be performed. These projections take into account all major space debris sources, like launches, explosion and collision events, and sinks, such as atmospheric drag, post mission disposal (PMD), and active debris removal (ADR). The long-term simulations are generally performed for time-frames of 200 years wherefore the final results contain large uncertainties. Nevertheless, by varying single modelling parameters, their impact on the long-term evolution can be ascertained, which then can be used to deduce measures towards a sustainable space environment. A starting point for these simulations is generally a business-as-usual (BAU) scenario. In this scenario, it is assumed that all parameters, that are governed by mankind, are perpetuated like in the past. This includes launch rates and any kind of mitigation measures, such as PMD, passivation, and collision avoidance as well as the possibility to perform ADR. As spaceflight is undergoing a significant change due to an increasing number of launches of small satellites and launches from private companies and the ascending likelihood of so-called mega-constellations, currently used BAU scenarios have become outdated. Therefore, this paper presents the development of a new BAU scenario, together with a parametric variation based on this scenario.

The first step in the development of a new BAU scenario is the estimation of future launch rates. For this purpose the launches of the past are categorized by launch countries, to be capable of mapping effects on single categories, e.g. the end of the Soviet Union or the entry of China into the space age. Private companies and satellites with a mass lower than ten kilogram are sorted in own categories. The received rates are then extrapolated to the future, utilizing a formula for logistic growth that is often used in biology to calculate bacterial growth. Contrary to usually used logarithmic extrapolation, this formula can map processes of saturation. Other parameters derived from past behaviour are PMD and passivation rates, and the number of explosions. Due to the direct extrapolation of data from the past, the created BAU scenario shows, in contrast to most of the other long-term simulations, a realistic possibility of the future space debris environment as it is indicated by current space flight activities.

Based on the new BAU scenario, a parameter study is performed in which the launch traffic (including the possibility to launch mega-constellations), passivation and PMD levels, collision avoidance performance, and the use of ADR are varied. A comparison between the different simulations of the parameter study enables to assess the importance of single parameters. Furthermore, the costs of each scenario are analysed to identify the efficiency of the various measures for an improvement of the future space debris environment.

PEDAS.1-0015-18 CHARACTERIZATION OF LOW EARTH ORBIT SPACE OBJECTS USING MULTIPLE MODEL ESTIMATION

Steve Gehly, steve.gehly@gmail.com

University of New South Wales Canberra, Campbell, Australia Rasit Abay, r.abay@student.adfa.edu.au

University of New South Wales Canberra, Canberra, Australia Andrew Lambert, a-lambert@adfa.edu.au

University of New South Wales Canberra, Canberra, Australia

Recent decades have seen the proliferation of man-made objects in Earth orbit, prompting the construction and maintenance of catalogs to predict potential collisions and ensure the safety of operational space assets. Although much of the emphasis in cataloging has been placed on estimating and predicting translational states and uncertainties, it is essential to additionally characterize parameters related to the size, shape, attitude, and material composition of space objects in order to accurately model their behavior and ascertain their origin and intent.

It is possible to extract features and estimate size, shape, and attitude parameters from resolved images, such as those obtained from space-based platforms in proximity operations or from powerful ground-based sensors imaging large objects. However, the majority of data collected for space situational awareness is produced by lower resolution ground-based sensors tracking small objects, which yields unresolved targets. Under these conditions, it is not generally possible to directly estimate the desired parameters, though useful information is still available from a combination of active and passive radiometric, photometric, spectral, and polarimetric sensors. This information can be exploited through the use of multiple model estimation techniques to characterize additional space object parameters.

Recent work has explored a variety of multiple model filters for object characterization, including multiple model adaptive estimation (MMAE), adaptive likelihood mixtures (ALM), and hierarchical mixture of experts (HME), primarily as applied to objects in geosynchronous orbit. This paper examines the relative performance of these techniques as applied to objects in Low Earth Orbit (LEO), which poses additional challenges in terms of visibility and sparseness of data availability. In addition, objects in LEO are subject to significant non-conservative perturbing forces such as atmospheric drag and lift, increasing the importance of accurately characterizing non-translation state parameters. Test cases evaluate the performance of the filters processing simulated optical measurements from a ground station in Canberra, Australia.

PEDAS.1-0016-18 HIGH AREA-TO-MASS RATIO OBJECT CHARACTERIZATION USING MACHINE LEARNING

Rasit Abay, r.abay@student.adfa.edu.au

University of New South Wales Canberra, Canberra, Australia Steve Gehly, steve.gehly@gmail.com

University of New South Wales Canberra, Campbell, Australia Melrose Brown, melrose.brown@adfa.edu.au

University of New South Wales Canberra, Canberra, Australia Russell Boyce, russell.boyce@adfa.edu.au

University of New South Wales Canberra, Canberra, Australia

High area-to-mass ratio (HAMR) objects at high altitudes have complex dynamical behav- ior due to their low mass compared to their high cross-sectional area exposed to the nongravitational forces. HAMR objects are observed by ground-based optical sensors because it is not only more efficient but also less costly compared to radar observations. However, dim light curves and complex dynamics of HAMR objects due to the attitude-orbit coupling challenge the optical surveys of ground telescopes to detect, track, and catalog them. The capability of characterizing such objects from astrometric, photometric, spectral, and polarimetric data without applying compute-intensive calculations is essential to promote the Space Situational Awareness (SSA).

Optical observations are sensitive to the material properties, size, shape, and attitude state of the space objects. It is possible to extract such features of the objects by fusing astrometric, photometric, spectral, and polarimetric data through the use of machine learning approaches. Although different varieties of multiple model adaptive estimation (MMAE) techniques are proposed to be used for the characterization of resident space objects (RSO), they are computationally expensive, and this makes them impractical for the optical surveys of HAMR objects. Machine learning models can provide near-real-time (NRT) predictions once they are trained. Recent research that applies machine learning methods to characterize the space objects uses continuous and dense astrometric or photometric data, and this makes it trivial for machine learning models to fit the data. However, the observational data are sparse due to the visibility challenges in the optical surveys.

This paper studies the practicality of using two different machine learning methods, namely Extreme Gradient Boosting (XGBoost) and Deep Neural Networks (DNN), to characterize HAMR objects from sparse astrometric, photometric, spectral, and polarimetric data. The training data are simulated data by using attitude-orbit coupled dynamics and high fidelity force modeling. The training data are divided in to train, development test and test datasets to test the generalization capability of the trained machine learning model.

PEDAS.1-0017-18 A COLLISION IN A CUBESAT CONSTELLATION

Fatoumata Kebe, fatoumata.kebe@gmail.com IMCCE, CNRS, Observatoire de Paris, Paris, France

Cubesats which are centimeters sized-satellites will represent a large part of the space objects population in the years to come. As the issue about space debris is growing, we need to define tools to study the impact of a fragmentation inside of a constellation composed of cubesats, a new low cost architecture that drastically reduce the access to space. We did a simulation by using the data of the European project QB50 which is led by the Von Karman Institute in Belgium. QB50 consists in a constellation of 50 cubesats that will orbit in one orbital plane to study the lower thermosphere (90-320 km). We made a virtual collision between a cubesat of the constellation with an other one which is not part of the constellation. Here we present our results about the evolution of the debris generated and their impact on the remaining cubesats. By using several representations of the relative motion we introduce the first tools adapted to the case of a fragmentation inside a constellation of satellite.

PEDAS.1-0018-18 OPTIMAL RE-ENTRY TIME PREDICTION OF RESIDENT SPACE OBJECTS FROM HIGHLY ELLIPTICAL ORBITS

Harishkumar Sellamuthu, hari251086@gmail.com Karunya University, Coimbatore-641114, Chennai, India Ram Sharma, ramkrishansharma@gmail.com

Karunya University, Coimbatore-641114, Coimbatore, India

About 5% of the catalogued resident space objects (RSO) around Earth are in highly elliptical orbits (HEO). The forecast of the distribution and lifetime of uncontrolled RSO is essential for carrying out stable and safe future space operations. With low perigee and high apogee, large uncontrolled RSO in HEO pass through high spatial density regions and are a potential source for increasing debris population. When RSO survive the re-entry disintegration process at the end of their lifetime, the resulting debris fragments may endanger terrestrial life. Re-entry time estimation of decaying HEO objects is a key area of debris mitigation and remediation.

The dynamics of the motion in HEO is governed by the influence of luni-solar gravity, atmospheric drag and oblateness of the Earth. The combination of atmospheric drag, varying with upper atmospheric density due to solar activity, and luni-solar perturbations alter the perigee altitude leading to lifetime variation from several weeks to decades. The orbital evolution and lifetime estimation of HEO objects are sensitive to the initial conditions which should be optimized for obtaining accurate re-entry time. Two initial parameters with significant uncertainties are the ballistic coefficient (B) and eccentricity (e). B, which varies with RSO's attitude during atmospheric passage, depends on the drag coefficient and RSO's area to mass ratio. e is uncertain since semi-major axis is easily computable from the orbital period.

The usage of complex perturbation models in nonlinear Newtonian equations of motion abets computational difficulties in obtaining accurate state vector. Using Kustaanheimo-Stiefel (KS) regularization method, linear differential equations of a harmonic oscillator with constant frequency is obtained and extended to perturbed motion. A regularized numerical orbit propagator (KSROP), with constant step-size, in terms of KS regular elements is developed. The Sun and the Moon ephemeris are computed using Plataforma Solar de Almería and a series expansion algorithms, respectively. An oblate atmospheric model using density scale height varying with altitude for drag and zonal harmonic terms up to J6 for oblateness effects, are considered.

In the present study, re-entry prediction of HEO RSO is treated as an optimal estimation problem. Two-line element sets of few RSO are used with SGP4/SDP4 theory to obtain initial osculating orbital elements. Optimal estimates of B and e are found using response surface methodology with genetic algorithm. KSROP is used to propagate the optimal initial parameters. Re-entry times are predicted with low error (<5%) when compared with actual data.

PEDAS.1-0019-18 THE DYNAMICAL PLACEMENT OF MEGA-CONSTELLATIONS

Nathan Reiland, nreiland@email.arizona.edu University of Arizona, Tucson, Arizona, United States

Moritz Aschenbrenner, moritz.aschenbrenner@unibw.de Bundeswehr University, Munich, Neubiberg, Germany Aaron Jay Rosengren, ajrosengren@email.arizona.edu University of Arizona, Tucson, Arizona, United States

An emerging concern for the Earth's orbital environment is the robustness of the current debris mitigation guidelines, which were based on the continuation of space traffic at the rates observed in the 1990s. Largely governed by geopolitical and economic factors, space traffic has always been subject to considerable fluctuations, however recent trends point to a significant increase of traffic in the low-Earth orbit (LEO) region. Companies such as SpaceX, OneWeb, and Boeing have each submitted ambitious satellite mega-constellation proposals to the FCC. The implementation of these mega-constellations involves the introduction of thousands of satellites to the LEO environment to provide low-latency broadband internet to the entire world. A permanent debris-control scheme, based more on remediation than mitigation, will have to be developed well in advance of the critical orbit-clogging point predicted by the Kessler Syndrome.

We investigate the effects of the proposed SpaceX and OneWeb constellations on the sustainability of LEO, as well as the efficacy of possible passive satellite removal techniques; particularly, the exploitation of dynamical instabilities caused by resonant perturbations. The results of this study are intended to serve as a baseline for the selection of orbital parameters for the proposed LEO and MEO mega-constellation satellites, which satisfy mission requirements and employ a passive decommission ideology.

Methods utilized here are based on lessons learned in the investigation of the chaos and stability of the navigation constellations in medium-Earth orbit (MEO) (see, e.g., Rosengren et al. 2017, DOI 10.1093/mnras/stw2459, and references therein). In order to better understand the governing dynamics of the individual satellites of these mega-constellations, the principle effects of atmospheric drag, solar radiation pressure, J2 (Earth oblateness), and lunisolar perturbations are investigated. Furthermore, the main resonances acting in the LEO region are mapped to give an idea of the possible chaotic regions affecting LEO satellites and the stability of the proposed disposal orbits.

The results of this case study provide insight into the stability and lifetime of satellite orbits in the LEO environment, aiding satellite constellation designers in the selection of initial and disposal orbital parameters. The optimal selection of these parameters will ensure the stability of satellite orbits throughout constellation life cycles and prevent decommissioned satellites in disposal trajectories from interfering with active satellites.

PEDAS.1-0020-18 BAYESIAN ORBIT UNCERTAINTY ESTIMATION USING LASER RANGING AND TLE DATA

Christoph Bamann, christoph.bamann@tum.de Technical University of Munich, Munich, Germany Urs Hugentobler, urs.hugentobler@bv.tu-muenchen.de Technische Universitaet Muenchen, Munich, Germany

Orbit uncertainty quantification is of utmost importance in space surveillance and tracking (SST). One of the most prominent use cases is conjunction assessment of operational satellites and potential collision targets like space debris. Estimating orbit uncertainty of such uncooperative objects is typically a data-sparse problem. This is due to the large object population and the limited availability of tracking sensors. Amongst them, laser ranging is a promising concept to complement future SST activities as it has several advantages over radar tracking. It is not only considerably cheaper but also about one order of magnitude more accurate. A major challenge is that orbit uncertainty grows and becomes non-Gaussian during long propagation intervals between successive measurements. Moreover, observability issues may arise in view of ill-distributed tracking geometries. These challenges call for non-Gaussian modeling of orbit uncertainty and data fusion with Two-Line Elements (TLEs), where the advantages of accurate but sparse tracking data and abundant but inaccurate TLEs are combined.

Therefore, we present the first application of a Gaussian mixture filter to assimilate real laser ranging and TLE data for uncertainty estimation of space debris in low-Earth orbit (LEO). While the a-priori uncertainty is derived from historical TLEs, real laser observations are processed in Bayesian state updates. To obtain the required statistical information of TLEs, we apply an uncertainty estimation method accounting for the new way of TLE generation, which has been gradually introduced in recent years. Process noise is primarily governed by atmospheric density mismodeling in LEO. We model these errors as a modified version of the stochastic Ornstein-Uhlenbeck process, which takes account of temporal correlations. A state space representation of this process is derived to facilitate covariance propagation for the individual Gaussian components.

Finally, we evaluate the potential of our approach based on parameter and sensitivity studies using data from a recent tracking campaign. In doing so, we compare our results with those obtained from a Particle Filter (PF), an Extended Kalman Filter (EKF) and batch least-squares (BLS) adjustment. While the PF serves as a benchmark provided that a-priori uncertainty and process noise are adequately tuned, the EKF demonstrates limitations due to Gaussian uncertainty modeling. Comparisons with BLS solutions provide insight into the benefits of process noise modeling.

PEDAS.1-0021-18 MODELLING ATMOSPHERIC DENSITY INDUCED UNCERTAINTY IN ORBIT PREDICTIONS

Paul Cefola, paulcefo@buffalo.edu Massachusetts, United States

One of the main tasks of a space objects catalogue is to support routine space operations with accurate orbital information and associated uncertainties. Uncertainties associated with an estimated orbit are provided through a covariance matrix, which in turn is used in estimating the probability of collision between the satellite of interest and other orbiting space objects. The estimate of collision probability is only as good as the quality of the input that is the covariance matrix. In order to make appropriate decisions during space operations, the realistic covariance matrix plays an important role. Therefore, a method for estimating realistic covariance will be significant within a space object catalogue maintenance system.

Generally, the batch least square orbit determination (BLSQ-OD) procedure is used in maintaining a space object catalogue. With this procedure, the estimated orbit and the confidence of estimation is obtained by fitting the modelled orbit to a given set of observations. Thus, the estimated covariance matrix mainly depends on the number of observations, length of the observation arc, and the time distribution of observations within the arc. The covariance associated with the estimated orbit in a BLSQ-OD does not take into consideration the quality of the force models used within the propagator. Generally with the BLSQ-OD process the estimated covariance matrix is optimistic. This tight covariance might not provide realistic information about the uncertainty associated with the orbit determination and prediction. Hence, it is required to include all the uncertainties within the estimated and propagated covariance, which are: 1. Uncertainty within force models 2. Uncertainty within the method of propagation 3. Uncertainty within the observation set.

The present study will target uncertainties associated with atmospheric density modelling and an empirical method to estimate them along the prediction arc lengths.

The LEO altitude atmospheric densities are both spatially and temporally correlated. To estimate or to include an uncertainty of such a system is a non-trivial task. In this study an interpolated Gauss-Markov process (smoothed Brownian motion) is used to approximate the uncertainty within the density models, and later a time power series is used for approximation. The order and powers of the polynomial are estimated by solving the Hill-Clohessy-Wiltshire equations with stochastic accelerations. The second part will discuss the process noise approximation for estimating the observation uncertainty together with the BLSQ-OD estimated covariance matrix. Later, results from the application of the method over real observation data sets are presented and discussed.

PEDAS.1-0022-18 AN ENSEMBLE KALMAN FILTERING APPROACH FOR ATMOSPHERIC DENSITY ESTIMATION USING ORBITAL DEBRIS

Shaylah Mutschler, shaylah.mutschler@colorado.edu

University of Colorado at Boulder, Boulder, Colorado, United States Penina Axelrad, penina.axelrad@colorado.edu

University of Colorado, Boulder, Colorado, United States Jeffrey Anderson, jla@ucar.edu

National Center for Atmospheric Research, Boulder, Colorado, United States

A key requirement for accurate trajectory prediction and space situational awareness is knowledge of non-conservative force effects on space object motion. These effects vary temporally and spatially, driven by the underlying behavior of space weather. Existing trajectory prediction algorithms adjust space weather models based on calibration satellite observations. However, lack of sufficient data and mismodeling of non-conservative forces cause inaccuracies in space object motion prediction, especially for uncontrolled debris objects. The uncontrolled nature of debris objects makes them particularly sensitive to the variations in space weather. Our research takes advantage of this behavior by utilizing observations of debris objects to infer the space environment parameters controlling their motion.

The hypothesis of this research is that it is possible to utilize debris objects as passive, indirect sensors of the space environment. We focus on estimating atmospheric density and its spatial variability to allow for more precise prediction of Low Earth Orbit (LEO) object motion. The estimated density portion of the estimated state is parameterized as a grid of values, distributed by latitude and local sidereal time over a spherical shell encompassing Earth; the position and velocity of each debris object is also estimated. This work builds upon our previous work in which an Ensemble Kalman Filter (EnKF) is used for assimilation of space object measurements to estimate density. More specifically, this research demonstrates the advantage of estimating the full density state at each measurement time, as opposed to a single density element closest to the debris object. One advantage of a fully extended state is that the uncertainty corresponding to each density element is available at all measurement times via the covariance, which allows for an observability analysis using the accumulated information matrix. A localization scheme is derived from the initial density state ensemble and applied in the filter measurement update to leverage density state correlations.

We investigate the validity of the hypothesis by comparing estimated and true density fields in an appropriate simulation. Synthetic measurements are generated by propagating space objects through a complex density field defined by the NRL-MSISE model to serve as truth. The truth model is sensed indirectly via noise-corrupted observations of space object motion (range, range rate, and angles) that are assimilated in the EnKF to produce an estimate of the true density field. The filter initially assumes the Jacchia Reference Atmosphere density model. This approach simulates a real world scenario in which a filter is initialized with a complex density model that differs from the true density field reflected in the measurements. For performance comparison, the scenario characteristics (number of objects, orbit diversity, measurement cadence, etc.) are based on a sensor tasking campaign executed for the High Accuracy Satellite Drag Model project.

The EnKF analysis details spatial comparisons between the true and estimated density fields, and quantification of the improved accuracy in debris object motion predictions due to more accurate drag force models from density estimates. This research focuses on LEO object motion, but if successful, the approach could also be extended to other orbital regimes for refinement of magnetic field and solar radiation models.

PEDAS.1-0023-18 ATMOSPHERIC REENTRY PREDICTIONS FROM TLE LONG TIME SERIES. APPLICATION ON THE TIANGONG-1 REENTRY DURING SPRING 2018.

The long term evolution of orbital parameters of a trajectory is efficiently driven following semi-analytical approaches. Software such as STELA designed to check the compliance of storage orbits with the IADC guidelines propagate time series of mean orbital elements very quickly, with an accuracy level that does not significantly suffer from the averaging approach. By propagating the mean variational equations jointly to the equations of motion, it is even convenient to adjust the mean model to data sets, such as TLE times series, even over long or very long time scales.

We propose in this paper to investigate to what extent TLE time series can be used jointly to STELA to give an insight into the reentry epoch of a low altitude orbit, by adjusting the trajectory to the available data. We analyse the impact of the number of data, their spread, and the latency before the event, through some charts to be seen as abacus. The method is applied to the chinese station Tiangong-1 that is about to re-enter the atmosphere soon, but which is still flying the Earth when submitting this abstract. But, in the presentation, we will use the time of reentry only as a reference, and we will investigate in these abacus the impact of the atmospheric density and solar activity models.

As a consequence, we focus also in this paper on the ballistic coefficient and the area-to-mass ratio that have to be evaluated jointly to the initial (mean) state vector of the satellite. For most of space debris, their a priori-value is frequently far from the one leading to the best compatibilty between the theory and the observations. This paper is also a great opportunity to present our method to calibrate these coefficients. Other examples as the Chinese station are also provided, with ballistic coefficients that are also available through as a database hosted by IMCCE at Paris Observatory.

PEDAS.1-0024-18 LIFETIME ANALYSIS IN LAUNCH WINDOW MAPS: DESIGNING SATELLITE ORBITS FOR DEMISE

Hossein Namazyfard, hnamazyfard@email.arizona.edu University of Arizona, Tucson, Arizona, United States Davide Amato, davideamato@email.arizona.edu University of Arizona, Tucson, Arizona, United States Aaron Jay Rosengren, ajrosengren@email.arizona.edu University of Arizona, Tucson, Arizona, United States

For the investigation of the Earth's magnetosphere and interplanetary space, satellites with orbits of large semi-major axis and large eccentricity are often used. While end-of-life (EOL) disposal options are well established for missions in low-Earth orbits (atmospheric decay) and the geosynchronous belt (near circular graveyards), existing mitigation guidelines do not fully regulate the whole, usable circumterrestrial orbital space, such as these highly eccentricity orbit (HEO) science missions; e.g., NASA's Magnetospheric Multiscale Mission (MMS) and ESA's INTErnational Gamma-Ray Astrophysics Laboratory (INTEGRAL). The non-negligible collision risks posed by these LEO-GEO transiting spacecraft has motivated both theoretical study and practical implementation.

The solution to the space debris problem, from LEO to GEO, can be found only by coupling a deep understanding of the circumterrestrial phase space with satellite mission analysis and design. For future missions, the EOL options have to be clearly identified during the early phases of the design, taking into account orbital interactions and environmental evolution. This more holistic vision parallels that of ESA's Clean Space initiative, fostering innovative techniques and tools in orbital dynamics to novel spacecraft design and manufacturing to reduce the space industry's environmental impact. We emphasize here the new paradigm of self removal of satellites through natural perturbations (passive disposal), and discuss how lifetime estimates can be incorporated into launch window constraints to ensure the future demise of the satellites.

For the science missions described above, the time of launch, and therefore the location of the orbit in space, must be chosen to satisfy a number of limiting constraints. In such launch window studies, the orbital lifetime is likely a factor to ensure the satellite exceeds the nominal mission time, but its reduction or control is hardly a consideration. For the purposes of space debris mitigation and remediation, we propose incorporating lifetime predictions as a fundamental mission constraint. Doing so will not only ensure that the missions will have predictable behaviors over both the nominal (and possibly extended) mission, thus avoiding an Interstellar Boundary Explorer (IBEX)-like situation, but that the satellites will eventually meet their demise through atmospheric reentry (without the need to make future significant orbital adjustments, à la INTEGRAL).

We have developed an extensive set of computational tools (regularized formulations of special perturbation theory and semi-

analytical averaged models) for the exploration and simulation of the dynamics of Earth-satellite orbits, accounting for gravitational and non-gravitational perturbations. Here we apply these capabilities towards lifetime predictions of HEOs, and adapt this to launch window analyses. Such dynamical assessments could have a profound and tangible influence on constellation design, perhaps attacking the debris problem at its source.

PEDAS.1-0025-18 PARAMETERIZATION OF HIGHLY ECCENTRIC ORBIT

Jingshi Tang, jstang@nju.edu.cn Nanjing University, Nanjing, China

Jiaming Wang, 141210032@smail.nju.edu.cn Nanjing University, Nanjing, China

Xiyun Hou, silence@nju.edu.cn Nanjing University, Nanjing, China
Jinglang Feng, jinglang@nju.edu.cn Nanjing University, Nanjing, China Lin Liu, lliu@nju.edu.cn

Nanjing University, Nanjing, China

In this report, we present a new way to parameterize the Highly Eccentric Orbit (HEO). The new parameterization is introduced to overcome the difficulty in propagating the HEO in restricted scenarios. By restricted scenarios, we mean the space debris where the HEO objects are numerous or the onboard environment where the hardware capability is limited.

In the restricted scenarios, it is time-consuming to use the numerical propagation since the large eccentricity requires the propagator to adaptively change the step size to obtain a good balance between accuracy and speed. Even so, propagation at the perigee is inevitably slow, not to mention that frequent adapting the step size itself comes at the cost of efficiency. The storage for HEO ephemeris is also a concern. Due to the fast motion at perigee, the ephemeris has to be saved at a reasonably small step size at perigee.

Analytical solution is another popular option in such scenarios, among which SGP is always used by many agencies. However, the analytical approach faces a critical problem with HEO, where the large eccentricity renders the expansion (with respect to the mean anomaly) highly inaccurate or even invalid. Many approximations applied to nearly circular orbits do not hold either in these circumstances and the neglected higher-order terms (with respect to the eccentricity) have to be reconsidered. All these restrictions compromise the current analytical solutions in the application of HEO.

There have been some earlier researches, providing alternative presentations of the orbits of the space objects, including HEO objects or debris. One effective approach is to follow the broadcast ephemeris in satellite navigation (GPS, Galileo, BeiDou) that uses certain numbers of parameters to fit the propagated orbit based on known variation pattern of the orbital elements. These parameters, together with predetermined model, are used to compute the orbit or position at real time. This approach always involves frequency analysis or Fourier analysis, to find the contributing periods. The limit of this approach on HEO is that, since the HEO objects move non-uniformly and it is not easy to model the orbit variation with simple combinations of various frequencies. To model the orbit using combinations of cos(ωkt) and sin(ωkt) could require a large number of terms.

In our approach, we start modeling the orbit from the underlying dynamics. Recognizing that the orbital element actually varies with respect to the true anomaly f, instead of the mean anomaly (or equivalently the time). The orbit variation is modeled in the form of summation of cos(kf) and sin(kf), together with other possible terms including linear or quadratic terms and/or monthly or semimonthly periods. The tricky part of this approach is about how to solve for the true anomaly when recovering the orbital elements from the fitting parameters. We use a recurrence approach to determine the true anomaly at the beginning of the orbit calculation and with the determined f time series, the other elements can be determined as well.

Preliminary tests show that it is easy to obtain high accuracy with this method, without having to include too many frequencies in the model. This new parameterization is feasible in terms of both the orbit accuracy and the data storage of fitting parameters.

PEDAS.1-0026-18 CHARACTERISTIC AND DISTRIBUTION OF TLE ORBITAL PROPAGATION ERRORS

Xiaoli Xu, xlxu@pmo.ac.cn

Purple Mountain Observatory, Chinese Academy of Sciences, Nanjing, China

The TLE catalog is a global public data source of space objects, and is widely applied for space missions, collision risk assessment, etc., but orbit accuracy is not available. Historical TLE and GPS precision ephemerides of CHAMP and GRACE are collected and compared to assess TLE orbital propagation errors. Evolution over time and spatial distribution of the errors are discussed, especially characteristic of the system biases. The biases can reach the level of kilometers, and are correlated with geographical locations. Removing system biases from orbit uncertainties will significantly improve orbit accuracy and provide credible collision risk assessment.

PEDAS.1-0027-18 DEVELOPMENT OF A HIGH-SPEED, RAREFIED PLASMA WIND TUNNEL FOR IONOSPHERIC AERODYNAMICS RESEARCH

Spacecraft orbiting in Low Earth Orbit (LEO) undergo complex and poorly understood interactions with their environment leading to large uncertainties in predicting orbits and an associated risk of collision with other satellites and space debris. The drag of orbiting spacecraft represents one of the largest sources of error for orbit determination. Spacecraft drag in LEO due to neutral particle interactions has been studied in detail, and significant reductions in uncertainties of spacecraft drag coefficients can be attributed to an improved understanding and modeling of gas-surface interactions. However, the interaction of the orbiting spacecraft with the charged particle environment in the ionosphere and the resulting perturbation to their orbit is less well understood. Research is underway at UNSW Canberra to enable the prediction of the orbits of near-Earth space objects with significantly greater fidelity - for the modeling of environment interactions - than currently possible. This is being achieved through an astrodynamics research program that closely couples physics-based supercomputer simulations of the complex plasma-spacecraft interactions in LEO (ionospheric aerodynamics) and benchmarkquality ground-based experiments as well as in-orbit flight experiments to address the research challenges associated with the development of enhanced space-situational awareness capability.

The work described in this paper provides insight into the development of a ground-based experimental plasma flow physics capability, applicable to ionospheric aerodynamics research. To enable this, a magnetically filtered hollow cathode plasma source has been coupled to a vacuum chamber (diameter 1m, length 2m) to simulate the high energy/low density charged particle interaction environment experienced by spacecraft orbiting in LEO. A plasma diagnostic suite consisting of a Langmuir probe to measure the plasma density and electron temperature, and a retarding potential analyzer to determine the ion energy have been employed to characterize the plasma flow properties. Plasma source operating parameters can be adjusted to vary plasma flow properties and thus enable scaling studies.

Charged drag measurements for grounded and negatively charged flat plate and cylinder test objects have been conducted successfully using a nano-Newton thrust stand. The ion current collected by the test objects was also recorded as a proxy for direct ion momentum exchange due to ions hitting the test objects' surface. Differences in the trends for total force and ion current measurements were observed with increasing negative surface potential. This can be attributed to indirect ion momentum exchange with the test objects. The latter effect is related to the electrostatic interaction between the streaming ions and the electrostatic sheath surrounding the charged test object. The resulting force counteracts, i.e. reduces, the direct charged force/drag (from ions hitting the surface) imparted on the charged test object. The experimental data corroborate previous findings from numerical simulations and clearly demonstrate the significance and complexity of charged aerodynamics effects for LEO plasma-body interactions.

PEDAS.1-0028-18 ESA ACTIVITIES ON COMBINING RADAR, OPTICAL, AND SLR OBSERVATIONS FOR SST: ANALYSIS ON THE INFLUENCE OF REALISTIC COVARIANCE ON CORRELATION

Srinivas Setty, srinivas.setty@esa.int ESA-ESOC, Darmstadt, Germany Tim Flohrer, tim.flohrer@esa.int

European Space Agency, Darmstadt, Germany Beatriz Jilete, beatriz.jilete@esa.int

GMV at ESA, Darmstadt, Germany Jan Siminski, jan.siminski@esa.int ESA/ESOC, Darmstadt, Germany Jose Castro, jose.castro@esa.int ESA-ESOC, Darmstadt, Germany Holger Krag, holger.krag@esa.int

European Space Operations Centre (ESOC), Darmstadt, Germany

The integration of the SST software components and the verification of their end-to-end functionalities and performance when dealing with real data will provide ESA with the necessary technical tools to independently conduct tests at large scale to routinely perform surveillance of space debris hazards. Within the SST Core Software, developed under ESA's SSA Programme, the observations are processed using Data Processing Chain (DPC) to maintain the catalogue of space objects. The main sources of input to the DPC are observations obtained through different sensors, external catalogue, and other third party data.

The current and future observation test campaigns are aimed at collecting a sufficient sample of real data from all SST sensor technologies: radar, passive optical telescopes, and satellite laser ranging (SLR). These data are used to validate the SST Core Software, to validate other software tools under development, and to populate a temporary test catalogue. The observation planning has been split according to the altitudes covered, into a LEO and a MEO/GEO part. The LEO campaign is planned to involve both of ESA's test-bed radars: the monostatic (MSSR) at Santorcaz, Spain and the bistatic (BSSR) at Palaiseau, France, together with the Austrian SLR station in Graz. The MEO/GEO campaign will involve the use of passive optical sensors including ESA's Test-Bed-Telescope and two other telescopes for survey activities (ZimSMART in Switzerland and Starbrook located in Cyprus and operated by the UK), and three telescopes for tracking (Deimos' DeSS Tracker2 in Spain, ESA's Optical Ground Station (OGS) at Tenerife,

Spain, and Zimlat in Switzerland).

The observations are needed to be correlated, linked with each other, or with the catalogued object. The accuracy of the correlator depends on several factors, such as quality of observations, quality of ephemerides, uncertainty associated with the ephemerides, etc, while covariance associated with a catalogued object plays an important role on false association of the observations. To ensure the optimal performance from the correlator, the data provided to the correlator must be to its maximum accuracy.

In the current presentation we intend to summarize the observation campaigns, discuss correlation results obtained from using different methods of covariance propagation, and conclude with an overview on future directions on improving the DPC to handle all sensor data.

PEDAS.1-0029-18 COMPARISON SPACE SELECTION TO ACHIEVE EFFICIENT TRACKLET TO OBJECT ASSOCIATION

Jan Siminski, jan.siminski@esa.int ESA/ESOC, Darmstadt, Germany

A major challenge when maintaining a space object catalog is the proper association of new measurements to already cataloged objects. Optical observations are typically associated by comparing the modelled observation with the measured one. The modelled observation is generated from cataloged object states by propagating them to the epoch of observation and transforming them from state space, e.g. orbital elements, to the observation space, e.g. right ascension and declination. In addition to propagating the states, their propagated uncertainty distribution is transformed to observation space as well. Statistical distance metrics, such as the Mahalanobis distance, are then evaluated to test whether the observation originated from the cataloged object or not. These distance measures often assume that the uncertainty can be represented with a Gaussian distribution. Assuming that the catalog state uncertainty is properly represented by a Gaussian, it can still be deformed during the propagation in time and the transformation to observation space. The uncertainty of the catalog state is typically much larger than the one from new measurements (only a few arc seconds for optical telescopes) and is therefore more affected by transformation distortions. It is therefore beneficial to perform the comparison in a space advantageous for the state representation. In the case of radar observations, this can be achieved by the use of object centered curvilinear coordinates. However, optical observation arcs do not provide enough information to directly map them into such a space. Instead, they can be projected into a state space, e.g. assuming the same radial distance as the tested catalog object. In this presentation, we will analyze the effect of the comparison space selection on the cataloging performance, i.e. we will systematically test if it is beneficial to compare directly a series of angles, angles and angular rates, or to do the comparison in a object centered frame.

PEDAS.1-0030-18 ON THE PRACTICAL EXPLOITATION OF PERTURBATIVE EFFECTS IN LOW EARTH ORBIT FOR SPACE DEBRIS MITIGATION

Volker Schaus, v.schaus@tu-braunschweig.de TU Braunschweig, Braunschweig, Germany Elisa Maria Alessi, em.alessi@ifac.cnr.it IFAC-CNR, Florence, Italy

Giulia Schettino, g.schettino@ifac.cnr.it IFAC-CNR, Florence, Italy

Alessandro Rossi, a.rossi@ifac.cnr.it IFAC-CNR, Florence, Italy

Enrico Stoll, e.stoll@tu-braunschweig.de TU Braunschweig, Braunschweig, Germany

This paper presents the results of a numerical evaluation of the natural lifetime reduction in Low Earth Orbit, due to dynamical perturbations. The study considers two values for the area-tomass ratio, a nominal ratio which resembles a typical value of spacecraft in orbit today, and an enhanced ratio which covers the surface augmentation. The results were obtained with two orbit propagators, one of a semi-analytical nature and the second one using non-averaged equations of motion. The simulations for both propagators were set up similarly to allow comparison. They both use the solar radiation pressure and the secular terms of the geopotential (J2, J4 and J6). The atmospheric drag was turned on and off in both propagators to alternatively study the eccentricity build up and the residual lifetime. The non-averaging case also covers a validation with the full 6x6 geopotential. The results confirm the findings in previous publications, that is, the possibility for de-orbiting from altitudes above the residual atmosphere if a solar sail is deployed at the end-of-life, due to the combined effect of solar radiation pressure and the oblateness of the Earth. At near polar inclinations, shadowing effects can be exploited to the same end. The results obtained with the full, non-averaging propagator revealed additional de-orbiting corridors associated with solar radiation pressure which were not found by previous work on space debris mitigation. The results of both tools will be compared for specific initial conditions. For nominal values of area-to-mass ratio, instead, it is confirmed that such an effect is negligible.

The paper then puts the findings in the perspective of the current satellite catalogue. It identifies space missions which are currently close to a resonance corridor and shows the orbit evolution within the resonances with a significantly shorter residual orbital lifetime. The paper finishes with a discussion on the exploitation of these effects with regards to the long-term simulation of the space debris environment and the operational considerations.

PEDAS.1-0031-18 SPACE DEBRIS DEFLECTION AND DE-ORBIT TO EARTH BY TUNED, INFLATED MIRROR BALLOONS

Daniele Fargion, daniele.fargion@roma1.infn.it

Physics Department, Rome University 1, INFN Rome 1,, Rome, Italy

The growing Space debris danger poses a hazard to all satellite survival and even to future astronauts safe flight in orbit. We suggest a novel solution based on two main procedure: 1) A preliminary location in all future satellite mission of a safe (final) inflatable balloon mirror, whose role it is to inflate at the end of the satellite life in case of a need of any soon (months) landing. The balloon size is related to the satellite mass by a simple law: for instance a mini satellite mass (about 10 kg) might needs a ten meter size ballon. 2) A more complex capture of already present debris in orbit requires a main cleaner "Mother satellite" that will reach as many as possible fragments in almost collinear nearby trajectories at comparable speeds. The Mother satellite station once along the debris fragment cluster will eject at each differential speeds a secondary "children" mini or nano satellites approaching each tuned single debris target. Once single satellite will approach the fragment at a small speed it capture it by an elastic net trap, linked and bounded to a inflatable mirror balloon whose size is correlated to the corresponding debris mass. The solar photon pression will hit and skim these spherical mirrors in a way pushing and forcing toward the Earth center the debris while in sunny side. The force it is weak but it is able to bring (for instance a 10 kg mass and a 10 meter radius balloons) in a few months the debris a few hundred kilometers below toward the Earth atmosphere. Below 800 km altitude the same diluted terrestrial atmosphere will act by its friction even much more efficently and faster than the same solar pressure. This is leading to a faster capture and deorbit of the debris. At 600 km the atmosphere friction it is 10 times larger (while at 400 hundred km it is 100 times larger) than solar pressure. Therefore the balloons role is ruling in deorbit debris from low height, while solar pressure on the large balloon areas at highest (above thousand km) altitude orbit. Effect of combined radiation pressure and aerodynamic forces at different altitudes is calculated. An evaluation of balloon radius required in relation to debris mass is provided, and of the corresponding payload.

PEDAS.1-0032-18 ACTIVE DEBRIS REMOVAL FROM ORBIT USING DRAG INDUCER CUBESATS (DICS)

Hafiz Faisal Rasool, hafiz.faisal@outlook.com

Pakistan Space & Upper Atmosphere Research Commision (SUPARCO), Lahore, Pakistan Kamran Haleem, engr. kamranhaleem@gmail.com

Pakistan Space & Upper Atmosphere Research Commision (SUPARCO), Lahore, Pakistan

Debris in useable orbits around the Earth has been increasing at an alarming rate over the last two decades with the increase in population of satellites particularly in LEO. The no. of tracked debris objects in space has almost doubled since 2005 as a result of Fengyun-1C and Iridium/Cosmos incidents. Active Debris Removal (ADR) is one of major areas of space research. The amount of non-operational objects in vicinity of valuable space assets significantly enhances the risk of collision. Applications for ADR include depopulation of non-operational space objects in usable orbits and development of collision detection and avoidance systems for future satellites. The work involves comparative study of debris classification techniques and selection of removable debris using ADR. An in-depth review of drag inducing mechanisms currently under study for ADR by space research organizations worldwide. This paper presents a novel approach in ADR research by using a master satellite in orbit with packs of single and 2-unit CubeSats stored inside. Such a system effectively allows us to establish an inventory of propeller devices in space. Small tumbling objects which cannot be accurately modelled by using ground-based instruments will be assessed and profiled in real-time from master satellite. Once the real-time characterization of debris is performed, Drag Inducer CubeSats (DICs) are ejected in the direction of target object. After the ejected satellite captures or tethers itself to the target debris, sails stowed in CubeSat are deployed perpendicular to the flight path of debris consequently increasing the drag coefficient. This causes the target debris to slow down and reenter Earth's atmosphere resulting in a burnout thus removing it from the orbit. Furthermore, preliminary system design budget of parent spacecraft with short to midrange lifetime will be presented. System level budgeting will involve preliminary structural, electrical, data-handling and propellant subsystem budgeting with focus on storage and in-orbit ejection/latching-on mechanism of Drag Inducer CubeSats. System budgets evolve concurrently after the comparative study of ADR method is concluded.

PEDAS.1-0034-18 ANALYSIS ON THE ACTIVE REMOVAL OF HIGH-RISK OBJECTS

Susanne Peters, susanne.peters@unibw.de

Universität der Bundeswehr München, Neubiberg, Germany Jonas Radtke, j.radtke@tu-braunschweig.de

Institute of Aerospace Systems, TU Braunschweig, Braunschweig, Germany Roger Förstner, roger.foerstner@unibw.de

Universität der Bundeswehr München, Neubiberg, Germany Enrico Stoll, e.stoll@tu-braunschweig.de

TU Braunschweig, Braunschweig, Germany

Space Debris and its impact on the near-Earth space environment has become a serious problem for active satellites. While modelling and observing make up a large portion of the discussion on how to limit the debris, the order of 'high risk objects' and the impact of an active removal is just as essential. High risk objects are can be ranked according to their mass, size and collision probability. Among the countless studies on their actual order according to risk probability, rocket bodies of the SL-16 and SL-8 type always rank high within the top 200. While some authors argue to actively remove the heavier SL-16 first, others debate for a multiple SL-8 removal within one mission. They have the advantage to orbit in close vicinity, a removal would limit the available impact area. The presented work compares, how the removal of SL-16 or multiple SL-8 would impact the space environment on the long term. A mission analysis is performed to collect the SL-8 fuel efficient, or in other words to find rocket bodies close enough to each other to be removed within one mission. An order of ranking for the removal for the SL-16 is presented, the comparing analysis follows this order. Both approaches are compared according to their expenditures and outcomes.

PEDAS.1-0035-18 LASER ABLATION FOR SPACE DEBRIS MITIGATION: A SYSTEMATIC STUDY

Roberto Iuppa, roberto.iuppa@unitn.it University of Trento, Trento, Italy

William Burger, william.burger@tifpa.infn.it FBK-TIFPA, Povo, Italy

Antonio Miotello, antonio.miotello@unitn.it Università di Trento and INFN, Povo, Italy

The increase in the number of artificial objects in orbit around the Earth represents a serious threat to the future utilization of space. The scope and nature of the problem require an international effort. The Trento Institute of Fundamental Physics and Applications (TIFPA) participates in the study of laser ablation for space applications, propulsion and space debris mitigation, in the context of New Reflections program of the Institute National of Nuclear Physics (INFN). An evaluation of the performance of laser ablation for debris removal in Low Earth Orbit (LEO), for different scenarios of ground-based and orbiting system configurations is presented. The results are obtained from a simulation developed in the MATLAB environment, which includes the relevant gravitational (Earth zonal model, solar and lunar gravity) and atmospheric models. Attention is also paid also to laser system features, e.g. pulse duration and intensity, repetition rate and light-material coupling coefficients, as determined from laboratory measurements performed on purpose in Trento. The relative merits of the different configurations are discussed.

PEDAS.1-0037-18 A SENSOR TASKING TOOL TO BUILD-UP AND MAINTAIN A CATALOGUE OF GEOSYNCHRONOUS SPACE OBJECTS

Andreas Hinze, andreas.hinze@dlr.de DLR, Wessling, Germany

Carolin Frueh, cfrueh@purdue.edu Indiana, United States

Hauke Fiedler, hauke.fiedler@dlr.de DLR, Germany

Thomas Schildknecht, thomas.schildknecht@aiub.unibe.ch Astronomical Institute, University of Bern, Bern, Switzerland

To protect the geosynchronous region the orbits of all space objects have to be known. Precise and accurate orbits are prerequisite of successful collision prediction. Two different observation types are usually employed: survey, which are performed to expand the catalogue caused by any change of the space object population and follow-up observations to maintain the accuracy and precision of ephemeris data within certain limits for each catalogued object. To perform these observations in the most efficient way, optimized sensor tasking is a key element. This paper presents a sensor tasking algorithm for an optical telescope network providing optimized survey and follow-up observations for catalogue maintenance. The algorithms is based upon genetic optimization of detectability based upon the phase angle and maximizing the information content relative to the orbit improvement. The proposed methodology is effectively balancing survey and follow-up observations. A simulated object population based on the current TLE catalogue is used to illustrate the effectiveness of the sensor tasking algorithms.

PEDAS.1-0039-18 SPACE DEBRIS IN THE NEIGHBORHOOD OF THE OPERATIONAL ARTIFICIAL SATELLITES

Jarbas Sampaio, jarbascordeiro@gmail.com

Instituto Federal de Educação, Ciência e Tecnologia, Camaçari, Brazil Ewerton Felipe B. P. Dos Santos, es.santos.felipe@gmail.com

Instituto Federal de Educação, Ciência e Tecnologia da Bahia, Camacari, Brazil

Most of the cataloged objects in Low Earth Orbits are space debris, considering that less than 7% are operational spacecraft. In this work, the orbital dynamics of space debris are studied in the neighborhood of the Brazilian satellites, CBERS and SCD, and around of the ISS - International Space Station. The results show that the collision risk of space debris with the operational satellites studied is high and preventive actions to avoid collisions are necessary.

PEDAS.1-0040-18 SPACE DEBRIS IN LEO REGION: ORBITAL DYNAMICS DESCRIBED BY RESONANT ANGLES

Jarbas Sampaio, jarbascordeiro@gmail.com

Instituto Federal de Educação, Ciência e Tecnologia, Camaçari, Brazil Rodolpho Vilhena De Moraes, rodolpho.vilhena@gmail.com

Instituto Nacional de Pesquisas Espaciais - INPE, São José Dos Campos, Brazil Sandro Da Silva Fernandes, sandro@ita.br

Instituto Tecnologico de Aeronautica, São José Dos Campos, Brazil

The Low Earth Orbits (LEO) has an increasing number of space debris justifying the interest in the observation and collision avoidance. The orbital dynamics of several of these objects involve different resonances distributed by the distinct altitudes. In this work, objects in resonant orbital motions in the regions of 14:1 and 15:1 resonances are studied. Using the two-line elements (TLE) of the NORAD, resonant angles are described to develop an analytical model and the time behaviors of the orbital elements. Frequency analysis shows possible irregular motions describing the orbital motions of these objects.

PEDAS.1-0041-18 ATTITUDE STATE STATISTICS FOR LEO ROCKET BODIES

Yao Lu, luyao@pmo.ac.cn

Purple Mountain Observatory, Chinese Academy of Sciences, Nanjing, China

For space debris remediation, the active removal of rocket bodies attracts a lot of attention, considering the large quantity and harmfulness of rocket bodies. The knowledge of attitude state and state changes of the target objects is required in the pre-early stage of the mission, and get statistics on a large number of samples will be especially helpful for understanding the evolution of attitude motion of rocket body and guiding the target selection for ADR.

Sequential photometric measurements, so called light curves, can be used to inverse the attitude state of space debris, e.g., using continuous glinting epochs in light curve to determine the directions of reflective surface. In our previous work, a new attitude inversion method has developed by using simulated light curves and machine learning. It relies on the features of entire light curve than the glinting points only, so much broader range of light curves of rocket bodies can be evaluated for attitude state inversion, for which the direction of precession axis in space and the tumbling angle and period are the most interesting parameters.

This paper will discuss a statistical analysis of the attitude states of dozens of LEO rocket bodies. Based on the MMT satellite photometric database and the attitude inversion method we developed, the attitude state history and state change rates were determined. The long-term evolution of rotational motion for different types of rockets was discussed and the parameters related to gravity gradient and eddy currents Torques were also evaluated.

PEDAS.1-0042-18 ESTIMATION OF ROTATIONAL MOTION OF CZ-2C ROCKET BODIES

Hou-Yuan Lin, linhouyuan@pmo.ac.cn

Purple Mountain Observatory, Chinese Academy of Sciences, Nanjing, China Chang Yin Zhao, cyzhao@pmo.ac.cn

Purple Mountain Observatory, Chinese Academy of Sciences, China

The rotational motion and its evolution of CZ-2C rocket bodies are estimated based on the ground observational data, which include the laser observational data of two targets and the optical observational data of another one. From the laser observation data, the attitude variation of rocket bodies and its short-term evolution can be obtained. And the long-term evolution of the rotational motion can be estimated from the optical data. The overall rotation law of CZ-2C rocket body can be confirmed through the combination of the two observations.

PANELS (P)

INTERNATIONAL COORDINATION OF SPACE EXPLORATION ACTIVITIES (PEX.1)

PEX.1-0001-18 THE EUROPEAN SPACE SCIENCES COMMITTEE ON INTERNATIONAL COORDINATION FOR SPACE EXPLORATION

Athena Coustenis, athena.coustenis@obspm.fr Paris Observatory, Meudon, France

European Space Sciences Committee

A. Coustenis, C. Aerts, N. Aghanim, M. Anand, E. Antonucci, S. Baatout, I. Brown, A. Chouker, P. de Bernardis, L. Eymard, B. Feuerbacher, H. Fraser, A. Kaab, M. Krol, D. Langevin, L. Lara, F. Montmessin, R. Morrow, K. Muinonen, H. Opgenoorth, G. Paar, A. Pavy-le-Traon, M. Perryman, R. Piazza, M. Plionis, P. Preu, R. Rettberg, S. Sterckx, H. Thomas, A. Tielens, J. Torra, S. Udry, P. Veefkind, R. Wimmer-Schweingruber, N. Walter

The European space sciences landscape is very diverse as it involves two major intergovernmental organisations (The European Space Agency-ESAand the European Commission-EC) and more than 25 countries that each have their national institutional setting and scientific planning approach. It has therefore always been essential to coordinate space science and exploration programmes throughout Europe and with international partners.

The European Space Sciences Committee (ESSC - www.essc.esf.org) is offering European scientists an independent voice providing advice and guidance on space science matters to ESA, EC, national space agencies, and other stakeholders. The ESSC is not a programmatic nor a political entity; it promotes space science not as a cost but as a high-return investment with a broad and exciting leverage effect on the people and the economy.

Similarly to other international advisory bodies, ESSC offers recommendations and implements other space exploration related activities; it delivers direct consolidated (solicited or proactive) input from the scientific community to programmatic institutions; but is can also represent an anchor for non-European scientific communities to interact and collaborate.

The ESSC has thus kept and developed very strong links with the Space Studies Board of the US National Academies (NAS-SSB), members from both sides of the Atlantic thus affording regular insight on European and US space programmes. These two bodies are also linked in some strategic planning issues and in studies related to Planetary Protection (e.g. on PhobosDeimos categorisation), Mars (Mars Special Regions), space weather or the icy moons of the giant planets. The ESSC has also tight contacts with Chinese, Russian and Japanese space agencies and research organisations.

This international bottom-up approach in space roadmapping has proven to be highly valuable in the past, a relevant example being the Cassini-Huygens mission. In the early eighties, the concept of a joint U.S.-European mission to explore the Saturnian system was delineated during a joint European Science Foundation-US

National Academies workshop, this was the spark of one of the most successful long-lived (2004-2017) planetary exploration missions to date.

A coordinated integrated position on programmatic space matters is key to maximise scientific return. Since the late nineties, the ESSC and its office have conducted studies and evaluations on the ESA Life and Physical Sciences in Space programme (ELIPS) as well as defining a Science-Driven Scenario for Space Exploration or roadmaps in the fields of human space exploration or astrobiology. ESSC has also been very active in providing inputs to the European Commission on the definition of its space strategy and space research work programme. The ESSC contacts with international bodies significantly contribute to the definition and implementation of exploration programmes in their respective countries and demonstrate that common initiatives allow us to promote the inputs from the scientific communities. A network of independent non-programmatic interdisciplinary bodies covering all the regions of the world would certainly improve coordination of space exploration at the global level.

References: all of the documents related to the aforementioned studies can be found at: http://www.essc.esf.org/list-of-publications/

PEX.1-0002-18 NASA'S PLANETARY SCIENCE MISSIONS PRESENT AND FUTURE PLANS

James Green, james.green@nasa.gov

NASA Headquarters, Washington, District of Columbia, United States Doris Daou, doris.daou-1@nasa.gov

NASA Headquarters, Washington, District of Columbia, United States

The exploration of the outer Solar System has recently revealed remarkable information regarding "ocean worlds". With these new discoveries, these worlds have become a focus in the search for possible life elsewhere in the Solar System.

Earlier Mars missions were designed to make discoveries under the theme of "Follow the Water." Progressive discoveries related to evidence of past and present water in the geologic record make it possible for next steps. NASA is currently following an exploration strategy of "Seeking Signs of Life." In addition to landing in a place with past evidence of water, we are seeking evidence of organics which potentially provide habitable conditions. Future Mars missions include NASA's InSight lander and the Mars 2020 rover that will produce rock cores from a geologically diverse sight for potential future return.

Furthermore, OSIRIS-Rex is expected to begin approaching Bennu in August 2018; Psyche and Lucy are in full implementation; and Dragonfly and CAESAR are in Phase A concept study; NASA's Planetary Science Division continues the formulation of the Europa Clipper and the implementation the InSight and MARS020 missions. We also continue work to deliver NASA's contributions to fly on international missions such as ESA's Jupiter Icy Moons Explorer (JUICE) mission.

International partnerships are an excellent, proven way of amplifying the scope and sharing the science results of missions. NASA has always encouraged international participation on our missions and other Space Agencies have reciprocated and invited NASA investigators to participate in theirs. As Director of Planetary Science at NASA, I will continue to seek cooperation with our strong international partners in support of planetary missions.

PEX.1-0003-18 CANADIAN SPACE AGENCY SPACE EXPLORATION UPDATE

Victoria Hipkin, victoria.hipkin@canada.ca Canadian Space Agency, St Hubert, Canada Denis Laurin, denis.laurin@canada.ca Canadian Space Agency, St Hubert, Canada Nicole Buckley, nicole.buckley@canada.ca Canadian Space Agency, St Hubert, Canada Christian Lange, christian.lange@canada.ca Canadian Space Agency, St Hubert, Canada Pierre Jean, pierre.jean2@canada.ca Canadian Space Agency, St Hubert, Canada Yves Gonthier, yves.gonthier@canada.ca Canadian Space Agency, St Hubert, Canada

Human Spaceflight, Space Astronomy and Planetary Science define the scope of the Space Exploration branch at the Canadian Space Agency.

The Canadian Space Agency undertakes Exploration activities in partnership and is active in international fora such as the International Space Exploration Co-ordination Group and International Mars Exploration Working Group. CSA is a partner in the International Space Station and the James Webb Space Telescope, and currently supports the Canadian APXS investigation on NASA's Mars Science Laboratory and OSIRIS-REx Laser Altimeter investigation on NASA's OSIRIS-REx New Frontiers mission. Following astronaut selections in 2012 and 2017, Canada has an active astronaut core of four, with David Saint-Jacques scheduled to fly on Expedition 58/59 in November 2018.

This paper presents an update on CSA Space Exploration Strategic Planning group activities and reports on recent studies and analogue activities exploring potential Canadian contributions to flagship international activities such as the Global Exploration Roadmap, Robotic Lunar Exploration and Mars Sample Return.

The CSA SESP is responsible for consultation with the Canadian community on Space Exploration priorities. A summary of the recent report 'Canadian Space Exploration: Science and Space Health priorities for next decade and beyond' will also be discussed.

PEX.1-0004-18 UTILIZING MODERN ADVANCED ROBOTICS SYSTEMS FOR THE IN-SITU EXPLORATION OF THE SOLAR SYSTEM

Hansjoerg Dittus, susanne.stiller@dlr.de

Deutsches Zentrum fuer Luft-und Raumfahrt (DLR), Cologne, Germany

With robotic systems on Earth obtaining new capabilities in a staggering speed, there is a golden opportunity to use these capabilities to reach once unreachable spots on large and small bodies in the Solar System to perform in-situ measurements and to gather the most pristine and interesting samples. Therefor DLR intends to use its in-situ heritage and robotic competence for exploration and support the analysis of the potential for life on planetary bodies. Based on DLR's recent efforts for MASCOT, HP3, ROBEX, Kontur-2, its contributions to the CORSAIR proposal and strong institute heritage in planetary science, system competence and advanced robotic systems, DLR proposes the expansion of in-situ science throughout the Solar System. In this paper an overview is given what, in the near future, shall be reachable on Mars and other planets as well as smaller bodies in our Solar System. The paper also addresses the need for international coordination and cooperation in the development of miniaturized payloads like cameras, VNIR-, IR-, UVund Raman spectrometers, temperatureand moisture sensors, lab-on-chip systems for "in-situ wet chemistry", micro sampling and return. The paper also addresses the need for cooperation in the preparation of the next generation of robotic systems for their exploration of caves, caverns, micro-g bodies and other geological, biological and geophysically interesting sites in the Solar System.

PEX.1-0005-18 REPORT TO COSPAR PEX FROM INTERNATIONAL LUNAR EXPLORATION WORKING GROUP (ILEWG) AND MOONVILLAGE WORKSHOPS

Bernard H. Foing, bernard.foing@esa.int ESA/ESTEC, Noordwijk, Netherlands

Moon Village Workshops Organisers 2017 - 2018

A. Kolodziejczyk, C. Heinicke, A.Lillo, I. Schlacht, A. Kapoglou, M. Harasymczuk, N.Verschoor,

Lizy-Destrez, S. Hettrich, H. Gassabian, J. Cami, V. Foing, J.L.Moro, I. Sisaid, E.Garcia Bourne, P-A. Joumel, L. Ferreira, TaiSik Lee, J. Silk, A. Decadi, A. Wendler, M. Wilde, T. Pacher, M-P.Boucher, J. Ivey, V. Beldavs, H. Rogers, J. Crisafulli, G. Reibaldi, C. Welch, O. Ben-Horin, J. Robberstad, I. Smegen, G. vd Sanden, A. Zaklynsky, A. Sitnikova, A. Izotova) * 1)ESA ESTEC, 2)ILEWG International Lunar Exploration Working Group, 3)VU Amsterdam (Bernard.Foing@esa.int)

The International Lunar Exploration Working Group (ILEWG) was established in April 1995 at a meeting in Hamburg, Germany. As established in its charter, this working group reports to COSPAR and is charged with developing an international strategy for the exploration of the Moon. It discusses coordination between missions, and a road map for future international lunar exploration and utilisa-tion. It fosters information exchange or potential and real future lunar robotic and human missions, as well as for new scientific and exploration information about the Moon. We give a report on ILEWG community activities, refer to COSPAR and ILEWG ICEUM and lunar conferences and declarations [1-18].

Ongoing ILEWG priorities from ICEUM 11 and follow-up events include:

Science and exploration

(recommendations will be discussed at COSPAR B3.1 Lunar science and exploration session)

Technologies and resources

A number of robotic missions to the Moon are now undertaken independently by various nations, with a degree of exchange of information and co-ordination. That should increase towards real co-operation, still allowing areas of competition for keeping the process active, cost-effective and faster.

Lunar landers, pressurized lunar rover projects as presented from Europe, Asia and America are important steps that can create opportunities for international collaboration, within a coordinated village of robotic precursors and assistants to crew missions.

We have to think about development, modernization of existing navigation capabilities, and provision of lunar positioning, navigation and data relay assets to support future robotic and human exploration. New concepts and new methods for transportation have attracted much attention and are of great potential.

Infrastructures and human aspects

It is recommended to have technical sessions and activities dealing with different aspects of human adaptation to space environments, the modeling of sub-systems, microbial protection and use of inflatable technologies

While the Moon is the best and next logical step in human exploration, we should make best use of the space stations as stepping stones for exploration and human spaceflight beyond Low Earth Orbit.

Further research is needed on lunar dust aspects in regard to humans and interaction with habitats. We note high interest in CELSS for Moon and Mars bases, and recommend further research and development.

We recommend the development and use of terrestrial analogues research sites and facilities, for technology demonstrations, comparative geology and human performance research, and public engagement. We endorse the proposal of development of world analogue sites for international Moon-Mars analogue research.

Moon, Space, Society and Young Explorers

We consider that the current legal regime as set out in the Outer Space Treaty and the Moon agreement are satisfactory for current and future missions, but may require further clarification for future exploration. Issues of transparency and security will need to be addressed.

Great things are happening for Young Lunar Explorers, with inspiring missions and hands-on activities as coordinated by ILEWG. Lunar exploration is encouraging students of all ages to pursue higher education.

More possibilities for participatory engagement should be offered to the society for example via interdisciplinary activities with the humanities.

We appreciate the work from COSPAR panel on Exploration PEX that should be shared further.

Continued cooperation should be enforced at all levels. The space community feels strongly that joining the forces of space faring nations to explore the Moon should be seriously implemented, with the views of expanding a Global Robotic Village and building in the long run a Manned International Lunar Base."

ILEWG has further integrated its activities with COSPAR, and developed a series of programmes to allow exchange of data, payload opportunities, collaborations on lunar missions, young lunar explorers grants for research projects, field campaigns and conference participation.

ILEWG has also supported a number of MoonVillage workshops and events in 2016-2018. This will be reported in PEX1 session concerning the international coordination of space activities, and in PEX2 concerning the synergy between human exploration of Moon, Mars NEOS.

PEX.1-0006-18 INTERNATIONAL COORDINATION RESULTING FROM SCIENTIFIC COLLABORATIONS

Patricia Beauchamp, pbeaucha@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Bernard Bienstock, bernard.bienstock@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology/ NASA, Pasadena, United States

International coordination is achieved in part as a result of existing scientific collaborations and relationships. Scientific collaborations happen at all levels but the ones made from early technical interactions are strong and last a lifetime. There are multiple ways to achieve these collaborations from participating on mission teams or on science and technology study teams to writing joint proposals to co-arranging workshops. There are many examples of these to be found, for example, the Cassini mission was an excellent example of international coordination at all levels and the study teams for the Europa and Ganymede missions that have led to the Juice and Europa Clipper missions are due in part to the relationships built during that mission. If there are no ongoing missions or studies in a particular field, then workshops can play a big role. Consistent interactions and relationship-building are key to promoting trust and cultural understanding, which lead to international collaboration and eventually coordination on a larger scale. One such workshop is the International Planetary Probe Workshop (IPPW), which is now in its 15th year. IPPW is an independent organization, without a permanent governing body. All those who participate in the organizing and award committees do so out of a desire to learn from the annual workshops and to share a week in an exciting location with long-standing associates. Many of the attendees have been to several past workshops. They continue attending to learn about the latest science and technology in the field of planetary probes. As with most ongoing workshops and conferences, a core group of enthusiastic volunteers re-volunteer to serve on committees and devote their own time to planning and conducting our yearly events. The past IPPWs have attracted 2000 professionals and students. In addition, 600 people have benefitted from the Short Courses offered prior to the annual workshops. Student attendance and presentations are encouraged and highly valued and, as a result, the students are highly motivated to stay in the field and often are employed by their more senior attendees' institutions. The workshop has maintained its international theme, with five of the twelve workshops conducted at European centers of planetary probe exploration. These collaborative efforts continue to initiate and build relationships that continue throughout the careers of the participants. Such foundational interactions are key to the larger scale international coordination that countries wish to have.

PEX.1-0007-18 ASTROBIOLOGY AS A GLOBAL ENDEAVOR

Penelope Boston, penelope.j.boston@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States

The intrinsically interdisciplinary study of astrobiology is also a highly international enterprise. Scientists from many nations regularly work in field sites, at laboratories, and with space agencies away from their home countries. This interaction is essential to the discipline by enabling the exchange of ideas and expertise, exposure of students and professionals to diverse scientific perspectives and specialties, and providing the potential to access important field sites in many lands both distant and near.

The NASA Astrobiology Institute (NAI), which is part of the Astrobiology Program at NASA, has an almost 20 year history of partnering with astrobiology institutes and other organizations in countries with significant astrobiology interests and activity. These partnerships were envisioned at the inception of NAI to encourage full access to important, even unique, facilities and field locations around the world including in the United States. Although international partnerships of this sort do not involve any exchange of funds between partners, to make these formal ties remain fruitful necessitates long-term commitment from the NAI and its partner institutions. It is a significant investment of effort to maintain engagement, information exchange, and interest in each other's activities and projects. This can be very challenging to accomplish as the individual fortunes of organizations change and the focus may morph over time, but ultimately the results are worth the effort expended.

Broadly speaking, healthy and vigorous international cooperation and exchange on astrobiological topics may help to grow the collaborations that produce new mission concepts, novel science questions, and potentially innovative payloads. Critically, astrobiology has a major scientific stake in the success of diligent and well-crafted planetary protection practices to preserve the scientific integrity of life detection missions. The framework for planetary protection is and has always been an international concern and obligation. Although astrobiology has a good history of international exchange and collaboration, much can still be done to continue this track record into the future to enrich the fundamental science, and mission opportunities in the future.

PEX.1-0008-18 INTERNATIONAL PARTNERSHIPS IN EXPLORATION SCIENCE

Gregory Schmidt, gregory.k.schmidt@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States Kristina Gibbs, kristina.gibbs@nasa.gov

KBRwyle - Solar System Exploration Research Virtual Institute, Mountain View, California, United States

Exploration Science is defined as the science of human exploration of the Solar System, including both science to enable humans to explore as well as the science enabled by human exploration. International interest and participation in Exploration Science efforts, particularly through the Solar System Exploration Research Virtual Institute (SSERVI), has increased exponentially over the past decade, leading to major efforts on a wide range of topics. International partnerships in this arena have the potential for strengthening scientific and human exploration efforts on all sides, leading to a new era of possibilities in robotic and human exploration of our Solar System. This talk discusses a sampling of these efforts, with an eye toward the important discoveries that will enable new approaches in human exploration in the coming decades.

PEX.1-0009-18 INTERNATIONAL COORDINATION OF SPACE EXPLORATION ACTIVITIES

Pascale Ehrenfreund, pehren@gwu.edu

Space Policy Institute, Washington, District of Columbia, United States

Panel Chairs: Pascale Ehrenfreund and Chris McKay

Panel speakers: Simonetta di Pippo, Clive Neal, Victoria Hipkin, Jeff Johnson, Chiaki Mukai, Bernard Foing

Ambitious plans to build new space infrastructure, transport systems, and space probes require international cooperation. To create a sustainable long-term space exploration program, space agencies are seeking consensus on priorities, objectives, and approaches. Furthermore, an increasing number of countries and organizations have shown interest in participating in future space exploration efforts. There are currently many independent groups planning activities relating to future space exploration scenarios of the Earth-Moon-Mars space. These address different stakeholders, including national space agencies as well as non-profit and commercial interests. In addition to COSPAR (PEX, PPP), the organizations and working groups that have been most active in recent efforts include the International Astronautical Federation (IAF) through its standing space exploration committee, the International Academy of Astronautics (IAA) which has organized recent "Heads of Space Agencies Summits", the International Lunar and Mars Exploration Working Groups (ILEWG, IMEWG), respectively, and the International Space Exploration Coordination Group (ISECG). Numerous reports and roadmaps have also been proposed by the international science organizations and working groups including the Mars Exploration Program Analysis Group (MEPAG), the Lunar Exploration Analysis Group (LEAG), the US National Academies' Space Studies Board (SSB) with its recent 2014 comprehensive report "Pathways to Exploration: Rationales and Approaches for a U.S. Program of Human Space Exploration" and the European Science Foundation's European Space Sciences Committee (ESF-ESSC). Support from organizations such as the International Institute of Space Law (IISL) and the United Nations Committee On Peaceful Uses of Outer Space (UNCOPUOS) guarantees the incorporation of international space law agreements and the interests of developing countries in the space exploration framework. 2018 will be an important "space year" with the International Space Exploration Federation ISEF in Tokyo, the Unispace +50 event in Vienna, the International Astronautical Congress 2018 in Bremen, and the COSPAR 2018 Assembly in Pasadena. COSPAR, through its Scientific Commissions and Panels provides an international forum that supports and promotes space exploration worldwide. This proposed COSPAR PEX Panel is intended to foster a dialogue with other international space organizations to explore pathways for improving coordination of space exploration activities.

PEX.1-0010-18 INTERNATIONAL COORDINATION OF SPACE EXPLORATION ACTIVITIES

Pascale Ehrenfreund, pehren@gwu.edu

Space Policy Institute, Washington, District of Columbia, United States

Part II Panel Chairs: Pascale Ehrenfreund and Chris McKay

In addition to COSPAR (PEX, PPP), the organizations and working groups that have been most active in recent efforts include the International Astronautical Federation (IAF) through its standing space exploration committee, the International Academy of Astronautics (IAA) which has organized recent "Heads of Space Agencies Summits", the International Lunar and Mars Exploration Working Groups (ILEWG, IMEWG), respectively, and the International Space Exploration Coordination Group (ISECG). Numerous reports and roadmaps have also been proposed by the international science organizations and working groups including the Mars Exploration Program Analysis Group (MEPAG), the Lunar Exploration Analysis Group (LEAG), the US National Academies' Space Studies Board (SSB) with its recent 2014 comprehensive report "Pathways to Exploration: Rationales and Approaches for a U.S. Program of Human Space Exploration" and the European Science Foundation's European Space Sciences Committee (ESF-ESSC). Support from organizations such as the International Institute of Space Law (IISL) and the United Nations Committee On Peaceful Uses of Outer Space (UNCOPUOS) guarantees the incorporation of international space law agreements and the interests of developing countries in the space exploration framework. 2018 will be an important "space year" with the International Space Exploration Federation ISEF in Tokyo, the Unispace +50 event in Vienna, the International Astronautical Congress 2018 in Bremen, and the COSPAR 2018 Assembly in Pasadena. COSPAR, through its Scientific Commissions and Panels provides an international forum that supports and promotes space exploration worldwide. This proposed COSPAR PEX Panel is intended to foster a dialogue with other international space organizations to explore pathways for improving coordination of space exploration activities.

PEX.1-0011-18 SCIENTIFIC GOALS FOR EXPLORATION OF THE OUTER SOLAR SYSTEM

Alfred McEwen, mcewen@lpl.arizona.edu

University of Arizona, Tucson, Arizona, United States Linda Spilker, linda.j.spilker@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

OPAG Steering Committee

Alfred McEwen, Linda Spilker, Jason Barnes, Pat Beauchamp, Jeff Bowman, Scott Edgington, Amanda Hendrix, Mark Hofstadter, Terry Hurford, Jeffrey Moore, Carol Paty, Julie Rathbun, Kunio Sayanagi, Britney Schmidt, Elizabeth Turtle

The 2018 draft goals document of NASA's Outer Planet Assessment Group (OPAG) has been posted for community comment (https://www.lpi.usra.edu/opag/reports/). This document will be a resource for defining technology development and research directions, for mission and instrument science objectives, and for international collaboration. Ultimately this document will guide preparation for the outer solar system portion of the next decadal survey, including mission studies being done in preparation for that survey. There are several major changes from the old (2006; 2015 draft) versions, based on new developments such as the Europa Clipper and JUICE missions, science results from Cassini, New Horizons, and Juno, the Ocean Worlds program and Roadmap to Ocean Worlds (ROW), and studies of an ice giants mission and a Europa lander. In addition, for the first time, this document includes the Kuiper Belt Object (KBO) planets.

One of the unique opportunities in the outer solar system is the chance to explore oceans. The outer solar system is replete with ocean worlds including Europa, Ganymede, Callisto, Enceladus, Titan, and probably Triton, among others. In the inner solar system only Earth has an ocean today, and oceans may be key to understanding the origin(s) and evolution of life. Ocean worlds may be the best places to search for extant life beyond Earth.

Two major planetary systems in our solar system have never had a dedicated spacecraft mission: the ice giants Uranus and Neptune. Voyager 2 flew through each system and gave a scouting report: these are exciting planetary systems. Given their importance to understanding planetary formation and evolution, exoplanets, and potential ocean worlds, as well as the unique environments on display there, exploration of ice giants was a top recommendation in Vision and Voyages, the current Decadal Survey. The recent Ice Giants study noted that preferential launch windows are in the 2029-2034 timeframe. Because of Triton, we favor a Neptune mission as top priority.

For Flagship-class missions, our top recommendation is to complete Europa Clipper. Our top priority for a new start is an Ice Giants mission. Our second new Flagship priority is a mission to search for life on an ocean world, most likely Europa or Enceladus. For New Frontiers class missions, OPAG supports opening competition to all solar system destinations, as recommended by the National Academies in 2008. In particular, we support the continued inclusion of Enceladus and Titan ocean worlds missions along with Io Observer and Saturn probes, and mission concepts to KBO planets. For Discovery class missions, we strongly support efforts that open up the outer solar system to Discovery, such as allowing radioisotope power systems (RPS). Smallsat missions are feasible as add-ons to larger missions to outer planets, and we support continued study and technology development for such concepts, leading to actual flight opportunities. We recommend a space telescope dedicated to planetary science. International coordination will likely continue to be essential for the success of missions to outer planet systems.

PEX.1-0012-18 THE ACTIVITIES OF SMALL BODIES EXPLORATION MISSIONS IN JAPAN AND INTERNATIONAL PARTNERS

In order to enhance our understanding of the origin and evolution in the early Solar System, it is very important to comprehensively connect small bodies in different evolution stages by exploring as many of them as possible, and to connect the chemical characteristics of target bodies obtained from sample return and/or on-site analyses with their geological features. The international collaborations in the two small body missions in Japan, Hayabusa2 and Destiny+, are known examples of multi-scale solar system science covering from interstellar medium to planetesimals. Hayabusa2, the Japanese C-type asteroid sample return mission, was launched on December 3, 2014 and is scheduled to arrive at the near Earth asteroid Ryugu on July 2018. During its 18-month stay, remote-sensing and lander observations will be carried out. The on-board lander of the Hayabusa2 spacecraft, Mobile Asteroid Surface Scout (MASCOT), was developed by DLR and CNRS. MASCOT includes Camera (Cam), Radiometer (MARA), Hyperspectral microscope (MicrOmega), and Magnetometer (Mag), which will carry out cm - mm scale observations of geology, mineralogy (hydrated minerals, especially), organic chemistry, temperature, thermal inertia (grain size), and magnetism of the asteroid surface, respectively. MASCOT plans to be released for exploring the region that is geologically similar to the 1st sampling site selected based on the remote observation data. The observation data from MASCOT is very important for selecting the 2nd and 3rd sampling sites. Thus, scientists from remote sensing team, MASCOT team, and sample analyses team have been closely work together to decide a landing site selection strategy by sharing the common picture of the multi-scale asteroid science. DESTINY+ (Demonstration and Experiment of Space Technology for INterplanetary voYage Phathon fLyby dUSt science) is a mission to flyby of Geminids parent (3200) Phaethon and in-situ dust analyses, which is planned to be launched in 2022. The science goals of this mission are i) to understand physical and chemical properties and origins of interplanetary dust particles, interstellar dusts and ii) to understand active asteroid Phaethon. The in-situ dust analyzer (DESTINY+ Dust Analyzer, DDA) is a time-of-flight mass spectrometer developed by Stuttgart University, Germany, with heritage of Cassini Cosmic Dust Analyzer (CDA) onboard Cassini. Great advantages of DDA is that flux, masses, velocities, orbits and compositions for the individual dust particles can be obtained. Thanks to DLR's support, application of two DDAs (for cation and anion modes) is currently under consideration. For promoting these international collaborations, Japan Society for the Promotion of Science (JSPS) core-to-core program, encourages young scientists to study at the partner institutions in USA, Switzerland, France, Germany, for several weeks to months. Ultimate goal of this program is to establish the international network of planetary sciences connecting solar system small bodies science with exoplanetology.

PEX.1-0013-18 THE ISECG SCIENCE WHITE PAPER: SCIENCE OPPORTUNITIES ENABLED BY THE GLOBAL EXPLORATION ROADMAP

Jean-Claude Worms, jcworms@esf.org

European Science Foundation, Strasbourg, France David B. Bussey, david.b.bussey@nasa.gov

NASA HQ, Washington, District of Columbia, United States Juergen Schlutz, juergen.schlutz@dlr.de

DLR - German Aerospace Center, BONN, Germany Francois Spiero, francois.spiero@cnes.fr

CNES, PARIS, France

ISECG Science Advisory Group

Gilles Clement, Ian Crawford, Mike Cruise, Masaki Fujimoto, Dave Hart, Ralf Jaumann, Tim McCoy, Clive Neal, Gordon Osinski, Maria Cristina de Sanctis, Masaki Shirakawa

The 15 space agencies of the International Space Exploration Coordination Group (ISECG) are discussing an internationally coordinated approach for human and robotic space exploration, as documented in ISECG's Global Exploration Roadmap (GER), i.e. a coordinated international effort to prepare for collaborative space exploration missions beginning with the Low Earth Orbit (LEO) and continuing to the lunar vicinity, the Moon, asteroids and, eventually, Mars.

The ISECG agencies have engaged the scientific community in a coordinated discussion with two goals: 1) promoting the scientific opportunities, and 2) improving the understanding of the priority science questions that can be addressed by near-term human exploration in to the Solar System. The ISECG set up in 2015 an independent Science Advisory Group (SAG) composed of scientists from a variety of nations and diverse science disciplines, and mandated this group to elaborate a Science White Paper to identify the scientific opportunities in nearterm exploration missions beyond LEO, the overarching science themes and their relevance to the GER mission concepts.

The SAG - together with ISECG agencies - organized a thorough consultation of the community using several conferences and dedicated events, starting with an interactive workshop at the European Lunar Symposium in May 2015 and continuing with a COSPAR-ISECG-ESF workshop in Paris in February 2016. The result is that international science communities' perspectives have been incorporated for a broad range of scientific disciplines including planetary and space sciences, astrobiology, life sciences, physical sciences, astronomy and Earth science.

The Science White Paper was published in December 2017 and is structured around the science themes "Understanding Our Place in the Universe" and "Living and Working in Space". The key science aspects also inform the future evolution of mission concepts considered in the GER.

We will present the contents of the Science White Paper, with particular emphasis on the benefits of such a Global Exploration Roadmap enabling scientific exploration.

PEX.1-0014-18 INTERNATIONAL COORDINATION OF SPACE EXPLORATION ACTIVITIES - THE NEXT GENERATION PERSPECTIVE

Harriet Brettle, harriet.brettle@spacegeneration.org

Space Generation Advisory Council, Pasadena, California, United States

International Coordination of Space Exploration Activities

- The Next Generation Perspective

Harriet Brettle - Strategic Partnerships Team Co-Coordinator, Space Generation Advisory Council

The Space Generation Advisory Council (SGAC) is a non-governmental organisation based in Vienna, Austria and is also a registered 501(c)(3) organisation in the United States. SGAC works on the international, national and local level to link together university students and young professionals to think creatively about international space policy issues and voice the new generation's point of view on international space policy creations. SGAC has obtained permanent observer status in the United Nations (UN) Committee on the Peaceful Uses of Outer Space (COPUOS) and is a member of the UN Economic and Social Council (ECOSOC), as well as the International Astronautical Federation (IAF).

As Strategic Partnerships Coordinator, I support SGAC's mission to represent students and young professionals to the United Nations, space agencies, industry, and academia. In my role I manage partnerships and sponsorships that enable SGAC to connect with the wider space community. We partner with leading space agencies, corporations and organisations from around the world to nurture the next generation of space leaders.

SGAC recognises the importance of developing strong partnerships with private industry, academia, space agencies, NGO's and other actors of the space community. Through international coordination we foster understanding and advocate progress within the space industry.

SGAC is continuously seeking to identify opportunities that bring the next generation of space leaders into the conversation. International coordination is one of SGAC's key strengths. SGAC is the largest network of students, young professionals and alumni in the space industry. Our global volunteer base of over 13,000 members in 150+ countries worldwide work on a range of space related projects.

SGAC organises events at the international, regional and local levels to bring our members together to discuss and engage with current leaders from space agencies, industry and academia.

Our eight project groups enable our members to shape key topics on space through technical papers, long-term project, policy briefs and recommendations. SGAC advocates for space exploration and inspire others in the next generation to get involved in space-related careers. SGAC provides scholarships that enable our members to participate in space-related events around the world. Finally, SGAC empowers its members with the skills and experiences to become the space leaders of tomorrow.

PEX.1-0015-18 THE FORUM FOR NEW LEADERS IN SPACE SCIENCE: 2014-2018

David H. Smith, dhsmith@nas.edu

National Academies of Sciences, Engineering and Medicine, Washington, District of Columbia, United States

The space science community is thoroughly international, with numerous nations now capable of launching scientific payloads into space either independently or in concert with others. As such, it is important for national space-science advisory groups to engage with like-minded groups in other spacefaring nations. The Space Studies Board of the US National Academies of Sciences, Engineering and Medicine has provided scientific and technical advice to NASA for 60 years. Over this period, the Board has developed important multilateral and bilateral partnerships with space scientists around the world. The primary multilateral partner is COSPAR, for which the Board serves as the US national committee. The Board's primary bilateral relationship is with the European Science Foundation's European Space Science Committee. Burgeoning Chinese space activities have resulted in several attempts in past decades to open a dialogue between the Board and space scientists in China. On each occasion, the external political environment was not conducive to success. The most recent efforts to engage Chinese space researchers began in 2011 and have proved particularly successful. Although NASA is currently prohibited from engaging in bilateral activities with China, the Board has established a fruitful dialogue with its counterpart in the Chinese Academy of Sciences (CAS). A joint National Academies-CAS activity, the Forum for New Leaders in Space Science, has been established to provide opportunities for a highly select group of young space scientists from China and the United States to discuss their research activities in an intimate and collegial environment at meetings to be held in both nations. The presentation will describe the current state of US-China space relations, discuss the goals of the joint NAS-CAS undertaking and report on the activities undertaken at the eight Forums held so far.

PEX.1-0016-18 UNDERSTANDING VENUS: AN INTERNATIONAL EFFORT

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Emmanuel Marcq, emmanuelmarcqemmanuel.marcq@latmos.ipsl.fr

LaboratoireAtmosphres, M ilieux, ObservationsSpatiales, F rance

Within five years of the dawn of the space age with Sputnik, the Mariner 2 fly-by (1962) and Venera-4 probe's entry (1967) into another atmosphere demonstrated that our nearest neighbor was a world very different from our own home planet. With regular launches from the Soviet Union in the early decades of exploration of Venus and missions launched by NASA, the knowledge about Venus grew significantly. It was only after the COSPAR general assembly held in Philadelphia in 1976 that collaboration began between US and USSR with exchange of data, leading to some small joint efforts with the Pioneer Venus Orbiter and Probe missions (1978-1983) followed by collaboration in planning and carrying out the VeGa mission in 1985 involving many countries.

The nearly two-dozen missions flown to Venus have painted a puzzling picture of Venus. Presently JAXA's Akatsuki orbiter is collecting observations that are adding more questions about the planet. They can be summed up by perhaps just one question: why did Venus evolve so differently from Earth? What we have learnt from the many missions to Venus is that to understand Venus, we need to observe its surface, sample its deep atmosphere, explore its magnetosphere and ionosphere, infer the interior structure and monitor the deep, global cloud cover. Just like Earth is being observed by multiple spacecraft in different orbits, airplanes, ships, automated surface and ocean stations, observing Venus and its environment requires a combination of platforms. Single, focused missions are effective at tackling some of the questions about Venus, but the synergy of near simultaneous and long term monitoring of Venus is needed for a better understanding of the planet.

The International space agencies and scientists have been considering various approaches to exploring Venus through small and large missions. The Venus Exploration Analysis Group (NASA) has developed a Venus Exploration Roadmap and a comprehensive list of goals, objectives and investigations (www.lpi.usra.edu/vexag). Venus science and questions for future missions have been periodically discussed by international Venus scientists at dedicated conferences. Following discussions at such meetings, the International Venus Exploring Working Group was formed during the 2012 general assembly in Mysore India to promote collaboration among the global Venus scientific community and coordination of efforts to explore Venus by the spacefaring nations, which worked so successfully for the VeGa, Venus Express and Akatsuki missions in particular.

At present a collaborative effort limited to Roscosmos and NASA is being conducted by the Joint Science Definition Team assembled to study the implementation approach for Russia's Venera-D mission. It is recognized that Venera-D would represent an important piece of an international Venus exploration strategy. Leading up to and following this step an ongoing effort and additional missions by all space agencies are desirable to address the many un-answered questions. ESA is currently evaluating EnVision, a proposed mission that could carry a small contributed probe (such as those being studied by NASA), allowing for a coordinated and complementary international exploration plan. Such a plan is needed to maximise the returns from future Venus exploration.

PEX.1-0017-18 INTERNATIONAL COOPERATION IN OUTER SOLAR SYSTEM EXPLORATION

Jet Propulsion Laboratory, Pasadena, California, United States Jonathan Lunine, jlunine@astro.cornell.edu

Cornell University, Ithaca, New York, United States

Exploration of the outer Solar System is challenging in terms of cost and mission duration. Some of the most successful missions to the outer Solar System have been international partnerships. An example is the Cassini-Huygens mission - built on a primarily US Saturn orbiter and a probe to the surface of Titan by ESA. Science goals for future missions to the ocean worlds of the outer Solar System will include the search for evidence of life. Such a search would benefit considerably from the ability to return samples to Earth. Two particular issues with an astrobiology sample return from an ocean world are mission duration/cost and the challenge of bringing potentially living organisms to Earth in a fully contained manner that meets the goals of planetary protection and minimizes the possibility of terrestrial contamination. In this paper we consider the illustrative example of a sample return from the plume of Enceladus. As a point design we postulate a joint mission by NASA and JAXA (these are the two agencies that have achieved sample return from targets beyond the Moon) and consider how such a mission could spread mission costs and solve the challenge of safe return.

Tsou, P., et al., 2012. LIFE: Life investigation for Enceladus a sample return mission concept in search for evidence of life. Astrobiology, 12(8), pp.730-742.

PEX.1-0018-18 ROLES FOR COSPAR PPP AND PEX IN FUTURE SPACE RESOURCES GOVERNANCE ACTIVITIES

John Rummel, jrummel@seti.org

SETI Institute, Champlain, New York, United States

The development of space-resource extraction activities has begun. Without a pre-existing framework to govern such activities, it is necessary to examine concepts that may lead to that governance, while ensuring that, to the maximum possible extent, they address existing treaty obligations regarding on-orbit operations and space resource rights. To be successful, these concepts will need to enable, support, and coordinate the steps leading to the use of space resources, while being acceptable to space-faring nations and other interested States. Over the last few years, a group known as The Hague International Space Resources Governance Working Group has developed and is circulating draft "building blocks" for the development of an international framework for the governance of space resource activities. In particular, the Working Group's Building Block 9, "Avoidance of harmful impacts resulting from space resource activities" should be of interest to COSPAR. It specifies that the international framework of space resources governance "should provide that States and intergovernmental organizations authorizing space resource activities shall adopt a precautionary approach with the aim of avoiding harmful impacts, including: a) Risks to the safety of persons, the environment or property; b) Damage to persons, the environment or property; c) Adverse changes in the environment of the Earth, taking into account internationally agreed planetary protection policies; d) Harmful contamination of celestial bodies, taking into account internationally agreed planetary protection policies; e) Harmful contamination of outer space, including the creation of harmful persistent space debris; f) Harmful interference with other on-going space activities, including other space resource activities; g) Changes to designated and internationally endorsed outer space natural or cultural heritage sites; and h) Adverse changes to designated and internationally endorsed sites of scientific interest. The relationship of these points to the Terms of Reference for both the Panel on Planetary Protection and the Panel on Exploration in COSPAR will be the subject of this presentation.

PEX.1-0019-18 THE MOON VILLAGE ASSOCIATION: AN INFORMAL, GLOBAL FORUM FOR COOPERATION AND COORDINATION IN LUNAR EXPLORATION

John Mankins, john.c.mankins@artemisinnovation.com

Artemis Innovation Management Solutions LLC, Santa Maria, California, United States Giuseppe Reibaldi, giuseppe.reibaldi@gmail.com

Moon Village Association, Vienna, Austria

The concept of a "Moon Village" (MV) is one that encompasses a wide range of prospective future human activities on the Moon - comprising early landers and orbiters, initial human and robotic exploration missions in the mid-term and eventual ambitious government and commercial operations (including eventual human settlements) In the far-term. During the past year, significant progress has been made to advance the vision of a Moon Village by a new non-governmental organization (NGO), the Moon Village Association (MVA). Working in concert with a variety of existing government and non-government organizations, this progress has centered around identifying, organizing broad-based international teams and beginning to undertake a variety of critical activities. These MVA efforts have included conventional topics such as identifying potential lunar missions and markets, examining options for Moon Village architectures (including high-level interface standards). However, the MVA has also undertaken consideration of cultural issues, cooperation and cooperation among diverse players, formulation of concepts for lunar analogues (both on Earth for the Moon, and on the Moon for missions beyond). This paper will review the core concepts that define the Moon Village, summarize recent progress to realize this vision with special emphasis on the methodology being used by the MVA, and define a notional international MV roadmap. It will conclude with a plan of action going forward.

PEX.1-0020-18 OPTIMISING HUMAN SPACE EXPLORATION STRATEGIES AND POLICIES

Serge Plattard, s.plattard@ucl.ac.uk

University College London, UK, London, United Kingdom

The three central players in human space exploration, understanding those who master the full spectrum of means to explore, are moving along with strategies that seem aimed at different goals, with different tempos and paths. For the United States, the long-term objective is to reach Mars and set up on the Red planet a sustained human presence. For NASA, this should proceed via a Deep Space Gateway (DSG) in cis-lunar orbit, providing the infrastructure as a springboard to Mars, and also using the Moon as a proving ground for a number of indispensable functions essential to long distance travel in the solar system. The strategy for this new course is consistent with the possibility to have the ISS privatised starting in 2025, freeing NASA to concentrate on human space programmes beyond LEO. While SpaceX, for its part, considers that a direct access to Mars is the way to go, regular shuttling from the Earth would support a first step for a permanent presence on this planet. China is taking a quite different approach: continue to learn more by establishing a larger space station, TienGong-3, in the next decade, with the possibility of having European astronauts on board, and later to deploy a permanent infrastructure on the Moon to explore and exploit resources of our natural satellite. Russia is still very much tied to the ISS activities and wishes to continue as long as possible with the international orbital outpost. Funding, a constant hurdle for the Russian space programmes, and the lack of heavy lifting capability are challenging issues when preparing for human exploration beyond LEO. Beyond the ISS, the plans for ESA are not yet formalised: the Moon Village is still a concept, while it may materialise, the European presence on the Moon is still quite vague: since Member States have decided not to fund autonomous human rated means to reach the Moon for some decades, they can be only contributors to non Europeans strategies, meaning they should concentrate on specifics needed by the US or China (e.g. Orion service module), and trying to be on critical paths of the two major players for particular functions/missions to play a significant role involving its space agencies and industries. Yet, it remains to be seen if such a demarche is acceptable by the Member States, to what extent of engagement, and how this will be received by the United States and/or China. Budgetary burden sharing is certainly a strong argument in favour of such an approach. Japan and Canada, both contributors to the ISS, will have to find their place in the on-going re-definition of future strategies by the "Big Three". After analysing these different strategies, weighting their strengths and weaknesses, the presentation will propose some scenarios based on a more holistic approach where the different players could contribute in a more synergistic mode, reducing costs and engaging throughout an improved path for a sustainable human space exploration; including public and private funding, contributions of new actors that have not being, so far, involved in human space exploration. The outcome of the 2nd ISEF will be taken into account in building the different scenarios.

PEX.1-0021-18 INTERNATIONAL COORDINATION OF COORDINATE SYSTEMS OF SOLAR SYSTEM BODIES BY THE IAU WORKING GROUP ON CARTOGRAPHIC COORDINATES AND ROTATIONAL ELEMENTS

Brent Archinal, barchinal@usgs.gov

U. S. Geological Survey, Flagstaff, Arizona, United States

IAU Working Group on Cartographic Coordinates and Rotational Elements including C. H. Acton, A. Conrad, G. J. Consolmagno, T. Duxbury, D. Hestroffer, J. L. Hilton,

L. Jorda, R. L. Kirk, S. A. Klioner, D. McCarthy, K. Meech, J. Oberst, J. Ping, P. K. Seidelmann, D. J. Tholen, P. C. Thomas, and I. P. Williams

Overview: Since 1979, the Working Group on Cartographic Coordinates and Rotational Elements (hereafter the "WG") of the International Astronomical Union (IAU) has, after most IAU General Assembly (GA) meetings, issued a report recommending coordinate systems and related parameters (body orientation and shape). This information can be used as a foundation for mapping Solar System bodies and other navigation and geophysical purposes in support of robotic and human exploration by all nations. These recommendations, which are open to further modification when indicated by community consensus, are intended to facilitate the use and comparison of multiple datasets by promoting the use of a standardized set of mapping parameters. We highlight here the WG's efforts and our just published report [1] covering 2012-2017. The WG encourages input and participation, and is available to assist users, instrument teams, and missions. See our website [2] for additional information. We also note that other IAU services exist to support space exploration, e.g. on Solar System ephemerides and planetary nomenclature.

Operation of WG: The Working Group consists currently of 18 volunteers. Volunteers may join at any time, but usually join for at least a three-year term to help with each new report following the IAU GA. The WG looks at new determinations of coordinate systems (e.g., body sizes and orientations) that preferably have been published in refereed papers, and makes recommendations as to which to use, based where possible on consensus decisions.

As a volunteer organization, the WG has no resources to verify results or conduct its own research so it relies only on published results and community input. For that reason, it is sometimes not possible to recommend one set of results over another. The WG cannot verify or "bless" any particular results. The WG has no "enforcement" powers, but tries, in reflecting the long term planetary community consensus, to make persuasive recommendations.

The WG does not deal with issues related to the formats of mapping products; such issues have largely been left to individual map

developers, archiving organizations such as the NASA Planetary Data System (PDS), or various coordination groups, such as the NASA Mapping

And Planetary Spatial Infrastructure Team (MAPSIT) [3], with whom the WG cooperates. In the past the WG has also been both a joint COSPAR and IAG working group.

General Changes: Following extensive discussion, substantial updates have been incorporated by the WG into our new report. An overview follows. First, the WG has reworded and clarified its recommendations regarding updating longitude. Second, mission and community input indicates a need for the WG to differentiate between planetary body shapes and sizes for image projection and scientific modeling vs. a reference surface for elevation and map scale. In particular, long-accepted values for the latter are documented for the Moon and (now recommended for) Titan. Third, the discussion of terminology for the poles (hemispheres) of small bodies has been modified. Fourth, updates to the orientation models of Jupiter and Saturn are not recommended at this time, as we await community consensus on a model for Jupiter and final results from the Cassini mission regarding the orientation of Saturn.

Changes for Specific Bodies: As highlights, new orientation models for Mars [4], Phobos, and Deimos are recommended for use. More precision in Martian longitude is provided by defining the position of the Viking 1 lander. Orientation models have also been updated for Neptune, Ceres, several asteroids and comets. Size information has been updated for Mercury, Ceres, Pluto, Charon, and asteroids Psyche, Europa, and Itokawa.

Other recommendations: We repeat our previous recommendations that planning and efforts be made to make controlled cartographic products. We now recommend that common formulations should be used for orientation and size and that historical summaries of the coordinate systems for given bodies should be developed. We point out that for planets and satellites planetographic systems have generally been historically preferred over planetocentric systems; and that in cases when planetographic coordinates have been widely used in the past, there is no obvious advantage to switching to the use of planetocentric coordinates.

Request for Input: The WG desires continued input from the planetary community, especially regarding the systems for specific bodies, the operation of the WG, our proposed question submitting process, and posting of updates via the WG website. We encourage volunteers to become WG members and help with our efforts. Our membership is open to all. Contact the author of this abstract for additional information.

PEX.1-0022-18 PLANETARY SPATIAL DATA INFRASTRUCTURE: PRESENT STATE, FUTURE NEEDS, AND INTERNATIONAL COOPERATION

D. Alex Patthoff, apatthoff@psi.edu

Planetary Science Institute, Pasadena, California, United States Brent Archinal, barchinal@usgs.gov

U. S. Geological Survey, Flagstaff, Arizona, United States Jani Radebaugh, janirad@byu.edu

Brigham Young University, Provo, Utah, United States

Planetary spatial data are the derived products from missions to planetary bodies, including remote sensing and in-situ data. The infrastructure needed to ensure these products are accessible, searchable, and useable, varies from world to world and mission to mission. We describe how the Mapping and Planetary Spatial Infrastructure Team (MAPSIT, https://www.lpi.usra.edu/mapsit/) has been tasked by the NASA Planetary Science Subcommittee of the NASA Advisory Council to identify and prioritize the spatial data needs of the community. Given the geological breadth of planets, moons, and other solar system bodies, diversity of missions over the past 50+ years, and wide range of instruments and data acquired, it is difficult to prioritize any single need. Instead, we are focusing on highlighting existing infrastructure, identifying what still needs to be achieved, and seeking input from the community for additional priorities. We are working to create a Planetary Geospatial Strategic Plan as a roadmap toward what needs to be done. Although MAPSIT is a NASA-tasked organization, our terms of reference include cooperation and collaboration with appropriate international organizations, space agencies, and missions. We therefore seek to let the international space community be aware of our existence and work and encourage collaboration with us.

Near-term issues that MAPSIT has identified are as follows: How should the current, unprecedented influx of high-volume, planetary mission data be geodetically controlled and integrated to enable science and operation of current and future missions? How should global, regional, and local mosaics, basemaps and topographic models be created from multiple data sets? What requirements should be developed for missions to follow during the formulation and definition stages to enable the availability, searchability and usability of all acquired data? How can planetary spatial data products be used to enable and facilitate future human exploration and in-situ resource utilization?

The greatest resource from any mission is the data returned, and we seek to ensure these data are useable to all interested researchers to yield the best possible return for all global space agency stakeholders.

PEX.1-0023-18 MORE MISSIONS FOR THE SAME MONEY

Leszek Czechowski, lczecho@op.pl University of Warsaw, Warszawa, Poland

Current efforts of investigation of the Solar System are often the subject of irrational political pressures often resulting from nationalistic motives. This causes huge scientific losses, but also, contrary to appearances, political losses. The better cooperation between national space agencies could be beneficial for the space exploration and for national space programs. Fortunately, recently private companies represent a new approach. The success of Spacex is not an example of a unique genius approach. It is a result of simple application of common sense to the astronautics. Similar breakthroughs have been observed many times when a technology has become so mundane that a simple economic approach can be applied to it. The best example was the Ford's approach to car production in the beginning of XX century. The success of privates companies in the development of space rockets still seems be ignored by decision makers. The better cooperation between space agencies could be beneficial for the space exploration and for national space programs. Instead of independent attempts to develop the technology already developed by others, the decisions makers could consider buying ready products, buying licences, exchanging of technology, etc. Why do not try the barter of Rosetta for Cassini? Why do not develop a new version of Huygens lander and barter it for Curiosity rover? It hardly to calculate the second copy of the Curiosity (the Martian rover), but evidently it would be much cheaper than the RD+first copy's production cost (2.5 billion US), probablynothigherthan1billionU S. The rationalization of space expenditures would allow a significant acceleration of the planetary research. I believe that with a small increase in spending by the space agencies with a decisive increase of cooperation, it is possible to achieve several Mars rovers (of the Curiosity class) on Mars, Titan or Enceladus.

Acknowledgements: The research is supported by BST fund of University of Warsaw.

PEX.1-0024-18 COMMUNITY EMPOWERED ROLE MODELS IN OUT REACH FOR SPACE EXPLORATIONS

Jagannatha Venkataramaiah, jagsiobbindia@gmail.com Indian Space Research Organization, Mysuru, India Shashishankar A, shasiananth(at)gmail.com

India

A review of the scientific Philosophical perspectives major developments during 600 BC to 2000 AD reveal incremental struggle of evolving logical strength of Space quests which are nothing but urges for space explorations. Further, sustained efforts in harnessing natural forces, Space as a tool for human evolution has been a reality. Dual use of Space Technology amongst nations has matured leading to a situation which sustains both " war and defence and space explorations" domains. While a opportunistic entrepreneur mind set gets victimised with amassing wealth for wealth. An adventurer conscience sustains space explorations. This is as evident in the 21st Century. Also, evolving entrepreneurships in societies have also empowered individual and community to try for space explorations and remain sustainable. A significant development in the evolution of human societies is emergence of United Nations. In the context of Outreach in space explorations few significant developments are worthwhile for individuals and community wellbeing. The first unique developments in empowering individual and communities is the promulgations of objectives of Environmental Education popularly cited as UNESCO/UNEP/IEEP/Tbilisi 1977. While UN charter facilitated evolution of a formal governance amongst member states for managing finite life supports on our only home the Earth, further priorities in the capabilities of individual and community for explorations is evident. These are available amongst the people science and popular community empowering movements all over the globe. In this paper best practices of space technology affecting community life style of developing nations are reported. An attempt is made to capture good space technology practices of resource management, and environmental data bases. It is inferred that Space governance mechanisms need to be evolved based on UN Sustainable Development Goals and national priorities. A specific vision agenda and time bound outreach activity plan for space explorations at community level is felt as a historical necessity. Enormous deluge of information need to be assorted and communicated in formal and informal educational opportunities.

PEX.1-0025-18 THE EUROPEAN UNION'S LEGAL COMPETENCE REGARDING SPACE ACTIVITIES

Eloi Petros, eloi.petros@idest-paris.org IDEST, Université Paris-Sud, Paris, France

The Treaty of Lisbon (2007) institutes a direct competence of the European Union (EU) regarding space activities. In order to promote scientific and technical progress, to implement its policies and to foster industrial competitiveness, the Union elaborates a European space policy. Among the tools it has been granted to accomplish those objectives, the EU can promote and coordinate common initiatives and support efforts in research and development. It also establishes all the useful relations with the European Space Agency (ESA). This competence of the EU makes it a new international actor in the large landscape of space cooperation. However, this competence has particular limits provided for in the treaties. This article will focus on the European Union as an international actor of space cooperation. It will address, through the study of its particular legal competence regarding space activities, the possibility and limits of its role as an international partner in international space cooperation.

PEX.1-0026-18 VENERA-D: MISSION CONCEPT FOR STUDY ATMOSPHERE,SURFACE AND PLASMA ENVIRONMENT OF VENUS

Ludmila Zasova, zasova@iki.rssi.ru

Space Research Institute (IKI), Russian Academy of Sciences, Moscow, Russia The Venera-D Joint Science Definition Team

D. Senske,L. Zasova, A. Burdanov, T. Economou, N. Eismont1, M. Gerasimov, D. Gorinov, J. Hall, N. Ignatiev, M. Ivanov, K. Lea Jessup, I. Khatuntsev, O. Korablev, T. Kremic, S. Limaye, I. Lomakin, A. Martynov, A. Ocampo, S. Teselkin, O. Vaisberg, V. Voron, V. Voronstsov

A Joint NASA-IKI/Roscosmos Science Definition Team (JSDT) was established in 2015 with the task of defining the science and architecture of a comprehensive mission to Venus. Building on the results of the highly succesful missions Soviet and US, as well current time Venus Express and Akarsuki orbiters the overarching goals were formulated to understand why Venus and the Earth took divergent evolutionary paths. Specific areas of Venera-D investigation would address questions focused on the dynamics of the atmosphere with emphasis on atmospheric superrotation, the origin and evolution of the atmosphere, and the geological processes that have formed and modified the surface with emphasis on the mineralogical and elemental Venera-D concept included origin and evolution of the atmosphere, and the geological processes that have formed and modified the surface with emphasis on the mineralogical and elemental composition of surface materials, and the chemical processes related to the interaction of the surface and the atmosphere The Venera-D mission concept includes baseline elements (Roscosmos): orbiter (more than three years lifetime) and lander (2-3 hours on the surface) with high capable scientific paloads. Additional long lived elements (possible NASA contribution) are considered: the aerial platform for long time important measurements in atmosphere and the small long lived station

(s) on the surface (one long lived station may be included as an instrument of the lander, and will continue working after lander death) and subsatellite for plasma measurements. To aid in refinement of the Venera-D science objectives, two community modeling workshops were held in 2017: in May in Glenn Research Center and in Octoder in Space Research Institute. The Venera-D JSDT Phase 2 report will be completed by January 31, 2019. Launch of the Venera-D mission is expected from Vostochny with Angara-5 (Proton) rocket in time frame from 2026 to 2031.

PEX.2-0001-18 RUSSIAN PLANS FOR ROBOTIC INVESTIGATIONS OF MOON AND MARS

Lev Zelenyi, lzelenyi@iki.rssi.ru

Space Research Institute of RAS, Moscow, Russia

Russia has now two coupled programs of Lunar and Martian investigations. Set of Lunar missions includes both landers Luna-25, Luna-27, Luna-28 and orbiter Luna-26. Program is aimed at investigation of previously weakly explored Lunar polar regions having the number of very unique and scientifically challenging properties. Program has very significant international contributions. Martian program starts from two EXOMARS missions accomplished jointly by Russian and European Space agencies and continues with BUMERANG project devoted to the return of Phobos samples. EXOMARS program was motivated by recent findings of surprisingly abundant methane eruptions in Martian atmosphere. First EXOMARS spacecraft -Trace Gas Orbiter -started already its observations of Martian atmosphere and its surface. Second part

-Russian landing scientific platform with ESA rover will be launched in 2020 and will start its observations of conditions at and below of Martian surface and the search of possible signatures of the past and even present primitive life. We consider also the return to Venus with longliving landing station at the end of the next decade.

PEX.2-0002-18 EARTHMOONMARS VILLAGE WORLDWIDE ACTIVITIES

Bernard H. Foing, bernard.foing@esa.int ESA/ESTEC, Noordwijk, Netherlands

Moon Village Workshops Organisers 2017 - 2018

Izotova) * 1)ESA ESTEC, 2)ILEWG International Lunar Exploration Working Group, 3)VU Amsterdam (Bernard.Foing@esa.int)

We give an update of Moon Village (MV) and MoonMars activities, with emphasis on events that took place in 2017 and 2018. The Moon Village is an open concept proposed with the goal of a sustainable human and robotic presence on the lunar surface as an ensemble where multiple users can carry out multiple activities. [1-3]. Why a Moon Village? Multiple goals of the Moon Village include planetary science, life sciences, astronomy, fundamental research, resources utilisation, human spaceflight, peaceful cooperation, economical development, inspiration, training and capacity building.

Moon Village 2017 international events:

Global Space Congress Abu Dhabi UAE 30 Jan-1 Feb

UN COPUOS Action team on Exploration 5-7 Feb 2017

UN COSPAR explo workshop Vienna 25 April, 22 May

European Lunar Symposium New Views of Moon, Muenster 2-4 May (HH, CN)

ISDC ST Louis (with ESA DG J. Woerner) 1-2 June

GLEX Global Exploration Conf Beijing 6-8 June

Concordia U Montreal MVWS 11-12 Aug (M-P B.)

Global Hands on Universe, Bowling Green 16-17 Aug

Nashville Adventure Sci Center, Eclipse 19-21 Aug (JI)

EPSC European Planetary Science Congress Riga, Moon Village Science, Explo. Technology Foresight 18-21 Sep

Adelaide Australia IAC Intl Astronautical Congress A3 exploration symposium plenaries 25-29 Sept

Hawaii International Moon Base Alliance 1-4 Oct (HR)

Columbia, LEAG Lunar Expl. Analysis Group 10-11 oct

Bremen Space Tech 24-26 Oct

ISU MVA MVWS 19-21 Nov (GR, CW, JM, AK)

ESLAB ESTEC Extreme Habitable Worlds 4-8 Dec (ESN)

MoonVillage Global Science Opera (performance over 15 countries including ESTEC event) 13 Dec (O. B.-O.)

We shall also give highlights of 2018 EarthMoonMars Village events.

Perspectives: A number of activities are planned. The EarthMoonMars Village will rely both on automatic, robotic and human-tendered structures to achieve sustainable surface operations serving multiple purposes on an open-architecture basis.

*Acknowledgements We thank Prof J. Woerner (ESA DG) for energizing the concept of MoonVillage. *We acknowledge co-conveners of MoonVillage Workshops and ILEWG EuroMoonMars field campaigns in 2016, 2017 and 2018 (including C. PEX.2-0003-18 FROM THE ROBEX EXPERIENCE TOWARD THE ROBOTIC DEPLOYMENT AND MAINTENANCE OF SCIENTIFIC INFRASTRUCTURE FOR FUTURE PLANETARY EXPLORATION MISSIONS

Armin Wedler, armin.wedler@dlr.de

Deutsches Zentrum fuer Luft-und Raumfahrt (DLR), Wessling, Germany

Abstract: During the project ROBEX (Robotic Exploration for extreme environments) the deployment of an active functional seismic network has been demonstrated during the analog field test on Mt. Etna, Italy in 2017. During this mission campaign, key functionalities of robotic operation for future mission has been demonstrated, such as autonomous long term navigation, scientific instrument detection and manipulation, deployment, precise positioning and operation. This experiment will be described in this paper as a baseline for future mission. During the ROBEX experiments modular payload carrier, interfaces and methods has been developed which allow the reuse and adaptions of such robotic technologies and methods for different scientific approaches. Various robotic operational modalities, such as tele-operation, supervised control and high autonomous functionalities will be enabling technologies for long term bases on planetary surfaces. A roadmap will be presented.

ROBEX: As key missions, a seismic network was deployed and a seismic profile measurement was conducted using only robots on the landing site. Further experiments has allowed long term autonomous navigation, exploration of craters as well as robot cooperation tasks with the aim of geological analysis and probe selection. During this one month analog campaign, a realistic mission scenario has been built up, including a control station 30km away from the remote site. The Mt. Etna site has mainly been chosen due to the high equivalence of its seismic activity to moon quakes. Earth quakes in this region have a focal depth of approximately 600 km, a value similar to what has also been considered for moon quakes. Furthermore, the region is seismically highly active, probably three to four events per day, which means that scientifically relevant data will be acquired within the one month duration of the mission. In addition, the site fulfills important criteria for an analog mission such as:

REUSE: The modularity and concepts developed from the DLR, demonstrated within the field test, allows us to proceed for the long term goal, the installation and maintenance of permanent bases on planetary surfaces, including the usage of multiple robots and agents, for various scientific experiments. In further projects the demonstration of interferometric instruments will be one use cases for cosmology. Other projects aim the autonomous cooperation between robots and the interaction with humans and astronauts.

OPERATIONS: Various operation modes for robots are currently used. Depended on the communication infrastructure and capabilities, the different modes varies from teleoperation, where the human is in direct contact to the remote robot, over shares and supervised control, where local autonomy allows the robot to operate simple sub tasks on its own, based on local perception and autonomy, up to highly complex autonomous functionalities which will allow long time autonomous operations, even in mission critically situations. In general the goal for future missions will be, to include as much autonomy on the robot site, to relive the human operator, the astronaut and reserve time for more important tasks.

All this mission and operational concepts are in line with the global exploration strategy, regarding the goal of human robot cooperation, the installation of permanent bases e.g. lunar village, and the CIS Luna habitat or the Deep Space Gateway. A robotic strategy will be presented in this paper.

PEX.2-0004-18 THE UNIVERSITY ROVER CHALLENGE: A COMPETITION HIGHLIGHTING HUMAN AND ROBOTIC PARTNERSHIPS FOR EXPLORATION

Heather Smith, heather.d.smith@nasa.gov NASA, Logan, Utah, United States

Kevin Sloan, urc@marssociety.org

The Mars Society, Lakewood, United States Andrew Duncan, desertsensors@gmail.com Desert Sensors, Logan, Utah, United States Darrel Robertson, urc@marssociety.org

The Mars Society, Lakewood, Colorado, United States Kurt Chankaya, urc@marssociety.org

The Mars Society, Lakewood, Colorado, United States Anne Anderson, urc@marssociety.org

The Mars Society, Lakewood, Colorado, United States

The University Rover Challenge began in 2007 with 4 American college teams competing, now in it's 12th year there are 95 teams from 12 countries registered to compete for the top rover designed to assist humans in the exploration of Mars. The Rovers compete aided by the University teams in four tasks (3 engineering and 1 science) in the Mars analog environment of the Utah Southern Desert in the United States. In this presentation we show amazing rover designs with videos demonstrating the incredible ingenuity, skill and determination of the world's most talented college students. We describe the purpose and results of each of the tasks: Science Cache Task, Extreme Retrieval and Delivery Task, Equipment Servicing Task, and the Autonomous Traversal Task. We explain the evolution of the competition and common challenges faced by the robotic explorers. For more information see: URC. MarsSociety.Org

PEX.2-0005-18 SSERVI ACTIVITIES PREPARING FOR ROBOTIC AND HUMAN EXPLORATION OF THE MOON, NEAS AND MOONS OF MARS

Gregory Schmidt, gregory.k.schmidt@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States Brad Bailey, brad.bailey@nasa.gov

Wyle Integrated Science and Engineering Group, Moffett Field, United States Kristina Gibbs, kristina.gibbs@nasa.gov

KBRwyle - Solar System Exploration Research Virtual Institute, Mountain View, California, United States

NASA's Solar System Exploration Research Virtual Institute (SSERVI) has 13 teams that focus on the intersection of science and human exploration of the Solar System. SSERVI encompasses a wide variety of scientific and technical tasks encompassing planetary science, heliophysics, astrophysics, technology development and focused human exploration studies; these tasks range from modeling and analysis of the early Solar System and formation of the Moon to studies of the early universe as enabled by the lunar farside, and from experimental studies of high-velocity impacts to studies of the effect of dust on tissues. Application of these studies to both robotic and human exploration is wide ranging; numerous payload and mission concepts have been developed through SSERVI's studies, and SSERVI Investigators have served and led numerous mission teams. This paper will describe how SSERVI addresses selected interdisciplinary, exploration-related science efforts centered around all airless bodies targeted as potential near-term human destinations, and will focus on SSERVI's activities aimed toward the next generation of robotic and human exploration, first of the Moon and then to objects beyond our nearest neighbor.

PEX.2-0006-18 HIGHLIGHTS OF SCIENCE AND EXPLORATION ACTIVITIES AT THE SSERVI ISET

William Bottke, bottke@boulder.swri.edu

Southwest Research Institute, Boulder, Colorado, United States

The NASA SSERVI team "Institute for the Science of Exploration Targets (ISET)" uses stateof-the art modeling, combined with interpretation of spacecraft data, to reveal what the Moon, Phobos and Deimos, and asteroids tell us about the origin and evolution of the inner Solar System. The ISET team does this over four main themes. Here we describe our progress over the last year. In Theme 1, "Formation of the Inner Solar System and the Asteroid Belt", we used new models of planet formation via pebble accretion to identify substantial problems with long held views of how planets form. We also showed a substantial fraction of asteroids were implanted into the asteroid belt from the outer solar system. In Theme 2, "Origin of the Moon and Phobos/Deimos", we showed that Phobos/Deimos could form from a debris disk produced by a Vesta-to-Ceres sized impactor striking Mars. In these models, the moons would mostly be composed of Martian debris. In Theme 3, "The History of NEAs and Lunar Bombardment", we tested models of late accretion to Earth and found the amount of material delivered may have been 2-5 times greater than previously thought, with implications for the early history of the Moon. We also found evidence that the lunar basins Imbrium and Serenitatis are actually similar in age, countering recent geological interpretations. Finally, we argued that the impact flux on the Earth and moon increased by at least a factor of 2 roughly 250 Myr ago. This result implies the apparent dearth of large terrestrial craters with ages between 250-650 Myr on stable terrains is a byproduct of a lower impact flux, not preservation bias. In Theme 4, "NEAs: Properties, Populations, New Destinations", we examined the evolution of small asteroids via YORP thermal forces that asteroids spin up and down. We found that if bodies reach a small enough size, the spin rates for disruption ensure that the body components will immediately escape, leading to a convergent series of spin-up events that rapidly disaggregate the rubble pile into its core constituents. We also led observations that looked for "minimoons", compelling nearby targets for NASA human and robotic missions.

PEX.2-0007-18 HIGHLIGHTS OF SCIENCE AND EXPLORATION ACTIVITIES AT THE SSERVI PROJECT ESPRESSO NODE

Alex Parker, aparker@boulder.swri.edu

Southwest Research Institute, Boulder, Colorado, United States Project ESPRESSO

Kevin Walsh, Alejandro Soto, Keith Nowicki, Sarah Horst, Silvia Protopapa, Mika McKinnon, Jamie Molaro, Will Grundy, Jennifer Hanley, Marcella Yant, Cristina Thomas, Kevin Lewis, Mark Cintala, Dan Durda, Tom Whitaker, F. Scott Anderson, and Kelsi Singer.

The Project ESPRESSO SSERVI node has been in operation for one year, and has forged ahead in the pursuit of its objectives of enhancing operational safety of future human and robotic exploration; enhancing target selection, sample selection, and ISRU potential; and enhancing target characterization and analysis capabilities. Here we will present the highlights of the first year of science and exploration activities at the Project ESPRESSO node. This includes the ongoing development of the Airborne Space Environment Chamber, a key resource for enabling large-scale experiments in lunarand asteroid-like gravity and pressure environments, commissioning of laboratories for the measurement of optical constants, LIBS spectra, and Raman spectra of materials likely to be present in the regoliths of asteroids and the Moon, calibration and deployment of field LIBS and Raman instrumentation for tests of their roles in future human exploration, and prototyping and tests of new classes of miniature impact probes for recovering regolith mechanical properties. We will conclude with a discussion of our plans for the coming year and opportunities for involvement in Project ESPRESSO efforts and facilities.

FINESSE (Field Investigations to Enable Solar System Science and Exploration) is an interdisciplinary team of scientists, technologists, and mission operations specialists focused on conducting field-based research to understand geologic processes on the Moon, asteroids, and Phobos and Deimos while simultaneously preparing for future human and robotic exploration of these destinations. FINESSE is funded by NASA's SSERVI (Solar System Exploration Research Virtual Institute) and includes team members from government, academia, and industry, including both domestic and international partners. The FINESSE Science Program is devised to improve our understanding of the effects of volcanism and impacts as dominant planetary processes on the Moon, Near Earth Asteroids (NEAs), and Phobos Deimos. The FINESSE Exploration Program is aimed at understanding which exploration concepts of operations (ConOps) and capabilities enable and enhance scientific return. We operate under the philosophy that "science enables exploration and exploration enables science." To that end,

FINESSE conducts science-driven field science investigations which simultaneously work to inform decisions and architectures for optimizing future robotic and human missions in the Solar System. FINESSE-supported fieldwork has been conducted at Craters of the Moon National Monument and Preserve in Idaho, the West Clearwater Lake Impact Structure in northern Canada, the volcanic fields of Hawaii, and newly erupted volcanic landscapes in Iceland. While in the field, new technologies and hand-held field portable instrumentation are tested in situ for both science and exploration. We compliment the fieldwork with laboratory analysis of geologic samples, analysis of remote sensing data, and have conducted laboratory experiments in unique facilities such as the Syracuse Lava Project where basalt is melted into lava and solidifies to form volcanic rock under controlled conditions. Work through FINESSE has resulted in new scientific understandings of impacts and volcanism as well as findings and recommendations regarding exploration ConOps and capabilities to optimize future exploration. FINESSE research showed that a new classification scheme for impact rocks is warranted to reflect the formation processes of impact craters throughout the Solar System. The team also demonstrated the power of impact crater age dating and showed that the East and West Clearwater Impact Structures did not form at the same time and instead are the result of two distinct impact events. Exploration of several impact age dating techniques has led to new recommendations regarding sample collection for planetary geochronology missions to accurately date planetary impact structures. We have also developed multiple new techniques for using remote sensing data (validated through ground truthing) to understand geologic formation histories of volcanic features, which is tremendously useful for lunar studies where in situ analysis is typically not possible and most science is conducted remotely. LiDAR scanning of lava tubes and volcanic features has provided new insights into the geologic formation of these features, as well as the utility of such datasets for planning and executing future missions to the Moon. In tandem, we have collected UAV data at the sub-cm scale to map and characterize rugged terrains otherwise not accessible by foot, thereby increasing our science return as well as demonstrating the use and operations of these platforms for data collection in otherwise inaccessible locations on the Moon. We have also conducted high fidelity mission simulations to assess the use and integration of handheld field portable instrumentation for planetary missions. The incorporation of new technologies into future robotic and human missions requires a detailed understanding of scientific objectives and instrument capabilities coupled with strategic and tactical integration into mission planning. Work through FINESSE has outlined optimized use cases for various instrumentation, required data and communications flows for telemetry, and best practices for optimizing scientific output during human and robotic exploration missions. This talk will focus on the new scientific knowledge collected through the FINESSE project and discuss the associated exploration implications based on the science-driven analog fieldwork.

PEX.2-0009-18 HIGHLIGHTS OF SCIENCE AND EXPLORATION ACTIVITIES AT THE SSERVI RIS4E NODE

Timothy Glotch, timothy.glotch@stonybrook.edu

Stony Brook University, Stony Brook, New York, United States

The Remote, In Situ, and Synchrotron Studies for Science and Exploration (RIS4E) team is one of 13 nodes of NASA's Solar System Exploration Research Virtual Institute. The RIS4E team, led by Stony Brook University, is comprised of over 60 co-investigators, collaborators, postdoctoral researchers, and students. Our work is divided into four separate, but inter-related themes designed to address the science and future human exploration of the Moon, near-Earth asteroids, and the moons of Mars:

Preparation for Exploration: Enabling Quantitative Remote Geochemical Analysis of Airless Bodies. Remote sensing enables human exploration and sample return by providing global chemical and mineral data for the targets of interest and a basis for identifying sites of maximum scientific impact for crewed exploration and sample return. The RIS4E team is conducting laboratory spectroscopic measurements in appropriate environmental conditions and pushing the state of the art in light scattering models to maximize the science return of remotely sensed infrared data.

Maximizing Exploration Opportunities: Development of Field Methods for Human Exploration. Science-motivated field work helps us evaluate the role of handheld and portable field instruments for future human exploration, enabling rapid, low-risk, comprehensive, and quantitative assessments of the local geology and regolith materials. These advances will quickly inform astronauts about where to go and which samples to select, and improve our understanding of how exploration plans based on available remote sensing data are implemented and revised in the field. Our field team has conducted several campaigns at the December 1974 lava flow at the Kilauea volcano on the Big Island of Hawaii and the Potrillo volcanic field in New Mexico to test new technologies and methodologies for crewed exploration of planetary surfaces.

Protecting our Explorers: Understanding How Planetary Surface Environments Impact Human Health. Future astronauts will be exposed to harsh environments with potentially harmful but unknown health effects. The RIS4E team is performing experiments to determine the reactivity and toxicity of lunar and analog materials to determine the potential respiratory health effects of exposure to planetary regoliths and dust.

Maximizing Science from Returned Samples: Advanced Synchrotron and STEM Analysis of Lunar and Primitive Materials. The National Synchrotron Light Source II (NSLS II) at Brookhaven National Laboratory (BNL) is a next-generation light source that provides unparalleled chemical and mineralogical analysis of precious lunar and primitive meteorite materials. Using this facility, as well as the Advanced Photon Source and a state-of-the art scanning transmission electron microscope at the Naval Research Lab, RIS4E team members are probing the oxygen fugacity and carbonaceous content of early Solar System materials and shedding new light on the process of space weathering, which occurs on every airless body in the Solar System.

This presentation will present results and discuss future directions for each of the four RIS4E science themes.

PEX.2-0010-18 HIGHLIGHTS OF SCIENCE AND EXPLORATION ACTIVITIES AT THE SSERVI CSLE NODE

David Kring, kring@lpi.usra.edu

USRA - Lunar and Planetary Institute, Houston, Texas, United States

The scientific objectives of the Center for Lunar Science and Exploration are tied together by collisional and impact cratering processes and the evolution of material, especially volatiles, that are delivered by those processes. We address the earliest phases of accretional collisions using a theoretical pebble accretion model (Kretke et al., submitted) and isotopic signatures of distinct nucleosynthetic reservoirs in the solar nebula (Bermingham and Walker, 2017; Bermingham et al., submitted). Previous analyses of Apollo samples by our team and its SSERVI international partners (e.g., Barnes et al., 2016) suggested water within the Earth-Moon system was delivered by planetesimals with carbonaceous chondrite affinities. New work suggests those carbonaceous, water-bearing materials may have accreted as planetesimals in the outer Solar System beyond Jupiter and then been transported and mixed into the inner Solar System. Interestingly, we found evidence in two meteorites that complex prebiotic chemistry occurred in one of those small, water-rich worlds circa 4.5 Ga during the first few million years of Solar System evolution (Chan et al., 2018). The final stages of collisional accretion that produce larger planets reshaped the nascent Earth and created the Earth-Moon system. In our own Earth's mantle, the concentrations of the volatile elements Bi, Cd, In, and Sn appear to have been set by volatile-depleted precursors and core formation. Analyses of lunar samples suggest, however, that all four of those elements, plus Zn, have mantle concentrations lower than expected and require an additional depletion mechanism such as loss during the giant impact or subsequent magma ocean (Righter et al., 2017a). Volatiles in the lunar interior can be vented at the surface by volcanic processes. Using analyses of Apollo samples, we calculated (Needham and Kring, 2017) the amounts of CO, H2O, H2, OH, and S vented during the eruption of the Moon's mare basalts, which cover more than 17% of the surface. During peak mare emplacement 3.5 Ga, gas was being vented faster than it could escape to space, so the Moon developed a transient atmosphere that persisted for 70 million years. At its peak, the atmosphere had a pressure 1.5 times greater than that at Mars today. The mass of volatiles vented was far greater than the mass of water ice estimated to exist in permanently shadowed regions (PSRs) around the lunar poles, so the mare may be an important indigenous source of those icy deposits.

In a parallel set of exploration studies, we found: (i) In situ robotic measurements of potential ice deposits should have a mass spectrometer for determining whether the ice has an indigenous source or a meteoritic source. Those measurements will help determine the transport and depositional mechanisms for volatiles and, thus, provide a model for estimating resource potential at other lunar locations; (ii) Tele-operation of small pressurized rovers (SPRs) between human landing sites can produce major surveys of permanently shadowed regions (PSRs) for water ice needed for a sustainable exploration program; (iii) Astronaut EVA in a SPR will be more efficient, productive, and easier on crew if it is a relatively low pressure vehicle (e.g., 8 psi) with suitports rather than a relatively high pressure vehicle (i.e., 14.7 psi) with an airlock; (iv) The Deep Space Gateway (DSG) could provide a platform for monitoring the impact flux to the lunar farside and, depending on the DSG orbit, nearside locations not observable from current Earth-based monitoring stations; (v) Human-assisted lunar sample return using tele-robotically driven rovers can address multiple science and exploration objectives and produce 15 to 20 kg of samples per mission; (vi) Data rates >1 Mbps are needed for human and human-assisted robotic ops in the vicinity of the Moon.

PEX.2-0011-18 FOR A NEW ROADMAP TO THE MOON AND MARS

Jacques Blamont, jacques.blamont@cnes.fr Centre National d'Etudes Spatiales, Paris, France

With a very distant objective for planetary exploration being the permanent occupancy of Mars, the use of lava tubes should be taken as a major pathfinder.

Presentation of latest results on lunar and Martian lava tubes.

Reasons for use of lava tubes as settlement sites.

The road map would follow two branches:

Scientific objectives: discovering listing and mapping of all lava tubes on the Moon and Mars, completed by in situ characterization of the most promising - Technology objectives: developing specific machinery needed for access to lava tubes and inflated structures introduced in lava tubes for life support.

The Moon will be considered as the base used for developing equipments and learning how to subsist in such an environment.

Favored options for management of the project: association of Space Agencies, directing a structure similar to the CNES Federation, a marriage of Agencies with participative volunteer groups as fablabs, makers . of all countries, representing a new method for involving forces present in the public. The first example would be the Lunar Robotic Village, detailed explanations of the concept will be presented.

PEX.2-0012-18 SCIENCE AND EXPLORATION HIGHLIGHTS FROM THE NASA-AUSTRALIA SSERVI PARTNERSHIP

Phil Bland, p.a.bland@curtin.edu.au Curtin University, Perth, Australia

Australia has a large and dynamic planetary science community, which includes scientists that have made fundamental contributions to our understanding of the Moon, Mars, and NEOs. In 2015 Australia and NASA came together in a formal partnership within the SSERVI program, pursuing common goals in planetary and exploration science. Since 2015 the partnership has flourished. NASA SSERVI colleagues are now collaborating with the Australian team that built the Desert Fireball Network to expand it, with new international partners, to form a Global Fireball Observatory. The result will be a global planetary facility that should observe >5 meteorite falls per month. Over 40 cameras have already been SENT to partners in the US, UK, Canada, Morocco, and Saudi Arabia. SSERVI Central is a key partner in this collaborative effort, identifying new partners and sites for cameras. Australia has a particularly high profile in geochronology, with contributions indicating a complex lunar impact history, and constraints on the geological evolution of the Moon and Mars (Norman and Nemchin). Technical advances in geochronology are continuing, with the nascent field of nanogeochronology using atom probe (Reddy, Science Advances). A very partial selection of additional recent research highlights includes: using ancient micrometeorites as a probe of the Archaen atmosphere (Tomkins, Nature); GRAIL data constraining the formation of the lunar Orientale basin (Miljkovic, Science); how giant meteorite impacts may have helped to kick-start global tectonics (O'Neill, Nature Geoscience); and how primordial planetesimals (which evolved into the asteroids that now deliver primitive meteorites) may have started life as unconsolidated mudballs (Bland, Science Advances). Regarding planetary exploration, Australia has representation on science teams for a number of current missions, including: OSIRIS-Rex [Phil Bland, Trevor Ireland]; InSight [Katarina Miljjkovic]; Mars Science Laboratory [Penny King]; Akatsuki [Frank Mills], BepiColombo [Phil Bland], ExoMars [Martin Towner], Hayabusa 2 [Trevor Ireland]. Finally, on 25 September 2017, the Australian Government announced its intention to establish an Australian space agency. This announcement was guided by input for the review of Australia's space industry capability. The agency will provide international representation, support to critical partnerships, coordination of a national strategy and activities and support for industry growth. SSERVI Australia is increasing its advocacy role in this new environment, highlighting the recognised, substantive and growing planetary science community, working with policy makers, academic and industry leaders to solidify its future capability. We are involved at every level to ensure that planetary science, space, and exploration science are key components of the future agency.

PEX.2-0013-18 HIGHLIGHTS OF THE GERMANY DLR LUNAR AND PLANETARY RESEARCH

Ralf Jaumann, ralf.jaumann@dlr.de DLR, Berlin, Berlin, Germany Katharina Otto, katharina.otto@dlr.de

German Aerospace Center (DLR), Berlin, Germany

Germany is contributing to solar system and extrasolar research by investigating planets and dwarf planets, their moons, asteroids and comets and their significance for life by comparing the solar system to other planetary systems using the best tools of geosciences and astronomy. Therefore Germany develops instruments, data processing methods and physical models as contribution to international space missions. The activities are conducted within cooperation that are complementary to the ESA Science Program as well as worldwide cooperation with main partners in the USA, France, Sweden, Norway, Italy, United Kingdom, Japan, and Spain. German solar system exploration and research activities are related to the following missions: Mars Express, Lunar Reconnaissance Orbiter, Rosetta, Messenger, Dawn, Hayabusa2/MASCOT, ExoMars, InSight, Mars 2020, Bepicolombo, JUICE, Cheops and Plato. The contribution to SSERVI is the provision of data mainly of cameras with the focus on three-dimensional topographic information as well as geological evaluation. This presentation will give examples for topographic evaluation of the surface of Moon, Mars Vesta and Ceres as well as the upcoming landing on the NEO Ryugu in context with the Hayabusa 2 mission.

PEX.2-0014-18 12U CUBESAT DEPLOYMENT FOR UV EXPLORATION

Ana Gomez De Castro, aig@mat.ucm.es Universidad Complutense de Madrid, Madrid, Spain David Ehrenreich, david.ehrenreich@unige.ch Université de Genève, Versoix, Switzerland

Shingo Kameda, kameda@rikkyo.ac.jp Rikkyo University, Tokyo, Japan Leire Beitia-ANtero, lbeitia@ucm.es

Universidad Complutense de Madrid, Madrid, Spain Juan Carlos Vallejo, juancval@ucm.es

Universidad Complutense de Madrid, Madrid, Spain Mikhail Sachkov, msachkov@inasan.ru

Institute of Astronomy RAS, Moscow, Russia

A 12U cubesat mission in Lunar orbit is proposed to determine the distribution of neutral gas in the Earth exosphere and its response to solar wind and magnetic activity, aiming at producing a large-scale 3D map of the Earth exosphere from outside by monitoring the Earth Lymanemission. Lunar surface observations in the UV range will be also carried out. The mission can be assembled in 2 years time from COTS elements for a very moderate cost.

A key question affecting the human race regards the possible presence of life outside of the Earth. In the last decades, more than three thousand planets have been discovered. UV observations of exoplanet atmospheres during transits allows understanding the physical processes driving the formation and evolution of planet exospheres and magnetospheres, giving access to important properties of the planets and their interaction with the parent star. Detailed calculations have been carried out to evaluate the instrumentation needed to detect bio-tracers in Earth-like planets by the transit method. Observations of the Earth as an exoplanet will obviously help in this area. This project aims at determining the distribution of neutral gas in the Earth exosphere and its response to the solar wind/activity. Solar Lyman- (Ly) photons are scattered by the Hydrogen (HI) atoms in the exosphere producing a Ly halo around the Earth that extends further than 38 Earth radii. The goal is producing the first 3D map of the Earth exosphere from outside by monitoring the Earth Ly emission. The variation of the line source function across the exosphere will be obtained allowing the detailed evaluation of the Ly flux. The spatial distribution of neutral Oxygen and Helium will also be measured. From the vantage point of a Lunar polar orbit, a cubesat with UV instrumentation on board may map the exosphere from outside measuring simultaneously the exospheric emission and the variable background obtaining the most accurate measurements of the Hydrogen distribution at large Earth radii because will allow to separate the contributions from solar radiation and other processes like excitation by high energy particles from the Sun or internal magnetospheric sources.

During is duty cycle, the satellite will also survey systematically the heliosphere in Ly, investigating the distribution of diffuse matter within the heliosphere: NEOs, cometary tails, planetary exospheres and dusty clouds. Moreover, the monitoring of the water content and the space weather in the Moon poles would be feasible.

PEX.2-0015-18 THE ISS AS A PLATFORM FOR A FULLY SIMULATED MARS VOYAGE

Guenther Reitz, guenther.reitz@dlr.de

German Aerospace Center (DLR), Koeln, Germany Livio Narici, narici@roma2.infn.it

INFN and University of Rome Tor Vergata, Rome, Italy

The ISS is the most valuable "analogue" for deep space exploration, since it can mimic the impact of microgravity, radiation, living and psychological conditions that astronauts will face during a deep space cruise, for example to Mars.

It is therefore conceivable to use the ISS as test bed for final integrated space tests for many of the individual scientific/technological solutions needed to allow for deep space voyages. These tests would optimize synergies in such operations. As individual issues are solved these can provide more and more "complete" tests, where a larger number of solutions are integrated in a single flight simulation.

At the end this will lead to a real 'dry-run' of a deep space mission (such as a mission to Mars), as close as reasonably possible to what will be the real voyage. This Mars ISS dry run could last several hundred days, mimicking most of the challenges which will be undertaken such as length, isolation, food provision, decision making, time delays, health monitoring diagnostic and therapeutic actions and more: not a collection of "single experiments", but a complete exploration simulation were all the pieces will come together for the first in space simulated Mars voyage. These results would provide essential information to best design more advanced tests on the planned Deep Space Habitat in cis-Lunar space.

At the time of the Mars ISS dry run all the science and technological challenges will have to be mostly solved by dedicated works. These solutions will be synergistically deployed in the dry run which will simulate all the different aspects of the voyage, the trip to Mars, the permanence on the planet and the return to Earth. During the dry run i) There will be no arrivals/departure of spacecrafts; 2) Proper communications delay with ground will be simulated; 3) Decision processes will migrate from Ground to ISS; 4) Permanence on Mars will be simulated. Mars ISS dry run will use just a portion of the ISS which will be totally isolated from the rest of the ISS, leaving to the other ISS portions the task to provide the needed operational support for the ISS survival as well as the support for emergency situations.

This talk will present some important issues still open to be addressed (see for example the disciplinary reports of the THESEUS project), some example of the challenging tests that could be performed, some of the operational challenges, as well as list some of the issues not likely/possible to be simulated.

PEX.2-0016-18 RADIATION EFFECTS ON VOLATILES AND THE EXPLORATION OF ASTEROIDS AND LUNAR SURFACES

Thomas Orlando, thomas.orlando@chemistry.gatech.edu

Georgia Institute of Technology, Atlanta, Georgia, United States
Brant Jones, brant.jones@chemistry.gatech.edu

Georgia Institute of Technology, Atlanta, Georgia, United States
Carol Paty, carol.paty@eas.gatech.edu

Georgia Institute of Technology, Atlanta, Georgia, United States
Stephen Robinson, stephen.k.robinson@ucdavis.edu

University of California, Davis, Davis, California, United States
Esther Beltran, esther.beltran@ucf.edu

University of Central Florida, Orlando, Florida, United States

Recent space exploration missions to a number of Solar System objects, including the Moon, Mars, Mercury, and near Earth asteroids (NEAs), have revealed a wide variety of physical conditions which give rise to a diverse assortment of environments and risks. Since many of these objects are currently under consideration by NASA as strategic destinations for future human exploration missions, a more complete description of their respective environmental conditions is desirable in order to mitigate human risk factors and determine the availability of in situ resources. Without an appreciable atmosphere, each of these potential destinations is constantly being bombarded by radiation from the solar wind, galactic cosmic rays and hypervelocity micrometeorite impacts from local (circum-planetary) or interplanetary sources. Ionizing radiation and micrometeorite impactors can deposit, transport, alter, and even produce volatiles such as water and methane in the surface materials of such bodies [1]. When one considers the possibility of human exploration of these airless bodies, ionizing radiation is known to produce DNA damage that is likely linked to cancer susceptibility, neurodegenerative disorders, developmental abnormalities, inflammatory responses, and accelerated/premature aging [2-4]. Thus, the constant radiation assault also possesses obvious, life-threatening, and program-limiting health risks for humans that must be understood, quantified, and mitigated. The Radiation Effects on Volatiles and Exploration of Asteroids and Lunar Surfaces (REVEALS) team will explore the fundamental, applied, and operational aspects correlated with radiation processing of natural regolith and man-made composite materials. The emphasis focuses upon: i) Understanding the fundamental condensed-matter physics and radiation chemistry leading to volatile formation, sequestration and emission from the Moon, Martian moons (Phobos and Deimos) and NEAs and ii) Developing and testing novel composite materials (including regolith) using 3-D printing and real-time radiation detectors based on 2-D materials. These efforts could lead to useful in situ resource utilization strategies and development of portable shielding materials, real-time radiation detection systems as well as radiation-hardened human habitats and spacesuits. Collectively, the team will help minimize risks and exposure during human exploration missions.

PEX.2-0017-18 RATIONALE AND CONCEPTS FOR ROBOTIC AND HUMAN OUTPOSTS ON PHOBOS

Olivier Witasse, owitasse@cosmos.esa.int European Space Agency, Noordwijk, Netherlands Bernard H. Foing, bernard.foing@esa.int ESA/ESTEC, Noordwijk, Netherlands

Elliot Sefton-Nash, elliot.sefton-nash@esa.int European Space Agency, Noordwijk, Netherlands

A concept of a permanent station on the martian moons is under study. Such mission can serve several purposes: (a) positioning system, (b) data relay stations for Mars surface assets or for interplanetary missions, (c) monitoring of the Mars environment, (d) scientific investigations of Mars and its moons, and (e) investigation for in-situ resources exploitation and precursory human or robotic based station. It can serve also as a Martian moon and Mars webcam. We show here a preliminary mission concept, with some applications in the study of the Mars environment

PEX.2-0018-18 SPACE RADIATION AND HUMAN EXPLORATION ON THE MOON, MARS AND NEOS - DOSIMETRY, MODELS AND CHALLENGES

Thomas Berger, thomas.berger@dlr.de

German Aerospace Center (DLR), Cologne, Germany Yukio Uchihori, uchihori@nirs.go.jp

National Institute of Radiological Sciences, Chiba, Japan Daniel Matthiä, daniel.matthiae@dlr.de

DLR - Inst. of Aerospace Medicine, Köln, Germany Christine Hellweg, christine.hellweg@dlr.de

DLR - Inst. of Aerospace Medicine, Koeln, Germany

Space programs are shifting towards planetary exploration and, in particular, towards missions by human beings to the Moon and to Mars. Radiation is considered to be one of the major hazards for human long-term missions beyond Low Earth Orbit (LEO). During transit to these far away destinations and during relevant extravehicular activities (EVA) on their surface, complete shielding of the highly energetic particles is impracticable. The two sources of radiation that can impact a mission outside the Earth's magnetic field are Solar Energetic Particles (SEP) and Galactic Cosmic Rays (GCR). The main goal for exploration missions is therefore the quantification and reduction of space radiation health hazards, with the goal of maximizing the number of days that may be spent in space. The research to be carried out has to support all phases of exploration including mission planning, component design, operation and post-flight studies. Having this in mind this calls for novel and improved radiation detector assemblies as well as extended calibrations, detector intercomparisons and analysis algorithms. New measurements are a prerequisite for reliable risk assessment, a crucial input for radiation source modelling, and are also needed for real-time calibration of the detectors thereby allowing for a detailed understanding of the radiation environment the astronauts are going to live in. For exploration missions, radiation risk assessment will predominately rely on simulation models. The reliability of these models needs to be optimized through a series of tests against a wide set of measurements at sites/conditions where instruments are available or can be made available. More and more radiation details are needed to correctly assess radiation risks, and this requires detailed model outputs to be tested against proper measurements. In the last years various radiation detector systems have been send either to the Moon (circulating in Moon orbit) or are already on the surface of Mars, providing thereby a tremendously needed data set for model validation and benchmarking and input data to face the challenges ahead of us.

PEX.2-0019-18 REVIEW OF SPACE RADIATION HEALTH RISKS FOR HUMAN EXPLORATION ON THE MOON, MARS AND NEOS

Francis Cucinotta, francis.cucinotta@unlv.edu

University of Nevada Las Vegas, Las Vegas, Nevada, United States Andrea Ottolenghi, andrea.ottolenghi@unipv.it

University of Pavia, Pavia, Italy

Galactic cosmic ray (GCR) and solar particle event (SPE) exposures present significant health risks for long-term space travel outside the protection of the Earth's geomagnetic field. Large uncertainties occur in projecting the risks of high linear energy transfer (LET) radiation, most notably GCR heavy ions and secondary neutrons, because no human epidemiology data for these types of radiation exists. The major health risks are fatal cancer risks and possible change to cognition and memory during a mission. Other more manageable concerns are acute radiation sickness from large SPE's and late effects such as cataracts, circulatory diseases and poorly defined central nervous effects. In this review we highlight current risk estimates for the various health risks relative to the various space agency standards. There is a great interest in mitigation approaches to space radiation risks such as shielding and biological countermeasures. The merits of radiation shielding are dependent on the model used to project risks, while biological countermeasures testing would only occur in experimental models leaving the projection to humans highly uncertain. Thus because of the need to accurately project risks in individual astronaut's, improvements in our ability to project risks from high LET radiation using data from experimental models remains the largest challenge for enabling long-term missions to the moon, Mars and near-Earth-objects (NEOS) within acceptable safety standards.

PEX.2-0020-18 TOWARDS SPACE EXPLORATION OF MOON, MARS & NEOS: RADIATION BIOLOGICAL BASIS

Christine Hellweg, christine.hellweg@dlr.de

DLR - Inst. of Aerospace Medicine, Koeln, Germany Thomas Berger, thomas.berger@dlr.de

German Aerospace Center (DLR), Cologne, Germany Christa Baumstark-Khan, christa.baumstark-khan@dlr.de DLR - Inst. of Aerospace Medicine, Koeln, Germany

Radiation has emerged as the most critical issue to be resolved for long-term missions both or- bital and interplanetary. Astronauts are constantly exposed to galactic cosmic radiation (GCR) of various energies at a low dose rate. Primarily late tissue sequels like genetic alterations, cancer and non-cancer effects, i.e. cataracts and degenerative diseases of e.g. the central nervous system or the cardiovascular system, are the potential risks. Cataracts were observed to occur earlier and more often in astronauts exposed to higher proportions of galactic ions (Cucinotta et al., 2001). Predictions of cancer risk and acceptable radiation exposure in space are subject to many uncertainties including the relative biological effectiveness (RBE) of space radiation especially heavy ions, dose-rate effects and possible interaction with microgravity and other spaceflight environmental factors. The initial cellular response to radiation exposure paves the way to late sequelae and starts with damage to the DNA which complexity depends on the linear energy transfer (LET) of the radiation. Repair of such complex DNA damage is more challenging and requires more time than the repair of simple DNA double strand breaks (DSB) which can be visualized by immunofluorescence staining of the phosphorylated histone 2AX (γH2AX) and might explain the observed prolonged cell cycle arrests induced by high-LET in comparison to low-LET irradiation. Unrepaired or mis-repaired DNA DSB are proposed to be responsible for cell death, mutations, chromosomal aberrations and oncogenic cell transforma- tion. Cell killing and mutation induction are most efficient in an LET range of 90-200 keV/µm. Also the activation of transcription factors such as Nuclear Factor κB (NF-κB) and gene expression shaping the cellular radiation response depend on the LET with a peak RBE between 90 and 300 keV/µm. Such LET-RBE relationships were observed for cataract and cancer induction by heavy ions in laboratory animals, with varying maximal efficiencies. Furthermore, there is always the added risk of acute exposure to high proton fluxes during a solar particle event (SPE), which can threaten immediate survival of the astronauts in case of insufficient shielding by eliciting the acute radiation syndrome. Its symptoms depend on absorbed total radiation dose, type of radiation, the dose distribution in the body and the individual radiation sensitivity. After the prodromal stage with nausea and vomiting and a subsequent symptom-free phase, depending on dose, the hematopoietic syndrome with suppression of the acquired immune system and thrombocytopenia (0.7-4 Sv), the gastrointestinal tract syndrome (5-12 Sv) or the central nervous system syndrome (> 20 Sv) develop and they are accompanied by exacerbated innate immune responses. Exposure to large SPE

has to be avoided by warning systems and stay inside a radiation shelter during the event. Treatment options encompass e.g. the administration of colony-stimulating factors (CSF), growth factors and blood transfusions to overcome the hematopoietic syndrome and the administration of antibiotics against secondary infections. A concerted action of ground-based studies and space experiments is required to improve the radiobiological basis of space radiation risk assessment and countermeasure development.

PEX.2-0021-18 MELISSA AND RUSSIAN INSTITUTES, 20 YEARS OF A DISCRETE BUT PUBLISHED COLLABORATION

Christophe Lasseur, christophe.lasseur@esa.int ESA, AG Noordwijk, Netherlands

Vyacheslav Ilyin, piton2004@bk.ru Russian Acad. of Sci, IMBP, Russia

Future manned missions to Moon or Mars, private or public, will be an international adventure. One of the challenges is the development of a robust closed life support system to sustain this international crew or potentially community. It is therefore crucial that system and sub-systems are developed in a collaborative mind more that with a prime to subs-contractors approach, where pieces are developed from different part of the world and only assembled at the end. This collaborative approach as the advantage to create motivation of all actors, more commitments and to technically reduced the risk with a better understanding of the distributed sub-systems. Over the 30 years of MELiSSA project, almost 20 years of them have seen collaborations with Russian institutes: - IBP Krasnoyarsk and - IBMP, Moscow. Initiated around 2000, in a difficult historical context and almost total ignorance of respective activities and culture, this collaboration has brought several successes, now published in international journals. More than a political declaration, this collaboration was more a human desire to discover, listen to existing experience and to collaborate for a common objective: the development of closed life support system. Started much before any European activity in Life Support, Russian research has accumulated a lot of experience either from Isolation manned facilities, flight hardware development and operation. At the contrary, started from almost non-European experience, the MELiSSA project benefitted of a virgin field. This collaboration mainly covered the 3 axes of MELiSSA project: - Basic D, - Flight Experiment and Isolation campaign via ground analogs (i.e. BIOS and MELiSSA Pilot Plant). The objectives of this presentation is of course to present the collaboration activities: Soil Like Substrat, Mobilisatie, Message, Nitrimel, BIOS upgrade, Higher plant activities, microbial contamination,. and the obtained results as well as to remind the historical context of this collaboration: - the general constraints, the difference and interest of the cultural and sociological approach. As a conclusion, this paper will summarize the main obstacles, which have been faced and overcome as well as the reasons why this collaboration continue.

PEX.2-0022-18 PREPARING HUMAN EXPLORATION ON MOON AND MARS: FROM SIMULATIONS TOWARDS A FUNCTIONAL BASE

Christiane Heinicke, christiane.heinicke@zarm.uni-bremen.de
ZARM, University of Bremen, Bremen, Germany

Human space flight to planetary bodies has gained new momentum over the past few years: Space agencies like ESA and NASA hope to reach the Moon within 20 years. Private companies occasionally announce more ambitious goals and timelines. Nevertheless, important technologies still have to be developed and improved before humans can face the risks and difficulties of interplanetary travel.

Meanwhile, a number of analog habitats have been built in the recent past, including habitats such as HI-SEAS or LUNARES. These habitats are built primarily for human factor studies. For example, HI-SEAS is looking into the psychology of groups in long-term isolation and confinement, among other things. Lunares takes are more physiological approach. Other habitat analogs have a more technical focus, such as the Habitat Demonstration Unit or the Inflatable Lunar/Mars Habitat (ILMH) located at the University of North Dakota. Nevertheless, all such habitats are built for the primary purpose of providing a location to conduct simulations.

With recent, impressive advances in rocket technology, it is time to advance technology for when astronauts not only lift off of Earth, but actually reach the surface of the Moon. Project MaMBA (short for Moon and Mars Base Analog) aims to apply the lessons learned from previous simulations that have been conducted at various analog bases, and combine them with the necessary technology to create a functional base that is not any more limited to terrestrial use.

Specifically, we draw lessons from (1) the longest simulation of a surface stay on Mars, conducted at HI-SEAS, (2) the first simulation with a physically disabled astronaut (ICAres-1), conducted at LUNARES, and (3) a number of two-week simulations at MDRS. All three types of simulations give insight into both errors that have been made in the respective habitat design, and features that have been received well by the respective crews.

As a result, MaMBA will consist of separate, connected modules which can be shut off independently from each other, and will adress the possibility of astronauts being (temporarily) incapacitated. Modules will be divided into work and leisure modules, and at least one of the modules will have a high ceiling to provide a 'feel' of spaciousness. The central piece of the habitat will be the laboratory module which is currently in the middle of its design phase;

construction of the first iteration of the laboratory module will commence at the end of this year. Scientists are playing an integral part in the design process for the laboratory. Moreover, as MaMBA aims to be a functioning habitat prototype, at its final stage it will have closed loops for water and air and a self-sufficient power supply. Functionality of the habitat will be verified during short and medium-duration simulations with analog astronauts starting next year.

PEX.2-0023-18 MOON DIRECT

Robert Zubrin, zubrin@aol.com

Mars Society, and Pioneer Astronautics, Lakewood, Colorado, United States Bernard H. Foing, bernard.foing@esa.int

ESA/ESTEC, Noordwijk, Netherlands

The recent amazing success of the Falcon Heavy launch offers America an unprecedented opportunity to break the stagnation that has afflicted its human spaceflight program for decades. In short, the Moon is now within reach.

Here's how the mission plan could work. The Falcon Heavy can lift 60 tons to Low Earth Orbit (LEO). Starting from that point, a hydrogen/oxygen rocket-propelled cargo lander could deliver 12 tons of payload to the lunar surface.

We therefore proceed by sending two such landers to our planned base location. The best place for it would be at one of the poles, because there are spots at both of the Moon's poles where sunlight is accessible all the time, as well as permanently shadowed craters nearby where water ice has accumulated. Such ice could be electrolyzed to make hydrogen-oxygen rocket propellant, to fuel both Earth-return vehicles as well as flying rocket vehicles that would provide the base's crew with exploratory access to most of the rest of the Moon.

The first cargo lander carries a load of equipment, including a solar panel array, high data rate communication geart, a microwave power beaming set up with a range of 100 km, an electrolysis/refrigeration unit, two crew vehicles, a trailer, and a group of teleoperated robotic rovers. After landing, some of the rovers are used to set up the solar array and communication system, while others are used to scout out the landing area in detail, putting down radio beacons on the precise target locations for the landings to follow.

The second cargo lander brings out a 12-ton habitation module, loaded with food, spare spacesuits, scientific equipment, tools, and other supplies. This will serve as the astronauts' house, laboratory, and workshop of the Moon. Once it has landed, the rovers hook it up to the power supply and all systems are checked out. This done, the rovers are redeployed to do detailed photographing of the base area and its surroundings. All this data is sent back to Earth, to aid mission planners and the science and engineering support teams, and ultimately forming the basis of a virtual reality program that will allow millions of members of the public to participate in the missions as well.

The base now being operational it is time to send the first crew. A Falcon Heavy is used to deliver another cargo lander to orbit, whose payload consists of a fully-fueled Lunar Excursion Vehicle (LEV). This craft consists of a 2-ton cabin like that used by the Apollo era Lunar Excursion Module mounted on a 1-ton hydrogen/oxygen propulsion system filled with 9 tons of propellant, capable of delivering it from the lunar surface to Earth orbit. A man-rated Falcon 9 rocket then lifts the crew in a Dragon capsule to LEO where they transfer to the LEV. Then the cargo lander takes the LEV, with the crew aboard, to the Moon, while the Dragon remains behind in LEO.

After landing at the Moon base, the crew completes any necessary set up operations and begins exploration. A key goal will be to travel to a permanently-shadowed crater and making use of power beamed to them from the base, use telerobots to mine water ice. Hauling this treasure back to the base in their trailer, the astronauts will feed the water into the electrolysis/refrigeration unit, which will transform it into liquid hydrogen and oxygen. These products will then be stored in the empty tanks of the cargo landers for future useprimarily as rocket propellant but also as a power supply for fuel cells and a copious source of life support consumables.

Having spent a couple of months initiating such operations and engaging in additional forms of resource prospecting and scientific exploration, the astronauts will enter the LEV, take off and return to Earth orbit. There they will be met by a Dragon - either the one that took them to orbit in the first place or another that has just been launched to lift the crew following them - which will serve as their reentry capsule for the final leg of the journey back home.

Thus, each mission that follows will require just one \$100 million Falcon Heavy and one \$60 million Falcon 9 to accomplish. Once the base is well-established, there will be little reason not to extend surface stays to 6 months. So assuming that the program hardware purchases will roughly equal its launch costs, we should be able to create and sustain a permanently occupied lunar base at an ongoing yearly cost of less than \$700 million. This is less than 4 percent of NASAs current budget – or about a quarter of what is being spent yearly on the agency ts now obsolete Space Launch System program which has been going on for over a decade without producing anything.

The astronauts will not be limited to exploring the local region around the base. Refueled with hydrogen and oxygen, the same LEV spacecraft used to travel to the Moon and back can be used to fly from the base to anywhere else on the Moon, land, provide onsite housing for an exploration sortie crew, and then return them to the base. We won't just be getting a local outpost: we'll be getting complete global access to an entire world.

Currently NASA has no such plan. Instead it is proposing the build a lunar orbiting space station dubbed the Deep Space Gateway. This boondoggle will cost several tens of billions of dollars, at the least, and serve no useful purpose whatsoever - except perhaps to provide a launch manifest for the Space Launch System. We do not need a lunar-orbiting station to go to the Moon. We do not need such a station to go to Mars. We do not need it to go to near-Earth asteroids. We do not need it to go anywhere. If we do waste our time and money building it, we won't go anywhere.

If you want to get to the Moon, you need to go to the Moon. We now have it in our power to do so. Let's seize the time.

PEX.2-0024-18 INFLUENCE OF SPACEFLIGHT ENVIRONMENT ON BIOLOGICAL SYSTEMS FOR THE MOON, MARS AND NEOS

Alexey Kondyurin, kond@mailcity.com University of Sydney, Sydney, Australia Galina S. Nechitailo, spacemal@mail.ru

Inst. of Biochemical Physics RAS, Moscow, Russia

Human exploitation of space is a great achievement of our civilization. After the first space flights and visit the Moon a development of artificial biological environment in space systems is a second great step. First biological experiments on a board of Salyut and Mir space stations were successfully performed in 70-90th of last century. The results are: first long time cultivation of plants in space (wheat, linen, lettuce, crepis); first flowers in space (Arabidopsis); first harvesting of seeds in space (Arabidopsis); first harvesting of roots (radish); first full life cycle from seeds to seeds in space (wheat); first tissue culture experiments (Panax ginseng L, Crocus sativus L, Stevia rebaundiana B); first tree growing in space for 2 years (Limonia acidissima). The success of these missions was estimated in Guinness records. These studies are continuing in the recent experiments on a board of Shenzhou Chinese space ships with plants and tissue culture. It was found that the space environment influences on the biological systems, but the space harvest is possible. The results of the space flight experiments are discussed in the light of future space flights and long term missions on the Moon, Mars and NEOS.

PEX.2-0025-18 HELIOPHYSICS SCIENCE ENABLED BY LUNAR ORBITING PLATFORMS

James Spann, jim.spann@nasa.gov

NASA/GSFC Heliophysics Science Division, Greenbelt, Maryland, United States Pamela Clark, pamela.e.clark@jpl.nasa.gov

JPL, Pasadena, California, United States

The current emphasis on returning to the Moon with a lunar orbiting platform provides an impetus and opportunity to explore newly enabled investigations that are relevant to heliophysics and to understand the coupling of the sun and its atmosphere to the magnetized space environment surrounding the Earth. To that end, a workshop focused on the science that the NASA Deep Space Gateway (DSG) platform enables was held with focused topics including heliophysics, space weather/radiation, Earth science, astrophysics, lunar and planetary, crosscutting technologies, telerobotics, human exploration support, and sample collection/return. Following this, a session at the Triennial Earth-Sun Summit (TESS) focused on the heliophysics science enabled by the DSG was convened. This talk will summarize the major heliophysics themes of those two meetings and provide context for science strategies that take advantage of lunar orbiting platforms, and for technologies required to realize the full benefit of the synergy of human and robotic exploration in the vicinity of the Moon.

PEX.2-0026-18 VARIANTS OF ROBOTIC/ HUMAN COMBINATION OF RUSSIAN LUNAR EXPLORATION PROJECTS

Anatoli Petrukovich, apetruko@iki.rssi.ru

Space Research Institute (IKI), Russian Academy of Sciences, Moscow, Russia George Karabadzak, gfk@tsniimash.ru

Russia

Lev Zelenyi, lzelenyi@iki.rssi.ru

Space Research Institute of RAS, Moscow, Russia Konstantin Raykunov, raykunovkg@tsniimash.ru TSNIImash, Korolev, Russia

Maria Danilova, danilovami@tsniimash.ru TSNIImash, Korolev, Russia

Current plans of Russian participation in international projects of Moon exploration are considered. Special attention is given to the Deep Space Gateway (DSG) project where a cis-lunar platform is planned by the ISS partners. We discuss a balance of robotic and manned operations at DSG station, in particular targeted at scientific tasks. Another focus of the paper is current Russian program of robotic spacecraft as a precursor for human exploration programs. The role of crew in joint human-robotic Moon missions is specified.

PEX.2-0028-18 LUNAR VICINITY, MOON, NEO AND MARS SCIENCE ENABLED BY THE GLOBAL EXPLORATION ROADMAP: THE ISECG SCIENCE WHITE PAPER

Jean-Claude Worms, jcworms@esf.org

European Science Foundation, Strasbourg, France David B. Bussey, david.b.bussey@nasa.gov

NASA HQ, Washington, District of Columbia, United States Juergen Schlutz, juergen.schlutz@dlr.de

CNES, PARIS, France

ISECG Science Advisory Group

Gilles Clement, Ian Crawford, Mike Cruise, Masaki Fujimoto, Dave Hart, Ralf Jaumann, Tim McCoy, Clive Neal, Gordon Osinski, Maria Cristina de Sanctis, Masaki Shirakawa

The 15 space agencies of the International Space Exploration Coordination Group (ISECG) are discussing an internationally coordinated approach for human and robotic space exploration, as documented in ISECG's Global Exploration Roadmap (GER), i.e. a coordinated international effort to prepare for collaborative space exploration missions beginning with the Low Earth Orbit (LEO) and continuing to the lunar vicinity, the Moon, asteroids and, eventually, Mars.

ISECG engaged the scientific community in a coordinated discussion to improve the understanding of the scientific opportunities, drivers and requirements of priority science questions that can be addressed by near-term human exploration missions to Solar System destinations as laid out in the GER. These span a deep space gateway in the lunar vicinity, the lunar surface, or a mission to asteroids. An independent Science Advisory Group (SAG) composed of scientists from a variety of nations and diverse science disciplines was set up by ISECG in 2015, with the goal of elaborating a Science White Paper (SWP) identifying the scientific opportunities in near-term exploration missions beyond LEO, the overarching science themes and their relevance to the GER mission scenarios.

Several consultation milestones were organized by the SAG, including a dedicated COSPARISECG-ESF workshop in Paris on February 2016, and making use of international events, to gather input on the SWP and incorporate feedback from the community on early versions of the white paper. These events generated input from a broad range of scientific disciplines including planetary and space sciences, astrobiology, life sciences, physical sciences, astronomy and Earth science.

The Science White Paper was published in December 2017 and is structured around the science themes "Understanding Our Place in the Universe" and "Living and Working in Space". It focusses on opportunities created by near-term mission themes in the GER, i.e. extended duration crew missions to an exploration gateway in the lunar vicinity; crewed missions to an asteroid; and crewed missions to the lunar surface.

We will present the contents of the Science White Paper, with particular emphasis on the various science opportunities enabled by the GER.

PEX.2-0029-18 LUNAR SCIENCE WITH HERACLES

Victoria Hipkin, victoria.hipkin@canada.ca Canadian Space Agency, St Hubert, Canada Junichi Haruyama, haruyama.junichi@jaxa.jp

Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, Sagamihara, Japan

Japan Aerospace Exploration Agency, Sagamhara, Japan James Carpenter, james.carpenter@esa.int

European Space Agency (HE Space Operations), Noordwijk, Netherlands Markus Landgraf, markus.landgraf@esa.int

ESA/ESTEC, Noordwijk, Netherlands

This paper provides a status of the development of the HERACLES lunar sample return mission concept.

ESA, JAXA and CSA are exploring common interests in human lunar exploration, which is one of the four cornerstones of the European Exploration Envelope Programme. It is currently a shared under-standing that the most affordable approach to the development of a human lunar exploration architecture is the flight-demonstration of key components of lunar vehicles (lander, rover and ascent vehicle) through a sub-scale demonstration mission launching in the mid-2020's timeframe. Initiated by ESA as the Human-Enabled Robotic Architecture and Capability for Lunar Exploration and Science (HERACLES), advanced studies for this mission concept are being undertaken in 2018 and 2019 in a collaborative framework with ESA in the coordination role and undertaking study of the ascent module, JAXA undertaking study of the lander, and CSA, study of the rover element.

Scientific knowledge gain is recognised by the HERACLES partner agencies as a signficiant socio-economic benefit that can be enabled by a human lunar exploration architecture. While the primary objective of HERACLES is to demonstrate key pre-cursor technologies, its initial surface operations sce-nario builds on the international science community motivation for lunar sample return [1][2] and in-volves landing at a site of high scientific interest and return of lunar samples of high scientific value be-fore conducting a long distance traverse that pro-vides further opportunities for science and exploration. Science planning for the HERACLES mission is co-led, with a multi-agency HERACLES Science Working Group responsible for developing a mission science management plan to describe science team and science payload selection processes, and data and sample policies.

The HERACLES Design Reference Mission: In the initial phase of mission planning, a HERACLES study team developed a nominal sce-nario with Schrödinger basin as the reference landing site, with a 70 day surface sample return mission, followed by a 1 year traverse encompassing one or more additional potential human exploration land-ing sites in the south pole region. The reference for returned smaple mass is 25kg, including container. A common reference set of mission science objectives was further developed by a Science Working Group in 2017, based on previous studies and agencies' consultations, and responding to the themes of the ISECG Science White Paper [3]. Cold-trapped volatiles are not included, as though these are a high scientific priority and of interest for In Situ Resource Utilisation, it was determined that a cryo-genic sample return was beyond the scope of this demonstration mission (though feasible in the architecture design). The reference science objectives have been used, with the help of a Canadian science study team, to provide a strawman science payload (imaging, elemental composition, mineralo-gy, sub-surface structure, radiation sensors, possible deployment of a small payload (<1kg) to the surface)) to assess the feasibility of payload accommodation within the current HERACLES rover concept. The capability to acquire fresh rock samples has been included in the reference, but at this time a drill capability has not.

Prioritisation of Science Investigations and Landing Site Selection: Further work is required to refine the HERACLES science scenario. The com-munity is invited to engage in the next step of trans-forming the reference scenario into prioritised inves-tigations (in-situ instrumentation and analysis of returned samples) and provide input to landing site selection. The HERACLES partner agencies are preparing a process by which the respective science communi-ties can engage and prepare their contributions. The next step is the creation of an international HERACLES Science Definition Team (HSDT) who will be tasked to generate a prioritised list of investi-gations, and make recommendations with regard to landing site selection. Sites other than Schrödinger may be considered, subject to engineering con-straints and additional exploration objectives. The HSDT report will then be used in the preparation of opportunities for science team membership and sci-ence instrument proposals, should the mission be approved for launch. Observer status in the HERACLES project is provided for agencies with common interests, with associated representation planned on the HSDT.

PEX.2-0030-18 SPACE AGRICULTURE FOR MANNED EXPLORATION OF ASTROBIOLOGY ON MARS

Naomi Katayama, naomik@nagoya-wu.ac.jp Nagoya Women's University, Nagoya, Japan Masamichi Yamashita, yamashita ISAS/JAXA, Kanagawa, Japan

Apace agriculture is a concept of bio-regenerative life support for manned exploration of space. Mars is the best target of astrobiology missions in this century. Major focus on Mars is finding either extant or extinct life and bio-related materials. We can study on characteristic of extraterrestrial life and universal principle of biology. Any missions to Mars should be cautiously planned and conducted to avoid contamination made by any terrestrial life forms and organic materials until science community would chew it up to conclude life history on Mars. Even space agriculture is planned for the mature phase of manned mission with large (more than 20) crew size and longer (more than 10 years) operation of their outpost base, it should meet the requirements from astrobiology. Microorganisms are confined within pressurized dome. Site of settlement is physically isolated from exploration site by appropriate distance. Risk of bio-contamination would be assessed during precursor unmanned missions. Another important subject during preparatory phase is the survey of on-site resource availability for space agriculture, which aims more than 100% recycling of materials by the use of water, atmosphere and other bio-elements on Mars. The highest priority of the manned space mission is survivability of crew. Better economy of recycling materials and psychological support for crew by raising pet plants and animals are merit of space agriculture, but they are never on the first line. In order to confirm solid performance of space agriculture, it operates for providing storage for the next crew turn. Interdisciplinary discussion is quite demanding for planning phased scenario of missions to Mars, and developing space agriculture step by step.

PEX.2-0031-18 SYNERGIES AND INTERACTION BETWEEN SPACE-ARCHITECTURE, ANALOGUE HABITATS & SUSTAINABILITY

Germaine Van Der Sanden, germaine.sanden@gmail.com ESA, Noordwijk, Netherlands

Bernard H. Foing, bernard.foing@esa.int ESA/ESTEC, Noordwijk, Netherlands

Louis Dubois, louis.dubois@student.isae-supaero.fr

European Space Research and Technology Centre, European Space Agency, Noordwijk, Netherlands

According to ESA's Director General Johann-Dietrich Wörner, a habitable station on the Lunar surface is the next step in reaching more distant destinations in deep space. Planetary habitats have also been proposed for Mars, asteroids or even the martian satellite, Phobos. The core idea of a planetary habitats deals with people working and living together at the same place. Simultaneously, it's a metaphor for international collaboration, a global community, which brings multiple actors together in our endeavors for future space exploration. The main research question is whether it is possible to form a new three spherical model that aims to identify the three interacting components, which constitutes positive human integration in a planetary world.

This research investigates the synergies and intersection between the following three pillars:

I) Space architecture, II) Analogue habitat experimentation on Earth and III) Sustainability.

I) Space Architecture is a critical component in the development of the lunar habitat. The interdisciplinary field of Space Architecture draws from a variety of fields such as engineering, architecture, design, human factor design, space sciences, medicine, psychology and the arts. Therefore, it is simultaneously technical, humanistic, scientific and artistic. II) Analogue habitats are an important extension of the field of Space Architecture, despite taking microgravity out of the equation. These missions are designed in extreme environments on Earth, in order to simulate the physical similarities of a space environment. III) The creation of a sustainable and livable habitat on a resource-poor surface can provide the perfect case study to innovate and come up with creative solutions that will eventually make the Earth a better place.

A three spherical model is created based on the perception of interconnectivity and system thinking. The aim is to explore whether these three pillars are critical for positive human integration in the moon environment, or are too simplistic. We will present a six-month investigation into the different compartments, how they interact and how they form a synthesis.

These three components are designed in such a way that they provide feedback loops in order to positively stimulate each other. At last, new study recommendations are given for further research and framing of this discourse.

PEX.2-0032-18 EVOLVING ADVICE ON THE ROLE OF PHYSICAL PROCESSES IN EXPLORATION TECHNOLOGY DESIGN AND OPERATION

Sandra Graham, sgraham@nas.edu

National Academies of Sciences, Engineering and Medicine, Washington, District of Columbia, United States

Despite decades of engineering research and development, high costs and exacting requirements for robust systems performance continue to create high barriers to achieving humanity's goal of exploring and creating outposts beyond low Earth orbit, including Mars. Over this same time period, an appreciation grew in the physical sciences community that research on fundamental behaviors of fluids and materials in a space environment could be used to inform the design of important classes of exploration technologies and processes, with the potential for lowering costs, decreasing weight, and increasing reliability. Under the auspices of the National Academies of Sciences, Engineering, and Medicine, the community has periodically come together to examine the research questions on physical behaviors most relevant to space exploration needs, as well as related programmatic issues, such as the barriers to communications between stakeholders. This talk explores the evolution of the issues and science questions examined by these groups, and some of the most significant findings and conclusions.

PEX.2-0033-18 THE NEED FOR A RATIONAL FRAMEWORK FOR COORDINATED MANAGEMENT OF FUTURE EXPLORATION, USES AND EXPLOITATION OF OUTER SPACE ENVIRONMENTS AND RESOURCES

Margaret Race, mracemom@aol.com

SETI Institute, Mountain View, California, United States William Kramer, williamkramer1@gmail.com

Maryland, United States

Although there is an acknowledged need to manage the environments of extraterrestrial bodies like the Moon, Mars, or even asteroids, there are currently no international policies for guiding space-based activities including exploration, resource use, and exploitation that could impact planetary environments (e.g., mining, energy production, and general construction of infrastructure required for landing areas, extended human habitation, large telescopes, or facilities away from bases, etc.) There is an obvious needed to develop a clear, justifiable and implementable framework in anticipation of proposals for diverse activities and uses beyond Earth, whether by governments, non-governmental, commercial, or private entities. In recent years, a variety of suggestions have been published on how to manage space environments, based on adaptations of various Earth based analogues (e.g., industry codes of conduct and best management practices; establishment of reserves; mitigation for or control of unavoidable impacts; monitoring of claims; developing review processes similar to environmental impact assessments, etc.). Clearly, standards or approaches to avoid harmful contamination or irreversible damage to extraterrestrial environments are warranted. Yet the path forward to achieving such policies is uncertain at best. What project planners and proponents need are clear guidelines and policies that include more than vague notions of responsible activities. The development of such policies will take considerable time-as evidenced by the nearly two-decade long process for considering COSPAR's Planetary Protection policy for human missions beyond Earth orbit. Already, COSPAR's Panel on Planetary Exploration (PEX) has begun to consider issues of space environmental management beyond planetary protection concerns, but it will undoubtedly take many more years to provide necessary details. In addition, while other groups are focusing on regulatory approaches and policies for exploration and uses of beyond Earth orbit, they are a long way from dealing with the implementation details needed to guide space activities for different bodies. In the meantime, there is no cross-sector plan or standardized framework for assessing how and to what extent human or directed robotic activities might affect surface environments during either general science exploration, commercial/private activities or resource exploitation. In addition, there are no criteria on which to gauge the direct, indirect or cumulative impacts on space environments or their sustainability over time. This is particularly problematic for areas of bodies that might be affected by inadvertent transfer of Earth associated microbes and materials - which might contaminate subsurface ices or other areas considered for resource utilization (different from planetary protection concerns per se). Looking ahead, it is certain that many considerations will need research attention. How might an effective and practical process be developed to assess the extent to which human or robotic activities may affect extraterrestrial environments? Would such a process include opportunities for public review and comment? Might a uniform protocol or set of voluntary guidelines be developed to encourage project proponents to fully describe their proposals, identify how they may affect extraterrestrial environments and describe measures that will be taken to mitigate or reduce adverse effects? Just as the development of planetary protection requirements for human exploration missions have required step-wise, cross-cutting, collaborative efforts involving both science and technology communities from many countries, so too will the development of guidelines and requirements for future exploitation and use of resources-and their sustainability. This presentation will discuss the diversity of science, protection, exploitation, use, management, stakeholder and societal concerns that will need to be included in project planning, review and approval to ensure responsible exploration and use of space resources and planetary surfaces for the benefit of all humankind. Considering that international missions to the Moon, Mars and asteroids involving multiple stakeholders and objectives are possible in the coming decade, it is important to begin the stepwise consideration of framing and analyzing environmental sustainability criteria soon.

PEX.2-0034-18 PEX2 SESSION PANEL WRAP-UP

Bernard H. Foing, bernard.foing@esa.int ESA/ESTEC, Noordwijk, Netherlands

PEX2 session panel wrap-up

The session COSPAR-18-PEX.2: "Human Exploration on the Moon, Mars and NEOs", cosponsored by Commissions B, F will include solicited and contributed talks and poster/interactive presentations. It will also be part of the 13th International Conference on Exploration and Utilisation of the Moon ICEUM13B from the ILEWG ICEUM series started in 1994. It will address various themes and COSPAR communities: Sci ences (of, on, from) the Moon enabled by humans; Research from cislunar and libration points; From robotic villages to international lunar bases; Research from Mars NEOs outposts; Humans to Phobos/Deimos, Mars and NEOs; Challenges and preparatory technologies, field research operations; Human and robotic partnerships and precursor missions; Resource utilisation, life support and sustainable exploration; Stakeholders for human exploration. One half-day session will be dedicated to a workshop format and meetings/ reports of task groups: Science, Technology, Agencies, Robotic village, Human bases, Moon Mars Villages, Society Commerce, Outreach, Young Explorers. COSPAR has provided through Commissions, Panels and Working Groups (such as ILEWG, IMEWG) an international forum for supporting and promoting the robotic and human exploration of the Moon, Mars and NEOS.

PEX.2-0036-18 ON THE METEOROID HAZARD TO THE ROBOTIC AND HUMAN EXPLORATION OF THE MOON, MARS AND NEOS

Svitlana Kolomiyets, s.kolomiyets@gmail.com

Kharkiv National University of Radio and Electronics, Kharkiv, Ukraine

Human and robotic space exploration in the coming decades will require the safety of this process. This task is also set in relation to exploration of the Moon, Mars and NEOs. One of the agents of danger in this case is the meteoroid environment. Here the question of constructing models of the meteoroid environment near the Earth's orbit and beyond is discussed.

PANELS (P)

NEAR-TERM EXPLORATION OF THE INTERSTELLAR MEDIUM (PIR.1)

PIR.1-0001-18 INTERSTELLAR PROBE: THE FIRST STEP OF A THOUSAND MILES

Ralph McNutt, ralph.mcnutt@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Robert Wimmer-Schweingruber, wimmer@physik.uni-kiel.de

Christian-Albrechts-Universität zu Kiel, Kiel, Germany Stamatios Krimigis, tom.krimigis@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Mike Gruntman, mikeg@usc.edu

University of Southern California, Los Angeles, United States Edmond Roelof, edmond.roelof@jhuapl.edu

Applied Physics Laboratory, Laurel, Maryland, United States

Exploration of the heliosphere and the far reaches of our solar system by the Voyagers and New Horizons and near-Earth observations of the Kuiper Belt and exoplanetary systems have all profoundly changed how we view our own home in space. An Interstellar Probe escaping beyond the solar-system boundaries with new observational techniques would be a bold move in space exploration, enabling detailed, new understanding of the global heliosphere in the context of other astrospheres, further discoveries of unexplored Kuiper Belt Objects, and the first observations of our circumsolar dust disk. These would offer insight into the evolution of the solar system and our understanding of exoplanetary systems. With the power supplies on the Voyagers nearing their end of life, the rapid pace of discovery of exoplanets in other stellar systems, and the evolution in our own understanding brought about results from the Voyager, Cassini, and Interstellar Boundary Explorer (IBEX) spacecraft, the time is right for looking at the next steps we can make into our stellar neighborhood. Travel to near-stellar systems has been a serious topic of discussion since the speculations of Tsiolkovsky, Goddard, Oberth, and Tsien. Such discussions over the years have also helped define and illustrate how momentous a challenge such voyages are. Hence, the question facing us today is what the appropriate next step - a true first step - is in negotiating the transition from science fiction to engineering reality. The scientific imperatives associated with reaching the near interstellar medium in order to understand our origins and our own current locale in the Milky Way trace to the beginnings of the Space Age, and they have been debated and refined since that time and into the current epoch with the ongoing discoveries of the Voyager Interstellar Mission. The subjects of interstellar travel, interstellar probes, and interstellar "precursor" missions are not new but have lacked traction with policy makers and the scientific community at large because of the states of both scientific knowledge and engineering realities. With the in situ scientific revelations of the Voyager Interstellar Mission and New Horizons and the remote images in energetic neutral atoms (ENAs) from Cassini and IBEX, it is clear that that the next

scientific understanding of the grand scheme of our surroundings will come from a multifaceted partnership between NASA's planned Interstellar Mapping and Acceleration Probe (IMAP) mission, other relevant assets deployed within the orbits of the classical planets, and a vanguard interstellar mission beyond the reach of the Voyagers and New Horizons. Predicting the best path to future scientific discoveries is always problematic and subject to debate, yet it is also clear that the effective strategy is to push out the frontier with the tools at hand. The next step in reaching to the stars will require the recognition of engineering limits, scientific trades, and scientific compromises, but this is new neither in science nor exploration. Such a step would be an "Interstellar Probe." If our ultimate destiny as a species is to persevere, then that journey will be amongst the stars, and probing those regions to understand the properties of both the nearby interstellar medium and of our own stellar system will be the first, necessary, and timely, step in that "thousand-mile journey" to the stars. An "Interstellar Probe" is that step. The time for the Interstellar Probe has come.

PIR.1-0002-18 INTERSTELLAR HELIOSPHERE PROBES (IHPS)

Qiugang Zong, qgzong@gmail.com Peking University, Peking, China

Supersonic solar wind streams away from the Sun in all directions, interaction with the local interstellar medium to form a giant plasma bubble, which is coined by A. J. Dessler as "heliosphere". Voyager 1 2 spacecraft have recently encountered the heliospheric boundaries of this plasma bubble, e.g. the termination shock, heliosheath and heliopause. To explore further on the dynamics on the heliospheric boundaries, even the hydrogen wall, and the local interstellar medium, an Interstellar Heliosphere Probes IHPsmission have been proposed to Chinese national space agency (two spacecraft, one towards the nose of the heliopause, one opposite). The plan is that the spacecraft is to reach 100AU when it is 100th anniversary of the PR China (2049). Thus, IHP will allow us to discover, explore, and understand fundamental astrophysical processes in the largest plasma laboratory– the heliosphere.

A probe designed to exit the solar system and explore interstellar space provides a prime opportunity for planetary science. During the time period while traveling to interstellar space, flybys of planets and small bodies should be planned to maximize the science outcome of such a mission. To start, a gravity assist flyby of Jupiter is likely to be necessary. This provides a prime opportunity to study the magnetosphere and atmosphere of Jupiter as well as to image Jupiter's moons and evaluate interaction of the moons with Jupiter's magnetosphere. In particular, equipping the probe with techology best suited to search for and characterize plumes from Europa would be of extremely high value.

As many close and distant flybys of other planets as the spacecraft trajectory allows should also be planned. During distant flybys, imaging campaigns targeting surfaces and atmospheres would be of high value. Close flybys would allow in situ studies of atmospheric loss and solar wind interaction with these bodies. Finally, the New Horizons flyby of Pluto showed unexpected complexity in Pluto's surface processes, the distribution of volatiles on the surface, and atmospheric chemistry and loss. This has clearly demonstrated the importance of future flybys of objects in the Kuiper Belt (KBOs), particularly large KBOs that are known to have volatiles on the surface and may have atmospheres.

Finally, planetary science with an interstellar probe should not be limited to studies of the planets while traveling to interstellar space. Observations of planets in our solar system could also be used to advance understanding of exoplanets. Work has already begun looking at the Earth and other planets in our solar system from an exoplanet perspective to better understand how biomarkers can be detected remotely. An interstellar probe equipped with instruments that can observe transits of planets in front of our Sun from 200 AU at the spatial and spectral resolution of current and future exoplanet missions, could provide critical insights into how best to interpret observations made of exoplanet atmospheres.

PIR.1-0004-18 WHAT SHOULD AN INTERSTELLAR PROBE MEASURE?

Eberhard Möbius, eberhard.moebius@unh.edu

Space Science Center and Physics Department, University of New Hampshire, Durham, New Hampshire, United States

An Interstellar Probe is a genuine mission of exploration that sets its sight on our outer frontier, the uncharted territory beyond the boundary regions of our home, the heliosphere. It will discover and characterize, for the first time in-situ, the pristine interstellar medium that surrounds the solar system with all its constituent matter and fields, and, on its way, it will obtain a detailed radial profile of the complete boundary structures. Building on the Voyager Interstellar Mission and the Interstellar Boundary Explorer (IBEX), the probe must sample neutral atom, plasma particle, and field conditions from the outer heliosphere into the, thus far completely unexplored, pristine partially ionized interstellar plasma. Because the interstellar material presents a current sample of our galaxy in comparison with the 4.5 billion older sample of the solar system, both elemental and isotopic composition for elements at least up to Ne are key observables to address Big Bang cosmology and the evolution of galactic matter. Likewise, such a probe must sample the cosmic ray and dust distributions and composition, unaffected by modulation of the heliosphere. This mission will also present a unique opportunity to obtain the direction and strength of the interstellar magnetic field and to test locally the "great power law in the sky" of magnetic turbulence. Guided of the recent findings by IBEX and Voyager, it appears advisable to send an Interstellar Probe on a trajectory that leads through the pressure maximum (for plasma and magnetic field combined) and thus also through the likely source region of the IBEX Ribbon in the upwind direction. Such a trajectory promises the shortest distance to the key boundary structures and the pristine interstellar medium, allowing unique observations that address a number of open questions posed by Voyager and IBEX observations. An Interstellar Probe should be complemented by a global view through ENAs and UV with a mission similar to IBEX or IMAP, thus providing for a simultaneous tomographic view of the heliospheric boundary regions.

Near-term Exploration of the Interstellar Medium (PIR.1)

PIR.1-0005-18 INTERSTELLAR PROBE OBSERVATIONS OF THE SOLAR SYSTEM'S DEBRIS DISKS

Carey Lisse, carey.lisse@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Ralph McNutt, ralph.mcnutt@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Pontus Brandt, pontus.brandt@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Andrew Poppe, poppe@ssl.berkeley.edu

University of California, Berkeley, Berkeley, California, United States Mihaly Horanyi, horanyi@colorado.edu

University of Colorado, Boulder, Boulder, Colorado, United States

Planetesimal belts and debris disks full of dust are known as the "signposts of planet formation" in exosystems. The overall brightness of a disk provides information on the amount of sourcing planetesimal material, while asymmetries in the shape of the disk can be used to search for perturbing planets.

The solar system is known to house two such belts, the Asteroid belt and the Kuiper Belt; and at least one debris cloud, the Zodiacal Cloud, sourced by planetisimal collisions and Kuiper Belt comet evaporative sublimation.

However these are poorly understood in toto because we live inside of them. E.g., while we know of the two planetesimal belt systems, it is not clear how much, if any, dust is produced from the Kuiper belt since the near-Sun comet contributions dominate near-Earth space. Understanding how much dust is produced in the Kuiper belt would give us a much better idea of the total number of bodies in the belt, especially the smallest ones, and their dynamical collisional state. Even for the close in Zodiacal cloud, questions remain concerning its overall shape and orientation with respect to the ecliptic and invariable planes of the solar system - they aren'texplainable from the perturbations caused by the known planets alone.

In this paper we explore the possibilities of using an Interstellar Explorer telescope placed at 1000 AU from the Sun to observe the brightness, shape, and extent of the solar system's debris disk(s). We should be able to measure the entire extent of the inner, near-earth zodiacal cloud; whether it connects smoothly into an outer cloud, or if there is a second outer cloud sourced by the Kuiper belt and isolated by the outer planets, as predicted by Stark Kuchner (2009, 2010) and Poppe et al. (2012, 2016). VISNIR imagery will inform about the dust cloud's density, while MIR cameras will provide thermal imaging photometry related to the cloud's dust particle size and composition. Observing at high phase angle by looking back towards the Sun from 1000 AU, we will be able to perform deep searches for the presence of rings and dust clouds around discrete sources, and thus we will be able to search for possible strong individual sources of the debris clouds - like the Haumea family collisional fragments, or the rings of the Centaur Chariklo, or dust emitted from spallation off the 6 known bodies of the Pluto system.

PIR.1-0006-18 WHAT CAN AN INTERSTELLAR PROBE TELL US ABOUT THE LISM?

Klaus Scherer, kls@tp4.rub.de

Ruhr-Universität Bochum, Bochum, Germany

The only spacecraft which may reach the pristine interstellar medium (ISM) are the two Voyagers. They are launched in the late 70s and their instrumentation allows not to answer some questions of contemporary developments of heliophysics. Also modern spacecraft, like IBEX, give us some hints, in-situ observations are necessary to verify physical concepts. Especially, the state of the interstellar medium is required to understand the nature of the interaction between the solar wind and the ISM, e.g. the strength and direction of the magnetic field, the composition and state of the ISM are required to understand the structure of the heliosphere. Additionally of interest is the low energetic end of the cosmic ray flux which is not accessible inside the heliosphere, but is important to understand the transport on galactic scales. Another issue is to understand the composition and dynamics of interstellar dust particles, in order to get a better understanding of protostellar disks and the like.

I will address these questions, despite their accessibility by a possible interstellar mission.

PIR.1-0007-18 SCIENCE FOR AN INTERSTELLAR PROBE MISSION: WHAT WE NOW KNOW, AND WHAT WE NEED TO KNOW

Edmond Roelof, edmond.roelof@jhuapl.edu

Applied Physics Laboratory, Laurel, Maryland, United States

High among the scientific goals of an Interstellar Probe (ISP) mission should be a deeper quantitative understanding of the heliosheath (HS), the immense region between the heliospheric termination shock (TS) and the heliopause (HP) that marks the outward beginning of the interstellar plasma and magnetic field. For one thing, the astrospheres of stars similar to our Sun may well have similar heliosheaths. For another, the interstellar plasma and magnetic field just beyond our HP are disturbed by the activity of our Sun (Burlaga and Ness, ApJ, 2016). This doesn't mean that we can't study the IS plasma there; we just have to understand the solar disturbances. 2-3 kHz plasma waves measured on VGR1/2 (Gurnett et al., ApJ, 2015) detect electron plasma oscillations from local shock-associated electron beams and remotely sense distant shocks driven by the pressure pulses. Krimigis et al. (Science, 2009), immediately deduced from the first IBEX and Cassini/INCA energetic neutral atom (ENA) images that the pressure in the HS resides overwhelmingly in the non-thermal protons (1-13 keV) - as revealed by the surprising deficiency of thermal pressure after Voyager 2 (VGR2) crossed the TS (Richardson et al., Nature, 2008). A further inference was that the HP was shaped more like a "bubble" than a long-tailed "comet" or "magnetosphere". Since non-thermal pressure controls the configuration and dynamics of the HS, we cannot understand its effects on the local IS medium without a quantitative theoretical description. ENAs provide 2D images of a 3D object, so ambiguities in the line-of-sight (LOS) dimension must somehow be constrained. ISP will provide its own "ground truth" while it transits the HS, but after that we will have to rely upon theory/simulations to fill in the LOS-compressed 3rd dimension in our ENA images. Our present challenge, then, is to provide clear scientific information for the design for an ISP mission by combining the ENA images from IBEX, Cassini/INCA (and the upcoming IMAP)

all limited to an "inside-out" view - with all the in situ ground truth from the complete suite of operating instruments on VGR1/2 for the remainder of their lifetimes. However, in order to reliably understand plasma disturbances beyond the heliopause, we need a new quantitative theory that properly describes a heliosheath dominated by non-thermal pressure.

PIR.1-0008-18 'IT TAKES A VILLAGE.' THE CASE FOR COLLABORATIVE OUTER PLANET MISSIONS.

Abi Rymer, abigail.rymer@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Kathleen Mandt, kathleen.mandt@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Ralph McNutt, ralph.mcnutt@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States

A mission to one or both of our local Ice Giants (Uranus and Neptune) emerged as a high priority in the most recent Planetary Science Decadal Survey [1] and was also specifically mentioned supportively in the Heliophysics Decadal Survey [2]. In 2016, NASA convened a science definition team to study ice giant mission concepts in more detail [3]. Uranus and Neptune represent the last remaining planetary type in our Solar System to have a dedicated orbiting mission. The case for a Uranus mission has been made eloquently in the Decadal Surveys. Here we summarize some of the major drivers that lead to enthusiastic support for an Ice Giant mission in general, and use the example of a Uranus Mission concept to illustrate opportunities such a mission might provide for cross-division collaboration and cost-sharing. The Cassini spacecraft has been able to make unprecedented observations of the heliosheath during its tour of the Saturnian system, due to a fortuitous combination of the capabilities of its instrumentation and the vision of a small group of plasma physics experts who recognized the opportunity post launch [4]. Future missions might not include such a comprehensive instrument suite without deliberate prior planning. A mission to the outer solar system pro-vides numerous opportunities for cross-disciplinary science and collaboration, including, but not limited to: 1) Heliophysics. Studies of the heliosphere via inclusion of energetic neutral atom (ENA) imaging technology could be performed during cruise and, like Cassini, make observations of both planetary and heliospheric ENA emission during an orbital tour. 2) Exoplanets. Exoplanetary studies would certainly benefit from in situ study of Uranus and Neptune since the majority of exoplanets that have been discovered are also Ice Giants [e.g., 5]. Measurements at infrared to millimeter wavelengths of dust in the inner solar system, looking inward from the outer solar system, could also be compared with what is seen when looking at proto-planetary and planetary disks around other stars to help put observations of distant solar systems in context.

3) Interstellar Probe. It is conceivable to combine an Ice Giants mission with the long desired follow up to the two Voyager spacecraft in the form of an "Interstellar Probe" to investigate the structure of the furthest reaches of our solar system and its interaction with the interstellar medium [6]. In this scenario, Ice Giant or-biter(s) and probe(s) could be dropped off en route

to the interstellar medium. 4) Astrophysics. Instrumentation could be specifically designed to make useful long-wavelength radio observations of the cosmic microwave background during interplanetary cruise to an Ice Giant planet and then to perform deep sounding of the atmosphere and satellites of the Ice Giant itself. 5) Interagency collaboration. Other agencies (e.g., ESA, JAXA) are pursuing many of the same overarching goals [e.g., 7] and there is much that a combination of agencies could achieve that a single agency alone cannot. However, different timelines and mission development processes can hamper coordination. As an example of one strategy to foster collaboration, NASA missions of opportunity have helped US participation in missions being developed by other agencies. The 'directed good fortune' represented by NASA MoOs is an excellent model which we suggest can be more broadly applied. These examples highlight how cooperation across NASA Divisions and between space agencies furthers the specific goals the Planetary Science Division has identified for this workshop. Most strongly, the "Origins" theme is addressed, using observations of solar system planets and the Sun's magnetosphere to connect our mature solar system to young and forming exoplanetary systems. (Cosmological studies would also address "Origins" in the most inclusive sense.) And interagency collaborations can enhance or enable investigations in all the Workshop's themes, by either expanding the scientific payload possible compare to a NASA-only mission, or in the extreme by enabling a mission that would not be feasible for budgetary or other programmatic reasons. Future missions, including a long anticipated voyage to Uranus and Neptune should consider not just the directed mission, but also ways to make the most of other logistical and scientific opportunites along the way. In this presentation we will pro-vide examples of what has been achieved through both fortuitous and directed collaboration and suggest strategies to enable cross-division collaboration and cost-sharing to improve collaboration over the upcoming decades. CODEX will explore the interstellar space surrounding our solar system and investigate it dynamic interaction with the heliosphere. A steady wind of interstellar atoms and dust grains penetrates to within several AU of the Sun *the inner edge of the interstellar medium* where CODEX's instruments, several hundred times more sensitive than any previously flown, will analyze the composition of this unique sample of matter in detail. These observations will reveal the physical properties and nucleosynthetic status of the present-day galaxy, answering questions about the origin of our solar system, the stars, our galaxy, and the universe. The instruments on CODEX can also reveal the properties of other sources of pickup ions in the solar wind, and may be able to make detailed observations of the composition of comets. CODEX is a mission to the inner edge of the interstellar medium and is an indispensable precursor to humankind's inevitable exploration of interstellar space.

PIR.1-0010-18 AN OPPORTUNITY FOR ASTROPHYSICS FROM THE OUTER SOLAR SYSTEM

Michael Zemcov, zemcov@cfd.rit.edu

Rochester Institute of Technology, Rochester, New York, United States

The outer solar system is a unique, quiet vantage point from which to observe the universe around us. Astrophysical measurements from beyond 5 AU can enable several niche astrophysical science cases that are too difficult to perform from platforms near Earth, including building a detailed understanding of the cosmic extragalactic background throughout the electromagnetic spectrum, measurements of the properties of dust and ice in the outer solar system, searches for moons and other small, faint structures around exoplanets, determinations of the mass of planets far from their parent stars using gravitational microlensing, rapid follow-up of gravitational wave transient events, and fundamental physics. A future mission to the ISM offers a unique opportunity to impact all of these science cases in a profound way not available from platforms closer to Earth. Further, performing astrophysical measurements during a cruise phase of such a mission offers an opportunity to provide both high-impact science during the long quiescent periods en route to the ISM, as well as to maintain technical expertise over generations of scientists and engineers. In this talk, I will outline some of the science impacts such a mission could have, and discuss some options for realizing instruments and measurements that would be of interest in the next decade and beyond.

PIR.1-0011-18 WHAT THE VOYAGERS AND ENA HAVE TAUGHT US ABOUT THE NEARLOCAL INTERSTELLAR MEDIUM (LISM)

Stamatios Krimigis, tom.krimigis@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States

In situ measurements by the two Voyagers over the past 14 years have revealed the presence of the long-predicted termination shock (TS) and heliopause (HP), albeit not where theory had placed them. Further, the advent of energetic neutral atom (ENA) imaging by Cassini/INCA since 2003 and IBEX since 2009 have provided images of the global heliosphere that have challenged our long-held views of its shape and the processes that are dominant in its formation (Krimigis et al, and McComas et al, 2009; Dialynas et al, 2017). In addition, continuing measurements from Voyager 1 beyond the HP, currently at 141.2 AU (1 AU=1.5x108 km, the Sun-Earth distance), have shown that the influence of solar activity extends well beyond the HP (at 121.6 AU), 20 AU into the LISM. This influence is manifested through the frequent appearance of anisotropies in the galactic cosmic rays (GCR) where none were predicted, that last as long as a year and are accompanied by electron plasma oscillations in the vicinity of the spacecraft. Further, Voyager 2 traversing the region south of the ecliptic, currently at 116.7 AU is still within the HS. Thus, an ISP mission with a fast (20 AU per year compared to Voyager's 3.62 AU/year) trajectory would traverse a dynamic region near and beyond the TS and HP, and enable imaging the shape of an apparently asymmetric (HS width 27 AU at V1, but > 33 AU at V2) heliosphere from beyond its boundaries through ENA. Further, it would monitor the influence of solar activity in the LISM and determine both, its shape and variability. In situ measurements should include the ISM magnetic field (ISMF), plasma density and distribution function, plasma waves, and neutral atom density and composition, as a minimum. All of these measurements would be new information with modern instrumentation that would place the very limited Voyager measurements into the proper context.

PIR.1-0012-18 THE COMPELLING SCIENCE DISCOVERIES ENABLED BY THE INTERSTELLAR PROBE, PERFORMANCE REQUIREMENTS AND CRITICAL RESOURCE CONSTRAINTS

Pontus Brandt, pontus.brandt@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Ralph McNutt, ralph.mcnutt@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Michael Paul, michael.paul@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States

Venturing on to an escape trajectory beyond the solar system offers science discoveries of different proportions that will naturally bridge planetary, helioand astrophysical disciplines by putting our solar system and heliosphere in the context of the increasing number of other exoplanetary systems and astrospheres detected. Science discoveries enabled by an Interstellar Probe include new understanding of the global structure of our heliosphere and its interaction with the Local Interstellar Medium (LISM), observations of the circum-solar dust disk providing insights in to planetary formation processes, discoveries of unexplored Kuiper Belt Objects such as Quaoar, transit observations of solar-system planetary atmospheres to provide standard candles to aide in the interpretation of exoplanetary observations, and possibly the first flyby observations of the hypothetical Planet Nine.

The first explicit Interstellar Probe will target up to 1000 AU distance from the Sun, which requires asymptotic speeds in excess of 10 AU/year. Two mission scenarios are studied enabled by the SLS Block 1B, assuming a New Horizons-like spacecraft: Direct inject to Jupiter followed by a passive Jupiter Gravity Assist (JGA), or a reverse JGA followed by an Oberth Maneuver close to the Sun requiring a heat shield, building on the flight experience of the Parker Solar Probe heat shield. Assuming a flown payload-to-spacecraft-mass fractions, the allowable payload mass is about 50 kg (including 30% reserve). Similarly, power supplied by a generalpurpose Radioisotope Thermoelectric Generator leaves about 50 W for a science payload. This illuminates the criticality of light-weight, low-power, compact instruments and innovative, yet reliable payload solutions.

A historical overview of the payload mass and power of past and current missions is given to guide further trade-off studies in resources and science return. Updates are presented on the compelling science targets of an Interstellar Probe, and on current mission trade-off studies that drive the high-level science requirements and define the choice of science payload. Resource requirements are summarized and anticipated characteristics of the science targets coupled with the mission performance are used to derive basic performance requirements.

PIR.1-0013-18 SIMULATIONS OF THE GLOBAL HELIOSPHERE IN PREPARATION OF AN INTERSTELLAR PROBE

Vladislav Izmodenov, vlad.izmodenov@gmail.com Lomonosov Moscow State University, Moscow, Russia

Current state of art in the modeling of the global heliosphere will be reviewed. The structure of the global heliosphre is determined by the interaction of the solar wind (SW) with local interstellar medium (LISM). The interaction models take into account multi-component nature of both LISM and SW, heliospheric and interstellar magnetic fields, time and latitudinal variations of the solar wind, etc. We will explore outstanding open questions that could be solved by Interstellar Probe in the light of recent spectacular results obtained by Voyager and IBEX spacecraft.

PIR.1-0014-18 PLANET NINE FROM OUTER SPACE

Konstantin Batygin, kbatygin@gps.caltech.edu

California Institute of Technology, Pasadena, California, United States Michael Brown, mbrown@caltech.edu

California Institute of Technology, Pasadena, California, United States

At the outskirts of the solar system, beyond the orbit of Neptune, lies an expansive field of icy debris known as the Kuiper belt. The orbits of the individual asteroid-like bodies within the Kuiper belt trace out highly elongated elliptical paths, and require hundreds to thousands of years to complete a single revolution around the Sun. Although the majority of the Kuiper belt's dynamical structure can be understood within the framework of the known eight-planet solar system, bodies with orbital periods longer than about 4,000 years exhibit a peculiar orbital alignment that eludes explanation. What sculpts this alignment and how is it preserved? In this talk, I will argue that the observed clustering of Kuiper belt orbits can be maintained by a distant, eccentric, Neptune-like planet, whose orbit lies in approximately the same plane as those of the distant Kuiper belt objects, but is anti-aligned with respect to those of the small bodies. In addition to accounting for the observed grouping of orbits, the existence of such a planet naturally explains other, seemingly unrelated dynamical features of the solar system.

PIR.1-0015-18 SHOCK WAVES IN THE VERY LOCAL INTERSTELLAR MEDIUM

Parisa Mostafavi, psm0011@uah.edu

University of Alabama in Huntsville, Huntsville, Alabama, United States Gary Zank, garyp.zank@gmail.com

University of Alabama in Huntsville, Huntsville, United States

Voyager 1 has made in situ measurements of the very local interstellar medium (VLISM) since August 2012 and its magnetometer has detected several shock waves in the VLISM. Interplanetary shocks propagate through the supersonic solar wind and then through the inner heliosheath after colliding with the heliospheric termination shock (HTS). Interplanetary shock waves can be transmitted through the inner heliosheath and then across the heliopause (HP) into the VLISM. The first in situ VLISM shock observed by Voyager 1 was remarkably broad and had properties different than shocks inside the heliosphere (Burlaga et al. (2013)). We present a model of the 2012 VLISM shock, which was observed to be a weak, quasi-perpendicular, low magnetosonic Mach number, low beta, and subcritical shock. Although the heliosphere is a collisionless environment, we use the Chandrasekhar function and show that the VLISM is collisional with respect to the thermal plasma since the electron and proton collisional mean free paths are relatively small. The thermal collisions introduce dissipation terms such as heat conduction and viscosity into the system. We show that the VLISM shock is determined by thermal proton-proton collisions, which is the dominant thermal collisional term. VLISM pickup ions (PUIs) that are generated by secondary charge exchange do not introduce a significant pressure nor dissipation through the shock transition meaning the VLISM shock is not mediated by PUIs but by the magnetic field and thermal gas only. Weak VLISM shocks are not controlled by wave-particle interactions and therefore are controlled by thermal particle collisions. As a result, we find that the weak VLISM shock is very broad with a thickness of about 0.12 AU, corresponding to the characteristic thermal heat conduction scale length.

PIR.1-0016-18 THE ASTROSPHERE AND MASS-LOSS RATIO OF PROXIMA CENTAURI

Merav Opher, mopher@bu.edu

Boston University, Boston, Massachusetts, United States Abraham Loeb, aloeb@cfa.harvard.edu

Harvard University, Cambridge, Massachusetts, United States Gabor Toth, gtoth@umich.edu

University of Michigan, Ann Arbor, Michigan, United States

Our understanding about the heliosphere dramatically evolved from the results from Voyager, Cassini and Interstellar Boundary Explorer (IBEX). With the rapid discovery of exoplanets in other stellar systems it is important to understand how this new acquired knowledge affects the astrospheres around other stars. In particular, recently the shape of the Heliosphere is being challenged by theoretical and observation work (Opher et al. 2015; Diyalinas et al. 2017). The nearest star to the Sun, Proxima Centauri, is particularly interesting as it was recently discovered to host an Earth-size planet in its "habitable zone", Proxima b. Here we investigate the astrosphere around Proxima Centauri. As the star moves through the surrounding partially-ionized medium, neutral hydrogen atoms penetrate the astrospheres and through charge-exchange with the supersonic stellar wind creating a population of hot pick-up ions (PUIs). We present global magnetohydrodynamic simulations that treats the PUIs as a separate fluid. Most global models treat the PUI and thermal component as a single fluid. Planetary atmospheres are affected by particle fluxes from their host stars. The only means by which coronal winds of Sun-like stars have ever been probed is by the circumstellar H Lyman-alpha absorption fin the interaction region between the wind and the interstellar medium, namely the "astrospheres". The Lyman-alpha constrains on the stellar wind based on Hubble Space Telescope measurements rely on prior hydrodynamical models. Here we revisit the constraints on the mass-loss of Proxima Centauri (Wood et al. 2011) with improved theoretical predictions and discuss the implications for Space Weather effects on Proxima b.

PIR.1-0017-18 JOHNSON THERMO-ELECTROCHEMICAL CONVERTER (JTEC), AN INNOVATIVE POWER SOURCE FOR FUTURE SPACE MISSIONS

Lonnie Johnson, ilinex@johnsonrd.com

Johnson Research & Development, Atlanta, Georgia, United States

Long-duration missions deep into the interstellar medium face a unique challenge when it comes to energy storage and power generation. Unfortunately, over the past five decades, the thermoelectric converter technology used in existing Radioisotope Thermoelectric Generators convert heat into electricity has only achieved a net efficiency of less than 10%. More critically, the performance degradation over time of systems such as the MMRTG may limit operations in the long decades after such a mission has left the solar system. Furthermore, alternative mechanical power conversion techniques, though higher in conversion efficiency, may be difficult to qualify for reliable operations for a 50-year mission. The Johnson Thermo-Electrochemical Converter (JTEC) is an emerging technology that may address both lifetime and efficiency issues.

The JTEC is a high efficiency, solid state, direct heat to electric converter that is projected to achieve over 40% conversion efficiency. It represents a game changing approach to platform energy conversion and system thermal management. This is a versatile technology that can operate in reverse as a heat pump for refrigeration or as a fully distributed electrical and thermal energy management system. It can be integrated into complex host spacecraft configured as distributed nodes that effectively supply and remove heat to and from various subsystems while converting excess heat into electrical power.

The JTEC operates on the Ericsson Thermodynamic cycle. In contrast to less efficient Brayton and Rankine thermodynamic cycles, the ideal Ericsson cycle is Carnot equivalent in conversion efficiency. The JTEC uses hydrogen as a working fluid and electrochemical Membrane Electrode Assembly (MEA) cells to perform the required heat engine gas compression and expansion processes.

PIR.1-0019-18 MISSION CONCEPT FOR DIRECT MULTIPIXEL IMAGING AND SPECTROSCOPY OF EXOPLANETS USING THE SOLAR GRAVITY LENS

Nitin Arora, arora@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Leon Alkalai, leon.alkalai@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology/NASA, Pasadena, United States

Delivering a moderately sized optical telescope to the Solar Gravity Lens (550 AU from the Sun) enables direct, multipixel (megapixel) imaging and high-resolution spectroscopy of a habitable Earth-like exoplanet situated up to 100 light years. It is possible to achieve an amazing, kilometer-scale resolution on its surface, enough resolve surface features and signs of habitability. While exciting, this opportunity presents immense engineering challenges both from an instrument development and mission, spacecraft design perspective.

In this paper we deal with the later issue and propose a mission, spacecraft concept, relying on near-term technologies, capable of delivering a moderately sized optical instrument to the SGL in less than 50 years from launch. Building upon various previous studies (from JPL, APL, KISS, NASA Innovative Advanced Concepts), the mission design relies on a Solar-Thermal Propulsion (STP) based kick stage, used deep in the gravity well of the Sun, allowing the SGL probe to achieve escape velocities in excess of 20 AU/Yr. In comparison the escape velocity of Voyager 1 is approximately 3.7 AU/Yr. To achieve large Delta-Vs at the perihelion, the STP engine concept utilizes heat from proximity to the Sun to heat up the Hydrogen (at 3400k) and expel it at high velocity, delivering an ISP of 1200-1350s. The probe, as designed with help JPL's Team-X, is a RTG based probe with 50 kg of Instruments (mainly the Optical Telescope), totaling to a wet mass of 600 kg. The optical telescope is also used as optical communications terminal for downlinking data to Earth from the SGL.

Given the early nature of this study, sensitivity analysis are performed, showing escape velocity contours vs. spacecraft mass, time of flight, launch year and launch vehicle types. Mission trajectories using other more advanced propulsion technologies like Nuclear Electric Propulsion (NEP) are also evaluated and compared to the above STP based baseline. Finally, impact of various space and time constraints from specific SGL exoplanet target, on mission design and mission concept of operations, are also discussed.

PIR.1-0020-18 THERMAL PLASMA MEASUREMENT REQUIREMENTS FOR INTERSTELLAR PROBE.

Abi Rymer, abigail.rymer@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States

An Interstellar Probe mission represents a natural, and long awaited, follow up to the Voyagers. In situ measurements from the Voyager spacecraft have provided vital information on our solar system plasma and beyond, while remote measurements, such as by IBEX and Cassini-INCA, provide maps of the edge of our solar system providing a tantalizing glimpse of the complex plasma environment in the interstellar medium. We will discuss what these observations tell us about the plasma environment and the implications of this to the plasma instrumentation required for such a mission. Relatively few missions have probed the distant Solar System, much less exceeded it. The earliest measurements of solar wind variation were made by the Mariner 10 spacecraft from 1973-1975. Mariner 10 pioneered the gravity assist manoeuvre to facilitate flybys of Mercury and Venus and en-route made measurements of solar wind plasma between 0.45 and 0.85 AU (one astronomical unit, AU, is 1.5x108 km). Results showed a decrease in the solar wind core (thermal) electron temperature (Te) with radial distance from the Sun as Te R-0.3 ± 0.08 [Ogilvie and Scudder, 1978]. A similar radial relationship, with Te R-0.34

± 0.16, was found by Sittler et al. [1981] reporting on solar wind data collected by Voyager 2 between 1.36 and 2.25 AU. By combining the Mariner 10 and Voyager 2 plasma analyser data sets from 0.45 to 4.76 AU, Sittler and Scudder [1980] found a similar polytropic relationship with Te R-0.37. One of the first studies to differentiate between 'types' of solar wind was by Feldman et al. [1979]. They found a relatively steep decrease in electron temperature in high-speed solar wind streams between 0.47 with 0.62 AU with a power law dependence of Te R-1.14. In the same study Feldman et al. found, perhaps surprisingly, that the high-speed solar wind actually gets hotter between 0.62 and 1.00 AU, with core electron temperature increasing as R+0.28. One of the studies covering the most vast distances was made by Richardson et al. [1995]. Using IMP 8 and Voyager 2 data, at 1 and 40 AU respectively, they report Te decreasing as R-0.49 ± 0.01. McComas et al. [1992] showed that the best fit power law for the core temperature, derived from Ulysses data from 1.15 to 3.76 AU, is R-0.7 and that the core electron density drops with increasing radial distance as R-2 as expected for constant velocity spherical expansion. This was also reported to be the case by Bougeret et al. [1992] for proton density between 0.3 and 1 AU based on Helios 1 and 2 data between 0.3 and 1 AU. Gazis and Lazarus [1982] reported that Te obeyed the same power law of R-0.7, this result was found using Voyager 1 and 2 data between 1 and 10 AU. Pillip et al. [1990] reported observations just prior to solar minimum with Helios 1 and (primarily) Helios 2, covering the distance range 0.3 to 1 AU, indicated varying power laws with values between R-0.3 and R-1.4. The Pillip et al. study separated observations 'roughly between four types of solar wind structure'. Previous work had not differentiated between low speed streams/sector boundaries or compression regions. The Pillip et al. result for high-speed streams, with the solar wind temperature increasing with distance, is almost the same as that found between 0.62 and 1.00 AU by Feldman et al. [1978b]. Despite four decades of study, theoretical models do not quantitatively describe the observed radial profile of solar wind electron temperature. As part of a one-fluid model of the solar wind Parker [1963] described a steady state expansion of thermally driven electron-proton plasma flowing out of the hot solar corona with Te R-0.28. Two-fluid models have also been used to take into account the different electron and ion temperatures and bulk velocities observed at 1 AU in the solar wind [Sturrock Hartle, 1966; Hartle Sturrock, 1968; Cuperman Harten, 1970, 1971; Hartle Barnes, 1970; Wolff et al., 1971]. In general these models find similar results, with a temperature fall off with distance between R-0.2 and R-0.3, depending on proton thermal conductivity and energy exchange rate. For adiabatic cooling we expect a reduction of Te as R-1.3. While if we expect the solar wind to behave as an isothermal gas the temperature would show no dependence on R, which Hoang et al. [1992] show to be the case from 1 to 4 AU based on observations by the Ulysses unified radio and plasma receiver (URAP). Any missions to the outer planets or beyond will provide invaluable additions to our current state of knowledge, providing the measurements are sufficiently comprehensive.

PIR.1-0021-18 THE PREDICTION OF PARTICLE BOMBARDMENT INTERACTION PHYSICS DUE TO IONS, ELECTRONS AND DUST IN THE INTERSTELLAR MEDIUM ON A GRAM-SCALE INTERSTELLAR PROBE

Kelvin Long, kelvin.long@i4is.org

Institute for Interstellar Studies, Charfield, United Kingdom

The Breakthrough Starshot initiative proposes to send a Gram-scale laser driven spacecraft to the Alpha Centauri system in a 20 year mission travelling at v 0.2c. One of the challenges of this mission as the spacecraft moves through the interstellar medium is the presence of dust and gas (mostly hydrogen). The dust has a typical matter-density of 2.57×1027gcm−3 with typical particle mass being 3×10−13g although some of the largest particles may be 5×10−9g in mass. These dust particle will deposit 1012-1016 MeV onto the spacecraft with an energy flux of order 0.3Js−1m−2. We consider the erosion of the spacecraft frontal area due to dust and also heating effects as well as charged particle penetration due to ions and electrons for which at the Project Starshot cruise speeds charged particle collisions can result in a collision energy as high as 75 MeV for the non-metals (hydrogen and helium) and as high as 300 MeV for the metals (Carbon and Oxygen). In this paper, we attempt to characterize the likely environment for the starshot mission and estimate the particle bombardment shielding requirements in terms of mass and thickness of material. We also examine the penetration effects and stopping power of the various bombarding particles and consider the implications for the success of the starshot mission. Current analysis estimates that the likely erosion rates are of order 10−10-10−11gs−1 and that the frontal area temperatures are in the range 200-400

K depending on the ratio of frontal area to radiating area in the range Ao/A 1-100. For an assumed shielding material with atomic number range 3- 13 (Lithium to Aluminium), this would suggest a shielding thickness of 1-3 mm, with a mass in the range 0.01-0.2; depending on the material choice. The aim of this work is to keep the shielding mass down to less than 5% of the total Gram-scale vehicle mass. The work presented highlights the close coupling in the Project Starshot spacecraft design between the chosen vehicle geometry and the particle bombardment requirements.

PIR.1-0022-18 ENABLING A SOLAR SYSTEM ESCAPE MISSION VIA THE NASA SPACE LAUNCH SYSTEM

Steven Vernon, steven.vernon@jhuapl.edu

NASA Marshall Space Flight Center, Huntsville, United States

Extending the reach of mankind well beyond our local solar system has been a very appealing dream and goal, to realized only by the significant advancements of technology, that was well beyond our capabilities until now. The act of sending a deep space probe beyond our local solar system has been explored and studied for decades. Unfortunately, to explore and reap the scientific benefits by the generation that launched the deep space probe, the extremely long flight times would thus, leave these scientific rewards, to our children or their children. To date, every solution proposed required significant, multi-decade, sustained investments in advancing technology that defied logical applications of the terrestrial societies financial and scientific and engineering resources, until now. The development of the heavy lift capacity Space Launch System and the critically important and efficient, exploration upper stage enables exploration of space well outside our local solar system with more realistically appealing flight times that would allow the mission scientists, to reap the rewards of exploration. This paper will demonstrate that, coupling the capabilities of SLS to current existing rocket propulsion stage systems, one can leverage the New Horizons and Solar Probe Plus engineering and integration experiences, where a small capable science probe, coupled with a clever mission design trajectory, can achieve launch energies (C3) on the order of 200-350 km^2/sec^2 can then reduce flight times to a goal of 200 Au in 23-30 years. The SLS system overview and capabilities will be presented. Several vehicle configuration engineering and orbit performance capability studies performed will be presented along with the candidate Spacecraft payload as the results of these studies performed will be provided. Additionally, a conceptual system development timeline will be presented that will close the case being made that exploration outside of our current solar system is achievable today when coupled to the capabilities currently under development by the SLS system.

PIR.1-0023-18 DIRECT MULTIPIXEL IMAGING OF AN EXO-EARTH WITH A MISSION TO THE SOLAR GRAVITATIONAL LENS

Slava Turyshev, turyshev@jpl.nasa.gov

NASA Jet Propulsion Lab / California Institute of Technology, Pasadena, California, United States

We discuss our recent study of a mission to the regions outside our solar system, with the objective of conducting direct high-resolution imaging and spectroscopy of a habitable exoplanet by exploiting optical properties of the solar gravitational lens (SGL). A mission to the focal area of the SGL (which lies beyond 548.7 astronomical unites (AU) on the line connecting the center of the exoplanet and that of our Sun, called the focal line of the SGL) carrying a modest telescope and coronagraph could deliver direct megapixel imaging and high-resolution spectroscopy of a habitable Earth-like exoplanet orbiting a host star at a distance of up to 30 parsec.

The remarkable optical properties of the SGL include major brightness amplification (1e11 at a wavelength of 1 um) and extreme angular resolution (1e10 arcsec) in a narrow field of view. The entire image of such an exo-Earth is compressed by the SGL into an instantaneous cylinder with a diameter of 1.3 km in the vicinity of the focal line. Moving outwards while staying within the image, the telescope will take photometric data of the Einstein ring around the Sun formed by the light from the exoplanet and will process the data to reconstruct the image of the exoplanet with a few km-scale resolution of its surface, enough to see its surface features and signs of habitability.

Recently, we evaluated the feasibility of the SGL-based technique for direct imaging and spectroscopy of an exoplanet and, while several practical constraints have been identified, we have not identified any fundamental limitations. We determined that the foundational technology already exists and has high TRL in space missions and applications. Furthermore, the measurements required to demonstrate the feasibility of remote sensing with the SGL are complementary to rotational tomography measurements and ongoing microlensing investigations, so our effort would provide high-value scientific information to other active astrophysics programs.

PIR.1-0024-18 HELIOPAUSE ELECTROSTATIC RAPID TRANSIT SYSTEM (HERTS)

Charles Johnson, les.johnson@nasa.gov NASA/MSFC, Huntsville, Alabama, United States

The Electrostatic Sail (E-Sail) is a new propulsion technology that uses the solar wind to produce thrust without the use of propellant, enabling low-cost, rapid trip times (10 years) to the edge of the solar system previously considered impossible. The E-Sail uses the momentum of solar wind ions for spacecraft propulsion with the help of long, positively charged wire(s). The system produces a thrust vector radially outward from the Sun, but which can be turned at will up to 30° angle and whose magnitude can be easily adjusted.

The E-Sail design is a novel approach to solar propulsion. The thrust produced by an E-sail declines at a rate of 1/r (where r is the solar distance) and can provide useful thrust out to distances of 30 Astronomical Units (AU). Unlike other propellantless concepts such as solar photon sails, the electric sail does not rely on a fixed area to produce thrust. In fact, as the electric sail moves away from the sun, the Debye sheath dynamically changes, allowing the positive electric field to grow, increasing the apparent area of the virtual sail as the solar wind plasma density decreases.

Studies performed at the NASA George C. Marshall Space Flight Center show that an E-Sail mission to the heliopause can be accomplished in less than 10 years, a feat Voyager 2 took 35 years to accomplish. E-Sail propulsion exceeds the 2012 Heliophysics Decadal Survey speed goal of 3.8 AU per year. Put in more human terms, the E-Sail technology will bring the time frame of heliopause (and beyond) missions to well within a person's career. Most of the subsystem technologies required to field an Electric Sail are at Technology Readiness Levels (TRL) greater than 4, with several having been previously space-qualified.

PIR.1-0025-18 DIRECTED ENERGY PROPULSION FOR RAPID INTERPLANETARY MISSIONS

Philip Lubin, lubin@ucsb.edu

University of California Santa Barbara, Santa Barbara, California, United States

All propulsion systems that leave the Earth are based on chemical reactions. Chemical reactions, at best, have an efficiency compared to rest mass of 10^{-10} (or about 1eV per bond). All the mass in the universe converted to chemical reactions would not propel even a single proton to relativistic speeds. While chemistry will get us to Mars it will not allow extremely rapid interplanetary mission nor ever allow interstellar capability in any reasonable mission time. However, recent advances in photonics and directed energy systems now allow us to realize extremely high speed missions using either direct photon propulsion or beamed power to ultra high Isp ion engines. The choice of the two modes depends on the specific mission requirement. It is the only known technology, besides matter-antimatter annihilation propulsion that is capable of relativistic flight. Photonics, like electronics, and unlike chemical and nuclear propulsion is an exponential technology with a current double time of about 20 months. The cost of such a system is amortized over the essentially unlimited number of launches and applications. In addition, the same photon driver can be used for many other purposes including planetary defense, space debris mitigation, standoff molecular composition analysis, solar system LIDAR, long range power beaming among others. This program has also spun off three additional NIAC programs using this core technology. This technology would be a profound change in human capability with enormous implications from very small to large spacecraft. Known as NASA Starlight, we are now in the third year of funding including a current NASA Phase II program. In addition to NASA and congressional support we have private sector support including the Breakthrough Foundation with a pledged 100M\$ Research and Development program to explore the fundamental technology involved (Starshot). The FY 2017 congressional appropriations request directs NASA to study the feasibility of an interstellar mission to coincide with the 100th anniversary of the moon landing quoting our NASA program as an option. We will discuss the many technical challenges ahead, our current laboratory prototypes and recent data on kilometer baseline arrays as well as the transformative implications of this program.

PIR.1-0026-18 PROTON SPECTRAL RADIATION ENVIRONMENT OF THE OUTER HELIOSPHERE AND LOCAL INTERSTELLAR MEDIUM

John Cooper, john.f.cooper@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States Natasha Papitashvili, natalia.e.papitashvili@nasa.gov

ADNET Systems, Inc., NASA/GSFC, Code 672, Greenbelt, Maryland, United States Steven Sturner, steven.j.sturner@nasa.gov

GPHI/UMBC, NASA/GSFC, Code 661, Greenbelt, Maryland, United States

Proton flux measurements at plasma to cosmic ray energies from the Voyager 1-2, Interstellar Background Explorer (IBEX), and Cassini spacecraft each provide partial basis for development of time-averaged flux models with applications to dynamics of particle acceleration, pressure balance at the heliopause and space weathering of extreme Kuiper Belt, Oort Cloud, and interstellar (e.g., 1I'Oumuamua) objects. Each spacecraft presently covers a unique range of space and energy with Voyager 1 reported to be in the local interstellar medium, Voyager 2 still in the heliosheath, and with IBEX and Cassini (through Sept. 2017 end of mission) remotely measuring energetic neutral atoms (ENAs) from some combination of heliosheath and local interstellar sources. Voyager 2 provides the only in-situ measurements of plasma, suprathermal, and higher energy proton distributions in the heliosheath, while IBEX and Cassini indirectly provide measurements of the suprathermal proton flux spectra from models for the ENA sources. Voyager 1 provides the only direct measurements of proton and heavier ion fluxes beyond the heliopause at few MeV and higher energies, while lower energy fluxes are respectively precluded at plasma and suprathermal energies by an inoperative sensor and penetrating cosmic ray background. The so-called secondary-ENA IBEX source beyond the heliopause in the very local interstellar medium could include a mixture of ENAs from charge-exchange interactions of heliospheric and interstellar suprathermal ions, although solar cycle dependence suggests a dominance of the heliospheric source. It has been suggested that remote observations of interstellar molecular cloud ionization rates limit the suprathermal flux spectrum, but sub-MeV ions would not penetrate into such clouds and would more likely arise internally as pickup ions in stellar wind flows within the clouds. Current limits on pressure balance at the heliopause do not preclude a substantial suprathermal component from the local interstellar environment. Future Voyager-2 measurements beyond the heliopause will directly sample the plasma environment but suprathermal fluxes would still be hidden beneath penetrating background and could only be measured by a future interstellar probe. We use moment and flux distribution data from the spacecraft sources, as available from the NASA Space Physics Data Facility (SPDF), the

NASA Virtual Energetic Particle Observatory (VEPO), and instrument team publications, to compile time-averaged data models for the proton flux spectra in the heliosheath and in the local interstellar medium. These models are then applied to sample calculations of total proton pressures, re balance at the heliopause, and of space weathering parameters for radiolysis and sputtering on more distant icy bodies of the Kuiper Belt and Oort Cloud.

PIR.1-0027-18 LOOKING BACK AT OUR HELIOSPHERE IN ENA

Robert Demajistre, bob.demajistre@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, SEVERNA PARK, Maryland, United States

Pontus Brandt, pontus.brandt@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Edmond Roelof, edmond.roelof@jhuapl.edu

Applied Physics Laboratory, Laurel, Maryland, United States

Energetic Neutral Atoms (ENAs) have been used over the past several decades to image space plasmas in planetary magnetospheres as well as the structure of the heliosheath. ENA measurements of the heliosphere have (obviously) all been taken from vantage points in the inner heliosphere which is a useful perspective. ENAs created in the inner heliosphere from the solar wind generally have an outward velocity, and thus do not reach sensors closer to the sun. Thus, solar wind plasma is only 'visible' in ENAs to an inner heliosphere observer after it reaches the termination shock, where it's outward motion is slowed and it is heated. This allows us to study the outer heliosphere with ENAs with limited background signal from the inner heliosphere. This perspective from the inside looking out is convenient to study the outer boundary of the heliophere, but contains no direct information about the plasma and processes occurring in the inner heliosphere. Further, since these are integrated line of sight measurements, the overall shape of the heliosphere is difficult to untangle from intensity variations/acceleration processes. ENA sensors placed outside the heliosphere, conversely, would allow us to remotely sense both the inner and outer heliosphere, allowing us full access to the evolution of the solar wind as it travels from the sun outward. Further, such a perspective would allow us to more directly measure the boundaries of the heliosphere with the LISM without the obscuration of the inner heliosheath. In this paper, we present modeled views of ENA images from the outside looking in, at a distances of 250 AU, highlighting both the added information about inner heliospheric processes and the boundary interactions with the LISM. From the images presented at different energies, we see that varios aspects of the heliosphere can be studied, including the overall shape, accelleration processes and pick up ion proceses in the inner heliosphere.

PIR.1-0028-18 THE COMPACT DUAL ION COMPOSITION EXPERIMENT (CODICE) FOR THE INTERSTELLAR PROBE MISSION

Mihir Desai, mdesai@swri.edu

Southwest Research Institute, San Antonio, Texas, United States Keiichi Ogasawara, keiichi.ogasawara@swri.org

Texas, United States

Robert Ebert, rebert@swri.edu

Southwest Research Institute, San Antonio, United States David McComas, dmccomas@princeton.edu

Princeton University, Princeton, New Jersey, United States Frederic Allegrini, fallegrini@swri.edu

Southwest Research Institute, San Antonio, Texas, United States Stefano Livi, slivi@swri.edu

Southwest Research Institute, San Antonio, Texas, United States

We have developed a new, versatile, fully integrated Compact Dual Ion Composition Experiment - CoDICE - that simultaneously provides high quality solar wind plasma, pickup, and energetic ion composition measurements over six decades in ion energy in a wide variety of space plasma environments, including the solar wind, inner and outer heliosheaths, as well as the local interstellar medium. CoDICE measures three critical ion populations namely: Elemental, isotopic, and charge state composition, and 3D velocity distributions of 10 eV/q-80 keV/q (1) plasma and (2) pickup ions, and Elemental and isotopic composition, and energy spectra and angular distributions of 30 keV-10 MeV/nucleon (3) energetic ions. CoDICE uses a common time-of-flight subsystem that requires significantly less mass and volume compared with two or three separate instruments, provides directionally-validated double and triple coincidence measurements and therefore excellent signal-to-noise ratios, and simplifies spacecraft interfaces and accommodation requirements for the Interstellar Probe Mission. This paper describes the design principles, ray tracing simulations, laboratory prototype testing, and proof-of-concept validation of the CoDICE concept, as adapted for measuring the solar wind plasma, pickup, and energetic ion populations expected to be present in the heliosphere en route to the termination shock and in the interstellar medium.

PIR.1-0029-18 MECHANICAL CONSIDERATIONS FOR INTERSTELLAR PROBE

David Napolillo, david.napolillo@jhuapl.edu

Johns Hopkins Applied Physics Laboratory, 20723, Maryland, United States

Mechanical considerations for Interstellar Probe Interstellar Probe, a mission to the 200-1000 AU region, could be made possible by leveraging APL's experience with several enabling technologies. Those technologies are heat shield technology similar to that employed by Parker Solar Probe (PSP), RTG technology like that employed on New Horizons and miniaturization of space vehicles similar to MBD. Implementing heat shield technology will be key to mission implementation. Accelerating the space vehicle using a gravity assist from the sun is necessary to achieve the speeds to reach the desired region of space in a reasonable amount of time. To achieve those speeds the vehicle will need to pass much closer to the sun than PSP. We will look at innovative ways to implement the PSP shield technology. Combinations of shield thickness, spacing and configuration should be examined. Shielding material should be reexamined to see if more advanced materials are available than those used on PSP. The material used on PSP, while effective for blocking heat, is lacking in mechanical strength. If a suitable, stronger material were available is would make shield stacks easier to implement. A cylindrical shield will also be examined to determine whether or not a spin stabilized vehicle could be used. Since solar arrays are not practical in the desired region an RTG or similar RPS will be required. During the design, integration and test of New Horizons a lot was learned. We will leverage what we learned so any design suggested can handle the heat of an RPS. Since an RPS can't be installed until late in IT, typically on the pad, lessons learned on New Horizons will help here as well. Any design will be scrutinized for late access for RPS installation. Access for personnel, integration fixtures, etc. will be considered. In any design suggested the minimization of the space craft size and mass it crucial. The smaller the space craft the smaller the shield required for the close approach to the sun. Less mass would also mean more energy delivered by the launch vehicle, reducing travel time. While a cube satellite like MBD is insufficient to perform the science mission the technology could be used to reduce size and mass. MBD was essentially a flying electronics box. Similar technologies should be looked at for interstellar probe. Reducing box to box harness, reducing box walls where possible, combining box functions are all ways to reduce size and weight. Flexible printed wiring assemblies should be considered for use as another method of reducing size and mass. Smaller payloads require smaller sun shield for close approach so the advantages of cube sat similar technologies are obvious. Mechanical considerations for Interstellar Probe Interstellar Probe, a mission to the 200-1000 AU region, could be made possible by leveraging APL's experience with several enabling technologies. Those technologies are heat shield technology similar to that employed by Parker Solar Probe (PSP), RTG technology like that employed on New Horizons and miniaturization of space vehicles similar to MBD. Access for personnel, integration fixtures, etc. will be considered. In any design suggested the minimization of the space craft size and mass it crucial. The smaller the space craft the smaller the shield required for the close approach to the sun. Less mass would also mean more energy delivered by the launch vehicle, reducing travel time. While a cube satellite like MBD is insufficient to perform the science mission the technology could be used to reduce size and mass. MBD was essentially a flying electronics box. Similar technologies should be looked at for interstellar probe. Reducing box to box harness, reducing box walls where possible, combining box functions are all ways to reduce size and weight. Flexible printed wiring assemblies should be considered for use as another method of reducing size and mass. Smaller payloads require smaller sun shield for close approach so the advantages of cube sat similar technologies are obvious.

PIR.1-0030-18 ENERGETIC NEUTRAL ATOM (ENA) AND ENERGETIC PARTICLE OBSERVATIONS FROM AN INTERSTELLAR PROBE

Joseph Westlake, jwestlak@gmail.com

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Pontus Brandt, pontus.brandt@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Donald Mitchell, donald.g.mitchell@jhuapl.edu

Applied Physics Laboratory, Laurel, Maryland, United States Robert Demajistre, bob.demajistre@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, SEVERNA PARK, Maryland, United States

Recent observations from the Interstellar Boundary Explorer (IBEX) and Cassini have revealed the interaction of our heliosphere with the very local interstellar medium (VLISM). This complex interaction has several features that appear unique to the specific configuration of the heliosphere with respect to the VLISM such as the narrow "ribbon" of enhanced ENAs below about 6 keV and the wider "belt" of ENA emissions above 6 keV. In-situ observations from the Voyager Interstellar Mission (VIM) have also shown a region of space where the pressure is dominated by pickup ions. These observations call for further investigation to understand the interaction of our Sun with the VLISM using the next generation of measurements. Here we describe the scientific contributions gained from a combination energetic neutral atom (ENA) imager and energetic particle spectrometer on an in-situ platform destined for several hundred AU. Specifically we detail remote and in-situ measurements that will advance our understanding of pickup ions and the interaction of the Sun with the VLISM inside of the termination shock, during transit of the heliosheath, and finally from a perspective outside of our heliosphere.

PIR.1-0031-18 AN ENERGETIC AND SUPRATHERMAL PARTICLE INSTRUMENT FOR AN INTERSTELLAR MISSION

George Ho, george.ho@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Matthew Hill, matt.hill@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Ralph McNutt, ralph.mcnutt@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States

Understanding the physical processes in both the solar system interplanetary environment and the interstellar medium will be one of the major objectives for an eventual Interstellar Probe (ISP) mission. As shown by the Voyager measurements, the non-thermal ions have key roles in mediating dynamical processes at the termination shock and in the heliosheath, the interface between the solar system and Very Local Interstellar Medium (VLISM). In the 1999 NASA Interstellar Probe Science and Technology Definition Team (IPSTDT) report, a capable energetic particle spectrometer is required to measure the non-thermal ions and electrons to characterize the influence of the interstellar medium on pickup ions, anomalous cosmic ray, and galactic cosmic ray particles. In particular such instrument should able to make energy, composition, directional measurements from above the solar wind plasma energy to several MeV/nucleon. These are the minimum measurement requirements to properly characterize the source and acceleration mechanism of the particle population. In the past, this type of in- situ particle observation has been obtained on platforms that could provide ample instrument resources such as mass, power, and telemetry. However, for a mission to the interstellar space, a new class of miniaturized instrumentation is required. The Johns Hopkins University Applied Physics Laboratory (APL) has been designing and flying field and particle instruments for both heliophysics and planetary missions to the outer solar system, such as Voyager and New Horizons. On both of these missions, the APL particle instruments have made breakthrough science discoveries in both planetary and the outer heliospheric environment. Specifically, the energetic particle instrument on New Horizons that was launched in January 2006 has mass and power that are less than 1.5kg and 2.5W respectively. Since then APL has been leveraging dramatic advances in modern electronics and senor technologies to develop new class of miniaturized instruments that can be accommodated on spacecraft such as ISP and other small satellites.

PIR.1-0032-18 PHYSICS-BASED ASSESSMENT AND ANALYSIS OF CRITICAL SUBSYSTEM FUNCTIONS AND ISSUES FOR AN INTERSTELLAR MISSION

Bradley Boone, brad.boone@jhuapl.edu

Johns Hopkins University, Batimore, Maryland, United States

The goal of a realistic interstellar mission to the nearest star recently announced by NASA as a new space exploration objective targeted for circa 2069, presents a daunting but exciting prospect for creating a pragmatic but visionary mission design. In light of such a long-range mission goal, potential technological developments that might be mission enablers are difficult to foresee with sufficient realism, but the basic physical principles underlying subsystem conceptual design for meeting the mission scientific objectives are well within our grasp. Consequently, an ongoing academically-inspired study at Johns Hopkins University will report on progress in analyzing and evaluating several critical subsystem issues. Contributions from students enrolled in the Applied Physics and Space System curricula will be summarized. These include but are not necessarily limited to the following: acquiring a quality mix of relevant compressed scientific data, optimizing trajectories during transit and destination arrival in the targeted system, insuring a survivable spacecraft bus in an ill-defined but harsh environment, providing an accurate navigation capability at sub-relativistic speeds, insuring a robust communication system over extraordinary distances, and maintaining a survivable but effective command and data handling subsystem. Given the options for a mission trajectory, maintaining spacecraft integrity in close-encounter gravity-assist maneuvers and through long-duration interstellar media at near relativistic speeds will be assessed and analyzed. Maintaining accurate navigation and guidance and control on the cusp of an ever-present "lost in space" condition and the need for exquisite pointing, tracking and stabilization will also be investigated. Finally, the acquisition, storage, and compression of scientific data and its transmission to earth are particularly important regardless of overall mission goals, and will likely require autonomous and intelligent in situ measurements and critical feature extraction. Wherever possible tradeoffs will be exercised and highlighted over the scope of possible missions and will be constrained with respect to system performance and spacecraft size, weight and power (SWaP) requirements. These trades will be made over a range of potential mission scales spanning an interstellar precursor mission (1000 AU) up to a Proxima Centauri scale mission to identify where and how much technology innovation is needed for a closeable design.

PIR.1-0033-18 IN-SITU INVESTIGATION OF THE INTERSTELLAR MEDIUM

Robert Wimmer-Schweingruber, wimmer@physik.uni-kiel.de Christian-Albrechts-Universität zu Kiel, Kiel, Germany

After the exciting in-situ observations of the termination shock and the entry of the Voyager 1 spacecraft into the inner and possibly outer heliosheath, there is a growing awareness of the significance of the physics of the outer heliosphere. Its understanding helps to clarify the structure of our immediate interstellar neighborhood, contributes to the clarification of fundamental astrophysical processes like the acceleration of charged particles at a stellar wind termination shock and beyond, and also sheds light on the question to what extent interstellar-terrestrial relations are important for the environment of and on the Earth and of exoplanets. In order to explore the boundary region of the heliosphere, it is necessary to send a spacecraft to perform advanced in-situ measurements particularly in the heliosheath, i.e. the region between the solar wind termination shock, and the heliopause, as well as in the (very) local interstellar medium. Solar activity is decreasing to 'normal values' below those of the Grand Solar Maximum which was typical of the space age so far. This is likely to reduce the size of the heliosphere and allows us to study a 'normal' heliosphere by launching an Interstellar Probe (IP) which will also provide within a shorter time than previously believed the first comprehensive measurements of key parameters of the local interstellar environment such as its composition, state, and magnetic field. Together with an accurate determination of the state of the heliospheric plasma across the heliosphere, these quantities are crucial to our understanding of how the heliosphere, and, much more generally, astrospheres, are formed and how they react to varying interstellar environments.

PIR.1-0034-18 APPROACH TO ADDRESSING RELIABILITY AND UNCERTAINTIES FOR A 50 YEAR MISSION

Clayton Smith, clay.smith@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Ralph McNutt, ralph.mcnutt@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Michael Paul, michael.paul@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Brenda Clyde, brenda.clyde@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States

NASA is currently studying a possible Interstellar Probe mission concept that would venture in to the unknown space between our star and other potentially habitable planetary systems. This mission could approach 20 AU/year asymptotic speed; target operations out to 1000 AU, meaning the spacecraft would need to operate for 50 years or more. In designing such a mission, the reliability of the spacecraft and instruments is critically important. This paper addresses the general approach to assess the reliability concerns for such an undertaking. The approach needs to integrate the understanding of failure mechanisms over time and environmental interactions with a robust fault management system, functionally redundant systems, and a resilient architecture. Included in this approach is the application of probabilistic methods to discern where uncertainties and risk drivers exist and inform a testing campaign to reduce them to an acceptable level of risk.

PIR.1-0035-18 PRAGMATIC MAXIMIZATION OF ASYMPTOTIC FLYOUT SPEED FOR NEARTERM EXPLORATION OF THE INTERSTELLAR MEDIUM

Brian Lathrop, brian.lathrop@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Ralph McNutt, ralph.mcnutt@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Michael Paul, michael.paul@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Steven Vernon, steven.vernon@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Olney, Wyoming, United States

Near-term exploration of the interstellar medium in the region of 200-1000 AU is possible with existing technology, but remains programmatically challenging due to the long travel times, long periods of mission inactivity, and overall mission costs. We consider multiple trajectories that will provide a range of possible science returns, including the in situ measurements so needed from the interstellar medium itself. Flybys of the gasor icegiant planets, observations of our solar system disk and zodiacal light, a second reconnaissance of Pluto, flybys of newly discovered Kuiper Belt Objects, or a close-up of the putative super-earth, “Planet Nine,” all present compelling opportunities but require different departure trajectories, or aim-points. Furthermore, an Interstellar Probe Mission departing the solar system at up to 20 AU/year will fly by objects in our solar system at many 10s of kilometers per second, several times faster than New Horizons’ flyby of Pluto. We will present trajectories that address these different objectives, possible overlapping solutions, challenges to achieving different families of solutions, and ultimate asymptotic fly-out speeds.

PPP.1-0001-18 RECENT CHANGES IN THE NASA OFFICE OF PLANETARY PROTECTION

Lisa Pratt, lisa.m.pratt@nasa.gov

NASA, DC, District of Columbia, United States

NASA has been active in the implementation of planetary quarantine/protection practices and policies since the 1950's when both COSPAR and NASA were founded. In 2017, NASA moved primary responsibility for planetary protection from the Science Mission Directorate to the Office of Safety and Mission Assurance. Reorganization within NASA allows for closer coordination between the Planetary Protection Office and the expanding technical needs of robotic and human spaceflight missions to comply with planetary protection requirements. In addition to supporting numerous missions, the Planetary Protection Office is NASA's focal point for interactions with COSPAR and other international agencies on matters related to terrestrial biological contamination during exploration of other planetary bodies and to extraterrestrial contamination of Earth during sample return. Research on scientific knowledge for planetary protection and development of advanced methods for life detection will be collaboratively managed by the science mission directorates and the Planetary Protection Office.

PPP.1-0002-18 PLANETARY PROTECTION ORGANIZATION ESTABLISHED IN JAXA

Akihiko Yamagishi, yamagish@ls.toyaku.ac.jp

Tokyo University of Pharmacy and Life Science, Hachioji, Japan
Kazuhisa Fujita, fujita.kazuhisa@jaxa.jp

Japan Aerospace Exploration Agency (JAXA), Tokyo, Japan

Japan Aerospace Exploration Agency (JAXA) has been contributing space exploration for several decades. During the period, JAXA space missions have been implemented and been evaluated to accord with planetary protection policy of COSPAR. However, there have been no JAXA organization specifically responsible for the management of planetary protection policy. We have established the planetary protection organization in JAXA, recently. Though we are still on the way of establishing organizations and preparing domestic code to accord with COSPAR planetary protection policy, we will report the current status of the JAXA planetary protection organization.

PPP.1-0003-18 PLANETARY PROTECTION AND THE LAW: LEGAL CONSEQUENCES OF OUTER SPACE CONTAMINATION

Eloi Petros, eloi.petros@idest-paris.org IDEST, Université Paris-Sud, Paris, France

Planetary Protection is (also) a legal principle. The prevention of “harmful contamination” is subject to an entire article of the Outer space treaty, the major international law instrument that governs space activities, in force in 105 countries. The legal nature of Planetary Protection may have legal consequences. This article will address the concrete mechanisms and possible solutions to be find in law in the hypothesis of outer space contamination. The diversification of space activities and the growing number of actors involved in it raise new issues regarding the general application of international space law. Among them, the recognized principle of Planetary Protection shall be addressed and its legal implications shall be studied. The question shall then be asked of what can be done, on a legal basis, regarding a planned activity which may lead in a “harmful contamination”. Which legal process may apply to prevent such a situation? What are the concrete tools that law provides to deal with this situation? Finally, the issues regarding the legal consequences of harmful contamination caused by a passed operation in outer space shall also be addressed. Answering those interrogation will involve to focus on the international law mechanisms that may apply and to determine the actors, such as States or international organizations, which could initiate a legal procedure. Studying Planetary Protection through its legal nature allows to consider its concrete implications and to reinforce the effectiveness of its recommendations.

PPP.1-0004-18 LACUNA IN THE UPDATED PLANETARY PROTECTION POLICY AND INTERNATIONAL LAW

Patricia Sterns, pms@astrolaw.com

Law Offices of Sterns and Tennen, Phoenix, Arizona, United States
Leslie Tennen, ltennen@astrolaw.com

Law Offices of Sterns and Tennen, Glendale, Arizona, United States

The Planetary Protection Policy (PPP) has proclaimed the lofty ideal "All the planets, all the time." Originally formulated as Planetary Quarantine Requirements (PQR), the policy imposed strict decontamination standards for spacecraft during the initial period of interplanetary exploration. The policy properly has been seen as a work in progress, continuously open to consideration of new data, and subject to periodic re-examination and question with a view toward improvement to better meet the goals of science. This process has led to several revisions of the PPP to improve, simplify and clarify the standards.

In keeping with past practice, the policy was recently revised in light of new data and experience, and the current update is pending before the COSPAR Bureau and Council for review and approval. Specific changes to the PPP add Enceladus to the group of target bodies within the solar system subject to heightened protective measures, and modify the provisions regarding the establishment of special regions on Mars.

These new updates mark another important development in the evolution of the PPP. The PQR and the PPP were based on the precept that outbound spacecraft to celestial bodies should not contaminate natural celestial environments with Earth organisms. Therefore, the policy generally requires that certain missions, particularly to target bodies that could harbor evidence of past or current alien life, take active measures to decontaminate the spacecraft. Nevertheless, recent and proposed missions demonstrate that significant gaps remain in the policy. Instead of enhancing decontamination the policy actually promotes purposely and intentionally enlarging the number of potentially contaminating Earth organisms carried by a spacecraft that could reach celestial bodies, including those bodies which are subject to active decontamination requirements. Thus, even with the new updates, the PPP may not be fully consistent with the international obligations of the Outer Space Treaty, and the continued existence of the entire PPP policy could be in jeopardy.

This article discusses the flight characteristics of two specific missions, one launched and one in development, which are consistent with the PPP but nonetheless pose a substantial risk of biological contamination of celestial bodies. The manner in which the risks can be reduced is identified, and suggestions are made to close some of the gaps that remain in the PPP to comply with international law.

PPP.1-0005-18 IMPLEMENTING PLANETARY PROTECTION MEASURES FOR COMMERCIAL SPACE MISSIONS: INTERNATIONAL STANDARDS AND NATIONAL LEGISLATION

John Rummel, jrummel@seti.org

SETI Institute, Champlain, New York, United States

When international discussions about protecting against biological and organic contamination began in the late 1950s, the subject was known as "spacecraft sterilization" or "planetary quarantine," and the discussants naturally assumed that space missions that might spread contamination would be state-sponsored. In fact, it was largely the United States that insisted that the 1967 United Nations Outer Space Treaty (OST) contain the possibility for private space flight to be allowable and subject to the OST, itself. Thus, Article VI of the treaty allows for activities in outer space to be carried out by non-governmental entities, but to "require authorization and continuing supervision by the appropriate State Party to the Treaty." Along with Article VI, a key set of provisions in the OST are to be found in Article IX, which requires States Parties to the Treaty to "pursue studies of outer space, including the Moon and other celestial bodies, and conduct exploration of them so as to avoid their harmful contamination and also adverse changes in the environment of the Earth resulting from the introduction of extraterrestrial matter and, where necessary, [to] adopt appropriate measures for this purpose." Also stated is the obligation that "If a State Party to the Treaty has reason to believe that an activity or experiment planned by it or its nationals in outer space. . would cause potentially harmful interference with activities of other States Parties. . it shall undertake appropriate international consultations before proceeding with any such activity or experiment." These basic treaty commitments bind any national government that is signatory to the OST to move carefully and thoughtfully when implementing national regulations that provide for authorization and continuing supervision of space activities conducted by private, commercial entities. Given that the COSPAR Planetary Protection Policy has been recognized by the UN Committee on the Peaceful Uses of Outer Space (COPUOS) "as a reference standard for spacefaring nations and in guiding compliance with Article IX of the Outer Space Treaty" it might be considered that adherence to the COSPAR policy, at least in broad outlines, should be a fundamental building block of national regulations implementing the OST, and of any further elaboration of international law regarding space exploration and use. Such an addition was recently included as a building block by The Hague International Space Resources Governance Working Group (their Draft Building Block 9), and is consistent with both recent regulations from Luxembourg and the intention (if not the specific wording) of recent space commerce legislation being considered in the United States. COSPAR has recently (March 2017) taken steps to ensure a broadened representation on the Panel of Planetary Protection to assist with the general understanding of the purpose and consequences of its planetary protection policy, and the Panel terms of reference document now contains the explicit provision that the policy "should be based upon the principle that COSPAR planetary protection policies should enable the exploration of the solar system, not prohibit it." COSPAR policies do not exist to prohibit space resource and other commercial use of outer space, but rather to inform that use and ensure that a full understanding of the costs and the benefits of space missions to other worlds is accessible and can be part of the decision process to approve such a mission.

PPP.1-0006-18 NEXT STEPS IN PLANETARY PROTECTION FOR HUMAN SPACEFLIGHT

Julie Mitchell, julie.l.mitchell@nasa.gov NASA/JSC, Houston, Texas, United States Cynthia Evans, cindy.evans-1@nasa.gov

NASA Johnson Space Center, Houston, Texas, United States Eileen Stansbery, eileen.k.standbery(at)nasa.gov NASA/Johnson Space Center, Houston, Texas, United States

Planetary protection is defined as: a) the prevention of contamination of extraterrestrial bodies by terrestrial microorganisms, and b) biohazard containment of returned samples from bodies in the Solar System that could harbor life.1 While the majority of interplanetary missions to date have involved robotic exploration, future missions will include human explorers. Current planetary protection requirements do not address the unique challenges associated with human exploration. The purpose of this abstract is to review planetary protection efforts for crewed missions and provide a forward plan for implementing them at the systems level.

Article IX of the UN Outer Space Treaty of 1967 provides the definition of planetary protection, outlined above.1 COSPAR holds the international standard in line with this treaty2, while NASA's Planetary Protection Policy (NPD 8020.7G) outlines the U.S. implementation of the COSPAR standard.3,4 NPI 8020.7 groups future human spaceflight planetary protection studies as follows: 1) microbial monitoring, 2) contamination mitigation and control, and 3) environmental effects. Additionally, a NPI 8020.7 outlines a five-step plan for forward work: 1) a literature review, 2) community inputs, 3) completion of recommended studies, 4) developing a draft NPR, and 5) implementation with NASA teams. The literature review was published in 2016.5 Inputs from the community were gathered at the Planetary Protection Knowledge Gaps for Human Extraterrestrial Missions, held in 2015.6 Johnson and Race (2016) outlined notional requirements and prioritized studies needed before final requirements can be produced. This prior work sets the stage for completing the necessary studies and finalizing planetary protection requirements for human spaceflight.

We propose a continuation of the systems engineering approach adopted thus far. The challenges associated with the implementation of notional requirements will be quantified in detailed discussions with internal stakeholders. The status and results of high-priority studies that have been completed since 2016 or are ongoing will be incorporated into discussions with stakeholders. In this way, we plan to bridge the gap between the science behind planetary protection and the engineering development that will implement it, allowing finalized planetary protection requirements to be developed for future human space missions.

The PPOSS project is an initiative supported by the European Commission under the H2020 programme (2016-2018) that provides an international platform and forum where science, industry and policy actors meet to nurture discussions and exchange knowledge on planetary protection of the outer solar system. This project is structured around three basic pillars that encompass the description of the state of the art and good practices to implement planetary protection requirements, the identification of scientific challenges and knowledge gaps in relation to the outer solar system and the development of an engineering roadmap for the European industry sector.

In the context of the findings and outcome from these activities, as well as targeted consultation with stakeholders, an overall integration is being made towards providing strategic advice and recommendations for planetary protection of outer solar system bodies.

A high level international integration committee, including representatives from space agencies and the scientific community, among others, will meet at two occasions during 2018 and as result, a policy briefing document substantiating the recommendations will be put forward to COSPAR Panel on Planetary Protection.

The PPOSS project Coordination and Support Action has received funding from the European Comission's H2020 Programme (2016-2018) under grant agreement 687373

PPP.1-0008-18 FORWARD CONTAMINATION PLANETARY PROTECTION FOR OCEANWORLD EXPLORATION: A STAKEHOLDER CONVERSATION

Brent Sherwood, brent.sherwood@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States Adrian Ponce, ponce@caltech.edu

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Michael Waltemathe, michael.waltemathe@rub.de Ruhr-University Bochum, Bochum, Germany

Robotic exploration of our solar system's ocean worlds - especially icy moons of Jupiter and Saturn with vast interior oceans - is imminent. Within decades, our probes could conceivably encounter alien microbial life. In Earth's analogues - seafloor hydrothermal vents and cryosphere - life abounds. This makes the risk of "forward con-tamination" real. How ready are we? What are humanity's obligations? Today's governing requirement is a single value: limiting to 10e-4 the probability of a viable Earth organism entering a liquid water reservoir. By international treaty, this forward-contamination requirement constrains NASA, JAXA, ESA, and private companies. It strongly drives concepts, procedures, technologies, and costs. But where did this value come from? Is it appropriate? Is protection of future science the only consideration that matters? The 10e-4 requirement has not changed since its origin. It may still be appropriate for the mission concepts we are now designing, but without a refreshed, explicit conversation among an international cross-section of stakeholders, mission plans may be at risk. Our technical community may learn that other viewpoints matter. Many changes could justify revisiting the requirement rationale: 1) improved technology for bio-assays; 2) expanded definition of self-replicating organisms; 3) recognition that diverse environments can be habitable; 4) understanding of multi-cellular community behavior; 5) expanded astrobiology target list; and 6) evolved sociological and international context for setting technology policy. We briefly describe the requirement's origin, and summarize progress in biology of extremophiles, scenarios for the origin of life, self-replication of non-life macromolecules, evolution in changing environments, and how microbial communities sustain habitability. All these factors affect how we might quantify the probability of survival and replication in a given alien environment. We summarize how policies are developed for low-probability, high-consequence risks, including compensation of cognitive limitations about probabilities and how perceptions of risk are acculturated. We consider the application of the risk of contaminating another world: an irreversible event affecting subsequent generations, albeit with-out physical hazard. We assess how decision responsibility might be distributed, and the ethical dimension that could affect our community's definition of forward-contamination requirements. We compare this case

to other cases where society has dealt with technical risks full of unknowns, and describe how a stable stakeholder consensus could be developed to underpin governing policy.

PPP.1-0009-18 REVIEW OF PLANETARY PROTECTION POLICY DEVELOPMENT PROCESS

David H. Smith, dhsmith@nas.edu

National Academies of Sciences, Engineering and Medicine, Washington, District of Columbia, United States

Joseph K. Alexander, joseph.k.alexander@hotmail.com

Alexander Space Policy COnsultants, Oro Valley, Arizona, United States

In response to a request from NASA, the National Academies of Sciences, Engineering, and Medicine has conducted a study to review the current state of the planetary protection pol- icy development process. The study addresses two key questions. First, is the U.S. and international policy-making process responsive to the present state of science, technology, and engineering? Second, can the current policy-development process be extended to encompass the commercial and exploration interests of state and non-state actors? The paper will present a summary of the study's main conclusions and recommendations on how to ensure that the planetary protection policy process is supportive of future scientific and societal interests, including traditional robotic spacecraft missions, human exploration activities, and burgeoning private sector endeavours.

PPP.1-0010-18 PLANETARY PROTECTION CHARACTERIZATION OF SAMPLE-RETURN MISSIONS FROM THE MARTIAN MOONS

David H. Smith, dhsmith@nas.edu

National Academies of Sciences, Engineering and Medicine, Washington, District of Columbia, United States

Emmanouil Detsis, edetsis@esf.org

European Science Foundation, Strasbourg, France

The Committee on Planetary Protection Requirements for Sample-Return Missions from the Martian Moons

David Pearce, Northumbria University, Newcastle, United Kingdom; Athena Coustenis, Observatoire de Paris, Meudon, France; Michael J. Daly, Uniformed Services University of the Health Sciences, Washington, D.C., USA; Abigail Fraeman, Jet Propulsion Laboratory, Pasadena, California, USA; Guy Libourel, Observatoire de la Côte d'Azur, Nice, France; Akiko Nakamura, Kobe University, Kobe, Hyogo, Japan; Robin Putzar, Fraunhofer Institute for High-Speed Dynamics, Freiburg, Germany; Kaliat T. Ramesh, The Johns Hopkins University, Baltimore, Maryland, USA; Norman H. Sleep, Stanford University, Palo Alto, California, USA; and Megan Bruk Syal, Lawrence Livermore National Laboratory, Livermore, California, USA;

COSPAR's planetary protection policy does not currently specify the status of sample-return missions from Phobos or Deimos, the moons of Mars. Although the moons themselves are not considered potential habitats for life or of direct relevance to prebiotic chemical evolution, recent studies indicate that a significant amount of material ejected from Mars in the recent past could be present on the surface of Phobos and, to a lesser extent, Deimos. Such interplanetary ejecta might mediate the transfer of viable organisms from Mars to its moons. JAXA, in cooperation with NASA and ESA, is developing the Martian Moons Exploration (MMX) mission to return samples from Phobos or Deimos to Earth in the late 2020s. The detailed design of MMX will depend on whether or not the samples collected are designated as restricted or unrestricted Earth return. The former designation, per NASA, ESA, JAXA and COSPAR policy, would require that MMX "break the chain of contact" between the sampled object and Earth. In addition, the samples will need to be maintained in high containment and undergo a biohazard test protocol after return to Earth. To lessen the scientific uncertainties concerning the planetary protection status of the martian moons, NASA and ESA commissioned research to assess the extent to which material from Mars might be deposited on its moons and to assess if the post-ejection environmental conditions might inactivate potential martian life transported to Phobos and Deimos. The tests included hypervelocity impact inactivation of relevant Earth organisms, as well as ionizing radiation and heat. To provide an independent assessment of the results of the aforementioned research activities and to recommend whether or not samples return from the martian moons be classified as restricted or unrestricted Earth return, NASA and ESA issued parallel request to the National Academies of Sciences, Engineering and Medicine and the European Science Foundation (ESF), respectively. The paper will briefly summarize the activities of the joint committee established by the National Academies and ESF to undertake the requested assessment.

PPP.1-0011-18 REPORT ON THE JOINT WORKSHOP ON INDUCED SPECIAL REGIONS

Michael Meyer, michael.a.meyer@nasa.gov

NASA Headquarters, Washington, D.C., District of Columbia, United States Catharine Conley, cassie.conley@nasa.gov

NASA Headquarters, Washington D.C., District of Columbia, United States Robert Lindberg, robert.lindberg@cox.net

University of Virginia, Charlottesville, Virginia, United States Clive Neal, cneal@nd.edu

University of Notre Dame, Notre Dame, Indiana, United States Ingrid Feustel, feustel.ingrid@epa.gov

US Environmental Protection Agency, Washington, District of Columbia, United States

The Joint Workshop on Induced Special Regions convened scientists and planetary protection experts to assess the potential of inducing special regions through lander or rover activity. A Special Region is defined as a place where water activity and temperature are sufficiently high and persist for long enough to plausibly harbor life. The Workshop, sponsored by both the former Planetary Protection Subcommittee and the Planetary Science Subcommittee, was anticipated to be the first of a series spanning the intersection of planetary protection and science.

Recognizing that the participants were approaching the concept of induced special regions from very different perspectives, the conveners provided a set of questions in advance of the workshop, to be answered by the intended participants. The intention was to develop: a common understanding of several disciplines needed to discuss Mars exploration potentially involving Special Regions, foundational knowledge for constructive workshop discussion, and input to help construct the agenda of talks and discussion groups for the workshop.

The Workshop was hosted by USRA at their headquarters facilities in Columbia, MD, November 29 - December 1, 2017. In the first part of the workshop, the conveners and participants reviewed the goals of the workshop and definitions of terms in order to establish a common base for discussion, including a review of the answers to the questions distributed before the workshop. Conveners then introduced three new, more specific questions addressing items that could directly affect mission operations and design. This was followed by introductory presentations by participants with pertinent expertise on four major subjects at play concerning those questions.

The questions presented were: 1. What is a safe stand-off distance, or formula to derive a safe distance, to a purported special region? a. What is viability/distance for micro-organism transport? b. Is there a residence time for a lander on Mars by when a rover/lander will be "safe"? 2. Questions about RTGs, other heat sources, and their ability to induce special regions:

a. Can a rover RTG on the surface induce a special region? Under what specific conditions? b. Can a buried RTG induce a special region? Does it pose a long-term contamination "threat?"

Is it possible to have an infected area on Mars that does not contaminate the rest of Mars?

What would be a proper buffer zone?

The participants were then divided into three subgroups, each possessing a balance of different expertise and personalities. All three subgroups addressed each question separately, and presented their answers in plenary sessions. Through this process, workshop conveners hoped to create an environment where everyone in the subgroups would have a voice, and each of the subgroups would have the opportunity to develop unique answers, in order to highlight areas of consensus and divergence. The resulting presentations from each group provided the opportunity for in-depth discussion in areas of disagreement with all expertise represented. On the final day, the participants were S. remixed into three new groups, and each group synthesized the responses to one of the workshop questions from material developed over the previous two days, with the goal of deriving the consensus view. In the final plenary session, the answers to the questions were reviewed, discussed, and consensus achieved.

The workshop participants reached a general consensus addressing the posed questions, details of which will be presented at the session. 1. While a spacecraft on the surface of Mars may not be able to explore a special region during the prime mission, the safe stand-off distance would decrease with time because the sterilizing environment that is the martian surface would progressively clean the exposed surfaces. However, the analysis supporting such an exploration should ensure that the risk to exposing interior portions of the spacecraft (i.e., essentially unsterilized) to the martian surface is minimized. 2. An RTG at the surface of Mars would not create a Special Region but the result depends on kinetics of melting, freezing, deliquescence, and desiccation. While a buried RTG could induce a Special Region, it would not pose a longterm contamination threat to Mars, with the possible exception of a migrating RTG in an icy deposit. 3. Induced Special Regions can allow microbial replication to occur (by definition), but such replication at the surface is unlikely to globally contaminate Mars. An induced subsurface Special Region would be isolated and microbial transport away from subsurface site is highly improbable.

PPP.1-0012-18 REPORT ON THE 2018 COSPAR PANEL ON PLANETARY PROTECTION COLLOQUIUM

Gerhard Kminek, gerhard.kminek@esa.int ESA, Noordwijk, Netherlands

In consultation with the COSPAR Scientific Commissions B (Space Studies of the Earth-Moon System, Planets, and Small Bodies of the Solar System) and F (Life Sciences as Related to Space), the COSPAR Panel on Planetary Protection is organising a colloquium to cover all aspects related to update the COSPAR Planetary Protection Policy, mainly:

Phobos/Deimos sample return planetary protection category and requirements 2. Icy moon planetary protection requirements 3. Mars Special Regions planetary protection requirements

These three topics are addressed in dedicated meetings and reviews and are reported during this session. Results and recommendations described in these report and consequences for the COSPAR Planetary Protection Policy are discussed during the colloquium. A consolidated update of the COSPAR Planetary Protection Policy, including editorial updates, is prepared during the colloquium for discussion during the 2018 COSPAR Scientific Assembly.

PPP.1-0013-18 REORGANISATION OF THE COSPAR PANEL ON PLANETARY PROTECTION

Gerhard Kminek, gerhard.kminek@esa.int ESA, Noordwijk, Netherlands

The COSPAR Panel on Planetary Protection is mandated to promulgate, and maintain with new scientific and technological advances taken into account, a planetary protection policy for the reference of spacefaring nations, both as an international standard on procedures to avoid organic-constituent and biological contamination in space exploration, and to provide accepted guidelines in this area to guide compliance with the wording of the UN Outer Space Treaty of 1967 and other international agreements. The Panel on Planetary Protection is cited in the COSPAR Strategy Statement, adopted March 2015, as a principle vehicle by which COSPAR fulfills one of its Missions: Support of Developed Space Programs. Henceforth, it is proposed that the COSPAR Panel on Planetary Protection Terms of Reference be updated so that the it can continue to fulfill its mandate of supporting spacefaring nations involved in planetary protection.

PPP.1-0014-18 CONSIDERING PLANETARY PROTECTION OF OUTER SOLAR SYSTEM BODIES - THE EUROPEAN PPOSS PROJECT

Patricia Cabezas, pcabezas@esf.org

European Science Foundation, Strasbourg, France PPOSS Team

Nicolas Walter Emmanouil Detsis Jean Louis Fellous Alissa Haddaji Petra Rettberg Elke Rabbow Jean-Charles Treuet Mark Septhon Sam Royle John R. Brucato Susan McKenna Lawlor

With the increasing evidences of the presence of liquid water in the outer solar system, the number of potential habitable environment increases, as a consequence, the issue of contaminating these environments is more and more important and relevant. There are currently six ongoing missions to the outer solar system and small bodies and the main space agencies are currently planning several exploration missions to the outer solar system (in particular asteroids and the Jovian system).

Space exploration missions are international endeavours and planetary protection is by nature an issue of global relevance. While planetary protection policy is discussed and defined at the international level, it is important to reach a common understanding of planetary protection issues, in particular in the context of future collaborative exploration missions.

The PPOSS project is an initiative supported by the European Commission under the H2020 programme that provides an international platform and forum where science, industry and policy actors meet to nurture and catalyse discussions, exchange of knowledge and produce policy recommendations on the matter of planetary protection. It will look at case studies, lessons learnt and good practices in order to pave the way for an improved and more informed policy for planetary protection of outer solar system bodies, in particular icy moons. Looking forward, PPOSS will identify scientific challenges and knowledge gaps as well as define scientific requirement for outer Solar system bodies planetary protection. PPOSS will also involve interactions with the European industry and will develop as set of European industry roadmaps. Eventually PPOSS will integrate the information and knowledge generated through the project to provide science and policy recommendations for the definition, improvement, and implementation of an adequate planetary protection policy for outer solar system bodies.

PPOSS will be active for three years (2016-2018) and is structure around a well-defined and coherent work plan that includes five lines of actions:

1) International Planetary Protection Handbook: describe the state of the art and good practice for implementing planetary protection requirements, and identify good practices and lessons to be learnt. 2) Research White Book: identify scientific challenges, scientific requirements and knowledge gaps related to planetary protection of outer solar systems bodies, including small solar system bodies. 3) European Planetary Protection Industry Roadmap: develop an European engineering roadmap for the industry sector. 4) Strategic advice and recommendations: review of the international outer solar system planetary protection regulation structure and categorisation, suggest improvements. 5) Transfer of knowledge: facilitate the dissemination of knowledge related to planetary protection.

The PPOSS project Coordination and Support Action has received funding from the European Comission’s H2020 Programme (2016-2018) under grant agreement 687373.

PPP.1-0015-18 FROM APOLLO TO THE FUTURE, THE NASA CURATION MODEL FOR ENGAGING THE SAMPLE SCIENCE COMMUNITY MAXIMIZES SCIENCE ON EXTRATERRESTRIAL SAMPLES

Judith Allton, judith.h.allton@nasa.gov

NASA/Johnson Space Center, Houston, Texas, United States Laurence Nyquist, laurence.e.nyquist@nasa.gov NASA/Johnson Space Center, Houston, Texas, United States Francis McCubbin, francis.mccubbin@gmail.com

NASA/JSC, Houston, Texas, United States Kevin D. McKeegan, kmckeegan2008@gmail.com UCLA, Los Angeles, California, United States Kevin Righter, kevin.righter-1@nasa.gov

NASA Johnson Space Center, Houston, Texas, United States

The Astromaterials Acquisition and Curation Office at Johnson Space Center (JSC) has enjoyed a long-term partnership (50 years!) with a broad community of planetary sample scientists. This partnership has enabled the curators of planetary samples to plan for and enact evolving requirements for preservation of sample scientific integrity and for handling and long-term storage. The basis for this relationship is a standing peer review advisory committee composed of leading scientists who are recognized for achievements in sample analysis. The committee and its descendants have brought familiarity with the most relevant scientific investigations and the associated analytical and contamination challenges.

Beginning with Apollo, the review committee was charged with oversight of curatorial operations and with ensuring fair access to samples. As additional samples from other planetary bodies were acquired, the committee evolved, taking on new responsibilities, reflected in committee name changes. However, oversight of curatorial operations and fair allocation of samples remain basic responsibilities. Committee recommendations are sent to the NASA Headquarters Discipline Scientist for approval. To minimize conflict of interest and maximize fair access, the rules governing the make-up of the committee is structured. Systematic rotation of leadership and staggered terms of membership allow the committee to retain expertise while bringing in fresh ideas.

The first peer review committee was called the Lunar Sample Analysis and Planning Team (LSAPT) and was formalized in early 1968 with about 15 members. Their function was to review a) the equipment and procedures used in the new Lunar Receiving Laboratory (LRL);

b) the proficiency and capability of the LRL staff; c) the sequence of sample analysis and allocation after quarantine release; and d) the findings of the Preliminary Examination Team (PET) [1]. According to the LSAPT member Gerald Wasserburg, one of the first issues they faced was deciding whether to have most of the sample analyses performed in house at the LRL or to distribute samples to members of the scientific community [2]. LSAPT concluded that the major scientific investigations should be carried out externally to the LRL by scientists chosen for their expertise in specific disciplines. Further they recommended that the PET's basic characterization of samples be circulated to the broad scientific community. LSAPT set its own agenda, paid attention to facility details, closely monitored the move of samples from the LRL to the interim curatorial facility in 1973, and was active in inspecting curation facilities. Between 1975 and 1979, a Facility Subcommittee of LSAPT oversaw the design and construction of a permanent facility for preservation of lunar samples. The result was an outstanding facility still in use today.

In 1977, a separate peer review committee, the Meteorite Working Group (MWG), was formed to evaluate requests for new meteorites then being collected in Antarctica under what would in 1980 become a 3-agency agreement (National Science Foundation, NASA, Smithsonian Institution) [3]. By 1979, after lunar samples were moved into the new permanent facility, the vacated gloveboxes and laboratory were prepared for meteorite curation. Recognizing that LSAPT had been helpful in setting up the JSC curatorial facility for Antarctic meteorites, JSC recommended the review committee be given expanded duties, including advice on curation and analysis of materials from other planetary bodies and the name be changed to Lunar and Planetary Sample Team (LAPST) [4]. In 1993, LAPST was renamed the Curation and Analysis Planning Team for Extraterrestrial Materials (CAPTEM) to reflect additional functions. CAPTEM is chartered to be (1) a community-based, interdisciplinary forum for discussion and analysis of matters concerning the collection and curation of extraterrestrial samples, including planning future sample return missions and (2) a standing review panel, charged with evaluating proposals requesting allocation of all extraterrestrial samples contained in NASA collections [5].

Efficiency and flexibility are gained through use of subcommittees, both ad hoc and standing. Transition of the MWG to a subcommittee of CAPTEM was completed in 2017. Today subcommittees review allocation requests for lunar samples, Antarctic meteorites, cosmic dust, Stardust cometary samples, Genesis solar wind samples, and samples returned from asteroids. Other subcommittees address facilities, informatics, and micro-cratered substrates. Planetary samples have been sent to research teams in over 30 countries world-wide. The expertise in the care and fair distribution of astromaterials by NASA using this model spans generations of planetary sample scientists and is a valuable resource to be tapped for future sample returns - OSIRIS-REx, Hayabusa 2, and Mars 2020.

PPP.1-0016-18 THE IMPORTANCE OF SAMPLE RETURN, CURATION, AND PLANETARY PROTECTION FOR NASA'S EXPLORATION OF OUR SOLAR SYSTEM

Eileen Stansbery, eileen.k.stansbery@nasa.gov

NASA Johnson Space Center, Houston, Texas, United States Cynthia Evans, cindy.evans-1@nasa.gov

NASA Johnson Space Center, Houston, Texas, United States Francis McCubbin, francis.mccubbin@gmail.com NASA/JSC, Houston, Texas, United States

Ryan Zeigler, ryan.a.zeigler@nasa.gov

NASA Johnson Space Center, Houston, Texas, United States

Sample return is an essential component of solar system exploration that enhances the understanding of our solar system acquired with fly-by, orbital, or surface missions, by providing a unique data set critical for understanding the formation and evolution of our solar system — material from another planetary body available for study in laboratories on Earth. The ability to perform analysis in well-equipped terrestrial laboratories enables scientific progress not possible with analyses performed in situ during a mission. These include, but are not limited to, much higher precision, replication of results, investigations at very small scales (down to picometers), sample manipulation capability and processing, and the ability to modify analytical experiments as logic and technology evolves. Analysis of returned samples contributes fundamental chronological and geochemical ground truth of planetary materials that enhances the value of both remotely sensed and surface observations beyond their stand-alone importance. Further, sample return is a critical component of the human exploration program for human health and safety issues as well as resource detection and characterization. [1]

As we visit other worlds, both robotically and with humans, we have a responsibility to comply with planetary protection provisions in support of U.S. obligations under the 1967 Outer Space Treaty. It is NASA's policy that the conduct of scientific investigations of possible extraterrestrial life forms, precursors, and remnants must not be jeopardized. In addition, the Earth must be protected from the potential hazard posed by extraterrestrial matter carried by a spacecraft returning from another planet or other extraterrestrial sources. Therefore, for certain space-mission/target-planet combinations, controls on organic and biological contamination carried by spacecraft shall be imposed in accordance with directives implementing this policy. [2] NASA requirements for planetary protection addresses: (a) the control of terrestrial microbial contamination associated with robotic space vehicles intended to land, orbit, flyby, or otherwise encounter extraterrestrial solar system bodies, and (b) the control of contamination of the Earth and the Moon by extraterrestrial material collected and returned by robotic missions. [3]

Because much of the research done on returned extraterrestrial samples involves high resolution analyses, small amounts of contaminants, whether obtained during system development/ fabrication, collection, or subsequent handling and storage on Earth, can degrade and impair scientific measurements and hence the value of the samples. Among the primary purposes of astromaterials curation are to (a) safeguard the scientific integrity of extraterrestrial materials and (b) make them available for scientific study. [4] As a result curation has a major role in sample collection and return mission planning especially in the areas of contamination knowledge and control. Early mission involvement provides a means to advise on decisions that affect long-term scientific integrity of collected extraterrestrial materials [5] and collect the information and spacecraft coupons necessary to archive direct evidence of the as-flown collection approach and condition to be able to resolve future potential analytical questions. A key benefit of terrestrial laboratory analysis of returned samples is the ability to replicate results. Important, unexpected, or ambiguous analyses can be verified by independent experimental techniques and independent laboratories but may also require access to pre-flight contamination knowledge or as-flown material coupons. [6] This is becoming increasingly important for new mission concepts associated with icy bodies, organically interesting destinations, and investigating indicators for extraterrestrial life.

Although the purpose and objectives of planetary protection and curation are very different, there is overlap in some of the activities and data needs—especially in the areas of contamination control and contamination knowledge which are of vital importance to both.

PPP.1-0017-18 INCREMENTAL PROGRESS TOWARDS DEVELOPING PLANETARY PROTECTION REQUIREMENTS FOR HUMAN MISSIONS: OVERVIEW OF RECENT WORKSHOPS, FINDINGS AND PLANS

Margaret Race, mracemom@aol.com

SETI Institute, Mountain View, California, United States

The Committee on Space Research (COSPAR) maintains a planetary protection policy with associated requirements as an international reference standard for spacefaring nations to guide compliance with Article IX of the UN Outer Space Treaty. Updating the COSPAR Plane- tary Protection Policy is an iterative process based on new discoveries, new understanding of scientific observations, and/or a response to needs identified to prepare future space missions. The current COSPAR policy for human missions to other celestial bodies is built around a set of qualitative principles and guidelines adopted in 2009, which address the rationale, but not the specific requirements for implementation of planetary protection on crewed missions. With plans underway for future human exploration beyond LEO, planetary protection measures must be re-considered and incorporated into the design, development and operations of diverse systems, including space suits, habitat modules, rovers, in-situ resource utilization (ISRU) equipment, waste disposal systems, containment hardware, and more.

Because of insufficient scientific and technological knowledge for establishing quantitative requirements, NASA initiated a stepwise path aimed at translating COSPAR Principles and Guidelines into detailed requirements. What followed from the initial NASA effort has been a multi-year, international and interdisciplinary process that has focused on three specific areas of importance to planetary protection and human missions: 1) Microbial and human health monitoring; 2) Technology and operations for contamination control; and 3) Natural transport of contamination on Mars. This presentation will provide a summary overview on recent stepwise progress towards the eventual goal of developing quantitative PP requirements for human missions.

As the first step in the process, NASA convened a workshop, Planetary Protection Knowledge Gaps for Human Extraterrestrial Missions (2015), to capture the current state of knowledge in the aforementioned three areas and to identify research needed to inform development of planetary protection requirements for the future human exploration. The workshop participants identified 25 separate knowledge gaps across the three study areas, and highlighted the crosscutting, collaborative research and technology-development work applicable to diverse mission phases-from pre-launch and in-route flight, to activities and infrastructure on the Martian surface, and during Earth-return and post-landing operations. Details of the 2015 NASA workshop are available online.

Subsequently, COSPAR (The Committee on Space Research), together with NASA and ESA, organized a follow-on interdisciplinary workshop in 2016 to consider next steps in the review and formulation of Planetary Protection Policy for future human missions beyond Earth Orbit. This presentation (in PPP1) will provide detailed information on the deliberations and summary findings of the COSPAR 2016 workshop, which was organized around the same themes as the 2015 NASA workshop– Microbial and human health monitoring; Technology and operations for contamination control; and natural transport of contamination on mars. In addition to analyzing potential microbial contamination, mitigation options, and dispersal concerns for human missions, this international workshop also discussed current gaps in COSPAR PP policy for future human missions to places other than Mars-particularly to asteroids and other bodies where biological contamination may not be of such significant concern.

In brief, the 2016 COSPAR Workshop on Refining Planetary Protection Requirements for Human Missions began by reviewing the findings of the 2015 NASA workshop and considered recent efforts, activities and the state of the art in the context of current COSPAR Planetary Protection Policy. As the three work groups deliberated about their suggested research and technology development needs, they also prioritized the research needs based on mission criticality and time priorities, and assessed the prospect of using different locations and mission opportunities to gather useful data. The COSPAR 2016 workshop was deliberately designed to collect inputs from both public and private space exploration organizations, thus providing a forum for international and interdisciplinary coordination and communication about future needs and efforts. The workshop report concluded by synthesizing the combined priority gaps of the three groups, and suggesting high priority actions to close the gaps though flight opportunities on robotic missions to Mars, on the ISS, or other missions, or Earth based research that could enable the needed measurements to fill the gaps in coming years.

This presentation will also provide cursory information on yet another recent workshop in this series: The 2nd COSPAR Workshop on Refining Planetary Protection Requirements for Human Missions, which was held in May 2018. This workshop aimed to align the previously identified knowledge gaps in planetary protection with mission opportunities in the timeframe between now and the first crewed flight to the Martian surface. Information from the 2018 workshop will feed forward into subsequent working meetings and will produce another COSPAR report (anticipated publication by end of 2018) to summarize and assess potential opportunities for addressing knowledge gaps in the 3 key areas flowing from all the workshops.

PPP.1-0018-18 BEYOND PLANETARY PROTECTION? PLANETARY SUSTAINABILITY AND THE RESPONSIBILITY OF SPACE SCIENCE

Andre Galli, andre.galli@space.unibe.ch

Physics Institute, University of Bern, Bern, Switzerland Andreas Losch, andreaslosch@web.de

University of Bern, Bern, Switzerland

The current COSPAR planetary protection guidelines address scientific space exploration only and they are primarily concerned with the issue of contamination (either contaminating celestial bodies with terrestrial micro-organisms or back-contamination of Earth). Other impacts of human space exploration that may be detrimental to space exploration itself are not covered. The best known example is the anthropogenic space debris orbiting Earth, but similar problems will occur in other places due to scientific and commercial space exploration in the near future. These problems share many similarities with environmental problems on Earth (tragedy of the commons etc.)

One possible approach to discuss and mitigate the impact of space exploration on the environment is to add the space environment as an additional goal to the 17 Sustainable Development Goals set by the United Nations. The resulting "Planetary Sustainability" and its ethical, scientific, economic, and legal ramifications were discussed during a workshop sponsored by the International Space Science Institute in March 2018. Here, we will first summarize the results of this workshop. Then we will discuss how this approach of Planetary Sustainability could help to plan future space missions. Finally, we will put a few propositions to debate what the role of space science in general could be, assuming space science is to support a sustainable development and is to avoid irreversible damage to the very thing it wants to study.

PPP.1-0019-18 PLANETARY PROTECTION IN EXTRASOLAR MISSION PROFILES

Michael Waltemathe, michael.waltemathe@rub.de Ruhr-University Bochum, Bochum, Germany Philip Lubin, lubin@deepspace.ucsb.edu

University of California, Santa Barbara, Santa Barbara, California, United States Pradeep Joshi, joshi@lifesci.ucsb.edu

University of California, Santa Barbara, Santa Barbara, California, United States Joel Rothman, joel.rothman@lifesci.ucsb.edu

University of California, Santa Barbara, Santa Barbara, California, United States Jatila Van Der Veen, jkvanderveen@ucsb.edu

University of California, Santa Barbara, Santa Barbara, California, United States

Current Planetary Protection regulations cover solar system bodies only as we are currently restricted to the confines of our solar system. There is no current regulation outside of our solar system as this has not been within our technological capability. With advanced mis- sion concepts like the NASA Starlight program, whose goal is to enable the first relativistic interstellar missions. This program is capable of sending life far outside our solar system in the future. It is important to consider the implications of such a program. The collaborative Extrasolar Travelers project (ET) at UC Santa Barbara is exploring the viability of sending small animals in stasis on interstellar missions. This is an interesting case study to further Planetary Protection (PP) policy for future mission profiles and challenges. This paper will address the standing of the ET project within the scope of current PP regulations concerning the chance of contamination of solar system bodies as well as extrasolar bodies. The Starlight missions be propelled by directed energy and accelerated to relativistic speeds allowing interstellar missions to nearby stellar and exo-planet systems. While direct physical interaction with exo-planets is not planned it is important to consider the possibility of accidently impacts. With the extremely large kinetic energy per mass of the spacecraft a direct impact or exoplanet atmospheric interaction would result in the spacecraft being vaporized and thus likely biologically sterilized. However, it is important to ensure responsible PP procedures. Specific scenarios for the brief time the craft will spend in the solar system and fall under current PP regulations need to be discussed as well as the field of extrasolar or interstellar contamination events. The concept of backward contamination does not play a role in these mission profiles. While it is perfectly feasible to apply existing regulations for forward contamination to the abovementioned missions while they traverse the solar system, a discussion of possible PP regulation policy for extrasolar space needs to take into account several additional factors. The primary rationale for planetary protection regulations in the solar system is the protection of future science by avoiding contamination of a potential habitat with Earth organisms. As we do not have any data on life beyond the confines of our planet, adhering to such rationale makes sense in the immediate vicinity of Earth. It is likely that life that has developed around the same star under comparable (or at least not vastly different) conditions could be similar to Earth life. Thus protection of scientific missions that may be challenged by contamination with comparable life-forms of a related biology and chemistry makes sense. The idea of panspermia is one of the main reasons for this argument. If the idea of panspermia can be upheld for interstellar distances will be discussed in the paper and the ramifications for PP considerations for interstellar missions discussed in this light. Also the implications of the massive change in order of magnitude when mission time and distance are concerned need to be considered for PP regulations outside of our solar system. Last not least human agency in the proliferation of life in a Universe in which we know of only one instance of existing life needs to be discussed.

PPP.2-0001-18 ESA MISSIONS PLANETARY PROTECTION STATUS

Gerhard Kminek, gerhard.kminek@esa.int ESA, Noordwijk, Netherlands

This presentation will report the planetary protection status of ESA flight projects with planetary protection requirements. It will cover Rosetta, Mars Express, ExoMars 2016, ExoMars 2020, JUICE, Solar Orbiter, and Bepi Colombo.

PPP.2-0002-18 OVERVIEW AND STATUS OF NASA'S PLANETARY PROTECTION MISSION PORTFOLIO

D.E. (Betsy) Pugel, betsy.pugel@nasa.gov

NASA Headquarters, Washington, District of Columbia, United States Lisa Pratt, lisa.m.pratt@nasa.gov

NASA, DC, District of Columbia, United States

NASA planetary science and exploration are pursued through a wide range of planetary science missions and instruments. This presentation focuses on the exciting range of missions and hardware that the Office of Planetary Protection has in its portfolio and provides an overview of mission-specific presentations that will be given on planetary protection activities at this COSPAR meeting. The currently growing portfolio contains over 30 missions and 15 cubesats, including international instrument contributions as well as commercial partners and spanning the full range of planetary protection categories from Category I through Category V as well as restricted and unrestricted Earth return. The Office of Planetary Protection, located at NASA Headquarters in the Office of Safety and Mission Assurance, is responsible for assuring that NASA missions and NASA contributions to missions with external partners are compliant with NASA requirements for planetary protection and consistent with COSPAR guidelines.

PPP.2-0003-18 PLANETARY PROTECTION PROGRESS OF HAYABUSA2 AND ITS PIGGYBACK PROCYON: LAUNCH, EARTH SWING-BY, OUTBOUND CRUISING AND ARRIVAL TO THE ASTEROID

Ryu Funase, funase@space.t.u-tokyo.ac.jp University of Tokyo, Tokyo, Japan

Yuichi Tsuda, tsuda.yuichi@jaxa.jp

Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, Sagamihara, Kanagawa, Japan

Hayabusa-2 is Japan's second asteroid sample return mission which was successfully launched into the planned Earth departure trajectory with the H-IIA rocket on December 3rd, 2014, together with a group of its interplanetary piggyback microspacecraft, including the PROCYON(Proximate Object Close flYby with Optical Navigation)spacecraft, the world's first 50 kg-class deep space micro-spacecraft developed by the University of Tokyo and the Japan Aerospace Exploration Agency.

The Hayabusa-2 spacecraft will go to Ryugu, a C-type NEO, and attempt surface investigations with daughter rovers (MINERVA-II series and MASCOT), artificial impact cratering experiment (SCI) and both surface and sub-surface sampling (Sampler) in 2018-2019 and plans to return to the Earth in December 2020.

The PROCYON mission objective was to demonstrate a micro-spacecraft bus technology for deep space exploration and proximity flyby to asteroids performing optical measurements.

Both of the above missions were fully evaluated by the COSPAR Planetary Protection Panel at the dedicated COSPAR colloquium

and scientific assembly in 2014 and the COSPAR PPP has endorsed the Category-2 for their outbound trajectories and the non-restricted Earth return for the inbound trajectory of Hayabusa-2.

As a part of the fulfillments of the Category-2 classification, both spacecraft must be compliant with the COSPAR PPP requirements of non-impact probability to Mars since they would have enough energy to reach and beyond the orbit of Mars, due to the Earth swing-by and ion engine operations for their outbound cruising.

As for the Hayabusa-2 spacecraft, it successfully performed its Earth gravity assist in December 2015, resulting on accurate orbit determination for the post-swing-by orbit to be ready to restart the ion engine operation. Thus the non-impact probability to Mars did not change from the estimate given by Chujo, et al. (2015). In the smmer of 2018, the spacecraft will arrive at teh asteroid Ryugu and start its rendezvous operation.

As for the PROCYON spacecraft after the completion of the bus system demonstration, it started deep space maneuver using the ion engines but the enginen failure prevented the spacecraft from insertion to the asteroid 2000 DP107 flyby trajectory via the Earth swing-by in 2015. Thus it now can be said that the spacecraft will never impact on Mars.

In this paper, we summarize the mission status of the both projects in terms of the COSPAR PPP perspectives.

PPP.2-0004-18 A ROVER OPERATIONS PROTOCOL FOR MAINTAINING COMPLIANCE WITH PLANETARY PROTECTION REQUIREMENTS

Melissa Jones, melissa.a.jones@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Ashwin Vasavada, ashwin.r.vasavada@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

The Mars Science Laboratory (MSL) mission, with its Curiosity rover, arrived at Gale Crater in August 2012 with the scientific objective of assessing the past and present habitability of the landing site area. It is not a life detection mission, but one that uses geological, geochemical, and environmental measurements to understand whether past and present conditions could have supported life. The MSL mission is designated Planetary Protection Category IVa, with specific restrictions on the landing site and surface operations. In particular, the mission is prohibited from introducing any hardware into a Mars Special Region, as defined by COSPAR policy and in NASA document NPR 8020.12D. Fluid-formed features such as recurring slope lineae are included in this prohibition. Finally, any evidence suggesting the presence of Special Regions or flowing liquid at the actual MSL landing site shall be communicated to the NASA Planetary Protection Officer immediately, and physical contact by the rover with such features shall be entirely avoided.

In January 2016, the MSL Project began using a daily rover operations protocol to ensure ongoing compliance with its planetary protection categorization. A particular challenge comes from the fact that the characteristics of potential Special Regions may not be obvious in the rover downlink data (e.g., landscape images, chemical measurements, or meteorology), or easily distinguishable from characteristics of other processes that do not imply Special Regions. For this reason, the first step in the process is for the lead scientist on that day of operations (a role that rotates through senior scientists on the mission) to scrutinize all the targets that may receive interaction by rover hardware, such as targets for arm contact, or paths for wheel contact. Based on the expertise of the lead scientist, and definitions of Mars Special Regions, if any features of concern are identified, other scientists on duty that day would be brought into a discussion. Typically the tactical team has a mix of experts in geology, astrobiology, geological materials, geochemistry, and meteorology. If this team cannot rule out the concern of introducing rover hardware into a potential Special Region, arm and wheel usage would be prohibited in that day's planning.

This halt in tactical operations would allow a separate Special Regions Team to re-consider the data more deliberately, but still on timeline that would allow rover operations to resume as quickly as possible. This team is chosen in advance to have a broad range of expertise that can weigh the evidence for a potential Special Region, including representatives from the institutional planetary protection organization and involvement of the MSL Project Manager. If this team cannot rule out the concern, rover operations continue to hold while the NASA Planetary Protection Office is engaged to determine the best course of action for the mission.

It is worth noting that evidence of modern, fluid-formed features at Gale Crater is not expected and would represent a major scientific discovery for the mission and Mars Exploration Program. However, this low-likelihood outcome still requires vigilance to ensure compliance with planetary protection requirements.

PPP.2-0005-18 PLANETARY PROTECTION IMPLEMENTATION ON EXOMARS MISSION 2016

Diana Beatriz Margheritis, diana.margheritis@thalesaleniaspace.com Thales Alenia Space Italia S.p.a., Turin, Italy

The ExoMars Mission 2016 was an ESA lead mission launched on March 2016 by a Roscosmos supplied Proton-M/Breeze-M rocket. The system consisted of an ExoMars Orbiter which accommodate scientific instruments and an Entry, Descent and Landing Demonstrator Module (EDM) to be landed in a non-special region on Mars. The project has been categorized by ESA as COSPAR Planetary Protection Category III for the Orbiter and Planetary Protection Category IVa for the EDM. Thales Alenia Space Italy (TAS-I) was the ExoMars Industrial Prime Contractor and was responsible for the Planetary Protection Implementation to ESA. Because microbial contamination could impact future science missions and compliance with international treaty was required, Planetary Protection measures were implemented on ExoMars 2016 hardware to verify bioburden levels complied with COSPAR regulation. The implementation of the Planetary Protection requirements for ExoMars Mission 2016 comprised restrictions on impact probabilities for flight hardware not intended to directly contact Mars and biological contamination control for the parts of the spacecraft to be in contact with Mars surface. This presentation reports the Planetary Protection implementation for ExoMars Mission 2016. It covers all the aspects of the mission: design, manufacturing, integration, tests, launch campaign at Baikonur Cosmodrome in Kazakhstan and the orbital transfer phase from Earth to Mars. Techniques and procedures applied to spacecraft, instruments and support equipment in order to meet planetary protection requirements as strategies used for spacecraft integration to achieve the bioburden level constraints required by planetary protection policy are described. The obtained results of Probability of Impact analysis as the final Bioburden budget results are also provided.

PPP.2-0006-18 PLANETARY PROTECTION STABILITY ASSESSMENT OF DAWN'S ENDOF-LIFE ORBIT AT CERES

Daniel Grebow, daniel.grebow@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States Marc Rayman, marc.d.rayman@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States

Dawn is a Discovery mission that launched in 2007. The purpose of the mission is to learn more about the epoch of planet formation and the evolution of the solar system by studying from orbit the protoplanet Vesta and dwarf planet Ceres. These are the two largest objects in the main asteroid belt. Dawn successfully completed its prime mission at Vesta and Ceres as well as an extended mission at Ceres. The lowest altitude at Ceres occurred in the originally planned end-of-life orbit, a circular orbit at 385 km. During the extended mission, the team raised the altitude to pursue new science objectives. Now the Dawn team is preparing for the second extended mission, in which the spacecraft will use its uniquely capable ion propulsion system to transfer into a highly elliptical orbit (orbital eccentricity = 0.8) with a periapsis altitude of 35 km for a new science campaign. The new end-of-life orbit has prompted the Dawn team to revisit the planetary protection (PP) requirements to ensure they can be satisfied. Dawn is categorized as a PP Category III Flyby mission due to the Mars gravity assist during the interplanetary transfer to Vesta. Vesta and Ceres are Category II bodies. According to the PP plan, the project must demonstrate the spacecraft will remain in Ceres orbit for greater than 20 years. In this work, we describe the final extended mission and planned destination orbit. We also summarize the results of our Monte Carlo study and in-depth orbit stability analysis, demonstrating that all PP requirements will be satisfied for the end-of-life orbit.

The InSight Project is a Discovery mission that consists of a single spacecraft with an overarching mission goal of illuminating the fundamentals of formation and evolution of terrestrial planets by investigating the interior structure and processes of Mars. The

flight system is comprised of a 2008 Phoenix mission heritage cruise stage, aeroshell (heatshield and backshell), and lander. The lander payload contains cameras, a seismometer, a mole to penetrate the regolith (5 meters) to measure the geothermal gradient of Mars, and an auxiliary payload sensor suite to measure wind, temperature, and pressure. As a Mars lander mission without life detection instruments, the InSight mission has been designated PP Category IVa. Therefore, planetary protection bioburden requirements are applicable to this mission and require microbial reduction procedures and biological burden reports. InSight will launch in May/June of 2018 and has completed an approved Planetary Protection Plan, Subsidiary PP Plans, PP Implementation Documentation, and has conducted 90% of the biological verification assays. The flight system is in the process of being assembled and being readied for launch. The status of the PP activities will be reported.

PPP.2-0008-18 EMM: PLANETARY PROTECTION IMPLEMENTATION PLAN

Mohsen Al Awadhi, mohsen.alawadhi@mbrsc.ae

Mohammed Bin Rashid Space Centre, Dubai, United Arab Emirates

Emirates Mars Mission: Planetary Protection Implementation Plan

The United Arab Emirates is planning to launch a spacecraft to Mars in 2020 as part of the Emirates Mars Mission (EMM). The EMM spacecraft, Amal, will arrive in early 2021 and enter orbit about Mars. Through a sequence of subsequent maneuvers, the spacecraft will enter a large science orbit and remain there throughout the primary mission. This paper describes the planetary protection implementation plan for the EMM mission.

The EMM science orbit, where Amal will conduct the majority of its operations, is very large compared to other Mars orbiters. The nominal orbit has a periapse altitude of 20,000 km, an apoapse altitude of 43,000 km, and an inclination of 25 degrees. From this vantage point, Amal will conduct a series of atmospheric investigations.

Since Amal's orbit is very large, the plan is to demonstrate a very low probability that the spacecraft will ever encounter Mars' surface or lower atmosphere during the mission. The EMM team has prepared methods to demonstrate as follows:

A. the launch vehicle targets support a 0.01% probability of impacting Mars, or less, within 50 years B. the spacecraft has a 1% probability or less of impacting Mars during 20 years; and C. the spacecraft has a 5% probability or less of impacting Mars during 50 years.

The EMM approach to planetary protection is to bias the trajectory away from Mars so that the resulting probability of impact with Mars meets the probability requirements. The approach assumes failure of the Space Segment and avoids the need for a probability of failure analysis. The project views this as a conservative approach and more defensible than leveraging a reliability analysis. The significance of this approach is that the launch vehicle must place the upper stage and observatory on trajectories that satisfy planetary protection, and the project recognizes the cost of additional fuel to maintain the trajectory bias. This approach is satisfied by trajectory and navigation. The description of the Space Segment is included for information only.

The purpose of the Planetary Protection Implementation Plan (PPIP) is to provide all relevant information about the detailed implementation (e.g. analysis, procedures, and activities) of the planetary protection requirements in line with the planetary protection plan.

The EMM mission design resembles the mission design of many previous Mars missions, differing only in the specific parameters and final destination. The mission involves a direct launch toward Mars, a 7-month Type I cruise to Mars, a standard Mars Orbit Insertion (MOI), a transition from the capture orbit to the science orbit, and a scientific investigation in a high orbit about Mars. Special care is given to each phase to ensure that planetary protection guidelines are followed.

PPP.2-0009-18 MARS 2020 PLANETARY PROTECTION STATUS

Melissa Jones, melissa.a.jones@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

The Mars 2020 (M2020) flight system consists of a cruise stage; an entry, descent and landing system (EDL); and a Radioisotope Thermoelectric Generator (RTG) powered roving science vehicle that will land on the surface of Mars. The M2020 Mission is designed to investigate key question related to the ancient habitability of Mars and will conduct assessments that set the stage for future human exploration of Mars. The project will also acquire and cache samples of rock and regolith for possible return to Earth by a subsequent mission. NASA has assigned the M2020 Mission as a Category V Restricted Earth Return due to the possible future return of collected samples. As indicated in NPR8020.12D, Section 5.3.3.2, the outbound leg of a Category V mission that could potentially return samples to Earth, Mars 2020 would be expected to meet the requirements of a Category IVb mission. The entire flight system is subject to microbial reduction requirements, with additional specific emphasis on the sample acquisition and caching subsystem. A bioburden accounting tool is being used to track the microbial population on the surfaces to ensure that the biological cleanliness requirements are met. Initial bioburden estimates based on MSL heritage allows M2020 to choose more precisely how the bioburden is allocated to each hardware element. Mars 2020 has already started to implement its Planetary Protection Plan and Planetary Implementation Plan. Planetary protection sampling activities commenced with the start of flight system fabrication and assembly. The status of the Planetary Protection activities will be reported.

The major goal of the planetary protection program in the international mission ExoMars-2020 is to preclude the possibility of Mars contamination by terrestrial microorganisms. For this mission the Russia side designs a descent module (DM) the key elements of each are a probe (ESA) and a landing platform with service and research systems, and equipment. Since one of the prime mission objectives is search for life forms using the probe tools, according to the COSPAR classification ExoMars-2020 generally falls into category IVb. DM (without the probe) must comply with the bioburden limits imposed to landers in the category IV missions that visit a target body with no intention to search for life. Within the ExoMars-2020 project the Russian side answers for the planetary protection on specific stages of spacecraft (SC) development including the DM manufacturing and integration with the transit module and rover, in-process testing, and pre-launch preparations on cosmodrome Baikonur. The procedures applied are aimed at: - bioburden reduction on the stage of DM elements and equipment preparations for assembly using the heat, radiation and ultraviolet methods compatible with the structural materials of elements, units and equipment with consideration for their individual bioburdens; microbiological control of the DM elements and assembly room cleanness according to the ISO class 8; - microbiological control of the SC bioburden during DM integration with the transit module and rover in the clean tent and cleanness of the latter according to the ISO class 7, SC in-process testing and pre-launch preparations. These procedures will ensure implementation of the planetary protection requirements in the ExoMars-2020 mission.

PPP.2-0011-18 OVERVIEW OF MMX MISSION AND ITS PLANETARY PROTECTION PLAN

Japan Aerospace Exploration Agency, Kanagawa, Japan

Martian Moons eXploration (MMX) is a mission proposed by ISAS/ JAXA, that is currently under Phase-A study. The goal of MMX is to investigate the origin of the Martian moons, and then to make a progress in our understanding of planetary system formation and of primordial material transport around the border between the innerand the outer-part of the early solar system.

MMX mission is designed to retrieve samples from Martian Moons to Earth. The spacecraft is planned to be launched in 2020s by an H3 rocket and transferred to Mars. After Mars orbit insertion, it will be located on the quasi-satellite orbit (QSO) of one of the Martian Moons. During the proximity operation phase, the spacecraft will perform remote-sensing observation of Martian Moons and Mars from the QSO, descent and land on a Martian Moon, collect samples, and then ascent back to the QSO. Flyby observation of another Martian moon is also planned. After 3-year stay in the Martian system, the spacecraft will be inserted into the escape orbit from Mars and go back to the Earth. The capsule including samples will be separated and re-enter the Earth atmosphere.

The mission must be compliant with the COSPAR PPP requirements. The MMX pre-project team has carried on preparations for establishment of the planetary protection plan with support by JAXA Planetary Protection Working Group. In this presentation, the overview of the MMX mission and its planetary protection plan are shown.

PPP.2-0012-18 EUROPA CLIPPER PLANETARY PROTECTION STATUS

The Europa Clipper mission will explore Europa and investigate its habitability utilizing a set of five remote sensing instruments that cover the spectrum from thermal emission through the ultraviolet, four in-situ fields and particles instruments, a two-channel radar, and a gravity science investigation. Key mission objectives will be to produce high-resolution images of Europa's surface, determine its composition, look for signs of recent or ongoing activity, measure the thickness of the icy shell, search for subsurface lakes, and determine the depth and salinity of Europa's ocean. Roughly 40 flybys of Europa-with closest-approach altitudes varying from several thousand kilometers miles to as low as 25 kilometers-will be executed over an approximately 3.5 year Prime Mission.

As an orbiter mission to a Jovian moon with a subsurface ocean, the Europa Clipper mission has been designated a Planetary Protection Category 3 mission that must meet the following requirement:

Reducing the probability of inadvertent contamination of an ocean or other liquid water body to less than 1 x 10-4 per mission

To implement this requirement, a multi-pronged approach of trajectory biasing, impact avoidance, biological probabilistic modeling and hardware biological allocation sampling will be employed. The baseline implementation approach for hardware cleanliness includes microbial reduction, spacecraft assembly in

an ISO 7 or better cleanroom environment, and recontamination control. The current status of the Europa Clipper PP approach will be presented.

PPP.2-0013-18 A SYSTEMS-LEVEL APPROACH TO PLANETARY PROTECTION AT EUROPA

Britney Schmidt, britneys@eas.gatech.edu

Georgia Institute of Technology, Atlanta, Georgia, United States Europa Planetary Protection Team

K. McCoy, J. Buffo, G. Collins, C. Phillips, R. Pappalardo, P. Doran, J. Bowman, C. Carr,

A. McEwen, J. Lawrence, K. Soderlund, T. A. Nordheim, M. Sephton, G. Tobie, J. Glass, C. Howett, A. Pontefract, J. Roberts, J. Westlake, K. Hand, L. Quick, M. Guidipati, P. Christiansen, G. W. Patterson

We are on the precipice of one or more missions to explore Europa and other ocean worlds. However, there are unique challenges in responsibly exploring worlds that are potentially rich in endogenous ecosystems and habitable niches. In order to protect Europa from forward contamination, and to achieve science goals that include assessing its habitability and searching for life, a more sophisticated approach to planetary protection is required than is reflected in current planetary protection paradigms. Significant progress has been made in the past decade to bound the nature and formation of Europa's surface features, its ice shell and ocean processes, and surface environment that should form the foundation for placing statistical bounds on the timescales over which contamination might occur.

We seek to provide the basis for revising COSPAR's planetary protection policies for Europa in short order, so as to enable ethically and scientifically responsible exploration in the near future. At present, planetary protection for Europa does not include consideration of its geological processes, whereas for Mars, geological timescales are integrated into COSPAR policies. The categorization of special regions on Mars has enabled progress in exploring its surface and subsurface, and thus provides a case study for how policies for Europa might be developed. For Europa, current requirements place restrictions on all missions that exceed those for Mars surface missions. A well-justified risk posture for future spacecraft exploration of Europa should include full consideration of how the ice shell works. Here we review accomplishments in understanding Europa's geophysical processes and surface environments, including all published models, and explore the impact of these discoveries on planetary protection, including considering the viability of potential contaminating organisms. We recommend strategies for calculating potential forward contamination, and for the establishment of Europan special regions.

PPP.2-0014-18 PLANETARY PROTECTION FOR HUMAN MISSIONS TO MARS: A FORWARD LOOK

J. Andy Spry, aspry@seti.org

SETI Institute, Silver Spring, Maryland, United States Margaret Race, mracemom@aol.com

SETI Institute, Mountain View, California, United States Lisa Pratt, lisa.m.pratt@nasa.gov

NASA, DC, District of Columbia, United States Bette Siegel, bette.siegel@nasa.gov

NASA Headquarters, District of Columbia, United States

Robotic explorers currently sent to the red planet have stringent planetary protection requirements imposed. The COSPAR international consensus planetary protection policy obliges nations sending these missions to comply with specific biological cleanliness levels for hardware that may end up on the surface. This preserves the ability of future missions to do science at Mars unhindered by the contamination left behind by preceding missions. Yet this paradigm is not readily compatible with crewed missions sent to the martian surface: A decision to allow humans and their life support systems on the surface implies a level of biological con-tamination orders of magnitude more than that permitted for robotic missions. Still, the same two-fold intent of planetary protection remains: ensuring that the conduct of scientific investigations of possible extraterrestrial life forms, precursors, and remnants is not jeopardized, and; protecting the Earth from the potential hazard posed by extraterrestrial matter carried by a spacecraft returning from an interplanetary mission (forwardand back-contamination, respectively). Other presentations at this Assembly are addressing the future path to planetary protection requirements for crewed missions, but this presentation takes a forward look at the impact of planetary protection implementation on the hardware and systems needed for crewed exploration at the martian surface, based on recent expert reports and NASA mission architecture studies. In conclusion, planetary protection implementation will be a feature of future exploration efforts for Mars, including crewed missions. Determining how planetary protection should be implemented for crewed missions is contingent on improved knowledge of the Mars environment. It will likely result in broad impacts to engineering design and surface operations, that need to be integrated in planning from the earliest stages.

"SLIM" is a project in ISAS/JAXA to demonstrate a "pin-point" landing on the lunar surface with small spacecraft. The spacecraft is designed to achieve 100 meter-order landing error ellipse in order to satisfy such needs for future surface explorations on a celestial body with gravity. Since the conventional ground-based navigation is not accurate enough to achieve this level of landing error ellipse, image-based onboard navigation system and autonomous landing will be demonstrated by the SLIM mission along with several other new technologies. Some of these new technologies aim to realize a light-weight spacecraft for future interplanetary missions. The SLIM spacecraft itself weighs 600 700 kg wet mass and 200kg-class dry mass, both of which are much lighter than any previous lunar landers. Its main engine consists of 500N-class bipropellant thruster with N2H4 and MON3. Although the SLIM's main mission is technology and operation demonstration described above, additional small scientific payloads will also be employed. SLIM project status is in phase-B at this moment, and will be launched with Japanese rocket in 2020 or

2021. Based on the mission scope and mission design mentioned above, the SLIM team categorizes the Luna lander into Category II of the COSPAR planetary protection policy, which mainly requires a planetary protection plan and other documentations, including the spacecraft organic inventory. In this talk, the overview of the SLIM mission and its planetary protection plan will be presented and discussed for requesting the COSPAR-PPP to support the Category II proposal in a timely manner.

PPP.2-0016-18 A MATHEMATICAL MODEL FOR ASSESSING THE EUROPA CLIPPER PROBABILITY OF CONTAMINATION REQUIREMENT

Kelli McCoy, kelli.j.mccoy@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Chet Everline, chester.j.everline@jpl.nasa.gov JPL, Pasadena, California, United States

Hayden Burgoyne, hayden.a.burgoyne@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States Michael DiNicola, michael.dinicola@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States

The planned Europa Clipper mission must comply with the NASA Planetary Protection requirement in NPR 8020.12D, which states: “The probability of inadvertent contamination of an ocean or other liquid water body must be less than 1×10-4 per mission”. Mathematical approaches designed to assess compliance with this requirement have been offered in the past, but no accepted methodology is in-place to trace the end-to-end probability of contamination. As a result, hardware can presumably be either overor under-treated. Over-specified microbial reduction protocols can greatly add to the cost (and schedule) of a project. On the other hand, if microbes on hardware are not sufficiently eliminated, there is increased risk of potentially contaminating another body with terrestrial organisms, adversely affecting scientific exploration and possibly conflicting with international treaty.

A mathematical model was developed by the Europa Clipper Project to demonstrate compliance with the NPR requirement stated above. Given an initial bioburden launched with the Clipper flight system, as specified in the Planetary Protection Equipment List (PPEL), the model calculates the probability of contaminating the Icy Bodies of Europa, Ganymede and Callisto. This calculation relies on two primary probabilistic calculations:

1) The probability that Clipper fails to perform a planned maneuver and impacts Europa, and 2) The conditional probability at least one viable microorganism survives the impact and reaches the Europa ocean.

Microorganism survival probabilities are calculated along each potential impact trajectory by quantifying organism mortality when exposed to the known lethality factors of space such as radiation, temperature and vacuum. The concept of a bio-region is introduced, a critical notion to this modeling which enables an understanding of how organism lethality depends on the flight system design and configuration.

Should an impact with Europa occur, impact heating and its effect on an organism's chance for survival is calculated. Modeling of this event considers the impact shock pressures and plastic deformation that are experienced by the Clipper flight system under potential impact velocities, angles, orientations, and ice composition conditions. Radiation exposure once on the Europa surface and timescales to a potential ocean contamination event are also folded into the survival calculation.

This objective mathematical framework enables Europa Clipper to ensure its Planetary Protection obligations are met, while minimizing impact to the Project.

PPP.2-0017-18 BIOBURDEN CONTROL ELEMENTS OF PLANETARY PROTECTION FOR THE EUROPA LANDER MISSION CONCEPT

Brian Clement, brian.g.clement@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Raymond Ellyin, raymond.ellyin@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

The Europa Lander mission concept would search for biosignatures, evaluate overall habitability and investigate geophysical properties and dynamics from the surface of Europa. The baseline instrument package would include provisions for imagery, organic and inorganic chemistry, microscopy, and geophysical activity monitoring. These instruments would characterize Europa's geophysical properties and dynamic processes while directly analyzing surface ice samples to identify microscopic features and quantify both inorganic and organic compounds.

The Europa Lander Mission would represent a novel challenge for Planetary Protection. COSPAR policy states that Europa missions must demonstrate less than a 1 in 10,000 probability of contamination, where contamination is defined as the introduction of one viable Earth organism into a liquid water body. The Europa Lander mission flight system concept, consisting of four distinct vehicles, magnifies and diversifies the challenge of preventing forward contamination of Europa by Earth organisms.

To meet the applicable requirements, the initial Planetary Protection architecture for the Europa Lander mission concept includes a diverse set of bioburden control elements: stringent microbial reduction, cleanroom assembly, a large biobarrier and a terminal sterilization system (TSS). Depending on sensitivity to microbial reduction processes, components and subsystems would be subjected to 6-log microbial reduction, full sterilization treatment, or situated in select locations for end-of-mission incineration by the TSS.

Once assembled and integrated into a four-vehicle stack, the upper three vehicles, all of which are planned to contact Europa, would be protected from recontamination by a biobarrier. To further reduce bioburden, vapor hydrogen peroxide would be applied behind the biobarrier after last access. After arrival at Europa, forward contamination from less-stringently treated components would be prevented by activating the TSS either prior to a non-nominal impact or at the end of the approximate 20-day surface sampling mission.

In combination, these elements would provide high levels of bioburden control for the Europa Lander mission concept; the current status of this approach and progress towards meeting the contamination probability limit will be presented.

Note: This abstract contains predecisional information, for planning and discussion only

PPP.2-0018-18 PLANETARY PROTECTION STRATEGY AND IMPLEMENTATION FOR MARCO, THE FIRST INTERPLANETARY CUBESAT MISSION

NASA Jet Propulsion Lab / California Institute of Technology, Pasadena, California, United States

Don Li, don.li@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

The MarCO technology demonstration spacecraft are launching as a secondary payload on the InSight mission's launch vehicle. The primary MarCO mission objective is to relay entry, descent, and landing telemetry from the InSight lander to Earth. To accomplish this objective, the two identical CubeSats will perform a Mars flyby and pioneer a number of small spacecraft technologies for interplanetary use.

MarCO is also pioneering meeting Planetary Protection requirements within the framework of a CubeSat mission. Classified as a Planetary Protection Category III flyby mission, the project is required to address both impact constraints for launch vehicle elements and the potential for contaminating InSight. Meeting these requirements by adopting the contamination analysis and control architecture typically applied to Mars missions would limit the benefits of the low-cost, highly-adaptable CubeSat paradigm. Instead, a strategy comprising bioassays of specific hardware,

conservative bioburden estimation, and worst-case vehicle breakup and burnup analyses was employed to ensure Planetary Protection compliance.

InSight contamination risk was addressed through bioassays and worst-case assessment of particle delivery to the InSight cruise stage from the MarCO thruster plumes. Plume contamination potential was determined using bioburden specification values, and the resulting propellant bioburden estimate was combined with worst-case assumptions on plume shape, direction and distance to InSight. These calculations indicated bioburden transfer of less than one spore for the entire mission. In parallel, internal bioassays of the propulsion units and the propellant demonstrated far less contamination risk than the plume calculation alone.

The Mars impact risk was addressed by estimating the fraction of spores surviving entry through Mars' atmosphere and comparing that against the requirement that launch vehicle hardware impact the planet with fewer than 500,000 spores. First, a spore burden estimate was developed for each flight module using spore density specification values. Then, entry heating for eighteen MarCO flight system elements was determined across a range of entry cases. Finally, a conservative estimate of bioburden reduction was calculated using appropriate heat microbial reduction parameters with the entry case that developed the least amount of entry heating.

Through these efforts, the project both demonstrated that the MarCO mission is in compliance with Planetary Protection requirements and developed a framework for small spacecraft bioburden analyses that can be used, and refined, for future CubeSat missions.

PPP.2-0019-18 BACKWARD PLANETARY PROTECTION FOR POTENTIAL MARS SAMPLE RETURN

Robert Gershman, robert.gershman@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Any concepts that propose to return samples from Mars would have to assure a very low probability of inadvertent release of Mars material into the Earth's biosphere in order to provide protection against the extremely unlikely possibility of biological hazards in the returned material. Backward planetary protection (aka containment assurance) requires breaking the chain of contact with Mars: any Mars material reaching Earth would have to be inside a robustly sealed sample container. And the integrity of the sample container would have to be maintained (with an unprecedented degree of confidence) until delivered to a secure receiving facility on Earth. NASA's Mars 2020 mission has identified, as one of that its principal objectives, caching of carefully selected samples on the Mars surface for possible delivery to Earth by a future mission (or set of missions). While no decision has been made as to if or when the future mission(s) might take place, the NASA Mars Exploration Program has initiated a preliminary investigation of options for implementation. This presentation describes the status of the ongoing effort to investigate architecture options for Mars sample return that could follow the collection of a cache by the 2020 rover and focuses on sample containment assurance aspects of the options. Potential planetary protection requirements and potential challenges to containment assurance are discussed, plans to assess and mitigate these challenges are outlined, and corresponding technology development is described.

The main purposes of "Expeditsia-M" interplanetary mission is landing "Boomerang" spacecraft (S/C) onto the Phobos surface, Phobos soil sampling and their delivery on the Earth inside a sealed indestructible container for physical and chemical study as well as a remote sensing of Mars and Deimos. According to COSPAR classification the stage of the Earth-Mars transit and the spacecraft flight in the near-Martian space are related to category III, while the mission stage on delivery of Phobos soil samples to the Earth falls into category V. Thus, in this mission, it is necessary to protect Mars from terrestrial microorganisms and the Earth from a potential threat when delivering soil from the Mars satellite. The first objective can be achieved by limiting the probability of S/C destruction (failure) and its fall on Mars, which is confirmed by calculation of S/C reliability at different mission stages and ballistic analysis of the flight trajectory. Taking into account the fact that the soil is returned from the Mars satellite and, thus, being aware of the responsibility for Earth's safety Lavochkin Association and IBMP RAS will provide measures to fulfill the requirements of the Earth's planetary protection in the delivery of Phobos soil that will include: 1) ensuring the tightness of the container with Phobosian soil at all stages of the mission, until landing on Earth. 2) analysis of non-sterile Phobos soil samples delivered to the Earth in conditions of rigid isolation in a specialized laboratory certified to carry out works with especially dangerous microorganisms. Detection of any sign of extraterrestrial life will result in isolation of the samples with subsequent sterilization prior to physical and chemical analyses. 3) "the break of the contact chain" between Earth and the equipment returned from Phobos.

PPP.3-0001-18 SCIENTIFIC CHALLENGES TO PREVENT THE BIOLOGICAL CONTAMINATION OF OUTER SOLAR SYSTEM BODIES - WHAT DO WE NEED TO KNOW FOR PLANETARY PROTECTION?

With increasing evidence of the presence of liquid water in the outer Solar System, the number of potentialy habitable environments has increased and, in consequence, the issue of contaminating other solar system bodies has become more important and relevant. Within the current Planetary Protection framework, the challenges to prevent the unwanted biological contamination of Outer Solar System bodies of astrobiological interest, here especially Europa and Enceladus, are tightly linked to the potential of Earth organisms to arrive at and survive and replicate in an environment in the Outer Solar system that would be habitable for them ("problematic species"). The identification of these relevant groups of organisms was addressed through background research, a dedicated international workshop and the consultation of additional experts in geology, geophysics, space radiation dosimetry, radiation biology, planetology, and microbiology. Problematic species for icy moons were identified as those that are able to survive long periods of desiccation and exposure to radiation and thereafter can replicate at low temperatures under oligotrophic anaerobic conditions in the presence of salts. There is a need for long-term microbiological research to characterise the cleanroom microbial community with respect to the presence of problematic species. The unknowns about the environment, especially the radiative environment, but also the extent of exchange processes between the moon's surface and the subsurface ocean, its composition and the temperature gradient in the ice shell also need to be explored in respect to their effects on microorganisms.

The Organic Contamination Control (OCC) aspect of the Planetary Protection of the Outer Solar System (PPOSS) project is aimed at preventing contamination between Earth and other bodies, in particular the icy moons, in the context of life detection missions. Organic contamination may be considered as any terrestrial organic material that could be mistaken for (false positive result), or whose signal could overwhelm and mask (false negative result), an extra-terrestrial organic signature. So far, the search for life beyond the Earth has focused on Mars and so current thinking towards avoiding forward contamination of potentially habitable environments is based upon our knowledge of the Martian environment. As there is now increasing evidence for the potential of life to exist on the icy moons of the outer solar system, it is necessary to think about the unique challenges for planetary protection and contamination control these environments hold. The OCC chapter of the PPOSS Whitebook discusses our current state of knowledge and best practices in OCC, identifies knowledge gaps, and works toward a goal of adapting and improving current policy for the Icy Moon environments. Due to the non-self-replicating nature of organic contaminants (unlike biological contaminants) OCC is primarily concerned with affecting the reliability of the current mission rather than damaging the future scientific prospects of the body, although this must still be considered. While organic compounds are highly scarce on Mars and the challenge is purely

to detect them, organics are likely to be plentiful on the icy moons. The complex radiation environment, which we are yet to fully understand, will create polymers and macromolecules leading to a complex and varied suite of organics. This means that the background level of indigenous abiotic organic compounds will be high and the challenge will be to distinguish between the sources of the observed organics. Specific contamination requirements will depend on the instrument(s) being flown and the science objectives of the mission. Because of this, instead of this project defining quantitative requirements for OCC (as there are for Biological Contamination), instead, it is suggested that a peer-reviewable framework should be developed which each mission must use to produce their own mission-specific level of acceptable contamination at the design phase. Planetary Protection and contamination control policy will need to be adaptable as our knowledge about the target bodies increases through future successful missions. The PPOSS project Coordination and Support Action has received funding from the European Comission's H2020 Programme (2016-2018) under grant agreement 687373.

Volcanism on ocean worlds [1-3] facilitates sample return missions, enabling flexible, sensitive, and specific analyses on Earth to study how far chemistry has evolved in these oceans. Such mission concepts have yet to quantitatively address planetary protection (PP) [4,5]. They fall in Cat. V-Restricted Earth Return [6], as icy world oceans contain chemical energy [7] and organics [8], are shielded from exogenic radiation by ice, and ocean material has likely not been naturally exchanged with Earth [9].

Quantifiable forward PP: The probability of introducing a single viable terrestrial microbe into a liquid-water environment must be < 104, an arbitrary but manageable value [10]. Current policy [9,11] requires that this probability be estimated from bioburden at launch (F1), organism survival to radiation during the cruise (F2) and near the target (F3), the probabilities of encountering the target (F4) and surviving landing/impact (F5), and subsurface transport mechanisms, timescales (F6), and survival (F7). The compliance and cost of specific designs could be assessed from measurements of molecular contaminants as robust proxies for microbial particulates [12] (F1); known microbial radiation tolerance [13] and planetary radiation budgets [14] (F2-F3); trajectory design (F4); projected impact velocities [15] (F5); ice transport timescales [16] (F6), and growth rates in ice [17] (F7).

As an alternative to the difficult quantification of these factors, a binary decision tree has been proposed [10]: Do current data indicate that the target body lacks (1) liquid water? (2) bioessential elements? (3) physical conditions in the range of extreme conditions for Earth life?

(4) chemical energy? (5) complex organic nutrients? (6) Is the likelihood of contact with the habitable environment less than 10−4? (7) Can treatment at 60°C for 5 h eliminate physiological groups that can propagate on the target body? If one or more of these decision points is evaluated negatively, the spacecraft must be heated above 110°C for 30 h for sterilization.

In contrast, current back PP requirements are only qualitative: Current policy [9,11] prohibits destructive impact upon return, and in the absence of sample sterilization, requires fail-safe sealing of the sample container with a method to verify its operation before Earth return (B1); containment until transfer to a receiving facility (B2); "breaking the chain of contact" with the target (B3); no return to Earth of uncontained hardware that contacted the target (B4); reviews and approval of mission continuation prior to launch from Earth, leaving the target for return, and commitment to Earth reentry (B5); and life detection and biohazard testing prior to any sample distribution (B6).

These provisions and their means of evaluation could be quantified. A maximum leakage rate could be specified for particles above 10 nm (the size of prions, the smallest known pathogens [18]) (B1-B2), even for impact at terminal velocity, accidental or intended (bypassing the risk of failure of the reentry system, but requiring monitoring of sample integrity). For leak detection, He is commonly used [23], but its van-der-Waals radius of 0.14 nm could place too stringent a constraint for containment of pathogens over 70 times larger. To meet (B3)-(B4), uncontained parts in contact with ocean world material could be jettisoned prior to reentry with maximum allowed probabilities of Earth/Moon impact, or of microbial survival upon reentry. (B6) could require life detection prior to or after opening the sealed container [19].

Next steps to set policy: An ongoing European effort, Planetary Protection of Outer Solar System, is seeking to make recommendations for the definition, improvement, and implementation of PP policy [20], and could help quantify provisions (B1)-(B6).

We have been monitoring environmental microbes of the Japanese Experiment Module KIBO's pressurize module of the International Space Station (ISS) from the beginning of operation and detecting a wide variety of microorganisms. It has long been known that the crew is a major source of microorganisms in manned spacecraft, such as the ISS. Thus far, we have been collecting environmental samples on board from the pressurized module using small swabs or tapes and analyzing microbiota on the ground. The method is suitable to quantitatively monitor population dynamics of microorganisms, however, it is not feasible to detect minor microorganisms with low numbers because of the quantity of each sample. Therefore, we considered the Inter-Module Ventilation (IMV) system on the ISS, giving that huge amount of dust often trap in the mesh and astronauts must clean it occasionally. Dust specimen from the IMV system in KIBO module was collected on board and, subsequently, it was subjected to DNA-based next generation sequencing on the earth in order to comprehensively analyze fungal microbiota. Our results showed that major fungal microbes in the dust of KIBO's IMV were not of commonly isolated environmental fungi such as Aspergillus or Penicillium, but human commensal species, such as Candida and Malassezia, which are known as opportunistic pathogens.

Introduction: The Astromaterials Acquisition and Curation Office at NASA Johnson Space Center (JSC) (henceforth referred to herein as NASA Curation Office) is responsible for curating all of NASA's extraterrestrial samples. Under the governing document, NASA Policy Directive (NPD) 7100.10F "Curation of Extraterrestrial Materials," JSC is charged with "The curation of all extraterrestrial material under NASA control, including future NASA missions." The Directive goes on to define Curation as including ". documentation, preservation, preparation, and distribution of samples for research, education, and public outreach." Here we describe some of the ongoing efforts to ensure that the future activities of the NASA Curation Office are working towards a state of maximum proficiency.

Founding Principle: Curatorial activities began at JSC (Manned Spacecraft Center before 1973) as soon as design and construction planning for the Lunar Receiving Laboratory (LRL) began in 1964 [1], not with the return of the Apollo samples in 1969, nor with the completion of the LRL in 1967. This practice has since proven that curation begins as soon as a sample return mission is conceived, and this founding principle continues to return dividends today [e.g., 2].

Advanced Curation: Part of the curation process is planning for the future, and we refer to these planning efforts as "advanced curation" [3]. Advanced Curation at NASA is founded as a cross-

disciplinary field of advanced research and development under the auspices of the NASA Curation Office. Advanced Curation conducts research, explores and invents new innovative technologies and techniques for collection, handling, characterization, analysis, and curation of astromaterials that could be used for both next-generation human and robotic space exploration missions and current collections. Advanced Curation has a primary goal of expanding the sample processing and storage capabilities of NASA's astromaterials curation facilities, preparing the Curation Office for future sample return missions as well as maximizing the science returns of our existing sample collections. In addition, the program integrates, tests, and evaluates new technologies and operational procedures for future sample return missions through human and robotic analog studies. These goals are aimed at improving our core curation functions of protecting the scientific integrity of NASA's astromaterials collections and serving as responsible distributors of astromaterials to the global community of sample scientists and educators in a fair, timely, and professional manner. The Advanced Curation initiatives described will allow for the reduction of contamination to astromaterials and the unprecedented preservation of the scientific integrity of all samples from mission inception through ATLO, sample collection, preliminary examination on Earth, curation, and secure delivery of the samples to Earth-based laboratories for in-depth scientific analyses.

Looking Forward: We are fully committed to pushing the boundaries of curation protocol as humans continue to push the boundaries of space exploration and sample return through both human and robotic exploration efforts. However, to improve our ability to curate astromaterials collections of the future and to provide maximum protection to any returned samples, it is imperative that curation involvement commences at the time of mission inception. Specifically, when curation involvement is at the ground floor of mission planning, it provides a mechanism by which the samples can be protected against project-level decisions that could undermine the scientific value of the returned samples.

Concluding Remarks: The return of every extraterrestrial sample is a scientific investment. The curation facilities and personnel are the primary managers of that investment, and the scientific community, at large, is the beneficiary. The NASA Curation Office has the primary goal of maintaining the integrity of all of NASA's astromaterials and ensuring that the samples are distributed for scientific study in a fair, timely, and responsible manner. It is only through this openness and global collaboration in the study of astromaterials that the return on our scientific investments can be maximized. For information on requesting samples and becoming part of the global study of astromaterials, please visit curator.jsc.nasa.gov

PPP.3-0006-18 NATURAL TRANSPORT OF CONTAMINATION ON MARS IN THE CONTEXT OF HUMAN EXPLORATION

Manish Patel, manish.patel@open.ac.uk

The Open University, Milton Keynes, United Kingdom Benton Clark, bclark@spacescience.org

Space Science Institute, Littleton, Colorado, United States

In the context of the human exploration of Mars, the issue of transport of viable microorganisms and organic contaminants from regions of exploration by human missions to Mars and eventual probabilities of reaching possible Special Regions needs to be considered. Natural transport consists of movement by aeolian processes, including abrasion/deflation, suspension and deposition of small particles (i.e. dust, microorganisms and organic molecules), as well as long-distance transport of larger particulates by intermittent saltation events.

Relative to other needs of atmospheric science to understand the present martian climate in terms of global circulation, including extrapolations backwards and forward in time, the concerns for planetary protection also require greater depth of knowledge of meteorological processes at or near the surface of Mars. Adequately understanding the efficiencies, frequencies, and durations of entrainment processes requires measurements at actual exploration zones to set limits on acceptable contamination by subsequent human missions.

Here we present the findings from a specialist study group investigation to identify the key priorities in the context of natural transport of contaminants arising from human exploration on Mars.

A new apparatus for the decontamination of sensitive material like space equipment using cold atmospheric plasmas (CAP) is developed, built and tested. CAPs are partly ionized gases, socalled plasmas, that can be produced in air providing a chemical reactive cocktail of molecules, atoms and charged species. These reactive nitrogen and oxygen species are responsible for the sterilizing nature of CAP. CAPs are used in medicine and hygiene and due to these interesting applications the field is one of the fastest growing fields in plasma physics over the last years. In a first project we investigated the use of afterglow plasma produced in a CAP for the decontamination of space equipment [1]. The afterglow plasma contains only the long-living species like ozone, NO2, etc. which allows the treatment of very sensitive materials at room temperature. In a follow-on project the apparatus was completely redesigned to gain efficacy, stability and reproducibility. Measurements of the decontamination efficacy combined with physical measurements of the produced reactive components and their effect on treated materials allow a better understanding of the involved processes. We will give an overview on the status of the plasma decontamination project funded by the Bavarian Ministry of Economics.

Planetary Protection ensures that spacecraft meet stringent cleanliness requirements to prevent forward contamination (microbial contamination of the solar system by Earth-launched spacecraft that could pose a hindrance to a mission's science objectives). Spacecraft assemblies with large surface areas, and those that are difficult to clean or possess limited access, often undergo Heat Microbial Reduction (HMR). This approach significantly reduces the bioburden as per ECSS-Q-ST-70-57C (dry heat bioburden reduction for flight hardware). Unfortunately, many thermally-sensitive materials cannot be exposed to such high temperatures and require different modes of microbial reduction. VHP, which is a low-temperature process capable of destroying microbes, has a protocol approved by NASA's Planetary Protection Office as an alternative sterilization modality. Although surface sterilization specification has been established, sterilization procedures for complex geometries (e.g., vented boxes and electronic chassis inside the warm electronics box of a rover) require the use of biological and chemical indicators to demonstrate efficacy of the process. Unfortunately, removal of the biological and chemical indicators exposes the sterilized surfaces to recontamination. Thus, this study aims to propose a standard protocol for a bounding set of different configurations and geometries that would not require biological and chemical indicators. In our testing campaign we modified various operational parameters of our VHP generator to develop a sterilization cycle capable of processing complex spacecraft hardware. This study also describes the development of a scalable modular enclosure that can be used in-situ (e.g., at the site of hardware integration in a cleanroom or on the launch pad). The development of aseptic assembly and in-situ sterilization techniques can provide an alternative sterilization method to HMR (especially following rework of hardware), as well as reduce the time for mission assembly, test, and launch operations.

PPP.3-0009-18 INVESTIGATION OF GAMMA IRRADIATION FOR PLANETARY PROTECTION PURPOSES

NASA Jet Propulsion laboratory, Pasadena, California, United States Fei Chen, fei.chen@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Laura Newlin, laura.e.newlin@jpl.nasa.gov

NASA Jet Propulsion Lab / California Institute of Technology, Pasadena, California, United States

The planetary protection requirements for Mars and icy-moon missions must be met prior to launch. These requirements protect future scientific investigations by preserving the target environment from unwanted Earth biological contamination. The current spacecraft bioburden reduction process relies primarily on Heat Microbial Reduction (HMR) and the occasional use of Vapor Hydrogen Peroxide (VHP) to reduce bioburden on spacecraft. However, many modern spacecraft materials cannot be exposed to such high temperatures and time durations. VHP, although a low-temperature process, is only a surface sterilization technique. Therefore, to provide additional options for spacecraft hardware sterilization, the planetary protection discipline is developing a gamma irradiation microbial reduction technique capable of penetrating bulk materials. Gamma irradiation is advantageous due to its ability to reduce the bioburden of complex geometry instruments, such as deployable antennas, reaction wheel lubricants, and composite structures such as aeroshells, which cannot be sterilized otherwise, or cannot be adequately sterilized by heat. Gamma irradiation is also an ambient temperature technique that can be used on many heat-sensitive subsystems, such as batteries. In this study, organisms that possessed varying resistance capabilities, such as resistance to heat, dry conditions, and radiation, were analyzed. The goal of this study is to provide the planetary protection discipline with a standardized test protocol to begin the validation of gamma irradiation as a standard sterilization technique for flight hardware.

PPP.3-0010-18 THERMAL INACTIVATION OF BACTERIAL SPORES USING A PRECISION TEMPERATURE CONTROL SYSTEM

Wayne Schubert, wayne.w.schubert@jpl.nasa.gov

University of Southern California, Los Angeles, California, United States Madeline Koldos, koldos@usc.edu

University of Southern California, Los Angeles, California, United States Paul Ronney, ronney@usc.edu

University of Southern California, Los Angeles, United States

Additional information about the thermal inactivation of bacterial spores is needed in the context of Mars sample return missions and icy moon exploration. Engineering areas that could benefit from this information include applications of brazing, sealing, impact heating and atmospheric entry heating. Most published information on spore inactivation does not include temperatures above 200 ºC. To address this information gap, an apparatus was built to heat microorganisms rapidly using a precision temperature control system and this apparatus was employed to study microbial spore inactivation, targeting temperatures from 125 to 500ºC. This apparatus consisted of a clear acrylic chamber, an aluminum stand securing tungstenhalogen lamps (the heat source), and a platform to support test silicon wafers that served as substrates for the spores. 1 cm square silicon wafers, 100 µm thick were chosen because silicon wafers have high absorptivity in the visible portion of the spectrum but low emissivity in the mid-infrared (enabling rapid heating), are available in very thin wafers (minimizing thermal response time), have very high thermal conductivity (which minimizes temperature differences across the sample) and are biologically inert. Temperatures were monitored by thermocouples attached to blank silicon wafers. Thermocouple voltages are recorded by a National Instruments data acquisition board and read by a laptop computer running LabView data acquisition and control software. Wafer heating employed a 'bang-bang' control program based on the temperatures read from the thermocouples. When the measured temperature was below a prescribed temperature-vs.-time profile, power was applied to the halogen lamps via a solid-state relay whereas when the measured temperature was at or above the profile value, power was removed. The control system could be programmed to execute any specified custom heating profile. Two bacterial spore types were studied: (1) Bacillus atrophaeus ATCC 9372, which are used in industry as a biological indicator for dry heat reduction processes and (2) the very heat resistant spore produced by

Bacillus sp. ATCC 29669. Samples were prepared by inoculating the silicon wafers with bacterial spores then dried under vacuum. The samples were exposed to a prescribed heating profile (ambient to target temperature in 60s with a linear heating ramp, followed by immediate cooling) under ambient atmospheric conditions. Spore survival was assessed by suspending, sonicating, diluting and pour plating in tryptic soy agar. After incubation, colony-forming units were counted. Test results for viability indicate that under these test conditions, B. atrophaeus did not survive above 200 ºC and the heat resistant spore ATCC 29669 was inactivated at temperatures of 225 ºC.

PPP.3-0011-18 A SUMMARY ON CUTTING EDGE ADVANCEMENTS IN STERILIZATION AND CLEANING TECHNOLOGIES IN MEDICAL, FOOD, AND DRUG INDUSTRIES, AND ITS APPLICABILITY TO SPACECRAFT HARDWARE

Raffaele Gradini, gradini.r@gmail.com

JPL SI R&TD Cleaning/Sterlization

Raffaele Gradini, Fei Chen, Richmund Tan, and Laura Newlin

Issued primarily by COSPAR (the Committee On SPAce Research), international planetary protection policies mandate that all spacecraft hardware in contact with extraterrestrial environments "of chemical evolution and/or origin of life interest and for which scientific opinion provides a significant chance of contamination which could compromise future investigations"

be sterilized. These policies seek to limit the (forward) biological contamination of the target body by terrestrial microorganisms on the spacecraft, so that future missions to the target body will provide accurate and reliable scientific results. Also these policies seek to prevent the (backward) biological contamination of the Earth by a sample returned from the target body. Bioburden reduction is an integral part of current space missions and its importance will magnify as sterilization requirements become more stringent in the future. Since life detection and sample return procedures require a sterile in situ environment (to protect scientific results), subsystems and instruments which will be in contact with extraterrestrial matter must be sterilized. Since the first Viking mission, Heat Microbial Reduction (HMR) has served as a well-understood common practice for sterilization. More recently, NASA and ESA have approved a standard protocol for Vapor Hydrogen Peroxide (VHP) sterilization to address some of the drawbacks of HMR by lowering operating costs and decreasing schedule impacts, as detailed in the certification processes conducted by NASA's Jet Propulsion Laboratory and Steris. Steris has also conducted many testing campaigns on behalf of JPL over the past 20 years. The main results of their campaigns are hence reported. However, even VHP has certain pitfalls that do not make it an all-encompassing sterilization modality for spacecraft hardware. Therefore, this review also investigates the state-of-the-art sterilization and cleaning techniques used in other fields, such as in the medical, food, and drug industries, for application to flight hardware. Major techniques covered include Cold Atmospheric Plasma, Electron Beam Irradiation, and Gamma Irradiation. Some techniques have proven to be good candidates for adaptation for future NASA spacecraft missions. Techniques such as gamma irradiation (rad), can broaden the scope of NASA-approved protocols and expand the currently limited toolkit. Cleaning is also an important aspect of bioburden reduction; despite the best sterilization technologies, dead microbes can interfere with and potentially invalidate the results of biosignature models of relevant celestial bodies. Therefore, cleaning techniques, such as carbon dioxide snow, can significantly contribute to the bioburden reduction process. With the development of standardized protocols for these additional sterilization and cleaning modalities – in combination with the well-known techniques with NASA and ESA approved protocols – we anticipate that future space missions may be able to achieve a higher biological standard.

PPP.3-0012-18 IT IS TIME TO UPDATE THE BIOHAZARD TEST PROTOCOL FOR A MARS SAMPLE RETURN MISSION

John Rummel, jrummel@seti.org

SETI Institute, Champlain, New York, United States

In the early 2000s, NASA envisioned a cooperative sample-return mission from Mars with CNES, and that international effort resulted in the development of a protocol to support the analysis of the samples in a containment facility. That protocol was called the "Draft Test Protocol" in that it was planned to be only the outline of the required preparations "for the safe receiving, handling, testing, distributing, and archiving of martian materials here on Earth," but not a complete listening of every procedure and test that might be required [1]. It was important that the Draft Test Protocol comprised a specific approach to the procedures to be used to conduct a biohazard test for a returned Mars sample, both to enable a critical appraisal of the protocol and to ensure that it would be following the recommendations of the Space Studies Board of the US National Academy of Science. Fast forward to the present, and NASA, with additional international partners (including ESA), is once again envisioning a Mars sample return suite of missions, which it is hoped will result in the arrival at Earth of a Mars sample near the end of the 2020s decade. The first mission in this suite is the sample collecting and caching rover (Mars 2020) which is due to be launched in two years time, setting in motion the clock that will result in the eventual sample return. If the sample will, indeed, arrive at a containment facility for analysis sometime at the end of the next decade, it is now time to revisit the Draft Test Protocol and develop a sample analysis and biohazard test plan that will allow the sample to be successfully evaluated for the presence of a biohazard, and ensure that it can be studied effectively when it returns to Earth. In 2016, the currently ongoing Planetary Protection of Outer Solar System (PPOSS) project was accepted for funding by the European Commission under the Horizon 2020 programme. It provides an international platform and forum where science, industry and policy actors meet, discuss and produce policy recommendations on the matter of planetary protection of outer solar system bodies. A partner in PPOSS, COSPAR is in charge of assembling and publishing an International Planetary Protection Handbook (IPPH). This handbook aims to analyse the international planetary protection landscape, delineate the state-of-the-art and identify the good practices implemented in current and past missions so as to establish them as standard practice. Through desk research, industry and science team consultations (interviews and workshops) including more than ten international partners (space agencies, universities/labs, and industry), the IPPH crystallises the global status of planetary protection implementation and rationales and makes this information available for introduction, education and training purposes. Understanding potential hazards is essential to pursue Space Exploration. Moreover, avoiding unnecessary challenges coming from introducing unwanted forward invasive Earth contamination while searching for extra-terrestrial life is key to efficiently pursuing exploration. Used as a teaching tool in three or four International Planetary Protection training workshops in 2017-18, the handbook explains the do's and don't in planetary protection and, through five detailed case studies, provides all the information needed to understand and apply Planetary Protection requirements to a space mission. The IPPH is intended to be maintained and updated by COSPAR, based on the outcomes of the PPOSS project and future applicable research.

PPP.3-0015-18 CHARACTERIZATION OF DISCONTINUOUS HEAT MICROBIAL REDUCTION TECHNIQUES FOR ATLO CRITICAL PATH IMPACT RELIEF

Zachary Dean, zachary.s.dean@jpl.nasa.gov

NASA Jet Propulsion laboratory, Pasadena, California, United States Lyssa Morgan, lyssa.e.morgan@jpl.nasa.gov

NASA Jet Propulsion laboratory, Pasadena, California, United States Wayne Schubert, wayne.w.schubert@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

To combat bio-contamination risks, current heat microbial reduction specifications employ continuous, uninterrupted heat microbial reduction (HMR). HMR is a proven, validated sterilization tool both at NASA as well as in the medical device industry, but is time-consuming-heat sterilization of a hardware component can last for several days, or even weeks, from start to finish. This lengthy sterilization time causes noteworthy scheduling concerns during assembly, test, and launch operations (ATLO). Additionally, a lengthy exposure at high temperatures for an extended time increases hardware failure risk during flight. Previous studies have shown that heat-resistant organisms are not only killed during the heating ramp-up and cool-down processes, but also that allowing for discontinuous heating, or pauses in the heat sterilization process, may even improve sterilization efficacy. In response, this investigation directly comparing the current continuous HMR requirements with discontinuous HMR has found similar bacterial inactivation characteristics in B. atrophaeus spores using both continuous and discontinuous processes. The characterization and implementation of discontinuous HMR processes can not only lessen ALTO critical path impact, but can also provide increased opportunity for hardware owners to take credit for manufacturing heating processes, such as electrical circuit burn-in before delivery.

PPP.3-0016-18 SPACECRAFT-ASSOCIATED MICROORGANISMS: THEIR SYSTEMATIC IDENTIFICATION, DOCUMENTATION AND LONG-TERM CURATION

Wayne Schubert, wayne.w.schubert@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Arman Seuylemezian, arman.seuylemezian@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, United States

Microorganisms isolated from robotic spacecraft have been preserved as a biological resource for studies relevant to planetary exploration and life detection since the Viking missions. This collection of microorganisms contains 5,000 isolates collected from missions to Mars where there was a requirement to quantify bioburden on spacecraft as a control measure for forward biological contamination. This collection is comprised of isolates gathered from ten Mars missions collected over a period of more than 45 years. This one of a kind collection includes specimens directly pertinent to planetary protection efforts, isolated from Viking through the current missions. Multiple copies of each isolate are preserved by freezing at -80°C with the cryo-protectant glycerol, commercial cryobeads and lyophilization. Genomic DNA resulting from the identification protocols, spacecraft and cleanroom bioassay wipes have been preserved as an additional resource.

Nearly all of the isolates that have been identified are gram-positive and more than 80% of the isolates are spore-formers. Based on 16SrRNA gene sequencing of 1,500 isolates, Bacillus is the genus found in the greatest abundance (72%), followed by Staphylococcus (6%), Paenibacillus (5%), Brevibacterium (2%), Micrococcus (2%), Sporosarcina (2%) and other genera at 1% or lower. More than 25 genera and 65 different species are represented. A significant fraction of isolates was identified as novel species candidates. The collection is rich in isolates that are resistant to microbial reduction techniques such as dry heat, vapor hydrogen peroxide, and UVC radiation.

The current approach to identify spacecraft isolates utilizes Matrix-Assisted Laser Desorption/Ionization Time-of-Flight

Mass Spectrometry (MALDI-TOF) spectra with comparisons to a custom spectral library comprised of 350 unique isolates from this collection with known 16S rRNA gene sequence information. Grouping the organisms by operational taxonomic units with 99% sequence homology, and obtaining MALDI-TOF spectra for each OTU eliminates the need to obtain a spectrum for every isolate. The use of the custom database containing 350 mass spectral profiles, improves the identification of new isolates from 7% to greater than 70%.

The spacecraft and cleanroom habitat is a unique microbial environment with little opportunity for cell division, dominated by rare hardy microorganisms that have survived desiccation and removal by cleaning. These microbes exist in a transport-driven environment that is strongly influenced by human activity and control measures. Improvements in our understanding of this spacecraft microbial archive collection was advanced through student internships and academic collaborations. These isolates can be made available for collaboration and new academic partnerships.

PPP.3-0017-18 ASSESSING EFFECTS OF UPPER ATMOSPHERE CONDITIONS ON SURVIVAL OF DEINOCOCCUS PHOENICIS.

Bryan Gunawan, bryan.gunawan95@gmail.com University of Houston, Houston, Texas, United States Samar Mathur, samarm96@gmail.com

Texas, United States

As missions continue to explore new celestial bodies, there is a growing need to understand how terrestrial biology reacts under these surface conditions. Europa, a Galilean moon of Jupiter, is a primary example with radiation receiving from Jupiter to its surface. Due to the stringent planetary protection requirements of Europa missions, any probability of contamination is required to be less than 1 x 10−4 permission. Along with the spore forming bacteria, known to be the most common spore forming bacteria are found to be tolerant to extreme environmental conditions. These organisms are more spore forming organisms on hardware under radiation exposure which is critical for future missions to calcul based simulation chambers or Space exposure studies on the International Space Station. Using weather balloon dried Deinococcusphoenicis 1P 10M E cells will ascend through the troposphere and stratosphere for approxim spore forming radiation resistant bacterial cells exposed to stratospheric radiation.Resultsof this study will h spore forming bacterial cells exposed to space radiation and assess forward contamination risk for future N A

This research is being conducted in collaboration with the University of California - Berkeley and the Jet Propulsion Laboratory, and is supported by the NASA's National Space Grant College and Fellowship Program and Science Mission Directorate.

PPP.3-0018-18 MICROBIAL ECOLOGY OF NASA CURATION CLEAN ROOMS

Aaron Regberg, aaron.b.regberg@nasa.gov

NASA Johnson Space Center, Houston, Texas, United States Aaron Burton, aaron.s.burton@nasa.gov

NASA/Johnson Space Center, Houston, Texas, United States Christian Castro, christian.l.castro@nasa.gov

JES Tech, Houston, Texas, United States Sarah Wallace, sarah.l.wallace

NASA Johnson Space Center, Houston, United States Francis McCubbin, francis.mccubbin@gmail.com NASA/JSC, Houston, Texas, United States

Clean room standards like ISO 14644 [1] used for facilities that construct spacecraft and store returned samples do not explicitly account for microbial contamination. While there are associated ISO standards for monitoring and controlling bio-contamination in clean rooms [2]2 it is not always standard practice to do so. The NASA Astromaterials Acquisition and Curation Office maintains seven separate clean labs for storing extraterrestrial samples from the Moon, meteorites, cosmic dust, asteroids, comets, solar wind particles, and microparticle impact samples. These labs are routinely monitored for particulate and trace metal contamination. However, the sample collections are either non-sterile at the time of collection (e.g., meteorites) or are no longer being used to address scientific questions that could be affected by non-sterile conditions (e.g., Lunar samples). Outside of isolated studies[3] there has not been a systematic, longitudinal characterization of the microbial ecology of NASA curation clean rooms. In accordance with the advanced curation initiative[4], and to prepare for future sample return missions, we have initiated a routine microbiological monitoring program in the Antarctic Meteorite Lab. This monitoring program will be used to determine what microbes are capable of surviving in these oligotrophic environments and whether or not they are capable of altering the sample collections in any significant manner. Repeat sampling will allow us to understand how routine use of these labs affects the microbial ecology over time. We chose to begin our investigation in the Meteorite Lab because it has a lower ISO cleanliness standard (ISO 7) than most of the curation labs (ISO 6 - ISO 5) and therefore is likely to contain a higher bio-burden that we can sample without decreasing the cleanliness level of the lab. Additionally, most of the meteorites were collected from Antarctica and have been exposed to the terrestrial environment for thousands of years. Thus, it is possible that some of the organisms in this lab are transplants from the Antarctic environment. As we establish a routine sampling protocol that does not affect sample integrity we will extend our sampling efforts to the ISO 4-6 labs with a special focus on the Lunar Lab. Preliminary results from the Meteorite Lab indicate that fungi may play a larger role in clean room ecology than previously recognized. Although overall counts were comparable to other cleanroom assessments, fungal colonies comprised 83-97% of the isolates from Meteorite Lab samples. This result is especially interesting since many fungal species are capable of producing amino acids like Aib (-aminoisobutryic acid) and Iva (isovaline) that are often considered to be extra-terrestrial when identified in meteorites[5,6]. Curation facilities for the upcoming OSIRIS-REx and Hayabusa2 missions will be carefully monitored for fungal contamination to avoid inadvertent alteration of pristine carbonaceous asteroid samples. We will present culture-based and culture-independent time-series data from several NASA curation clean rooms that demonstrate how routine usage affects the microbial ecology. The results of this work will inform astrobiology and Planetary Protection efforts for upcoming missions.

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

The key objective of the Planetary Protection discipline is to ensure that NASA's spacecraft meet biological cleanliness requirements and prevent inadvertent contamination of other planetary bodies, which may jeopardize a given mission's science objectives. This is achieved by assembling spacecraft in cleanrooms and monitoring microbial bioburden on spacecraft and associated surfaces. The Jet Propulsion Laboratory (JPL) has maintained the largest archive of bacterial strains isolated during the microbial monitoring of spacecraft and associated surfaces since the 1970s. Identification of these isolates was routinely performed by sequencing the 16S rRNA gene. Although this technique is an industry standard for bacterial identification, it requires time consuming laboratory work (DNA extraction, PCR, amplicon purification, sequencing, and sequence analysis) with a minimum 4-5 day turnaround, and has insufficient resolving power at the species level for some taxa. Matrix-assisted laser desorption/ionization time of flight (MALDI-TOF) mass spectrometry is widely used in clinical diagnostics and is a promising method to replace standard 16S rRNA sequencing. However, manufacturer provided databases lack bacterial isolates found in spacecraft-assembly cleanrooms. This study reports development of the first and largest custom database of MALDI-TOF MS profiles of bacterial isolates obtained from spacecraft surfaces and cleanroom environments. With the use of this accurate, custom, in-house developed database, 454 bacterial isolates were successfully identified in concurrence with their 16S rRNA sequence-based classifications. Additionally, MALDI-TOF MS was able to resolve strain level variations, identify potential novel species and distinguish between members of taxonomic groups, which is not possible using conventional 16S rRNA sequencing. MALDI-TOF MS has proved to be an accurate, rapid, and cost-effective approach for identification of bacterial isolates during the spacecraft assembly process.

PPP.3-0020-18 ASEPTIC OPERATIONS FOR POST DHMR PROCESSING OF MOMA MASS SPECTROMETER

Erin Lalime, erin.lalime@nasa.gov

SGT, Inc., Greenbelt, Maryland, United States Erin Lalime, erin.lalime@nasa.gov

SGT, Inc., Greenbelt, Maryland, United States John Canham, john.canham@orbitalatk.com Orbital ATK, Beltsville, Maryland, United States Radford Perry, radford.l.perry@nasa.gov

Goddard Space Flight Center, Greenbelt, Maryland, United States

Mars Organic Molecule Analyzer - Mass Spectrometer (MOMA-MS) is an instrument in the MOMA instrument suite for the European Space Agency (ESA) ExoMars 2020 Rover. The rover is Planetary Protection Mission Category IVb, the first IVb mission since the Viking missions in the 1970s. Within the sample path of MOMA instrument suite the hardware surfaces of the must be sanitized to a level of 0.03 spore/m2. To meet this requirement, the MS sample path is subjected to Dry Heat Microbial Reduction (DHMR) to decrease the number of viable spores by 4 orders of magnitude from a measured 88 spores/m2 to 0.009 spores/m2. Before DHMR, the hardware is handled using standard cleanroom practices. After DHMR, planetary protection filters protect the sample path for most of integration, but when sample path exposure is required, aseptic operations are instituted and exposure times are kept to an absolute minimum. The surface area of exposure is also taken into account to determine safe exposure times. Before work begins, the ISO class 5 aseptic workspace is cleaned and tested for surface and airborne bioburden, and all tools that will contact or be used near sample path surfaces are sterilized. During the exposure activity, sterile garments are worn, sterile gloves are changed as often as necessary, and the environment is monitored with active and passive fallout for bioburden and real time airborne particle counts. Sterile tools are handled by a two person team so that the operator touches only the tool and not the exterior surfaces of the sterilization pouch, and a sterile operating field is established as a safe place to organize tools or parts during the aseptic operations. In cases where aseptic operations are not feasible, localized DHMR is used after exposure. Any breach in the planetary protection cleanliness can necessitate repeating instrument level DHMR, which not only has significant cost and schedule implications, it also become a risk to hardware that is not rated for repeated long exposures to high temperatures.

PPP.3-0021-18 THE IMPORTANCE OF CONTAMINATION KNOWLEDGE - INSIGHTS INTO MARS SAMPLE RETURN

Andrea Harrington, andrea.d.harrington@nasa.gov NASA/JSC, Houston, Texas, United States Michael Calaway, michael.calaway@nasa.gov

Jacobs/Johnson Space Center, Houston, Texas, United States Aaron Regberg, aaron.b.regberg@nasa.gov

NASA/JSC, Houston, Texas, United States Marc Fries, marc.d.fries@nasa.gov

NASA Johnson Space Center, Houston, Texas, United States Ryan Zeigler, ryan.a.zeigler@nasa.gov

NASA Johnson Space Center, Houston, Texas, United States Francis McCubbin, francis.mccubbin@gmail.com NASA/JSC, Houston, Texas, United States

The Astromaterials Acquisition and Curation Office at NASA Johnson Space Center (JSC), in Houston, TX (henceforth Curation Office) manages the curation of all past, present, and future extraterrestrial samples returned by NASA missions and shared collections from international partners, preserving their integrity for future scientific study while providing the samples to the international community in a fair and unbiased way. The Curation Office also curates all reference and witness materials for each mission (e.g., flight and non-flight hardware coupons; lubricants; non-flight, flight-like, and flown witness plates). These reference and witness materials provide the scientific community with the fundamental ability to reconstruct the contamination/alteration history of the sample collection through the course of the mission, with the overall goal of strengthening the scientific conclusions drawn from the study of returned materials.

The information gained from characterizing the physical, biological, inorganic, and organic chemical properties of reference and witness materials is defined as the Contamination Knowledge (CK) of the sample collection. Unlike the data collected for Contamination Control (CC) and Planetary Protection (PP), CK is exclusively concerned with preserving reference and witness materials for study by future scientists upon sample return. Although CC and PP data collected for sample integrity and forward contamination purposes can be complementary to

CK, they are two separate data sets with distinct objectives. A robust collection of samples for CK is necessary to allow the extraterrestrial material in a returned sample to be distinguished from terrestrial contamination. Traditionally CK is utilized by sample scientists in order to accomplish the mission's scientific objectives, however this information can also be utilized by the Office of Planetary Protection to help evaluate the presence of any back contamination.

Mars 2020, the first phase of a potential multipart Mars Sample Return (MSR) campaign, is expected to contribute to NASA's Mars Exploration Program Science Goals by filling in knowledge gaps concerning: 1) the existence of past or present life on Mars, 2) the past and present climate of Mars, 3) the geology of Mars, and 4) hazards associated with human exploration of Mars [1]. Although there is debate concerning which samples will best answer these questions, the necessity for proper sample blanks is well-understood. The CC and PP requirements, driven by the restricted Class V mission designation, are the most stringent of any sample return mission in recent history. The extremely low levels of allowable terrestrial contamination on the spacecraft and rover can complicate these analyses given the detection limits of current analytical instrumentation, especially in the case of biological contamination. By collecting and curating unanalyzed samples specifically for CK, future sample scientists will not be relegated to: 1) relying on data collected using possibly obsolete tools and techniques for return sample blanks, or 2) using remnants of extracted and/or cultured samples from ATLO, which could be incompatible with the desired experimental endpoints or state-of-the-art techniques available at the time of sample return.

The addition of biological experimental endpoints to a sample return campaign's objectives broadens the requisite range in preservation environments (e.g. inert ultra-pure nitrogen gaseous environment at 18°C versus -80°C) and types of CK samples. As a result, the Curation Office will also curate the following CK samples at -80°C for the Mars 2020 mission:

1) unanalyzed swabs and wipes in sterile containers, 2) all recirculation filters from the clean rooms used for sample and caching subsystem assembly and all filters from the laminar flow benches used to assemble sample intimate hardware, and 3) witness plates collecting airborne contamination within the assembly cleanrooms.

It has been Curation Office policy since the Apollo missions to preserve as many pristine samples as possible for future scientific research [2, 3]. Although CK is required to be collected for all stages of the MSR campaign, the CK for the Mars 2020 mission is the most critical for understanding contamination in the returned samples given the intimacy between the martian samples and the Mars 2020 flight hardware. This presentation highlights the importance of CK for sample return missions as well as the traditional and novel types of CK samples required for a successful MSR campaign.

Projects such as EXOMARS 2020, Juice or Mars Sample Return and other further planned project with dedicated planetary protection constraints lead to new challenges due to simultaneously achieving extreme levels of particulate, molecular and biological cleanliness levels. The presentation will cover results from an ESA-supported investigation to collect lessons learned for mechanism assembly with the focus on quality and contamination requirements verification. The need to apply the findings in the challenge of subcontractor managing is shown.

The heritage of OHB is based on the direct contribution, such as the High Resolution Camera, the Sample Processing and Distribution System (SPDS), the optical harness and the Analytical Laboratory Drawer (ALD) developments for the ExoMars2020 mission. The contributions cover the full range of cleanliness deliverable status from visible clean components to be finally cleaned by the Customer up to components integrated in the ultra clean zone. An additional source of experience was gained by exchange and support from and for other suppliers. In this regard, aspects from manufacturer to customer covering material compatibility, cleaning, sterilization and verification, documentation had to be covered.

To cover these open challenges, OHB and IPA Fraunhofer experts signed a cooperation agreement. The combination of non-space application heritage and the laboratory infrastructure at IPA Stuttgart has initiated several valuable impulses, developments and systematic studies. One study covers the assembly of a representative mechanism in different environments, including the judgement on particulate, molecular and biological requirements achievement. The main objectives of the study were risk assesment, logistics effort, duration and quality aspects.The results sall be summarized in the presentation. The possibility to extract system engineering and design guidelines is currently in preparation at OHB and shall be briefly outlined. The key findings might lead to contributions to improve schedule, effort and mitigation action planning and might reduce cost and delays. This project was cofounded by ESA and OHB.

The cooperation of IPA and OHB System reported in the presentation, focussing on cleanliness, cleaning process development and verification methods is supported by ESA.

PANELS (P)

STATE-OF-THE-ART ASSAY TECHNOLOGIES (PPP.4)

PPP.4-0001-18 PLANETARY PROTECTION TECHNOLOGIES FOR PLANETARY SCIENCE INSTRUMENTS, SPACECRAFT, AND MISSIONS

D.E. (Betsy) Pugel, betsy.pugel@nasa.gov

NASA Headquarters, Washington, District of Columbia, United States John Rummel, jrummel@seti.org

SETI Institute, Champlain, New York, United States

Planetary bodies like Mars, Europa, and Enceladus pose the question, "How to study them without contaminating them and destroying the object of study?" The natural trade-off, of course, is that the cleaner your spacecraft, the more you can explore such a body without contaminating it. As chartered by NASA Headquarters, the Planetary Protection Technology Definition Team (PPTDT) was asked to provide a report on six different tasks related to the engineering and technology challenges of implementing planetary protection requirements on solar system exploration missions: • Assessment of technical and engineering challenges to applying available microbial-reduction methods, including recontamination prevention, to spacecraft hardware and instruments, to meet current NASA requirements on preventing the forward contamination of potentially habitable worlds by future spacecraft missions (orbiters, atmospheric missions, landers, penetrators, and drills); • Identification of spacecraft and instrument materials known to be compatible with existing planetary protection protocols; • Planetary protection protocols/processes available or which appear promising, and areas ripe for technological development; • The technical and engineering challenges in ensuring that spacecraft hardware and instruments can meet organic cleanliness requirements needed to ensure high confidence in differentiating Earth contamination from extraterrestrial signals to avoid false negative as well as false positive results; • Approaches for mitigating the identified challenges, that would allow instruments to be flown successfully at the required levels of cleanliness and microbial reduction, beginning with identification of commonly used materials and spacecraft hardware that are compatible (or particularly vulnerable) to planetary protection protocols; • Engineering, technology, and scientific research and development that could be funded by NASA to provide future capabilities to field scientific instruments and spacecraft on missions that require either subsystem or system-level microbial reduction and recontamination prevention.

PPP.4-0002-18 MICROBIAL CONTAMINATION DETECTION AT LOW LEVELS BY [125]I RADIOLABELING

David Summers, david.p.summers@nasa.gov

SETI Institute/NASA Ames Res. Center, Moffett Field, California, United States Travis Boone, travis.d.boone@nasa.gov

NASA, Moffett Field, California, United States

This work seeks develop a new method for the determination of bioburdens (and the detection of microorganisms and life) for planetary protection purposes. It would work by the detection of the organism's protein by labeling them with a radioactive label, 125I. This would provide greater sensitivity while preserving a good turn-around time for analysis. This method will utilize the current NASA sampling techniques and thus could be directly compared against existing methods.

Radiolabeling techniques are inherently sensitive and 125I benefits from a 60 day half-life, providing greater activity and signal per unit number of labels. Additional sensitivity can be obtained by use of a Multiphoton Detection. This should enable detection to lower levels than previously possible, down to single cells.

By utilizing a universal biosignature (cell proteins), this method provides broad generality with regard to the range of organisms that can be detected and isn't restricted to any type(s) of organism, the ability of the organisms to be cultured, etc. This work would develop a quick and simple method for detecting the proteins from cells. This detection would involve:

Separation of cells/spores.

Lysis of cells.

Labeling of released proteins separation from unreacted label.

Detection by standard or multiphoton detection.

Previous work has shown the desirability of mechanical lysis methods. We will use OmniLyse mechanical lysis method from ClaremontBio Solutions which has been used successfully in NASA's Wetlab-2 project.

The method would also have applicability for testing returned samples hardware and for the testing sterilization methods as well as other Astrobiological applications. Future work could extend to species such as viruses and prions.

This work was support by NASA's Planetary Protection Program

PPP.4-0004-18 DEVELOPMENT OF METAGENOMIC APPROACH FOR ULTRA-LOW BIOMASS SAMPLES FROM SPACECRAFT SURFACES

Lisa Guan, lisa.guan@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Parag Vaishampayan, vaishamp@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

The inadvertent introduction of terrestrial microorganisms via spacecraft to other planetary bodies could compromise sciencific objectives of future missions, such as the search for extraterrestrial biosignatures. Given the highly specialized and extreme environment of spacecraft hardware surfaces, a unique but highly complex microbial diversity can be found on the spacecraft and associated surfaces. To monitor terrestrial microorganisms that are possible sources of forward contamination, it is important to develop a comprehensive inventory of microbes that are present on spacecraft to avoid interpreting their traces as authentic extraterrestrial biosignatures. Culture-based methods can only detect a small subset of total microorganisms present while genetic (DNA-based) identification techniques are able to capture the broadest spectrum of the microbial communities. The principal objective of this study is to establish phylogenetic diversity and functional traits by exploring the entire gene content (metagenome) of the spacecraft hardware. With the low amounts of biomass present on spacecraft hardware, existing molecular biology techniques are incapable of generating a high-quality metagenomics library. The methods presented here include the development and optimization of new laboratory protocols that are at the cutting-edge of environmental genomics technology and will have significant implications for the design and interpretation of microbial burden studies for ongoing and future Mars, sample return, and icy moon missions.

PPP.4-0005-18 TARGETED GENE(S) AMPLIFICATION-BASED NGS ANALYSIS OF LOW BIOMASS SAMPLES FROM SAF/SPACECRAFT SURFACES

Jet Propulsion Laboratory, Pasadena, California, United States

As per COSPAR PP policy, all spacefaring nations, when conducting the scientific investigations of possible extraterrestrial life forms, precursors, and remnants, are required to follow the appropriate forward contamination control procedures and met planetary protection requirements. In addition, the Earth must be protected from the potential hazard posed by extraterrestrial matter carried by a spacecraft returning from another planet. Therefore, for certain space mission/target planet combinations, controls on contamination shall be imposed, in accordance with issuances implementing this policy. The COSPAR PP policy states that it requires technologies to clean and sterilize spacecraft systems and technologies to validate that the required cleanliness dictated by the mission's PP category has been met. All of these available technologies are focused on eradicating bacterial contaminants, but it is important to understand that low biomass samples contain microbial signatures from both Eukaryotic and Prokaryotic domain, which need to be cataloged in an unbiased manner. The amplicon based next generation sequencing methods like AmpliSeq from Ion Torrent and targeted gene(s) sequencing from Illumina, will assist in understanding cross-domain low biomass surface organisms posing a threat of forward contamination. It will also enable the development of suitable cleaning/sterilization procedures and enhance PP verification protocols. The targeted gene(s)- based method relies on polymerase chain reaction-based technology that uses a low amount of starting material for experiment initiation, which is a requirement for ultra-low biomass samples such as spacecraft surfaces. The targeted gene(s) based amplification technology makes use of specified panel design, which can be as high as 24,000 targets simultaneously studied in a single tube. It will also assist novel species discovery and study their genetic variation without the GC biases. Use of these recent technologies will deepen our understanding of microbial population associated with low biomass samples and their functional characteristics. It will also help in cataloging nucleic acid-dependent life surviving extreme conditions of the spacecraft Assembly, Testing, Launch, and Operation (ATLO) environments. The targeted gene(s) based amplification method has potential to reduce sequencing cost and processing time associated with total metagenome analysis as well as tailor to catalog the microbial genes of interest to a specific mission (e.g. psychrophilic, anaerobic, radiation resistant microbes for Europa). This novel strategy will help to measure forward microbial contamination and enable to track them on the samples returned from exploring planet(s).

PPP.4-0006-18 A PROTOTYPE TOOL FOR ASSESSING FORWARD CONTAMINATION FROM SPACE SUITS

Crewed exploration missions dramatically increase the capability for large-scale sample collection and return activities, but they also increase the possibility and likelihood of forward contamination. Systematic research on forward contamination from uncrewed spacecraft has steadily progressed since the Viking missions, but parallel research on contamination from space suits has not. Current space suits have leakage rates as high as 100 cc gas/min.1, but it is unclear how many or what types of microbes are exiting the suits along with this gas. The Human Forward Contamination Assessment team at NASA's Johnson Space Center (JSC) has developed a prototype swab tool2 that is capable of maintaining sterility during pressure changes associated with entering and exiting vacuum. The primary objective of recent Extravehicular Activity (EVA) Swab Kit testing is to characterize the type of microorganisms typically found on spacesuit external surfaces under suit differential pressure conditions. Most humanassociated microorganisms can fit through a 0.5 to 1.0 µm gap. Understanding potential leak paths will inform future hardware design decisions. Knowing which types of microorganisms may leak from EVA suits provides a basis for subsequent studies to characterize the viability of those organisms under destination conditions, as well as how far they might spread through natural or human-influenced processes. The results of EVA suit molecular microbial community analyses will inform NASA exploration mission operations and hardware design, and help close Strategic Knowledge Gap B5, Forward Contamination to Mars We sampled suits as a secondary activity during tests conducted in two different vacuum chambers at Johnson Space Center. Samples were analyzed at Johnson Space Center and at the Jet Propulsion Laboratory using a variety of culture based techniques to grow bacteria collected from space suit surfaces during vacuum testing. We also used 16S rRNA tag sequencing and shotgun metagenomics to characterize uncultivatable microbes and environmental DNA from these surfaces.

Preliminary testing with this tool has confirmed that the design is capable of maintaining sterility while transitioning in and out of vacuum. We were unable to culture bacteria or fungi from negative control samples that were sterilized prior to testing and witnessed the entire testing procedure without being opened. Culture based results indicate more than 10 bacterial and at least one fungal species from space suit surfaces are capable of surviving up to 4 hours at vacuum. Current protocols for cleaning space suits prior to use are focused on crew health and safety rather than sterilization of the suits and thus microbiology of suit external surfaces are indistinguishable from the environment in which they are tested. In order to characterize and quantify forward contamination from space suit leakage, more controlled testing with these tools is necessary.

We have developed and tested a prototype tool for collecting samples from space suits during Extra Vehicular Activity. Preliminary testing of this tool has demonstrated that it can be used to collect samples at vacuum and that these samples will remain uncontaminated during testing. Additional testing will provide valuable insight into Planetary Protection, Astrobiology, Space Biology, ISS, and Human Research Programs needs as we prepare to send human explorers in search of life beyond Earth.

Peter Emanuel, peter.a.emanuel.civ@mail.mil

US Army Edgewood Chemical Biological Center, Aberdeen Proving Ground, Maryland, United States

Currently, there are several biological surface sampling kits that are designed to acquire and safely transport biological specimens. In these kits, many of the items are individually packaged and require both hands for optimal use. Since many of these items are packaged individually, the operator will generate a large amount of waste that will need to be managed during the course of a sampling mission. We have designed a sampling device to facilitate biological sampling using one-hand and reduce waste materials, which we have named the Mano Sampling Device. The advantage of this device versus currently available sampling technology is that this device acts as the actual sampler as well as the transport packaging, therefore, speeding up sampling times and reducing waste. The one-handed operation of the device will simplify sampling while wearing mission oriented protective posture (MOPP) gear in a hazardous environment. This design indicates a major step forward in biological sampling technology.

Planetary protection represents an additional set of requirements that generally have not been considered by developers of technologies for Environmental Control and Life Support Systems (ECLSS). Forward contamination concerns will affect release of gases and discharge of liquids and solids, including what may be left behind after planetary vehicles are abandoned upon return to Earth. A crew of four using a state of the art ECLSS could generate as much as 4.3 metric tons of gaseous, liquid and solid wastes and trash during a 500-day surface stay. These may present issues and concerns for both planetary protection and planetary science. Certainly, further closure of ECLSS systems will be of benefit by greater reuse of consumable products and reduced generation of waste products. It can be presumed that planetary protection will affect technology development by constraining how technologies can operate: limiting or prohibiting certain kinds of operations or processes (e.g. venting); necessitating that other kinds of operations be performed (e.g. sterilization; filtration of vent lines); prohibiting what can be brought on a mission (e.g. extremophiles); creating needs for new capabilities/ technologies (e.g. containment). Although any planned venting could include filtration to eliminate microorganisms from inadvertently exiting the spacecraft, it may be impossible to eliminate or filter habitat structural leakage. Filtration will add pressure drops impacting size of lines and ducts, affect fan size and energy requirements, and add consumable mass. Technologies that may be employed to remove biomarkers and microbial contamination from liquid and solid wastes prior to storage or release may include mineralization technologies such as incineration, super critical wet oxidation and pyrolysis. These technologies, however, come with significant penalties for mass, power and consumables. This paper will estimate the nature and amounts of materials generated during Mars transit and surface stays that may be impacted by planetary protection requirements or be controlled for the protection of planetary science.

PPP.4-0009-18 INSTRUMENTATIONS AND CAPABILITIES FOR "OMICS IN SPACE" THAT ARE REQUIRED FOR HUMAN MISSIONS

Kasthuri Venkateswaran, kjvenkat@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States Microbial Tracking and OIS Team

Checinska Sielaff, A. Fox, G.E. Frey, K. Jaing, J. Landry, K Malli Mohan, G.B. Mason, C. Mehta, S. Perry, J. Pierson, D.L. Regberg, A. Sinclair, D. Singh, N.K. Smith, D.J. Urbaniak,

C. Weislogel, M. Wong, S. Zhang, Y.

The NASA Space Biology program funded two multi-year studies to catalogue International Space Station (ISS) environmental microbiome where samples were brought back to Earth and analyzed using molecular methods. The first Microbial Tracking (MT) experiment generated a microbial census of the ISS surfaces and atmosphere using advanced "omics" techniques, supported by traditional culture-based methods. The MT-2 experiment is measuring presence of viral and select bacterial and fungal pathogens on ISS surfaces and correlate their presence on crew. The microbial burden, diversity, and characterization of select microorganisms of ISS environmental surfaces and air particulates revealed that ISS strains exhibited more virulence than their Earth counterparts. The iTag sequencing to generate microbiome and shotgun sequencing to measure metagenome of the ISS environmental surfaces and air filtration systems showed presence of microbial members more closely related to human.

The safety of crewmembers and the maintenance of hardware are the primary goals for monitoring microorganisms in this closed habitat. The "omics" methodologies of the MT experiments will serve as the foundation for an extensive microbial census, offering significant insight into spaceflight-induced changes in the populations of beneficial and potentially harmful microbes. Bioinformatics data on the microbial diversity, antimicrobial resistance, virulence, and pathways are archived in the NASA GeneLab bioinformatics system that are open to the scientific research community.

The next generation sequencing using the MinION platform and PCR instruments were demonstrated on ISS by NASA in 2016 and were successful in sequencing libraries that had been prepared on Earth and shipped to the ISS. The limitation in this ISS demonstration study was that samples had to be prepared on Earth before sequencing could be performed on the ISS, as there are no technologies in place to process samples, extract biomolecules, and prepare libraries for NGS sequencing. However, NASA needs to develop instrumentations for extracting nucleic acids and sequencing methodologies for inflight detection and measurement of several biomolecules related to physiological and immunological effects related to spaceflight (e.g., aging, crew health, elevated antimicrobial resistance, and virulence).

The "Omics In Space (OIS)" project, funded by the Translational Research Institute for Space Health, recognizes these limitations and will be developing an automated Sample Processing Instrumentation for nucleic acid extraction in space that is streamlined, requires minimal crew time, reduces the amount of contamination between samples, and produces consistent results. In this regard, onboard ISS we will generate "omics" data related to microbiome (targeted for bacteria, fungi, and viruses) to address the microbial composition, metagenome (crew and environments) for functional characteristics, miRNA for immunological function, as well as epigenetic data to elucidate radiation-induced damage, cellular disruption, and aging of astronauts.

The development of an all-encompassing, integrated OIS bioinformatics database for closed habitat will enable various phylogeneticand pathogenic-based strategies of screening for, and identifying, specific subsets of microorganisms (e.g., dominating viral and microbial pathogens, as well as those that bear resistance traits relevant to antibiotics). This dataset will (a) create a capability for NASA to compare fluctuating microbial communities to "baseline" standards;

(b) enable more accurate assessments of crew health associated with mission planning; (c) allow evidence-based development of future bio-load management policies, particularly for long duration missions; and (d) capitalize on parallel research from non-NASA institutions efforts.

NASA maintains a planetary protection policy to avoid the inadvertent biological contamination of solar system bodies, that would obscure our ability to find life elsewhere, by assembling spacecraft in cleanrooms and monitoring microbial bioburden on spacecraft and associated surfaces. Though it was hypothesized that humans are the key contributors of bioaerosols and inert particles in a spacecraft assembly cleanroom, it has not yet been systematically assessed. Cleanroom certifications and cleanliness assessments are performed by monitoring and assessing particle size distribution per cubic meter of the air. The majority of particle counters assess particle size distribution and their abundance but cannot discern inert particles from bioaerosols. We performed real-time quantification of size-resolved bioaerosols and inert particles in spacecraft assembly cleanrooms using BioVigilant IMD-A® 350 system (Azbil Corporation, Tucson AZ, USA). The IMD-A 350 air monitoring system is based on optical spectroscopy that can differentiate aerosolized inert particles and bioaerosols, by targeting intrinsic fluorescence of airborne particulates. We performed sampling with 10-second resolution continuously during both six hours of normal operational activities (at work) and no activities (at rest) in six cleanrooms (ISO Classes 6, 7, and 8) at three time points at the Jet Propulsion Laboratory (JPL). A positive correlation was established between human presence and elevated bioaerosol counts. Our results show that on average, smaller size particles (0.5 and 1 micron) constitute 90.98 % (pm±0.063 SE) of the total bioaerosols detected at work, consistent across all the cleanrooms. This study represents the first continuous air monitoring of spacecraft assembly cleanrooms for simultaneous detection of bioaerosols and inert particles.

Projects such as EXOMARS 2020, Juice or Mars Sample Return and other further planned project with dedicated planetary protection constraints lead to new challenges due to simultaneously achieving extreme levels of particulate, molecular and biological cleanliness levels. Beside the difficult task to translate the performance goals into requirements on prime and subco level the presentation shall focus on the topic of verification. The heritage of OHB is based on the direct contribution, such as the High Resolution Camera, the Sample Processing and Distribution System (SPDS), the optical harness and the Analytical Laboratory Drawer (ALD) developments for the ExoMars2020 mission. The contributions cover the full range of cleanliness deliverable status from visible clean components to be finally cleaned by the Customer up to components clean integrated in the ultra clean zone. The aspect of coordination of subcontractors across europa and cooperation with US subcontractors in combination with the regulations of assay taking and documentation lead to the development of the MUCA concept. MUCA shall become a mobile, flexible to use high end laboratory system to be used for at least the following aspects: Temporary operation of assay task on subcontractor side, education for planetrary protection training and hands on experience, standardisation between laboratories, on side control at test houses and launch side, lessons learned distribution. Results of a feasibility study covering aspects like necessary equipment, logistic, cleanliness levels and monitoring have been collected and shall be presented. A schedule to set MUCA in operation for national and international missions with high demands on contamination control will be shown. We believe that MUCA could provide a positive impact on standardisation between different agencies, contries and subcontractor. Key questions of limited duration between sample taking and analysis plus data handling of large assay numbers is covered. Overall MUCA sahll lead to schedule, risk and cost reductions.

The MUCA concept was created within a cooperation between OHB and the expert from the IPA Fraunhofer institut. The combination of space and non-space application heritage lead to new interesting aspects.

The concept and its applications shall be presented and we are looking for an open discussion.

PPP.4-0012-18 A GROUND SUPPORT BIO-BARRIER FOR RECONTAMINATION PREVENTION

NASA Jet Propulsion Lab / California Institute of Technology, Pasadena, California, United States

The planetary protection discipline is concerned with protecting celestial bodies that have the potential for life (e.g icy moons and Mars special regions) from terrestrial biological contamination. During the spacecraft assembly process subsystems undergo functional testing, a Mission Assurance task that verifies critical components can survive from launch through the duration of the mission. Despite efforts to keep spacecraft clean during ground support testing operations recontamination frequently occurs, resulting in the need to further clean the spacecraft and increasing risks to the assembly critical path schedule. In response, a ground support bio-barrier capable of protecting flight hardware continuously from an up-to 150°C bake-out sterilization and throughout the functional testing process has been designed. The bio-barrier consists of Nomex fibers combined with a PTFE weave for increased structural integrity over standard fiberglass HEPA filters, and improved electro-static discharge and heat resistant characteristics over statically-charged polymer HEPA filters, typical microbiology-standard filters. The Nomex/PTFE bio-barrier exhibited 97.07% filter efficiency for 0.3 m particles, but a doublelayered configuration presented 99.86% efficiency for 0.3 m particles. A double-layered configuration has additionally been given preliminary Contamination Control approval. Finally, the recontamination-prevention bio-barrier uses an 80/20 aluminum frame to prevent bio-barrier contact with critical spacecraft hardware. The recontamination-prevention bio-barrier can provide a safety-net against microbiological re-contamination during critical functional testing, decreasing the need for re-cleaning and reducing schedule impact risk.

Alfredo Ferrari, alfredo.ferrari@cern.ch CERN, Geneva, Switzerland

This work presents Monte-Carlo simulations based on the Fluka code aiming to calculate the contribution of the neutron albedo at a date (representing the solar modulation) and altitude above the Earth, both of them chosen by the user. Results consist of three-parameter distribution, the energy and two angles characterizing the incident direction of the albedo particle, and are provided according to 9°x15° meshes all around the Earth at the chosen altitude. A very interesting feature of this model is the method used for filtering incident cosmic rays before reaching the Earth's atmosphere, MASHcode instead of the more classical Störmer filtering, guaranteeing a better estimate of protons at the level of the atmosphere thanks to inverse ray tracing. Such accuracy is of great importance for both applications of this models, i) the estimation of ambient neutrons for assessing the displacement damages and background level of detectors operated at LEO, and ii) the estimation of the main source of protons > 40 MeV of the inner radiation belt (CRAND). A future work will consist in using the outputs from this model to improve the CRAND process modelling in the ONERA Salammbô code.

ONERA, Toulouse, France

Markus Brugger, markus.brugger@cern.ch CERN, Switzerland

Alfredo Ferrari, alfredo.ferrari@cern.ch CERN, Geneva, Switzerland

The dynamics of highly energetic trapped protons (above tenth of MeV) in the Earth radiation belts are very difficult to accurately model. Many chaotic physical processes act and from time to time the external part of the belt can be wiped away or a second one may appear during strong solar flares. However during solar minimum, the occurrence of solar flares decrease and the outer bound tends to slide toward greater Lshell. In parallel, cosmic rays can reach the Earth atmosphere more easily during solar minimum, thus producing more albedo neutron that will disintegrate inside the extended protons radiation belt region, thus playing the role of an internal source. It is the co-called CRAND process (Cosmic Ray Albedo Neutron Decay). For two years now, ONERA has been collaborating with CEA on this topic, CEA focusing on the estimation of albedo neutron generation using Fluka simulations. Based on this significant breakthrough, we are now able to feed our recently upgraded CRAND model in the Salammbô proton code with more realistic distribution of albedo neutrons, both in terms of latitude and longitude, and in terms of direction of emission (elevation and azimuth). We aim at presenting at COSPAR the first results thanks to this new models coupling.

PRBEM.1-0003-18 MODELING OF THE EARTH'S RADIATION BELTS: RESPONSE TO CMEAND CIR-DRIVEN GEOMAGNETIC STORMS

Frederic Effenberger, feffen@gfz-potsdam.de

German Research Centre for Geosciences, Potsdam, Germany Nikita Aseev, naseev@gfz-potsdam.de

German Research Centre for Geosciences, Potsdam, Germany Yuri Shprits, shprits@gmail.com

German Research Centre for Geosciences, Potsdam, Germany Adam Kellerman, akellerman@igpp.ucla.edu

UCLA, Los Angeles, California, United States Alexander Drozdov, adrozdov@ucla.edu UCLA, Los Angeles, California, United States

The Earth's magnetosphere responds differently to storms driven by coronal mass ejections (CME) and co-rotating interaction regions (CIR). CME-driven storms are characterized by their occurrence during solar maximum, irregular occurrence patterns, a very dense plasma sheet, stronger ring current, and less frequent enhancement of relativistic electron fluxes in the radiation belts. CIRs are usually observed during the declining phase of a solar cycle with a 27- day recurrence period and result in a less dense but hotter plasma sheet, weaker ring currents, longer intervals of strong magnetospheric convection, and higher values of relativistic electron fluxes. To understand the effects of geomagnetic activity on the inner and outer magnetosphere, CMEand CIR-driven storms should be considered separately.

In this work, we investigate the impact of both types of storms on the radiation belt environment during the Van Allen Probe era, using the Versatile Electron Radiation Belt (VERB) code. To classify storms, we use, among others, the HELCATS (HELiospheric Cataloguing, Analysis and Techniques Service) catalogs of CIR and interplanetary CME events. We use the Kp index as a measure of geomagnetic activity to parameterize wave models, diffusion coefficients, and the plasmapause location. The electron population is considered to originate from the plasma sheet, and we set up the outer boundary conditions at geostationary orbit using GOES and LANL data. We model each storm individually and compare the simulation results with spacecraft measurements (e.g. Van Allen Probes and POES) to validate the model performance. We use data assimilation methods to assist with initial and boundary conditions and the validation. The work shows, how well we understand the response of the belts to CME and CIR drivers and helps to identify the applicability of present wave models to CMEor CIR-driven storms.

PRBEM.1-0004-18 IS IT POSSIBLE TO ORGANIZE AUTOMATIC FORECASTING OF EXPECTED RADIATION HAZARDS FROM SOLAR COSMIC RAY (SCR) EVENTS FOR SPACECRAFTS IN HELIOSPHERE AND GEOMAGNETOSPHERE AND FOR AIRCRAFTS IN LOW ATMOSPHERE?

Lev Dorman, lid010529@gmail.com

Tel Aviv University, Moscow, Tel Aviv, Russia

We present method of automatically forecasting on line of expected radiation hazards from SCR event during 20 -30 minutes caused after beginning. We use model of solar cosmic ray diffusion and coupling functions for neutron monitors network with different altitudes and cut-off rigidities, including also space detectors like GOES. Another observational data for estimation of energy spectra is multiplicity of CR registration by some neutron monitors. We demonstrate algorithms for automatic estimation of the SCR event starting, determination time-evolution of SCR in space by coupling functions in the frame of spectrographic method, solving inverse problem for SCR generation in solar corona and propagation in the interplanetary space, automatic determining on the basis of CR observation data parameters of SCR generation in solar corona, escaping into solar wind, and propagation in space. We show that on the basis of these parameters it can be automatic forecasting on the basis of first about 20 - 30 one-minute data expected level of radiation hazards for full time of event (up to several days) for objects in space on different distances from the Sun, in magnetosphere at different orbits, and in low atmosphere at different altitudes and cutoff rigidities for any airline. If for some objects expected level of radiation hazards will be dangerous, after about 0.5 hour from event beginning will be formatted and sent corresponding Alert. We take into account that for the first about 0.5 hour data from event beginning, when coming mostly only small flux of high energy particles - radiation hazards expected very small in comparison with more delay time when coming main part of SCR with energy 1 GeV, formatted sufficient part of radiation hazards.

PRBEM.1-0005-18 THE RADIATION-BELT ELECTRON PHASE-SPACE-DENSITY RESPONSE

TO STREAM-INTERACTION REGIONS: MULTI-POINT OBSERVATIONS, DATAASSIMILATION, PHYSICS-BASED MODELING, AND FORECASTING

Adam Kellerman, akellerman@igpp.ucla.edu UCLA, Los Angeles, California, United States

Presented is an analysis of the phase-space density (PSD) response to stream-interaction regions (SIRs), which utilizes a reanalysis dataset principally comprised of the data-assimilative Versatile Electron Radiation Belt (VERB) code, Van Allen Probes and GOES observations. The dataset spans the period 2012-2017, and includes several SIR storms.

Using a snapshot analysis technique, the electron PSD is examined for evidence of injections, transport, acceleration, and loss by considering the instantaneous and time-averaged change over multiple adiabatic invariant values, simultaneously. The energies covered correspond to ring-current, relativistic, and ultra-relativistic electrons. Specific times are identified for every storm, where clear non-adiabatic changes were taking place, which allows one to separate cases where one mechanism may dominate over another, both external and internal to the magnetosphere, in causing the observed non-adiabatic change(s). For select cases, model simulations are conducted to test whether the observed non-adiabatic changes can be replicated through state-of-the-art modeling. This work utilizes an advanced data-driven technique to inform both our understanding, and the physics-based modeling of the radiation-belt response to the SIR.

The results of this analysis are also discussed in relation to the operational data-assimilative radiation-belt forecast model, running every 2 hours at UCLA and now also at GFZ Potsdam.

PRBEM.1-0006-18 PLANNED UPGRADES TO THE AE9/AP9-IRENE SPACE RADIATION CLIMATOLOGY MODEL

Atmospheric and Environmental Research, Inc., Lexington, Massachusetts, United States

We describe expanded capabilities in development for the AE9/AP9-IRENE space radiation climatology model suite. Version 1.6 will introduce kernels-based computation of radiation effects. Version 2.0 will see transition to a modular architecture: adding modules for solar protons and a sample solar cycle fly-through, expanding specifications in existing modules, and supporting inclusion of additional hazards in later versions. With expanding international collaboration in development, this version will also fully transition to the name International Radiation Environment Near Earth (IRENE).

A new modelling approach for the unified description of the energetic particle radiation environment and its effects - attributed from various sources - in near Earth space is presented. The European Space Radiation Environment Modelling (ESPREM) system applies a statistically robust and efficient methodology to combine existing and newly developed space radiation environment models of Trapped Particles, Solar Protons and Galactic Cosmic Rays (GCR). The architecture of ESPREM is modular, allowing the selection of various models for each particle radiation source and the integration of suitable radiation effects tools.

For the description of the trapped radiation, the widely used AE9/AP9/SPM (IRENE) model

[1] and the newly developed Trapped Energetic Particle Environment Model (TREPEM) have been integrated. TREPEM is a purely data driven, statistical model of the trapped energetic particle populations, that is built by assimilating measurements from several radiation monitors and particle detectors. The measurements are mapped onto an L* vs aeqgridcapturingf oreachgridpointthe def inedpercentiles.

For the description of the solar proton radiation environment, the Virtual Enhancements - Solar Proton Event Radiation (VESPER) model [2] was developed and integrated into ESPREM. VESPER utilizes the ESA SEPEM RDS v2.0 and employs a novel probabilistic approach for the modelling of the energetic proton environment at 1 AU attributed to Solar Proton Events (SPE). For a user-defined mission duration, VESPER produces multiple scenarios of virtual SPE flux time-series allowing the derivation of probability

functions for critical variables of interest such as the Peak Fluxes or the Cumulative differential Fluences over the spacecraft mission duration.

For the modelling of the GCR environment, ESPREM integrates Matthiä model [3] that was developed at the German Aerospace Center (DLR). The model, which is actually an effective update of the standard ISO model [4], describes the GCR spectra based on a single parameter (Wolf parameter). The values of this parameter, for different solar modulation conditions, are derived from measurements of the Advanced Composition Explorer (ACE) spacecraft and the Oulu neutron monitor count rates. ESPREM incorporates the shielding effects for both solar and galactic cosmic flux series, along the spacecraft orbit, due to the Earth's magnetosphere, using the Magnetospheric Shielding Model (MSM) [5].

ESPREM as a system integrates the radiation models with trajectory tools and a series of state-of-the-art radiation effects tools (MULASSIS, IRONSIS and MCICT). The Multi-Layered Shielding Simulation Software (MULASSIS) [6] is a simulation tool that assesses radiation shielding performance for simple user-defined shield geometries (multi-layered planar or spherical shields). IRONSSIS [7] treats 1D multi-layer shielding structures using a straight-ahead, continuous, slowing-down approximation approach, while the MCICT [8] is an internal charging analysis tool. Upon completion of the simulation, ESPREM can provide a series of outputs such as particle fluxes, ionizing and non-ionising dose, LET spectra and charging currents. The system is capable of deriving probability distributions for the various effects, from all possible sources of radiation (trapped, SEP GCR), which can then be merged statistically, assuming various degrees of intercorrelations, in order to produce confidence levels for the combined radiation effects that the satellite will encounter.

The ESPREM system is accessed by the user as a Remote Procedure Call (RPC) service or a Python library. The system's primary use case is to be deployed in a web server, making it available to users' RPC endpoints, through which they can either use any of the subcomponents independently or the full system in a pipeline mode. In the first case, the user requests to run any single sub-module of the system (models or effect tools) e.g. for a given orbit, the TREPEM model is run to produce the trajectory's average fluxes. In the pipeline mode of operation multiple tools are invoked sequentially and intermediate results are forwarded internally in the system e.g. the user provides an orbit and a geometry specification and requests the total dose from protons, in which case ESPREM will run the trajectory tool, the TREPEM, VESPER and GCR models and MULASSIS/IRONSSIS, handling all data transformations required between the tools.

Acknowledgment: ESPREM development was supported by ESA/ESTEC contract 4000112863/14/NL/ in the framework of the HERMES project.

The four-dimensional Versatile Electron Radiation Belt (VERB-4D) code has been developed to model combined electron ring current and electron radiation belt dynamics. The code takes into account convective transport of electrons in prescribed electric and magnetic fields, radial diffusion, local pitch angle, energy, and mixed diffusion due to resonant interactions with plasma waves (e.g. hiss, chorus, whistler mode lightning, and electromagnetic ion cyclotron waves), and electron loss into the interplanetary medium and atmosphere. In this work, we show the comparison of simulation results with satellite observations (Van Allen Probes, POES, THEMIS, etc.) over a wide energy range from 10 keV to several MeV. We show how the code can be used as a nowcasting tool of both ring current and radiation belt electron populations if only the Kp index and particle observations at geostationary orbit are given.

PRBEM.1-0009-18 SPECIFICATION OF KEV ELECTRON RADIATION ENVIRONMENT AT GEO AND MEO

Natalia Ganushkina, natalia.ganushkina@fmi.fi Finnish Meteorological Institute, Helsinki, Finland Stepan Dubyagin, dsmonch@mail.ru

Finnish Meteorological Institute, Helsinki, Finland

Jean-Charles Matéo-Vélez, jean-charles.mateo_velez@onera.fr ONERA/DESP, Toulouse, France

Surface charging anomalies at near-Earth orbiting satellites have been attributed to electrons of energy below 100 keV. Accurate specification of the space environment at different orbits is of a key importance. We present the operational model for low energy (< 200 keV) electrons in the inner magnetosphere, Inner Magnetosphere Particle Transport and Acceleration model (IMPTAM). This model has been operating online since March 2013 (http://fp7-spacecast.eu and imptam.fmi.fi) and it is driven by the real time solar wind and IMF parameters and by the real time Dst index. The presented model provides the low energy electron flux at all L-shells and at all satellite orbits, when necessary. IMPTAM is used to simulate the fluxes of low energy electrons inside the Earth's magnetosphere at the time of severe events measured on LANL satellites at GEO. There is no easy way to say what will be the flux of keV electrons at MEO when surface charging events are detected at GEO than to use a model. The maximal electron fluxes obtained at MEO (L = 4.6) within a few tens of minutes hours following the LANL events at GEO have been extracted to feed a database of theoretical/numerical worst-case environments for surface charging at MEO. All IMPTAM results are instantaneous, data have not been average. In order to validate the IMPTAM output at MEO, we conduct the statistical analysis of measured electron fluxes onboard Van Allen Probes (ECT HOPE (20 eV-45 keV) and ECT MagEIS (30 - 300 keV) at distances of 4.6 Re. IMPTAM eflux at MEO is used as input to SPIS, the Spacecraft Plasma Interaction System Software toolkit for spacecraft-plasma interactions and spacecraft charging modelling (http://dev.spis.org/projects/spine/home/spis). The research leading to these results was funded by the European Union's Horizon 2020 research and innovation programme under grant agreement No 637302 PROGRESS.

PRBEM.1-0010-18 SPACE IONIZING RADIATION ENVIRONMENT AND EFFECTS (SIRE2) MODEL FOR SATELLITE DESIGN

Institute for Space and Defense Electronics, Nashville, Tennessee, United States

We will describe a space radiation environments model that addresses the limitations of earlier tools. SIRE2 provides space environment and effects calculations for orbiting satellites based on the latest models of the space radiation environment. In this model the radiation environment just outside the Earth's magnetosphere consists of the galactic cosmic ray environment as described by the Badhwar-O'Neill 2014 Model and the solar energetic particle model as described by a probabilistic model developed by Robinson and Adams (2017). The description of the transmission of this environment to a satellite orbiting within the magnetosphere is based on the Smart-Shea 2005 model. The trapped radiation environment (both protons and electrons) at this satellite is described using the 2017 IRENE model. Finally, SIRE2 provides a means to transmit the radiation environment to points of interest within the satellite.

SIRE2 provides the total dose rate from protons and electrons and the Linear Energy Transfer (LET) spectrum at the point of interest within the satellite. It also provided characterizations of the radiation effects on electronic parts based on the methods used in CREME96. It has the capability to efficiently process large batches of parts in order to obtain characterizations of their response to the radiation environment. In addition, batches of environments can be created and used for parts characterizations.

SIRE2 has a graphical user interface that displays all the ways in which calculations can be set up and run. This includes choices of how the satellite's orbit is defined, what assumptions are made about the space weather conditions, how the results of the calculations are to be presented, viewed and preserved. This interface also affords access to the full capabilities of CREME96 for modeling radiation effects on electronics.

PRBEM.1-0011-18 RECURRENT NEURAL NETWORKS FOR MODELING THE GLOBAL PLASMASPHERE DYNAMICS

Irina Zhelavskaya, irina.zhelavskaya@gmail.com

Helmholtz Centre Potsdam, GFZ German Research Centre for Geosciences, Potsdam, Germany Yuri Shprits, shprits@gmail.com

German Research Centre for Geosciences, Potsdam, Germany

Plasmasphere is a torus of cold plasma surrounding the Earth and is a very dynamic region. Its dynamics is driven by space weather, and having an accurate model of the plasmasphere is very important for wave-particle interactions and radiation belt modeling. In the recent years, feedforward neural networks have been successfully applied to reconstruct the global plasmasphere dynamics in the equatorial plane [Bortnik et al., 2016, Zhelavskaya et al., 2017, Chu et al., 2017]. These neural network-based models have been able to capture the large-scale dynamics of the plasmasphere such as plume formation and the erosion of the plasmasphere on the night side. These models explicitly took as an input the time history of various geomagnetic and solar wind activity over a certain period of time in the past and modelled the electron density as a function of these inputs and the location. These models did not take into account, however, the spatiotemporal behaviour of the electron density which could put limitations on their performance. Recently developed recurrent neural networks, specifically long short-term memory neural networks (LSTMs), are very effective at including temporal effects in the model implicitly. The time history is aggregated in the hidden nodes of an LSTM during training, and in such way, the LSTMs are capable of selecting important features of the given problem internally without the need to select optimal inputs manually. In this work, we present the results of applying LSTMs to reconstruct the global plasmasphere dynamics. To train LSTMs we use electron density database from Van Allen Probes obtained using the NURD algorithm (covering Oct 2012 - Dec 2017 [Zhelavskaya et al., 2016]). We validate the model similarly as in Zhelavskaya et al. 2017, by measuring model's performance on independent datasets withheld from the training set and by comparing the model predicted global evolution with global images of He+ distribution in the Earth's plasmasphere from the IMAGE Extreme UltraViolet (EUV) instrument. We compare the performance of RNNs to several other empirical models and demonstrate results of global density reconstruction.

PRBEM.1-0012-18 PROBABILISTIC MODELING OF THE SPACE RADIATION ENVIRONMENT

Zachary Robinson, zachary@5thgait.com

DISTRIBUTION STATEMENT A. Approved for public release; distribution is unlimited. Approved for Public Release 18-MDA-9478 (22 Jan 18)

Design of and planning for space missions must account for possible solar energetic particle (SEPs) events during these missions. Historically, missions account for SEPs by designing or planning to survive in the worst known operating environment. While this approach ensures that the satellite is protected against the worst environment on record, it usually leads to expensive over-design of the satellite. For this reason, it is important to choose a missionspecific design reference environment which will lead to the desired mission reliability while avoiding expensive over-design of the satellite.

We will describe two different probabilistic models for Solar Energetic Particle events. These models allow the user to tailor the design reference environment to his mission (characterized by its start date and duration) and to specify a confidence level for reliable mission operations which he wishes to achieve.

The first model is an episode-integrated fluence model. It is intended to estimate the highest dose that could be accumulated over periods ranging from a few weeks to several years. It is valid through 2053. The second model is a peak mission flux model. This model can be used for mission durations ranging from 10's of minutes to many years. It is also valid through 2053. It is used for estimating peak single event effect rates in satellite electronics. Both models use the probabilistic modeling techniques developed by Xapsos et al. (1998). For short missions (10s of minutes), the peak flux model uses a new data driven approach to create the reference environment. For longer missions it follows the method of Xapsos, making use of an extended database.

PRBEM.1-0013-18 APPLICATION OF NARMAX METHODOLOGY TO THE FORECAST OF RADIATION ENVIRONMENT IN THE GEOSPACE.

Michael A. Balikhin, m.balikhin@sheffield.ac.uk University of Sheffield, Sheffield, United Kingdom Richard Boynton, rboynton85@gmail.com University of Sheffield, Sheffield, United Kingdom Simon Walker, simon.walker@sheffield.ac.uk University of Sheffield, Sheffield, United Kingdom

Among methodologies, used in the field of System Science the Nonlinear AutoRegressive Moving Average models with eXogenous inputs (NARMAX) represents a powerful approach to system identification that already resulted in the development of a few space weather forecasting models. The results of NARMAX applications to the forecast of fluxes of energetic electrons at GEO and modelling of key magnetospheric plasma emissions that affect dynamics of these electrons are reviewed. The challenges in the future development of NARMAX based forecasting tools that will be able to forecast fluxes of relativistic electrons within the whole region of radiation belts are discussed.

PRBEM.1-0014-18 LONG-TERM VERB CODE SIMULATIONS OF RELATIVISTIC AND ULTRARELATIVISTIC ELECTRONS

Alexander Drozdov, adrozdov@ucla.edu UCLA, Los Angeles, California, United States Yuri Shprits, shprits@gmail.com

German Research Centre for Geosciences, Potsdam, Germany Nikita Aseev, nikita.aseev@gfz-potsdam.de

German Research Centre for Geosciences, Potsdam, Germany Adam Kellerman, akellerman@igpp.ucla.edu

UCLA, Los Angeles, California, United States

The dynamics of the outer radiation belts is controlled by several physical processes. One of the dominant process that drives acceleration and loss is radial diffusion which affect the electrons in a wide energy range. Another important mechanisms are localized energy and pitch-angle diffusion due to wave-particle interactions. Recent observations and modeling showed that the dynamics of the relativistic and ultra-relativistic electron populations can be quite different. This difference is a combination of many factors where electromagnetic ion cyclotron (EMIC) waves play an important role.

In this study, we perform several long-term simulations with the Versatile Electron Radiation Belt (VERB) code, and we compare results of the simulation with the Van Allen Probes observations. We investigate the sensitivity of the several parameterizations of the radial diffusion [e.g. Brautigam and Albert, 2000; Ozeke et al., 2014; Ali et al., 2016; Liu et al., 2016] and the effect of the EMIC waves on the radiation belts modeling. Incorporation of the EMIC waves in the long-term simulations is a challenging task due the the sporadic nature of the EMIC wave occurrence. We investigate different geomagnetic indexes and solar wind parameters as the potential drivers of the waves in our simulations. The comparison shows that simulations with obtained model of EMIC waves presence provide a better agreement with the observations.

PRBEM.2-0001-18 SPACE SCIENCE ON THE EXPERIMENTAL ALBERTAN SATELLITE #1 (EXALTA-1) CUBESAT MISSION

Ian Mann, imann@ualberta.ca

University of Alberta, Edmonton, Canada The Ex-Alta-1 Team

I.R. Mann, C. D. A. Nokes, C. Cupido, D. Elliott, D. M. Miles, M. Ciurzynski, D. Barona,

B. Narod, J. R. Bennest, A. Kale, B. Bruner, S. Damkjar, T. Haluza-DeLay, C. Lange, D. Sameoto, and D.K. Milling.

Cube-satellite (CubeSat) platforms are increasingly being considered for scientific research, with the goal of achieving future constellation class missions for studies of geospace. We describe the design, validation, test, and initial on-orbit results from the University of Alberta Experimental Albertan Satellite 1 (Ex-Alta-1) Cube Satellite, launched in 2017 from the International Space Station as part of the QB50 constellation mission. The payload includes a miniature, lowmass, low-power, and low-magnetic noise boom-mounted fluxgate magnetometer flown, a multineedle Langmuir Probe, and a radiation dosimeter. The miniature magnetometer achieves a magnetic noise floor of 150-200pT/Hz at 1Hz, consumes 400mW of power, has a mass of 121g (sensor and boom), stows on the hull, and deploys on a 60cm boom from a three-unit CubeSat reducing the noise from the onboard reaction wheel to less than 1.5nT at the sensor. The magnetometer's capabilities are being demonstrated and validated in space with flight on ExAlta-1 with a view to its use for monitoring plasma waves at high resolution for space science, magnetosphere-ionosphere coupling, and space radiation studies. We present on-orbit data from the magnetometer boom-deployment and initial operations of the fluxgate sensor and illustrate the potential scientific returns and utility of using CubeSats carrying such fluxgate magnetometers to constitute a magnetospheric constellation mission. We further present results from the dosimeter which characterises the radiation from the low Earth orbit of the Ex-Alta-1 CubeSat.

Interest in CubeSats has grown dramatically in the past decade within the space physics community. While CubeSats are generally accepted now to be useful tools for education and technology development/demonstration, their ability to provide scientific value is often still questioned. Radiation belt physics, however, is one area in which the scientific utility of these small platforms has been demonstrated and continues to offer great promise. Here we'll present some highlights from recent, along with upcoming, radiation belt-related CubeSat missions. The Colorado Student Space Weather Experiment (CSSWE) CubeSat, launched in 2012 and designed, built, and operated by students at University of Colorado, was one of the first of now a long line of successful CubeSats designed to study radiation belt dynamics. Results from CSSWE will be presented, with an emphasis on how these measurements have been combined with those from balloons and larger satellite missions to better understand radiation belt electron acceleration and loss processes. A status update of the more recent Compact Radiation belt Explorer (CeREs) CubeSat, built at NASA/Goddard and scheduled for an April 2018 launch, will also be presented. Finally, we'll discuss a plan to move beyond low Earth orbit (LEO) with the upcoming GTOsat CubeSat currently in development, which will fly in a geosynchronous transfer orbit providing energetic electron measurements through the heart of the radiation belts. Radiation belt studies are a prime example of how small, low-cost spacecraft can be used to provide valuable scientific measurements and complement larger missions.

PRBEM.2-0003-18 THE RELATIVISTIC ELECTRON ATMOSPHERIC LOSS (REAL) CUBESAT

Montana State University, Bozeman, Montana, United States

The Relativistic Electron Atmospheric Loss (REAL) CubeSat mission will characterize different modes of atmospheric loss by making high time resolution measurements of the electron pitch angle and energy distributions, in low Earth orbit (LEO), over a wide energy range, from keV to MeV. LEO is ideal for measuring precipitation since the atmospheric loss cone is larger (60 deg) than at the equator (few degrees). In particular, it is possible to measure the pitch angle distribution within the loss cone, revealing information about the scattering process. Significant progress has been made in identifying the plasma waves that drive atmospheric precipitation [e.g., Thorne, 2010 for review]. However, the physical "modes" in which these act is not well specified: electrons may be scattered slowly through a diffusive process [e.g., Shprits et al., 2008 review], or rapidly through nonlinear processes [e.g., Albert, 2000; Bortnik et al., 2008, Omura et al., 2015]. The physical mode determines the scattering rate and thus the impact on the radiation belts. Therefore, it is important to establish where and how frequently loss mechanisms act in different modes for particles of different energies. REAL will investigate the physical mechanisms responsible for scattering radiation belt electrons into the atmosphere by determining when and where different precipitation loss modes (diffusion, strong diffusion, and nonlinear scattering) occur. The pitch angle-resolved measurements will also allow us to distinguish between precipitating, quasi-trapped, and trapped populations of electrons, thus more accurately quantifying the electron loss rate from the radiation belts.

In order to resolve the spatial and temporal variations of the various microscale plasma structures on the topside ionosphere, SNIPE mission consisted of four 6u nanosatellites (12 kg) will be launched into a polar orbit at an altitude of 500-600 km. Two pairs of satellites will be deployed on orbit and the distances between each satellite will be from 10 to 100 km controlled by a formation flying algorithm. The SNIPE mission is equipped with scientific payloads which can measure the following geophysical parameters: density/temperature of cold ionospheric electrons, energetic electron flux of hundreds keV, and magnetic field vectors. All the payloads will have high temporal resolution of 16 Hz. This mission is planned to launch in 2020. We have developed a 6U nanosatellite bus system as the basic platform for the SNIPE mission. Three basic plasma instruments shall be installed on all of each spacecraft, solid state telescope (SST), langmuir probe (LP), and fluxgate magnetometer (MAG). The SNIPE mission's scientific goals are as following; (1) electron microbursts, (2) trough and polar cap patches, (3) equatorial plasma bubbles/blobs/MSTIDs, (4) electro-magnetic ion cyclotron (EMIC) waves, and (5) field aligned current (FAC). Electron microbursts are observed at 50-70 degrees of latitude during the storm recovery phase, mainly at local dawn sector. Through the electron microburst observation experiment of the SNIPE mission, we expect to obtain the spatial scale and energy dispersion of electron microbursts. The multiple satellite LPs' observations with high sampling rates in high temporal (less than 1 second) and spatial (10 km - 100 km) resolutions enable us to comprehensively investigate the sub-auroral trough morphology, especially latitudinal and longitudinal small-scale (< 100 km) structures, and to understand the behavior of the small-scale temporal (less than 1 second) and spatial (10 km - 100 km) variations of the trough during geomagnetic storms. Using formation flying SNIPE satellites, we would also expect to discern the spatial and temporal structures of EMIC and to analyze the correlation between proton/electron precipitation and EMIC waves by using multi-satellites' observations such as SNIPE, GOES, Arase, VAP and other ground stations.

Air Force Research Laboratory, Kirtland AFB, New Mexico, United States

In 2018, the Air Force Research Laboratory will launch its Demonstration and Science Experiments (DSX) mission to investigate wave-particle interactions and the particle and space environment in medium Earth orbit (MEO). The DSX spacecraft includes three experiment packages. The Wave Particle Interaction Experiment (WPIx) will perform active and passive investigations involving VLF waves and their interaction with plasma and energetic electrons in MEO. The Space Weather Experiment (SWx) includes five particle instruments to survey the MEO electron and proton environment. The Space Environmental Effects Experiment (SFx) will investigate effects of the MEO environment on electronics and materials. We will describe the capabilities of the DSX science payloads, planned science campaigns, and opportunities for collaborative studies such as conjunction observations and far-field measurements.

We describe a new procedure for estimating and removing inner zone background contamination in the Van Allen Probes MagEIS electron measurements. This new procedure is based on the underlying assumption that the primary source of background contamination at L<3, energetic inner belt protons, is relatively stable. This allows us to build a model of the background contamination by binning the MagEIS histogram data from each detector in time and L, when the measurements are known to be background-dominated. While this new procedure is inherently limited in several aspects (e.g., temporal cadence, energy coverage, spatial coverage), it is demonstrated to be an improvement upon the routine background corrections that are part of the standard data processing. In particular, we are able to extract more foreground signal out of the relativistic electron data in the inner zone, which reveals that the 1 MeV injection reported in Claudepierre et al., [2017] is distributed more broadly in L than was previously thought, and persists in the inner zone longer than was previously thought. We discuss these new results and

compare with more recent data that also shows 1 MeV electron injections into the inner zone during the September 2017 shock event.

Geospace Exploation Project; ERG addresses what mechanisms cause acceleration, transportation and loss of MeV electrons of the radiation belts and evolutions of space storms. Cross-energy and cross-regional couplings are key concepts for the project. In order to address questions, the project has been organized by three research teams; satellite observations, ground-based observations, and modeling/data-analysis studies, and interdisciplinary research are realized for comprehensive understanding of geospace. The Arase satellite was successfully launched on December 20, 2016. After the initial operation including maneuvers, Arase has started normal observations since March, 2017. Arase has observed several geomagnetic storms driven by coronal hole streams and CMEs, and several interesting features are observed associated with geomagnetic disturbances. The six particle instruments; LEP-e/LEP-i/MEPe/MEP-i/HEP/XEP have shown large enhancement as well as loss of wide energy electrons and ions and variations as well as changes of pitch angle and energy spectrum. The two field/wave instruments: PWE and MGF observed several kinds of plasma waves such as chorus, hiss, EMIC as well as large scale electric and magnetic field variations. The project has collaborated with the international projects, EISCAT, SuperDARN and other ground-based observations, and various data are obtained from such international collaborations. Moreover, multi-point satellite observations by collaboration with other satellites; Van Allen Probes, THEMIS and MMS have been going. In this presentation, we will report overview and initial highlights for the first year and discuss importance of synergies of multi-satellites and ground-based observations that are realized by international collaborations.

We discuss the observations of the locally trapped and precipitating particles from the LEO orbit. Observations from this vantage point provide a unique opportunity to resolve the drift and bounce loss cone, understand the loss processes in the radiation belts and measure precipitating fluxes that can change upper atmospheric chemistry. We report on the first results obtained from the Electron Losses and Fields INvestigation on board the Lomonosov satellite (ELFIN-L). The main objective of the project is to determine the rate of storm-time relativistic electron precipitation during geomagnetic storms and to understand the mechanisms responsible for the precipitation. ELFIN-L provides in-situ measurements of the trapped electron fluxes and electron fluxes in the loss cone over the period of six months from June until December 2016. Orientation of the ELFIN-L instruments allows us to sample both trapped and precipitating fluxes on a three-axis stabilized spacecraft. By measuring the electron precipitation rate and determining the dominant loss mechanism of relativistic electrons during storms, ELFIN-L allows us to quantify electron losses as a function of energy for use in global predictive models of the near-Earth radiation environment.

PRBEM.2-0010-18 OBSERVATIONS OF TRAPPED ELECTRONS AND POSITRONS WITH ENERGY MORE THEN 50 MEV IN THE INNER RADIATION BELT WITH THE PAMELA MAGNETIC SPECTROMETER

Vladimir Mikhailov, vvmikhajlov@mephi.ru

National Research Nuclear University "MEPhI", Moscow, Russia

Trapped electrons and positrons with energy above 50 MeV were observed in PAMELA experiment on board Resurs DK satellite. The instrument consists of magnetic spectrometer, imaging calorimeter, time of flight system, anticoincidence and neutron detectors that provide unique particle identification and background rejection. The satellite orbit with altitude 350- 600km and inclination 70 degrees crosses the inner radiation belt in South Atlantic Anomaly. PAMELA was collecting data since June 2006 till January 2016. The trapped electrons and positrons were selected on the basis of a trajectory simulation in the Earth magnetic field. Features of energy spectra of trapped electrons and positrons were analyzed.

PRBEM.2-0011-18 RECENT AND UPCOMING OBSERVATIONS OF THE CARACTéRISATION ET MODéLISATION DE L'ENVIRONNEMENT (CARMEN) MISSION

Robert Ecoffet, robert.ecoffet@cnes.fr

Centre National d'Etudes Spatiales, Toulouse, France Françoise Bezerra, francoise.bezerra@cnes.fr

CNES, TOULOUSE, France

Denis Standarovski, denis.standarovski@cnes.fr CNES, Toulouse, France

Sebastien Bourdarie, sebastien.bourdarie@onecert.fr ONERA/DESP, Toulouse, France

Vincent Maget, vincent.maget@onera.fr ONERA/DESP, TOULOUSE, France

We have developed a series of instruments for energetic particle measurements, associated with component test beds "MEX". The aim of this program is to check and improve space radiation engineering models and techniques. The first series of instruments, "ICARE" has flown on the MIR space station (SPICA mission), the ISS (SPICA-S mission) and the SAC-C low Earth polar orbiting satellite (ICARE mission 2001-2011) in cooperation with the Argentinian space agency CONAE. A second series of instruments "ICARE-NG" was and is flown:

CARMEN-1 mission on CONAE's SAC-D, 650 km, 98°, 2011-2015, along with three "SODAD" space micro-debris detectors

CARMEN-2 mission on the JASON-2 satellite (CNES, JPL, EUMETSAT, NOAA), 1336 km, 66°, 2008-now, along with JAXA's LPT energetic particle detector

CARMEN-3 mission on the JASON-3 satellite in the same orbit as JASON-2, launched 17 January 2016, along with a plasma detector "AMBRE", and JAXA's LPT again.

The ICARE-NG spectrometer composed of a set of three fully depleted silicon solid state detectors used in single and coincident mode. The on-board measurements consist in accumulating energy loss spectra in the junctions over a programmable accumulation period. The spectra are generated through signal amplitude classification using 8 bit ADCs and resulting in 128/256 channels histograms. The discriminators reference levels, amplifier gain and accumulation time for the spectra are programmable to provide for possible on-board tuning optimization.

Ground level calibrations have been made at ONERA-DESP using radioactive source emitting alpha particles in order to determine the exact correspondence between channel number and particle energy. To obtain the response functions to particles, a detailed sectoring analysis of the satellite associated with GEANT4/MCNP-X calculations has been performed to characterize the geometrical factors of the each detector for p+ as well as for ewith different energies.

The component test bed "MEX" is equipped with two different types of active dosimeters, P-MOS silicon dosimeters and OSL (optically stimulated luminescence). Those dosimeters provide independent measurements of ionizing and displacement damage doses and consolidate spectrometers' observations.

The data sets obtained cover more than one solar cycle. Dynamics of the radiation belts, effects of solar particle events, coronal mass ejections and coronal holes were observed. Spectrometer measurements and dosimeter readings were used to evaluate current engineering models, and helped in developing improved ones, along with "space weather" radiation belt indices. The paper will provide a comprehensive review of detector features and mission results.

PRBEM.2-0012-18 INTERNAL CHARGING IN MEO USING THE SURF SENSOR

Keith A Ryden, k.ryden@surrey.ac.uk

University of Surrey, Guildford, United Kingdom Alex D P Hands, a.hands@surrey.ac.uk University of Surrey, Guildford, United Kingdom

The SURF instrument is a shielded current sensor with fA/cm-2 sensitivity which measures the key space weather hazard of internal charging in a very direct fashion. One such sensor has been operating in a GPS-like medium earth orbit (MEO) on the Giove-A spacecraft for a full solar cycle with only a few interruptions. Using three stacked shielded plates we observe internal charging currents due to electron energies from about 500keV to >3MeV. These currents have been converted to differential fluxes using plate response functions alongside some assumptions about spectral shape. No dead-time corrections are required since there is no counting process involved. In addition there is negligible contamination from protons even during intense solar particle events. The simplicity of the instrument and careful reference irradiations before flight mean that the results are highly reliable. We will present data obtained over the solar cycle and review periods of particular interest including the electron desert period in 2009 and the recent upsurge in internal charging events in the decline from solar maximum. We also describe a new model of the outer belt, MOBE-DIC, which has been developed from the SURF data which is intended for engineering applications. Furthermore reference is made to an earlier data set from the very first SURF instrument in geostationary transfer orbit which found significant inner belt charging currents which is at odds with recent Van Allen Probes measurements from this region and thus that data might be more significant than first thought. Looking to the future a further SURF instrument should be launched on DSX in June 2018 so further results from MEO should soon be available.

PRBEM.2-0013-18 MULTIPOINT ENERGETIC ELECTRON AND PROTON MEASUREMENTS FROM THE GLOBAL POSITIONING SYSTEM CONSTELLATION

Steven Morley, smorley@lanl.gov

Los Alamos National Laboratory, Los Alamos, New Mexico, United States Matthew Carver, mrcarver@lanl.gov

Los Alamos National Laboratory, Los Alamos, New Mexico, United States John Sullivan, sullivan@lanl.gov

Los Alamos National Laboratory, Los Alamos, New Mexico, United States

The Global Positioning System (GPS) satellites are distributed across six orbital planes and follow near-circular orbits, with a 12 hour period, at an altitude of approximately 20200 km. The six orbital planes are distributed around the Earth and are nominally inclined at 55 degrees. Energetic particle detectors have been flown on the GPS constellation for more than two decades; by February 2016 there were 23 GPS satellites equipped with energetic particle instrumentation. Electron data from the Combined X-ray Dosimeter (CXD), which is flown on 21 GPS satellites, has been cross-calibrated against data from the Van Allen Probes mission, demonstrating its utility for scientific research and radiation environment specification. Energetic particle data from these instruments were publicly released in 2017, including the crosscalibrated electron fluxes. Recently the CXD energetic proton data has been cross-calibrated against GOES Space Environment Monitor data using a set of Solar Energetic Particle (SEP) events. We will describe the GPS constellation from the perspective of its use as a monitor for space weather, including the electron radiation belts and SEPs. We will review the crosscalibration of the particle data and will discuss the advances enabled in understanding Earth's radiation environment by the availability of these data.

PRBEM.2-0014-18 COMPREHENSIVE OBSERVATIONS OF EMIC WAVES DURING THE FOUR GEM QARBM CHALLENGE INTERVALS: COMBINING WAVE DATA FROM SPACECRAFT AND GROUND OBSERVATORIES WITH POES PROTON PRECIPITATION DATA

Mark Engebretson, engebret@augsburg.edu

Augsburg College, Minneapolis, Minnesota, United States EMIC Team for the GEM QARBM Challenge

Jennifer Posch Augsburg University Wen Li Boston University Qianli Ma UCLA and Boston University Adam Kellerman MIT Craig Kletzing University of Iowa John Wygant University of Minnesota Harlan Spence University of New Hampshire Daniel Baker University of Colorado Vassilis Angelopoulos UCLA Howard Singer NOAA Space Weather Prediction Center Marc Lessard University of New Hampshire Ian Mann University of Alberta Tero Raita Sodankyla Geophysical Observatory Kazuo Shiokawa Nagoya University Ravil Rakhmatulin Institute of Solar-Terrestrial Physics Eldar Dmitriev Borok Geophysical Observatory Elena Ermakova Radiophysical Research Institute

This study presents observations of EMIC waves from multiple data sources during the four challenge events in 2013 selected by the GEM focus group on Quantitative Assessment of Radiation Belt Modeling: March 17-18 (Stormtime Enhancement), May 31-June 2 (Stormtime Dropout), September 19-20 (Non-storm Enhancement), and September 23-25 (Non-storm Dropout). In addition to EMIC wave data from the Van Allen Probes, GOES, and THEMIS spacecraft in the near-equatorial magnetosphere and from several arrays of ground-based search coil magnetometers worldwide, we show localized ring current proton precipitation data from low-altitude POES spacecraft. Each of these data sets provides only limited spatial coverage, but their combination shows consistent occurrence patterns and reveals some events that would not be identified as significant using near-equatorial spacecraft alone. Relativistic and ultrarelativistic electron flux observations from the REPT instrument on the Van Allen Probes during the two dropout intervals and one enhancement interval show several cases during which EMIC waves are plausible candidates for flux dropouts that are localized in L.

PRBEM.2-0015-18 CHORUS ELEMENT PROPERTIES: STATISTICS OF SWEEP RATE AND WAVE POWER

Craig Kletzing, craig-kletzing@uiowa.edu University of Iowa, Iowa City, Iowa, United States Ananya Sen Gupta, ananya-sengupta@uiowa.edu The University of Iowa, Iowa City, United States Ivar Christopher, ivar-christopher@uiowa.edu University of Iowa, Iowa City, United States

Using novel signal processing techniques, we have developed autonomous algorithms that can analyze Van Allen Probes waveform observations to determine the characteristics of individual chorus elements. In particular, the methods allow us to determine the frequency/time sweep rate of chorus elements for a large number of events without the need for manual identification of the elements. This enables statistical studies of the properties of the individual chorus elements which has been limited in the past to small numbers of events identified and analysed by hand. We present the basics of the technique and show initial results of the statistics on the range and character of chorus element sweep rate and correlations with other plasma properties. We also show initial work on understanding the power in chorus elements by themselves as compared spectral averages over time and frequency.

PRBEM.2-0016-18 EMIC WAVE DRIVEN ELECTRON PRECIPITATION - ENERGETIC, RELATIVISTIC, ULTRARELATIVISTIC, OR ALL OF THE ABOVE?

J. Rodger, crodger@physics.otago.ac.nz University of Otago, Dunedin, New Zealand Aaron Hendry, ahendry@physics.otago.ac.nz University of Otago, Dunedin, New Zealand Mark Clilverd, macl@bas.ac.uk

British Antarctic Survey, Cambridge, United Kingdom Andrew Kavanagh, andkav@bas.ac.uk

British Antarctic Survey, Cambridge, United Kingdom

It has long been predicted through theory that Electromagnetic Ion Cyclotron Waves (EMIC) should drive significant energetic electron precipitation from the radiation belts into the lower ionosphere. Recently, ground based observations of EMIC waves and ionospheric disturbances have been combined with Low-Earth Orbit precipitation measurements made by the POES constellation to conclusively identify hundreds to thousands of examples of EMIC driven electron scattering into the atmosphere [e.g., Hendry et al., doi:10.1002/2015JA022224, 2016]. However, this large set of events appear to have significant fluxes of electrons with energies of hundreds of keV, which is generally lower than that expected by theory based on first order cyclotron resonance. Differential electron fluxes tend to peak at 250 keV, with only 11% of the events peaking in the 1-4 MeV range [Hendry et al., doi:10.1002/2016GL071807, 2017]. These experimental observations appear to confirm the theory of Non-Resonant Interactions with EMIC waves with “sharp edges” [Chen et al., doi:10.1002/2016JA022813, 2016].

At the same time, there is a growing body of satellite observations suggesting that EMIC waves are efficient scatters of 2-8 MeV ultra-relativistic electrons [e.g., Usanova et al., doi:10.1029/2013GL059024, 2014]. These observations are supported by theory [e. g., Shprits et al., doi:10.1038/ncomms12883,

2016], where cyclotron resonance is most efficient at ultra-relativistic energies, and can lead to non-reversible electron “dropouts” in the trapped fluxes populations. Multiple case studies have been presented [e.g., Shprits et al., doi:10.1002/2016GL072258, 2017; Aseev et al., doi:10.1002/2017JA024485, 2017], and there appears to be growing conviction in the commu- nity around the importance of these waves in this energy range. However, at this time there is a lack of any clear observations of the ultra-relativistic electron precipitation - despite dramatic changes in the trapped fluxes being predicted.

In this presentation we attempt to apply multiple ground-based experimental datasets to test if the observations are indeed consistent with the presence of ultra-relativistic electron precipitation. Specifically, we examine the wide beam riometer at Halley (Antarctica), and the EISCAT incoherent radar measurements from Tromsø (Norway), along with observations from the low-Earth orbiting POES satellites.

PRBEM.2-0017-18 THE FASCINATING DYNAMICS OF THE HIGH-ENERGY VAN ALLEN RADIATION BELTS

NASA Goddard Space Flight Center, Greeneblt, Maryland, United States

High-energy particles contained within the Van Allen belts can be dangerous to sensitive electronics in space, and can affect human activity on the Earth's surface. Precipitating radiation leaving the radiation belts for the Earth's atmosphere can play a role in terrestrial weather and climate systems. Over the nearly six years of high-energy particle measurements obtained by the Relativistic Electron Proton Telescope (REPT) instrument onboard NASA's Van Allen Probes mission, a fascinating array of variation and dynamics can be observed in the outer belts. Here we present several key results showing how the belts can be accelerated up to these very high energies. We also show that it is difficult to generalize from one event to the next, since the resulting dynamics are a complex interplay between various acceleration and loss mechanisms. No two storm events or non-storm events are quite alike, and as such we point out the need for event-specific simulation efforts to enhance our understanding of the full system.

PRBEM.2-0018-18 CALIBRATION OF THE GOES 13/15 HIGH-ENERGY PROTON DETECTORS BASED ON THE PAMELA SOLAR ENERGETIC PARTICLE OBSERVATIONS

Alessandro Bruno, alessandro.bruno-1@nasa.gov NASA GSFC, Greenbelt, Maryland, United States

The Energetic Proton, Electron, and Alpha Detector (EPEAD) and High Energy Proton and Alpha Detector (HEPAD) instruments on the Geostationary Operational Environmental Satellite (GOES) spacecraft have served over many years as monitors of the solar particle intensities, surveying the Sun and measuring in situ its effect on the near-Earth solar-terrestrial environment. However, the reconstruction of the differential energy spectra is affected by large uncertainties related to the poor energy resolution, the small geometrical factor, and the high contamination by out-of-acceptance particles. In this work, the high-quality data set from the Payload for Antimatter Matter Exploration and Light-nuclei Astrophysics (PAMELA) space mission is used to calibrate the high-energy (>80 MeV) proton channels of the EPEAD and the HEPAD sensors on board the GOES 13 and 15, bringing the measured spectral intensities inline with those registered by PAMELA. Suggested corrections significantly reduce the uncertainties on the response of GOES detectors, thus improving the reliability of the spectroscopic observations of solar energetic particle events.

For over 16 years, the Cluster mission passes through radiation belts of the Earth at least once every two days for several hours, measuring the energetic electron intensity at energies from 40 to 400 keV by RAPID/IES instrument. This vast amount of observations has previously been considered as rather useless due to contamination by penetrating energetic particles. In this study, we assess the efficiency with which aluminum shielding of RAPID/IES detector filters out bombarding particles. For this we used a radiation transport code (Geant4). In our simulations, we employ the incident particle energy distribution of the AE9/AP9 radiation belt models. We identify the Roederer L-values and energy channels that should be used with caution and show an example of misinterpreting the data. We propose methods to correct the data in contaminated regions. After applying the corrections we compare the data with electron observations from the Van Allen Probes/MagEIS. The comparison shows that the data from the RAPID/IES measured in the radiation belts is still useful for scientific applications and show examples.

PRBEM.2-0020-18 SPLITTING OF THE OUTER RADIATION BELT DURING SUBSTORMS AT SOLAR ACTIVITY MINIMUM AS SEEN BY CORONAS-PHOTON SATELLITE INSTRUMENTS

Oleksiy Dudnik, dudnik@rian.kharkov.ua 1) Institute of Radio Astronomy of NAS Ukraine, 2) Kharkiv V.N.Karazin National University, Kharkiv, Ukraine

Janusz Sylwester, js@cbk.pan.wroc.pl

Space Research Centre of the Polish Academy of Sciences, Wroclaw, Poland

The satellite telescope of electrons and protons STEP-F and the solar X-ray spectrophotometer SphinX, placed in close proximity to each other, have collected data on particle fluxes aboard circular low Earth orbit CORONAS-Photon satellite during deep minimum of solar activity, which took place in 2009. Whilst STEP-F, comprising a set of silicon PIN and scintillation sensors, served as detector for direct registration for particles, the SphinX has detected not only soft X-rays of solar corona but also bremsstrahlung and line emission in bandwidth of X-rays arising as a result of interaction of high energy electrons with the satellite's housings and instrument's frames. These emissions provide a number of new information on the physics of radiation belts.

In this research we discuss phenomena of outer radiation belt splitting during weak geomagnetic substorms of May and August 2009, detected by both instruments. We make use of the data on particle fluxes observed at L1 Lagrange point and geostationary GOES satellites for context analysis. Double-peaked L-profile of the outer radiation belt and increase of electron fluxes were recorded by STEP-F and SphinX instruments during recovery phase of weak geomagnetic storm on May 8, 2009. STEP-F recorded also barely perceptible outer belt splitting on August 5 2009, after arrival of interplanetary shock.

As far as instruments' fields of view were orthogonally oriented, this allowed to record particle beam at onset of May's substorm by SphinX instrument only that prompted to suggest different mechanisms of populating enhanced electron fluxes during the onset and recovery phases of substorm. At onset of substorm processes of rapid radial diffusion of narrowly directed lowenergy electron fluxes from the boundary layers of the Earth's magnetosphere to the region of steady particle capture prevailed. During the main phase of storm the pitch-angle scattering caused the emptying of outer radiation belt, which was observed both at low altitudes and at altitudes of geostationary satellites.

SCIENTIFIC BALLOONING: RECENT DEVELOPMENTS IN TECHNOLOGY AND INSTRUMENTATION (PSB.1)

PSB.1-0001-18 OVERVIEW OF THE NASA SCIENTIFIC BALLOON ACTIVITIES

Debora Fairbrother, debora.a.fairbrother@nasa.gov

NASA WFF / 820, Wallops Island, Virginia, United States David Gregory, david.d.gregory@nasa.gov

NASA WFF / 820, Wallops Island, Virginia, United States

NASA's Balloon Program has incorporated several changes over the past four years to improve upon safety of operations and to incorporate advanced technologies to achieve more science. Balloon launch campaigns have been conducted domestically and internationally including the re-initiation of Palestine, Texas as a launch location. The Wallops Arc Second Pointer has become qualified as a balloon support system and has become the fine pointing system for several balloon science missions. The development of the super pressure heavy-lift balloon remains at the forefront of the technology development efforts with three southern hemisphere test flights flown from New Zealand. More efficient balloon power systems and higher bandwidth telecommunications systems have been in development to offer greater reliability at lower mass. The current state of NASA's scientific balloon program, its operations, and technology development will be presented, along with plans for the future.

PSB.1-0002-18 10-YEAR SCIENTIFIC BALLOONING IN TAIKI

Tetsuya Yoshida, yoshida.tetsuya@jaxa.jp

Japan Aerospace Exploration Agency (ISAS/JAXA), Kanagawa, Japan

Since 2008, Japan Aerospace Exploration Agency (JAXA) has conducted scientific ballooning at Taiki Aerospace Research Field (TARF) in Hokkaido. In these 10 years, we carried out 30 balloon-borne experiments. Using wide field of TARF to advantage, we can launch larger balloons than before which enable us to realize much complex and the cutting-edge experiments. On the other hand, due to the recent unstable stratospheric wind condition, we can provide short duration flights, mostly less than two hours. Therefore, flight opportunities in Taiki are not suitable for high-statistical astronomy or cosmic-ray experiments, and atmospheric observations and space engineering demonstrations become dominant objectives in the domestic balloon flights.

In this presentation, we summarize JAXA's 10-year scientific ballooning at TARF. We also introduce our overseas activities which is complementary to the domestic ballooning and technology developments for future space science.

PSB.1-0003-18 SWEDISH BALLOON ACTIVITIES SINCE LAST COSPAR ASSEMBLY

Mattias Abrahamsson, mattias.abrahamsson@sscspace.com
Swedish Space Corporation, Kiruna, Sweden

Since the last COSPAR assembly in Moscow, Swedish Space Corporation (SSC) has worked with several balloon missions from its Esrange facility in the north of Sweden. A total of 57 balloons have been launched since August 2014, and 51 of these have been launched and operated by SSC, with the rest being flown by CNES and a US university. The missions have been from several fields of science, e.g. astrophysics, aerodynamics and meteorology, as well as educational and technical flights, and some flights for commercial customers. The flights have been throughout the full envelope of balloon missions, from a few kg to 2 ton payload, from 2 hour flights to 7 days and from 10 to 40 km altitude. The Swedish National Space Agency funded one of the flights within the Swedish balloon programme, and has one more mission currently planned in that programme. For the agency flight, SSC also provided all flight equipment as well as the payload, except the scientific instrument. In the coming 5 years, several balloon missions are planned for users from all over the world. Balloon missions performed by SSC are also being planned to be launched from locations globally.

PSB.1-0004-18 HEMERA - AN OPPORTUNITY FOR SCIENCE USING STRATOSPHERIC BALLOONS

André Vargas, andre.vargas@cnes.fr

Centre National d'Etudes Spatiales, Toulouse, France Felix Friedl-Vallon, felix.friedl-vallon@kit.edu

Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany

HEMERA is an European infrastructure for scientific ballooning. The objectives of HEMERA are to provide balloon access to the troposphere and stratosphere for scientific and technological research, to enlarge the fields of research conducted with balloons, to improve the balloon service offered to the users and to reduce costs by standardization, use of synergies and industrialization through joint ventures. Partners are space agencies and space access providers, research centers, universities and relevant industry. The infrastructure is funded by the Horizon 2020 framework program of the European Union. HEMERA offers to users a possibility to fly small to medium payloads at no cost on CNES or SSC gondolas under Zero Pressure Balloons and Sounding Balloons. Technical details of the offer and the access process will be described.

PSB.1-0005-18 FRENCH BALLOON ACTIVITIES NATIONAL REPORT 2016–2019

Vincent Dubourg, vincent.dubourg@cnes.fr

Centre National d'Etudes Spatiales, Toulouse, France Philippe Raizonville, philippe.raizonville@cnes.fr CNES, Toulouse, France

André Vargas, andre.vargas@cnes.fr

Centre National d'Etudes Spatiales, Toulouse, France Philippe Cocquerez, philippe.cocquerez@cnes.fr CNES, Toulouse Cedex09, France

Stéphane Louvel, stephane.louvel@cnes.fr CNES, Toulouse, France

Muriel Saccoccio, muriel.saccoccio@cnes.fr CNES, Toulouse, France

Frederi Mirc, frederi.mirc@cnes.fr CNES, Toulouse, France

Thoumieux Frédéric, frederic.thoumieux@cnes.fr CNES, Toulouse, France

The French Centre National d'Etudes Spatiales (CNES) goes on supporting a significant balloon program and infrastructure, for scientific and technological purposes. Designed to be mobile, the CNES balloon systems and operation means can be deployed and operated worldwide, at several latitudes. The extended range of vehicles and payload gondola support provided by CNES allow addressing several kinds of missions such as astronomy, atmospheric physics and chemistry, stratospheric and tropospheric meteorology. The main undertaking of the past decade was to deeply renovate the CNES balloons command and control systems and flight operation processes to comply with more stringent Safety constraints and with growing performance and reliability requirements. This is done for large zero pressure balloons (ZPB), and in progress for the other lines of products. Since 2014, 18 successful scientific flights of heavy ZPBs have been carried out from Timmins (Canada), Kiruna (Sweden), and Alice Spring (Australia). In the field of long duration balloons, CNES decided, in june 2016, the development of the STRATEOLE 2 project, for the study of the low stratosphere in equatorial regions (UTLS). Based on the use of fleets of small super pressure balloons (SPB) flying up to 3 months each, the program consists in two launch periods in late 2020 and 2023. The related infrastructure will be available no later than end of 2018, paving the way to a new capacity for long duration flights in general. A synthesis of the launch campaigns of the past two years will be presented: Regarding ZPB flights, a focus will be made on the results of the AUSTRAL 2017 flights from Alice Springs, Aiustralia, were 3 successful flights could be performed in 2 weeks (a record !); A status will be given about the preparation of the launch campaign of the FIREBALL UV payload will be given. An outlook of the new systems currently developed at CNES will be given, in particular regarding the SPB system for Strateole 2 and the preparation of the qualification launch campaign, as well as

the perspectives for new developments and collaborations, such as the CNES participation to the European HEMERA H2020 Infraia project on balloon services, accepted by EU in August 2017.

PSB.1-0006-18 SCIENTIFIC BALLOONING IN INDIA: RECENT ACTIVITIES AND DEVELOPMENTS OF THE TIFR BALLOON FACILITY, HYDERABAD

Suneel Kumar Buduru, bsuneel@tifr.res.in

Tata Institute of Fundamental Research, Hyderabad, India

The Balloon Facility of Tata Institute of Fundamental Research (TIFR-BF), Hyderabad launches zero pressure scientific balloons every year during October-April for the study of various scientific applications, especially in the field of Astronomy (Infrared and X-Ray), high energy physics, Earth's magnetic field and atmospheric science studies, etc. Recently, TIFR-BF provided the launch support for different balloon campaigns such as Tropical Tropopause Dynamics (TTD) to study the water vapour content in Upper Tropospheric and Lower Stratospheric (UTLS) region over Hyderabad and a balloon flight campaign to study the Asian Tropopause Aerosol Layer (BATAL) during the Indian summer monsoon season in collaboration with different national and international research laboratories. The BATAL campaign was the first campaign to conduct balloon launches during Indian summer monsoon (South-West monsoon) season with different sizes of zero pressure plastic balloons. TIFR-BF also floated a small zero pressure balloon of volume 300 cubic meters at UTLS region for a few hours. In recent times, TIFR-BF also designed and fabricated a zero pressure balloon with payload carrying capacity upto 3 ton using four layers of 25 microns film, and also designed and fabricated small oblate spheroid shaped balloons of volume ranging from 10 to 100 cubic meters for testing of newly developed satellite payloads in laboratory at different environmental conditions. In this paper, we present the summary of balloon launches conducted during the recent times, design and fabrication of zero pressure balloons along with the latest developments in balloon components and control instrumentation.

PSB.1-0007-18 SCIENTIFIC BALLOON ACTIVITIES IN BRAZIL: NATIONAL REPORT

Joao Braga, joao.braga@inpe.br INPE, Sao Jose Dos Campos, Brazil

In this talk I will present the latest developments in scientific balloon activities in Brazil, and prospects for the future. Since the last COSPAR Scientific Assembly, the activities at INPE, Brazil's National Institute for Space Research, have been concentrated in the development of the protoMIRAX experiment and its balloon gondola. protoMIRAX is a prototype of the space experiment MIRAX (Monitor e Imageador de Raios X - Monitor and Imager of X Rays) that is currently under revision by INPE and the Brazilian Space Agency. protoMIRAX is a hard X-ray (30 to 200 keV) coded-mask imager with an angular resolution of 1.75 degrees in a 20 x 20 degrees fully-coded field-of-view. The detector plane comprises and array of 13 x 13 planar CdZnTe detectors with dimensions 10mm x 10mm x 2mm. The X-ray imager is housed in a balloon gondola with a complete attitude control and pointing system developed in a partnership between INPE and COMPSIS, a private company in Sao Jose dos Campos, Brazil. The development of protoMIRAX has given the Ballon Launching Center at INPE the opportunity to upgrade its technology and prepare for the provision of important services to the scientific ballooning communities both in Brazil and abroad. I will also present some recent initiatives carried out in Brazilian universities and centers to conduct astrobiology-related and atmospheric experiments in small balloons.

PSB.1-0008-18 WORLD VIEW BALLOON PROGRAM

Sebastian Padilla, sebastian@worldview.space

World View Enterprises Inc., Tucson, Arizona, United States

World View® is pioneering a new frontier at the edge of space and leading the way in the emerging stratospheric economy. As an active, full-service commercial launch provider, World View's technology is already opening up new realms of possibility for commercial customers around the world. World View's disruptive Stratollite flight platform enables previously unthinkable applications at a fraction of the cost of existing technology. Stratollites serve a variety of mission functions - from short duration research flights to long-duration flights over specific areas of interest - and serve a broad range of critical commercial needs and applications. This paper presents an overview of Worldview's capabilities, the innovative technologies, and summary of operations to date.

PSB.1-0009-18 USING METEOROLOGICAL BALLOONS TO EDUCATE A NEW GENERATION OF SCIENTISTS BY DEVELOPING NEW PROFESSIONAL INSTRUMENTS FOR ATMOSPHERIC SCIENCE AND AURORAL PHYSICS

Edgar Bering, eabering@uh.edu

The Undergraduate Student Instrumentation Project is an educational initiative released by the NASA Science Mission Directorate that solicits university proposals to develop Earth or space science payloads to be flown on a NASA suborbital vehicle. The initiative engages undergraduate students in STEM related majors in a full fledged, hands-on project while simultaneously developing technical and project management skills that will be necessary in their future careers in STEM related fields. The USIP group at the University of Houston is wrapping up its third round of funding, with five ambitious field campaigns now under its belt. The mission of the UH USIP is to design, build, and fly instruments on board high altitude latex balloons to study atmospheric and auroral phenomenon near the Arctic Circle. The three campaigns that will be discussed in this paper were conducted during the second and third rounds of USIP, or what we simply call USIP-II. The three campaigns USIP-II took part in was the NASA/Dartmouth BARREL-4 campaign in Kiruna, Sweden, and the USIP-II-UHab campaigns in Fairbanks, Alaska, which were planned and conducted by the USIP students. The instruments designed by this USIP group include a Total Electron Content(TEC) detector, a Very Low Frequency(VLF) radio receiver, a digital to analog IRIG-B Time Code encoder, an atmospheric extremophile organism collection device, a balloon-borne imaging Spectroscope, various Gaseous Compound detectors, a balloon-borne Star Tracker device, and a ground based all-sky imager for detecting atmospheric airglow.

PSB.1-0010-18 INSTRUMENTAL DEVELOPMENTS OF THE METEOROLOGICAL-BALLOON BORNE DETECTORS FOR SPACE EXPLORATION

Debashis Bhowmick, debashisbhowmick@gmail.com Indian Centre for Space Physics, Kolkata, India Arnab Bhattacharya, arnabseacom@yahoo.com Indian Centre for Space Physics, Kolkata, India Sandip Kumar Chakrabarti, chakraba@bose.res.in

S.N. Bose National Centre for Basic Sciences, Kolkata, India Ritabrata Sarkar, ritabrata.s@gmail.com

Indian Centre for Space Physics, Kolkata, India

Measurement of extraterrestrial radiation and atmospheric radiation due to cosmic rays are being conducted on regular basis by Indian Centre for Space Physics, Kolkata over past several years. Light-weight radiation detectors like crystal scintillator detectors, GM counters are used on board small meteorological balloons which serves as the primary instrument for this purpose and are carried near the top of the atmosphere (42 km) using meteorological balloons. These main detectors are supported by several other ancillary instruments developed in a modular approach, to gather and extract sensible data and to execute the execute the experiments seamlessly. Here we briefly discuss the goals and technicalities of the mission operations and describe the instrumental modules in details to some extent.

PSB.1-0011-18 BALLOON-BORNE TURBULENCE MEASUREMENTS IN THE TROPOSPHERE AND STRATOSPHERE USING LITOS

Jens Söder, soeder@iap-kborn.de

IAP, Kuehlungsborn, Kuehlungsborn, Germany Michael Gerding, gerding@iap-kborn.de

Leibniz-Institute of Atmospheric Physics (IAP), Kühlungsborn, Germany Franz-Josef Luebken, luebken@iap-kborn.de

Leibniz-Institute of Atmospheric Physics (IAP), Kuehlungsborn, Germany

Gravity waves play a key role for the understanding atmospheric dynamics as they transport energy and momentum from the troposphere into the middle atmosphere. Parts of the gravity waves dissipate already in the stratosphere, producing smaller and smaller spatial structures down to scales of millimeters. Therefore, these turbulent processes can be best resolved by in-situ measurements. We developed the balloon-borne instrument LITOS (Leibniz-Institute Turbulence Observations in the Stratosphere) to infer kinetic energy dissipation rates by measuring the inner scale of turbulence at spatial scales of typically a few centimeters.

We will demonstrate the concept of LITOS and show case studies from recent measurements in Northern Scandinavia and at our institute location in Germany. A special focus is on general aspects of balloon-borne wave and turbulence measurements, like the ambiguity of horizontal and vertical wave scales and influences of subcritical and supercritical flow around the balloon on the ascent rate. Additionally, we will demonstrate the potential influence of wake turbulence created by the payload suspension or the balloon itself as well as strategies to mitigate these influences. These concepts are expected to be important for many high-resolved sounding methods.

PSB.1-0012-18 SIMULATED RADIATION FROM CRAB PULSAR DETECTED IN A LIGHTWEIGHT PHOSWICH DETECTOR ON BOARD METEOROLOGICAL BALLOON

Ritabrata Sarkar, ritabrata.s@gmail.com

Indian Centre for Space Physics, Kolkata, India Sandip Kumar Chakrabarti, chakraba@bose.res.in

S.N. Bose National Centre for Basic Sciences, Kolkata, India Debashis Bhowmick, debashisbhowmick@gmail.com

Indian Centre for Space Physics, Kolkata, India Arnab Bhattacharya, arnabseacom@yahoo.com Indian Centre for Space Physics, Kolkata, India

In the course to study the detector capability and observation limit under specific conditions, we calculated the detectable radiation from the Crab pulsar in a light-weight, 5”-diameter phoswich detector inboard meteorological balloon along with the background radiation in the detector. For this purpose we simulated the source radiation for the atmospheric absorption and detector response using Geant4 simulation toolkit. We also compared the calculated radiation with observed radiation in a small balloon borne experiment with the similar detector configuration conducted by Indian Centre for Space Physics, India. The height and angular dependence of the detector was taken care during the comparison using the actual sensor data from the mission. Here we present the comparative estimation of the light curve, spectrum and the overall sky image due to the source and background radiations.

PSB.1-0013-18 LOW COST BALLOON BORNE SCIENCE PROGRAMME OF ICSP IN NEAR SPACE AND ITS FUTURE GOALS

Sandip Kumar Chakrabarti, chakraba@bose.res.in

S.N. Bose National Centre for Basic Sciences, Kolkata, India

Indian Centre for Space Physics has been flying low-cost mainly meteorological balloons (both rubber and polythene) for about 10 years and successfully completed 109 such missions. Some of them even had multiple balloons in order to achive longer flights at specific heights. We carry main instruments (geiger counters, bicrons, phoswiches and other X-ray detectors), gps units, degree-of-freedom measuring units, sun sensors etc. The payload is typically less than 5 kilogram and we typically reach about 40km, height being about 42km. We recover all the payloads and thus our recurring cost is less than 500 USD per flight. We have no pointing devices or ballasts as in larger and expensive counterparts. We do not require larger space for launching either. Yet, we have achieved major scientific goals such as (a) monitoring cosmic ray variations year after year (b) solar flare light curves and spectra (c) X-rays from Crab nebula and its pulses (d) e+epair annihilation lines, (e) gamma ray bursts etc. We often traced mysterious radiations spread in 20-22 km height for days on. Based on out inputs we compute the aviation safety and radiation hazards. We believe that our pioneering method may be a very useful tool to test cansats, nanosats and cubesats prior to their flights.

PSB.1-0014-18 E3TRATOS MISSION MONITORING CO2 FROM THE GROUND TO THE STRATOSPHERE IN COLOMBIA

Universidad Industrial de Santander, Bucaramanga, Colombia

CO2 is one of the most common and important trace gases in the atmosphere-ocean-Earth system, is the most important greenhouse gas (GHG) associated with human activities and the second most important gas in global warming after the water vapor. This gas has anthropogenic and natural sources. Monitor the spatial and temporal variation of the CO2 concentration on both, global and local scale is a main duty concerned to the environmental authorities. The global monitoring of CO2 has been achieved by the use of space missions like NASA's Orbiting Carbon Observatory-2 and local scale measurements are assured by the exploding number of scientific stations. In developing countries, like Colombia, accessing these measurements is a quite difficult task. If satellite data repositories are no open, local authorities have budget issues to obtain the required data. Otherwise, local measurements are more difficult to obtain because the high costs of the required instrumentation and logistics fees that are proportional to the number of measuring stations. In Colombia we found a very weak network of scientific stations monitoring atmospheric variables with less than 3000 weather stations covering a surface of 1,142 million of square kilometers. Here we present the status of the "E3Tratos"

mission, which is the first stratospheric balloon research project with scientific payload that is being developed at the Universidad Industrial de Santander in Colombia, South America and that will

be launched by the fall of 2018. The main objective of the mission is to launch lowcost and autonomous scientific instrumentation towards the stratosphere and thus observe the surface of the Earth from the upper limit of the atmosphere at approximately 35 km in height. The displacement of the balloon and its payload will allow measuring meteorological variables and GHGs along its ascending route. The portability capabilities of the instrumentation seek to validate future low-price high efficiency scientific stations that will serve to ameliorate the local monitoring of GHGs in developing countries. We will show the final design as well as the characterization of some of the implemented subsystems that includes: Scientific instrumentation based on high resolution cameras in the visible, a portable meteorological station, an atmospheric CO2 concentration sensor, control electronics based on reduced-board computers that control the entire experiment, a radio link that, together with a station on the ground, will allow monitoring the position of the probe balloon and receive the telemetry data, The mechanical interfaces composed of a gondola that will serve as a mechanical interface to house the payload (< 3500 g) and a propulsion-recovery system based on a stratospheric probe balloon (3000 gram) and a parachute. We present the final design of the instrument capable of measuring in-situ the concentration of GHGs. The design of the CO2 concentration sensor is based on the tunable diode laser spectroscopy technique TDLS that consists of varying the emission wavelength of a near-infrared room temperature laser diode through the modulation of the current signal that polarizes the laser diode. This variation of the current allows changing the wavelength of the laser diode over a bandwidth of less than one nanometer. The bandwidth and the central wavelength of emission of the laser diode are previously selected (2004 nm for CO2) in order to be able to sample a strong atmospheric absorption band that is due to the exclusive presence of CO2. A two-mirror multipass absorption cell that is operated open to the atmosphere receives the modulated beam, absorption on the beam due to the atmospheric gases is then measured at the multipass cell output with In-GAs photodiode. Direct-differential detection in conjunction with the cell to record the atmospheric spectra in situ, give us access to the molecular line shape with no distortions. Then, by reconstructing the full molecular line shape with a nonlinear least-squares fit to retrieve the mixing ratios, atmospheric CO2 concentration will be monitored over large ranges in pressure, temperature, and concentration with an achieved precision error within a few percents. The instrument will be capable to work under hard environment conditions. Future works will focus on monitor of other GHGs. This will be achieved changing the central emission of the selected diode laser.

PSB.1-0015-18 A LIGHT-WEIGHT DEVICE FOR PAYLOAD ATTITUDE MEASUREMENT USING MICRO-ELECTRONIC INERTIA-MEASUREMENT UNIT SUITABLE FOR SMALL BALLOON BORNE MISSIONS

Arnab Bhattacharya, arnabseacom@yahoo.com Indian Centre for Space Physics, Kolkata, India Ritabrata Sarkar, ritabrata.s@gmail.com

Indian Centre for Space Physics, Kolkata, India Debashis Bhowmick, debashisbhowmick@gmail.com Indian Centre for Space Physics, Kolkata, India Sandip Kumar Chakrabarti, chakraba@bose.res.in

S.N. Bose National Centre for Basic Sciences, Kolkata, India

Small meteorological weather balloon borne payloads cannot accommodate conventional pointing device due to the restriction on payload weight. Thus it is subjected to rotate freely around an axis and also suffers other random motions and oscillations due to wind gusts and drag forces. These motions enables it to scan a part of the sky depending on the payload construction and detector collimator. In particular, for the detectors to study radiations from astrophysical sources, we need to know the instantaneous the direction of the detector to locate the source of the data. For this purpose we use an attitude and heading reference system using micro-electronic modules, to determine the payload attitude. Here in this work we describe the design and work of such a device made to measure the attitude of a payload on board weather balloons.

PSB.1-0016-18 DEVELOPMENT AND EVALUATION OF A QUASI DECENT-CONTROL TYPE PAYLOAD SYSTEM FOR SMALL SOUNDING BALLOONS

Takamasa Hiratsuka, hiratsukatakamasa@gmail.com

Kochi university of Technology, Graduate School of Electronic and Photonic System Engineerings, Kami, Japan

Hiroki Kono, h.kono0502@gmail.com

Stratospheric Balloon Project, Atsugi Kanagawa, Japan Masayuki Yamamoto, yamamoto.masa-yuki@kochi-tech.ac.jp Kochi University of Technology, Kami, Japan

In-situ stratospheric observation up to 30 km altitude by using small sounding balloons has been increasing as a transport equipment in the recent years. A small rubber balloon with a diameter of about 3 m is used with small observing sensor devices, being separated at a target altitude and usually landed with a parachute for recovery. By using a small rubber balloon, inexpensive and small-scale experiments become possible with somewhat freehand launching opportunities. However, as there is no vast flat land in crowded small island area of Japan, tracking and recovering of such sounding balloons in the area of urban, mountainous areas, and oceans are difficult, or it needs extra equipments and efforts for preventing a lost of the instruments. For this reason, the use of sounding balloons has not been advanced in small-scale balloon projects.

In order to solve the geographical constraints and realize efficient operation, our laboratory has been working on development of a sounding balloon system mounted with quasi decentcontrol type payload. The operation method is to perform a soft landing guidance working with a parafoil with on-board servo-motor control system while selecting the multiple reachable landing points among pre-set safety landing point candidates on the payload. As a final goal, we prepare a payload system with a sensor mass of 500 g and the total payload size of 60 mm cube. Throughout these evaluating flight tests, we aim to develop the entire decent-control system along with our main target. Our laboratory developed prototype payload system and performance experiments were carried out. As a result, we obtained a simple performance evaluation with a glide ratio of about 3 as well as a turning radius of about 15 m, resulting in a design validity of the developed system. On the other hand, we found, flight evaluation was only very basic at that time due to flight altitude shortage and lack of some sensors and destruction of the system caused by rotational motion during its landing.

Currently, we are developing new payload system based on the tasks found in the previous experiments. And, we will evaluate flight performance through manual flight control experiment from 100 m altitudes. In this presentation, we will present our recent activities to make challenging small-ballon devices, results of the parafoil system to be used for manual control flight test, and future scientific applications with microphones for infrasound sensing in middle atmosphere.

PSB.1-0017-18 SMILE-II+: THE 2018 BALLOON CAMPAIGN IN AUSTRALIA OF MEV GAMMA-RAY TELESCOPE

Kei Yoshikawa, yosikawa@cr.scphys.kyoto-u.ac.jp Kyoto University, Kyoto, Japan

SMILE(MeV gamma-ray telescope)

T. Tanimori, A. Takada, Y. Mizumura, T. Takemura, Y. Nakamura, K. Onozaka, K.Saito, H. Kubo, S. Komura, T.Kishimoto, T. Taniguchi, S. Kurosawa, K. Miuchi, K. Hamaguchi, T. Sawano

The observations of celestial nuclear gamma-rays in the MeV energy band provide more understanding of various phenomena such as nucleosynthesis in supernovae and merger of neutron stars. However, the observation in this band is very difficult due to huge background and unclear imaging. The background is created by the interactions of the cosmic particles with the satellite body. The current telescopes, based on coded aperture imaging or classical Compton imaging, cannot overcome this problem, because these telescopes cannot measure two angles of the incident gamma-ray, event by event.

We have developed an electron-tracking Compton camera (ETCC) as a next generation telescope. In comparison with the classical Compton imaging, the ETCC measures a 3D track of a recoil electron using a gaseous detector, and provides a two-dimensional point spread function defined by two angles of the incident gamma-ray. If a satellite with an ETCC having an effective area of 200 cm^2 and half power radius (HPR) observes all sky during 1 year, the detection sensitivity will reach to 1 mCrab.

We have promoted Sub-MeV gamma-ray Imaging Loaded-on-balloon Experiment (SMILE) to certificate the performance of ETCC. We carry out a 1-day balloon observation of Australia in spring in 2018 (SMILE-II+) supported by ISAS/JAXA. We certificate the capability of imaging spectroscopy by observing the Crab nebula and the positron-electron annihilation line in the galactic center region as bright celestial objects. The field of view of ETCC is 4 sr and the both effective observation time of these objects are over 5 hours. For detection of these objects over 5 significances, an ETCC requires HPR of 10 degree (662 keV) and an effective area of 3 cm^2 (511 keV). We develope SMILE-II+ ETCC and measure the HPR and the effective area in order to certificate to meet the requirement.

In this talk, we present a flight report and a preliminary result of SMILE-II+.

PSB.1-0018-18 PERFORMANCE OF SMILE-2+ ELECTRON-TRACKING COMPTON CAMERA (ETCC)

Taito Takemura, take2physics5neutrino@gmail.com Kyoto University, Sakyo-ku,Kyoto-shi, Japan SMILE (MeV gamma-ray telescope)

T. Tanimori, A. Takada, Y. Mizumura, K. Yoshikawa, Y. Nakamura, K. Onozaka, K. Saito, S. Komura, T. Kishimoto, T. Taniguchi, H. Kubo, S. Kurosawa, K. Miuchi, K. Hamaguchi, T. Sawano,

MeV gamma-ray astronomy does not advance in the last 20 years, though there are many science treasures. This reason is conventional MeV gamma-ray telescopes without an accurate imaging capability, and the environment with huge backgrounds. We developed an electron-tracking Compton camera (ETCC) with an accurate imaging by a well-defined point spread function (PSF), and we are planning "Sub-MeV gamma-ray Imaging Loaded-on-balloon Experiment" (SMILE) leading to the satellite observation since 2006.

We launch a 1-day flight at Alice Springs, Australia at April, 2018 to demonstrate the imaging capability of the ETCC by the brightest objects (SMILE-2+). The observation targets are Crab nebula and annihilation line from the Galactic Center region. It requires the effective area of 4 cm^2 (200 keV) and 3 cm^2 (511 keV) and PSF (in which 50% of the events are included) of 10 degrees (662 keV). The SMILE-2+ ETCC consists of a 30-cm-cubic gaseous detector, which measures the energy and direction of a recoil electron, and the pixel scintillator arrays surrounding the gaseous detector, which measure the energy and hit position of a scattered gamma-ray. We measure the effective area and the PSF of the ETCC in the laboratory using RI sources, to confirm that the ETCC satisfy the requirements.

In the future observation, we will start scientific observations using the long duration balloons with a ETCC having an effective area of 20 cm^2 (200 keV) and 15 cm^2 (511 keV) and a PSF of 5 degrees (SMILE-3). For this purpose, we will use two ETCCs filled by a CF4 with a pressure of 3 atm. The effective area of SMILE-3 increases by 8 times of that value of SMILE-2+ because the probability of Compton-scattering is proportional to the electron density of the scattering target. Finally, we aim to a satellite with an effective area of 200 cm^2 and HPR of a few degrees for 1 MeV gamma-ray, which would reach approximately 0.1 mCrab.

In this talk, we present the measured performances of SMILE-2+ ETCC and the expected observations by the long duration balloons and a satellite in the future.

PSB.1-0019-18 GRAINE PROJECT AND A 2018 BALLOON-BORNE EXPERIMENT

Satoru Takahashi, satoru@radix.h.kobe-u.ac.jp Kobe University, Tsurukabuto, Nada, Kobe, Japan GRAINE collaboration (2018)

Observations of high-energy cosmic γ-rays provide us with direct information of high-energy phenomena in the universe. Fermi-LAT is observing a γ-ray sky and offering new insights. On the other hand, past and current observations have some limitations. Improvements in an angular resolution and polarization sensitivity are one of keys for a breakthrough of the limitations.

We are developing GRAINE project, the project of a 10 MeV – 100 GeV cosmic γ-ray observations with a precise (0.08 degree @ 1 – 2 GeV) and polarization sensitive large aperture area (~10 m2) emulsion telescope by repeating long duration balloon flights.

A feasibility and performance of the emulsion γ-ray telescope were demonstrated using accelerator beams with γ-rays / electrons / muons and atmospheric γ-rays at mountain height.

In 2011, the first balloon-borne, emulsion γ-ray telescope experiment was successfully performed with a 125 cm^2 aperture area and 4.3 hour flight duration on JAXA scientific ballooning at TARF Japan. By the flight data analysis, we demonstrated a feasibility of the balloon-borne emulsion γ-ray telescope experiment.

In 2015, we had a JAXA scientific ballooning with a 3780 cm^2 aperture area and 14.4 hour flight duration in Australia. Overall performance of the telescope is being demonstrated by the flight data analysis.

In April 2018, we have a JAXA scientific ballooning with a ~0.4 m2 aperture and >~18 hour flight duration in Australia for a demonstration with a detection and imaging of a known γ-ray source, Vela pulsar. In 2021 or later, with a 10 m2 and >24 hour flight duration, we aim to start scientific observations.

An overview and status of the GRAINE project and the 2018 balloon-borne experiment are presented.

PSB.1-0020-18 IN-FLIGHT PERFORMANCE OF THE PILOT BALLOON-BORNE EXPERIMENT

Jean-Philippe Bernard, jean-philippe.bernard@irap.omp.eu

Institut de recherche en Astrophysique et Planétologie, Toulouse, France

Measuring precisely the faint polarization of the Far-Infrared and sub-millimetre sky is one of the next observational challenges of modern astronomy and CMB cosmology. I will describe the concept and science goals of the PILOT balloon-borne instrument, dedicated to measuring the linear polarization of the faint interstellar diffuse dust emission in the Far-Infrared in our Galaxy and nearby galaxies. I will present the in-flight performance of the experiment, as measured during the two successful flights of PILOT from Timmins, Canada in September 2015 and from Alice Springs, Australia in April 2017. Finally, I will show the first polarization maps obtained and discuss preliminary results and future objectives.

PSB.1-0021-18 EXPLORING NEW DIRECTIONS IN GAMMA RAY ASTROPHYSICS WITH COSI

Steven Boggs, boggs@ssl.berkeley.edu

University of California, Berkeley, Berkeley, California, United States

The Compton Spectrometer and Imager (COSI) wide-field gamma-ray telescope (0.2-5 MeV) is designed to probe the origins of Galactic positrons, uncover sites of nucleosynthesis in the Galaxy, and perform pioneering studies of gamma-ray polarization. COSI is the first science payload designed to fly on NASA's 18 MCF superpressure balloon. COSI underwent a successful 46-day science flight in 2016, the first science payload to launch from New Zealand. I will discuss the science goals and status of results of COSI, the technological advances of the instrument, future goals for the COSI program, and the potential of NASA's superpressure balloon program.

PSB.1-0022-18 SPECTRAL ANALYSIS OF THE CRAB WITH THE COMPTON SPECTROMETER AND IMAGER

Clio Sleator, sleator@berkeley.edu

University of California, Berkeley, California, United States Jarred Roberts, jmr078@physics.ucsd.edu

University of California, San Diego, San Diego, United States

The Compton Spectrometer and Imager (COSI) is a balloon-borne, soft gamma-ray (0.2-5 MeV) telescope designed to study astrophysical sources, including compact objects. COSI utilizes a compact Compton telescope design with 12 germanium detectors and is inherently sensitive to polarization. In May 2016, COSI was launched from Wanaka, New Zealand, and completed a successful 46-day flight on NASA's Superpressure balloon. The Crab Nebula is among the sources detected during the 2016 flight. We present an update on our spectral analysis of the Crab, and describe the spectral analysis pipeline we have developed for COSI. We have constructed an accurate instrument model as required for the response matrix. By carefully selecting background events, we are able to fit background-subtracted spectra in XSPEC, a well known spectral fitting program. We have also developed a model of the atmosphere above COSI to include in our spectral fits. Furthermore, we will discuss prospects for measuring the Crab polarization with COSI.

PSB.1-0023-18 POGO+ STRATOSPHERIC BALLOON MISSION FROM ESRANGE, SWEDEN, TO VICTORIA ISLAND, CANADA

Mattias Abrahamsson, mattias.abrahamsson@sscspace.com Swedish Space Corporation, Kiruna, Sweden

Christian Lockowandt, christian.lockowandt@sscspace.com Swedish Space Corporation, Solna, Sweden

PoGO+ was a stratospheric balloon project with a cosmic ray experiment from KTH, Stockholm, Sweden, that was launched on July 12th, 2016 for a 7 day flight from Sweden to Canada. The payload mass was 1728 kg and an Aerostar SF-39.57 balloon was used to reach the float altitude of 40 km. In 2013 a similar experiment flew from Esrange to Norilsk in Russia in a circumpolar flight that lasted 2 weeks. That balloon was called PoGOLite. The experiment on PoGO+ was a balloon-borne hard X-ray polarimeter operating in the 25 - 240 keV energy band from a stabilised observation platform. Observations were conducted from a stabilised stratospheric balloon platform at an altitude of approximately 40 km. The primary targets were the Crab - a pulsar and associated wind nebula in the constellation of Taurus, 6500 light years from Earth, and Cygnus X-1 - a black hole binary system. A custom attitude control system kept the polarimeter field-of-view aligned to targets of interest, compensating for sidereal motion and perturbations such as torsional forces in the balloon rigging. After a launch at 03:17 UTC, the balloon reached float altitude after almost 10 hours, due to a cold stratosphere with slow ascent. A slower than anticipated wind took the balloon over the Atlantic for a landing in Canada on July 18th at 22:26 UTC. Landing latitude was 71.84747 N, longitude 110.885 E on Victoria Island. The mission was very successful with all systems both scientific and support and balloon systems working nominal during the complete flight. A huge amount of scientific data was collected during the flight that will be analysed. The flight lasted 7 days and this was longer than expected resulting in more scientific data. The landing and recovery was performed nominal and the scientific data were recovered and delivered to the science team within 12 days after landing. The mission was managed by SSC and SSC was also responsible for the gondola structure, housekeeping and communication systems, power systems and part of the balloon flight systems. SSC was handling the launch, flight and recovery operations. KTH was responsible for the instrument, X-ray polarimeter, including all subsystems for controlling and monitoring the systems including thermal management. DST Control, Sweden was responsible for the dual axis pointing system. New Mexico State University, USA, was responsible for part of the balloon flight systems.

PSB.1-0024-18 THE EUSO-SPB2 MISSION

Fred Sarazin, fsarazin@mines.edu

Colorado School of Mines, Golden, United States Lawrence Wiencke, lwiencke@mines.edu

Colorado School of Mines, Golden, Colorado, United States Angela V Olinto, aolinto@uchicago.edu

University of Chicago, Chicago, Illinois, United States

The Extreme Universe Space Observatory Super Pressure Balloon second mission (EUSOSPB2) is currently in preparation. This long duration mission will measure fluorescence and Cherenkov signals from high-energy cosmic-ray showers and search for Cherenkov signals from up-going showers from tau neutrinos. The instrument features three optical telescopes. Two of them are designed to detect direct Cherenkov light near the direction of the Earth's limb, while the third one uses the fluorescence technique to measure near horizontal showers. The launch date is planned for 2021 from the NASA launch pad located in Wanaka, New Zealand. This balloon mission will also test techniques and methods for the Probe of Extreme Multi Messenger Astronomy (POEMMA) space mission, currently studied under a NASA sponsored conceptual design.

PSB.1-0025-18 EUSO-SPB1: A BALLOON BORN FLUORESCENCE TELESCOPE FOR COSMIC RAY DETECTION

Johannes Eser, jeser@mines.edu

Colorado School of Mines, Golden, Colorado, United States Angela V Olinto, aolinto@uchicago.edu

University of Chicago, Chicago, Illinois, United States Lawrence Wiencke, lwiencke@mines.edu

Colorado School of Mines, Golden, Colorado, United States

The measurement of ultra-high energy cosmic rays from space via the fluorescence method is very compelling because the observable area can be very large. The development of an instrument with this capability is the goal of the Extreme Universe Space Observatory collaboration. In April 2017 the collaboration made a major step forward with the launch of the Extreme Universe Space Observatory on board a Super Pressure Balloon (EUSO-SPB1). The instrument was designed to measure cosmic rays for the first time via their fluorescence signal by looking down on the atmosphere. The instrument was flown as a NASA mission of opportunity from Wanaka, NZ on the 27th of April 2017 with a planned flight duration as long as 100 days. The telescope viewed the atmosphere from an altitude of 33 km.

The flight terminated prematurely after 12 days, about 300 km SE of Easter Island. We will present the instrument, the mission and preliminary results of the ongoing data analysis. A discussion of a second EUSO-SPB mission is presented in a separate contribution.

To make radiometric measurements of the light generated in extensive air showers (EASs), it was necessary to calibrate the Extreme Universe Space Observatory Super Pressure Balloon (EUSO-SPB) instrument before its flight. This was accomplished in several steps. First a flat-field calibration was done in Golden, Colorado. Next the instrument was moved to the Telescope Array site near Delta, UT where it was calibrated using a laser and a light-emitting diode (LED). Finally the flat field calibration was repeated in Wanaka prior to the launch.

The first flat-field measurements were made at the Colorado School of Mines in Golden, CO. This was done in a darkened room. A Tyvek-covered screen was installed 4.65 m in front the

EUSO-SPB instrument, filling its field of view. This screen was illuminated by a UV LED, operated in a pulsed mode and mounted in the center of the front lens of the instrument. A second flat-field calibration was performed outside the instrument preparation hanger at the Wanaka, NZ airport. This time the instrument was suspended from a crane with the entrance aperture facing the ground. A Tyvek screen was spread on the ground beneath the

instrument filling its aperture. It was also illuminated by the LED installed in the center of the front lens of the instrument. The results of both calibrations will be reported.

The calibration measurements at the Telescope Array site with the instrument was placed on Black Rock Mesa, viewing west and away from distant city and village lights. A laser was located at a 24 km in front of the EUSO-SPB. From this location the laser fired pulses of UV light into the sky. The light scattered from these pulses was recorded by EUSO-SPB. This provided a test the instrument trigger, the geometrical reconstruction algorithm for the EASs, and a radiometric calibration that depended on an understanding of the scattering mechanism in the atmosphere. In addition, a UV LED was placed on a tower at distance of 45.11 meters in front of EUSO-SPB to provide an absolute radiometric calibration of a few points on the focal surface of the instrument. These calibrations, combined with the flat-field calibrations enabled EUSO SPB to launch with the capability to make absolute radiometric measurements of the light emitted by EASs in the atmosphere below the balloon that result from the interaction of very high energy cosmic rays in the atmosphere. Such measurements would also be required to reconstruct the energy of any cosmic rays observed.

In the process of space exploration in X-rays with small balloon borne detectors, we designed a radiation detector using a 5″ diameter phoswich scintillator detector. The detector can be carried up to a height of about 42 km above the atmosphere using a plastic meteorological balloon where radiation detection from extraterrestrial objects are possible. Here in this paper we present the design considerations and characterization of the detector used for this purpose. Using the data from an experiment designed to detect radiation from Crab pulsar, we discuss about the background radiation in the detector in such experimental environment which is very crucial for these kind of experiments. We empirically modeled the background at various altitudes of the payload which are to be used in spectral analysis when actual measurement of background is not possible. Considering the background radiation level and limitations on the detector we also calculate the minimum detection limit for radiation sources in this experiment.

We also present results of radiation detection from Crab pulsar in this experiment. We show that the data clearly gives $\sim$ 33 ms pulse signature.

SUNRISE is a balloon-borne, stratospheric solar observatory dedicated to the investigation of the structure and dynamics of the Sun's magnetic field and its interaction with convective plasma flows and waves. The previous science flights of SUNRISE in 2009 and 2013 have led to many new scientific results, so far described in around 90 refereed publications. This success has shown the huge potential of the SUNRISE concept and the recovery of the largely intact payload offers the opportunity for a third flight.

The scientific instrumentation of SUNRISE 3 will have extended capabilities in particular to measure magnetic fields, plasma velocities and temperatures with increased sensitivity and over a larger height range in the solar atmosphere, from the convectively dominated photosphere up to the still poorly understood chromosphere. The latter is the key interaction region between magnetic field, waves and radiation and plays a central role in transporting energy to the outer layers of the solar atmosphere including the corona.

SUNRISE 3 will carry 2 new grating-based spectro-polarimeters with slit-scanning and context imaging with slitjaw cameras. The SUNRISE UV Spectro-polarimeter and Imager (SUSI) will explore the rich near-UV range between 300 nm and 430 nm which is poorly accessible from the ground. The SUNRISE Chromospheric Infrared spectro-Polarimeter (SCIP) will sample 2 spectral windows in the near-infrared, containing many spectral lines highly sensitive to magnetic fields at different formation heights. In addition to the two new instruments the Imaging Magnetograph eXperiment (IMaX), an etalon-based tunable filtergraph and spectropolarimeter flown on both previous missions, will be upgraded to IMaX+, enhancing its cadence and giving access to 2 spectral lines in the visible spectral range. All three instruments will allow investigating both the photosphere and the chromosphere and will ideally complement each other in terms of sensitivity, height coverage and resolution.

A new gondola with a sophisticated attitude control system including roll damping will provide improved pointing/tracking performance. Upgraded image stabilization with higher bandwidth will further reduce residual jitter, maximizing the quality of the science data.

SUNRISE 3 is a joint project of the German Max-Planck-Institut für Sonnensystemforschung together with the Spanish SUNRISE consortium, the Johns Hopkins University Applied Physics Laboratory, USA, the German Kiepenheuer Institut für Sonnenphysik, the National Astronomical Observatory of Japan and the Japan Aerospace eXploraion Agency (JAXA).

The SUNRISE balloon-borne solar observatory carries a 1 m aperture optical telescope, and allows us to perform seeing-free continuous observations at visible-IR wavelengths from an altitude higher than 35 km. In the past two flights, in 2009 and 2013, observations mainly focused on fine structures of photospheric magnetic fields. For the third flight planned for 2021, we are developing a new instrument for conducting spectro-polarimetry of spectral lines formed over a larger height range in the solar atmosphere from the photosphere to the chromosphere. Targets of the spectro-polarimetric observation are (1) to determine 3D magnetic structure from the photosphere to the chromosphere, (2) to trace MHD waves from the photosphere to the chromosphere, and (3) to reveal the mechanism driving chromospheric jets, by measuring heightand time-dependent velocities and magnetic

fields. To achieve these goals, a spectro-polarimeter called SCIP (Sunrise Chromospheric Infrared spectroPolarimeter) is designed to observe nearinfrared spectrum lines sensitive to solar magnetic fields. The spatial and spectral resolutions are 0.2 arcsec and 200,000, respectively, while 0.03% polarimetric sensitivity is achieved within a 10 sec integration time. The optical system employs an Echelle grating and off-axis aspheric mirrors to observe the two wavelength ranges centered at 850 nm and 770 nm simultaneously by two cameras. Polarimetric measurements are performed using a rotating waveplate and polarization beam-splitters in front of the cameras. For detecting minute polarization signals with good precision, we carefully assess the temperature dependence of polarization optics, and make the opto-structural design that minimizes the thermal deformation of the spectrograph optics. Another key technique is to attain good (better than 30 msec) synchronization among the rotating phase of the waveplate, read-out timing of cameras, and step timing of a slit-scanning mirror. On-board accumulation and data processing are also critical because we cannot store all the raw data read-out from the cameras. We demonstrate that we can reduce the data down to almost 10% with loss-less image compression and without sacrificing polarimetric information in the data. The SCIP instrument is developed by internal collaboration among Japanese institutes including Japan Aerospace Exploration Agency (JAXA), the Spanish Sunrise consortium, and the German Max Planck Institute for Solar System Research (MPS) with a leadership of the National Astronomical Observatory of Japan (NAOJ).

PSB.1-0030-18 THE LARGE BALLOON REFLECTOR (LBR): GAME CHANGING APPROACH TO REALIZING LARGE SPACE AND NEAR-SPACE APERTURES

Christopher Walker, cwalker@as.arizona.edu University of Arizona, Tucson, Arizona, United States

I. Steve Smith, steve.smith@swri.org

NASA Jet Propulsion laboratory, Pasadena, California, United States Douglas Stetson, dstetson@freefallaerospace.com

FreeFall Aerospace, Tucson, Arizona, United States

The Large Balloon Reflector (LBR) development and test program provides a path forward to the realization of 10+ meter telescopes in near-space and serves as a pathfinder for larger space based apertures. In particular, LBR is a progenitor of the TeraHertz Space Telescope (TST) concept to be submitted to the upcoming Astronomy and Astrophysics Decadal Survey. As a demonstration of the scientific potential of an LBR in near space, we propose a series of flight tests with a 5 meter LBR. The performance of LBR will be validated by performing spectroscopic observations of sources with line strengths determined previously using smaller telescopes and through total power measurements of the Sun, Moon, and planets. The proposed investigation builds upon studies of LBR funded by the NASA Innovative Advanced Concepts (NIAC) program. Both NIAC Phase 1 and 2 studies have been completed (Walker 2014) and key technologies for the flight system validated. A number of LBR subsystems share heritage with the Stratospheric TeraHertz Observatory (STO) which was successfully flown from Antarctica during the 2016-2017 austral summer

PSB.1-0031-18 THE GUSTO BALLOON MISSION

Pietro Bernasconi, pietro.bernasconi@jhuapl.edu

Johns Hopkins Applied Physics Laboratory, Laurel, Maryland, United States Christopher Walker, cwalker@as.arizona.edu

University of Arizona, Tucson, Arizona, United States Craig Kulesa, ckulesa@as.arizona.edu

University of Arizona, Tucson, Arizona, United States

The Galactic/Extra-Galactic ULDB Spectroscopic Terahertz Observatory (GUSTO) is a NASA Explorer Mission of Opportunity mission led by PI Dr. Christopher Walker of the University of Arizona. The project goal is to develop a Terahertz observatory and balloon-borne platform for conducting a spectroscopic survey of the Milky Way (MW) and Large Magellanic Cloud (LMC) to determine the composition energetics and dynamics of the Interstellar Medium (ISM).

The University of Arizona will provide the GUSTO 0.9-m aperture telescope and instrument, which will incorporate an array of 3x8 cryogenic Terahertz superconducting heterodyne receivers built in a collaborative effort with the Massachusetts Institute of Technology, Arizona State University, SRON Netherlands Institute for Space Research, Virginia Diodes (VDI), and Ball Aerospace. The Johns Hopkins University Applied Physics Laboratory (JHU/APL) will provide the gondola with all its subsystems: Avionics, Guidance and Control, and Power. JHU/APL will also provide day-to-day project management, mission systems engineering.

GUSTO will launch from McMurdo Antarctica in December 2021 and is designed to stay aloft for 100 days or more by utilizing the 100-day flight potential of the new Super Pressure Balloon (SPB), provided by NASA's Balloon Program Office (BPO). During the flight the mission will measure the THz emission from three important interstellar lines: [CII], [OI], and [NII] at 158, 63, and 205 microns, respectively, spread throughout the Milky Way and the neighboring Large Magellanic Cloud. GUSTO will provide the first complete study of the life cycle of the interstellar medium, the gas and dust from which all stars and planets are formed.

GUSTO will employ a development approach that uses flight heritage from the Stratospheric Terahertz Observatory (STO) and the Balloon Observation Platform for Planetary Science (BOPPS) and other prior balloon missions.

PSB.1-0032-18 BALLOONS ARRAY TO TRACK AND INSPECT UPGOING HADRON AND NEUTRINO AIRSHOWERS

Daniele Fargion, daniele.fargion@roma1.infn.it

Physics Department, Rome University 1, INFN Rome 1,, Rome, Italy

Balloons offer a peculiar sky view at few or tens km altitudes. For instance following UHE neutrino astrophysics by ICECUBE we should expect once every few cube km volume, a PeVs tau neutrino (born by flavor mixing in cosmic flight) rarely crossing the Earth cord. These upgoing tau neutrinos, their eventual interaction on external terrestrial crust, it is making inside the soil an Ultra Relativistic Tau lepton, whose exit upward Earth and whose decay in air atmosphere lead to upward tau airshower. An unique PeV-EeV tau shine in air billions of secondaries amplifying its discover by huge number and widest area disk. Because such PeV EeV cannot be atmospheric they offer a guaranteed noise free Neutrino Astronomy. On the other horizon edges the escape of downward horizontal Cosmic Ray Airshower offer a well known abundant hadronic and nuclear signature. These events are ruled by energy and by nuclear composition. Their signature (slath depth) growth it is logaritmically related to their nuclear spectra. Moreover the terrestrial magnetic field offer an additional bending filter of the charged (mostly electron pairs) secondaries, leading to a wide airshower angle spread. At tens km altitude the poor dense air do not make longer electron random walk: therefore one expect (along East-West axis) an ideal geomagnetic spectrometer able to spread in a thin cone the upgoing horizontal hadronic atrshowers. These effects must be better recorded by (scintillators, Cherenkov optical, Radio.) detector array. The building of such array long tail (km tail lenght) balloon system possibly in coordinate flight may open a new era of both UHECR and UHE neutrino Astrophysics and Astronomy. A rich Anita-like balloon array spread every few ten km distance and located at tens km altitude with a hundreds meter long tail elements may disentangle UHECR composition and tau neutrino signal in area and mass volume well comparable and often much superior to AUGER-TA ground array detectors and to ICECUBE neutrino mass detector. references: 1) D.Fargion, Discovering Ultra High Energy Neutrinos by Horizontal and Upward tau Air-Showers. PSB.1-0033-18 THE LARGE BALLOON REFLECTOR (LBR): ARCHITECTURE AND CONCEPT OF OPERATIONS

Ira “Steve” Smith, sismith@swri.edu

Southwest Research Institute, San Antonio, Texas, United States Christopher Walker, cwalker@as.arizona.edu

University of Arizona, Tucson, Arizona, United States Ethan Chaffee, ethan.chaffee@swri.org

Southwest Research Institute, San Antonio, Texas, United States William Perry, bill.perry@swri.org

Systems Engineering & Assessment Ltd., San Antonio, United States

Southwest Research Institute (SwRI) and the University of Arizona (UA) have been focused on the development and demonstration of the technologies required to realize a spherical large balloon reflector (LBR) antenna. The focus has been on a suborbital, balloon borne, 10 meter class balloon reflector suitable for operation for radio to THz frequencies. Looking up and out into deep space, the LBR could serve as a telescope. The realization of a low cost large, near-space 10 meter class reflector for THz astronomy and microwave/millimeter-wave remote sensing and telecommunications has long been a goal of NASA and the DoD. Looking down, the LBR can be used for remote sensing or telecommunication activities. In particular, for the DoD, such a facility could be used to host high resolution, millimeter-wave radar, chemical detection equipment, and serve as a high bandwidth, telecommunications hub, thus, providing our warfighters with invaluable intelligence. This paper addresses the overall system architecture, testing, analysis and concept of operations.

PSB.1-0034-18 CNES STRATOSPHERIC BALLOONS FOR SCIENCE AND APPLICATION TO THE PILOT EXPERIMENT FOR ASTRONOMY

Muriel Saccoccio, muriel.saccoccio@cnes.fr CNES, Toulouse, France

After more than five years of development and qualification, the CNES (French Space Agency) Zero Pressure Balloon (ZPB) operational activities resumed in 2014 with a new improved system: NOSYCA (New Operational System for the Control of Aerostats). This system is especially adapted to the Zero Pressure Balloons (ZPB) and allows to fly up to 40 km high with a scientific gondola up to a bit more than 1 ton. NOSYCA complies with the safety rules (fail safe architecture) and is fully qualified. We can implement two S-Band stations to extend our flight area. In addition to the NOSYCA balloon system, our flight train is adapted for heavy payload flights, especially with a new large parachute. This improvement allows us to fly big scientific gondolas including one or a few instruments for climate observation or astronomy. CNES has now a new operational stratospheric balloon system fully compliant with the safety regulations and the air traffic control rules. The launching system allows to launch big scientific gondolas (up to 1,06 ton) with a limited sensitivity to ground winds. This allows scientific ZPB campaigns in various countries in the world, located in the 2 hemispheres, and lets room for further improvements of performance of our actual flight configuration and flight duration. CNES organizes 1 big ZPB campaign every year, either in Canada, in Sweden or in Australia (so far), depending on scientist requirements for observations. 3 scientific campaigns have been successfully led with this system, in Canada, in 2015 (6 flights in 4 weeks), in Sweden in 2016 (2 flights in 10 days), and in Australia in 2017 (3 flights in 2 weeks) and the next one in Canada is being prepared for 2018. In addition, CNES has developed a concept of generic and certified mechanical platform, allowing to implement a wide range of instruments, alone or together to constitute scientific gondolas, and adaptable but reliable generic ground segments to conduct the flights in the best way to optimize scientific observations. This concept, offers various services to instruments (electrical power, command-control, heating, doors, real-time coarse or fine pointing.). CNES has also developed a generic pointing system including an accurate daytime stellar sensor and high bandwidth closed loop devices, allowing a one arc second pointing accuracy for astronomy missions. The presentation will focus on the CNES AUSTRAL 2017 campaign in Australia, that illustrates the current performances of this operational system for stratospheric balloon flights. To concretely show this, we will talk about one of the major scientific flights which happened there, and allowed to beat records: the second flight of the PILOT gondola, dedicated to study the magnetic field in and out of our galaxy, and the interstellar dust which limits the observations of the Cosmic Background. PILOT (Polarized Instrument for the Long-wavelength Observations of the Tenuous interstellar medium) is a balloon-borne astronomy experiment to study and characterize the polarization of dust emission in the diffuse interstellar medium in our Galaxy and nearby galaxies. PILOT is able to measure the polarization properties of dust emission in the Far Infra-Red (at 1.2 THz). Future cosmology space missions will concentrate on

measuring the polarization of the Cosmic Microwave Background, which potentially carries invaluable information about the earliest phases of the evolution of our universe. Such ambitious projects will ultimately be limited by the sensitivity of the instrument and by the accuracy at which polarized foreground emission from our own Galaxy can be subtracted out. Experiments under stratospheric balloons are useful to technically and scientifically prepare future experiments onboard satellites, complement the set of data obtained by satellites, and allow some measurements not feasible from ground. For example, none of the Herschel satellite instrument was sensitive to polarization, the Planck satellite did obtain polarization measurements only at lower frequencies, and submillimeter infrared signals emitted from dust cannot be measured from ground. A stratospheric balloon-borne experiment like PILOT is a good tool to complete the available set of data. PILOT has already flown twice under a CNES stratospheric balloon, in both hemispheres, with improvements of the instrument performances and of the observation strategy between the 2 flights. The conditions of these flights will be presented in this talk, while the performances of the experiment, and scientific results already obtained, will be presented by J.P. Bernard et al. in other talks.

PSB.1-0035-18 COST-EFFECTIVE HIGH-ALTITUDE SCIENTIFIC BALLOON DEVELOPMENT AND ITS FLIGHT TEST WHILE CONSIDERING SEA-RECOVERY OPERATION

Jungpyo Kang, navypyo@snu.ac.kr

Aerospace Vehicle Design Lab, Seoul National University, Republic of Korea, Seoul, Korea Kwanjung Yee, kjyee@snu.ac.kr

Seoul National University, Seoul, Korea Hweeho Kim, thehio@snu.ac.kr

Seoul National University, Seoul, Korea Gyujin Shim, dbzlf123@snu.ac.kr

Seoul National University, Seoul, Korea

The high altitude scientific balloon has been used for decades in advanced aerospace countries such as United States, France, and Italy to carry out various research objectives. One of the great strengths of the high altitude scientific balloon is the relatively low development and operating costs since they can be retrieved after completion of a flight mission. However, considering the environmental conditions in Republic of Korea, having a lot of inaccessible mountainous terrain, high population density, and surrounded by sea-water, the landing and recovery areas for the separated balloon system are limited. In this study, a zero pressure balloon prototype considering sea-recovery was developed in order to secure flight safety and to improve its the recovery success rate. In the future, operational reliability of the balloon system will be verified throughout multiple flight tests, and its sea-recovery operation procedure will be established.

PSB.1-0036-18 DESIGN, FABRICATION AND LAUNCH OF SMALL ZERO PRESSURE PLASTIC BALLOONS FOR FLOATING AT UPPER TROPOSPHERE AND LOWER STRATOSPHERE REGION FOR ATMOSPHERIC SCIENCE EXPERIMENTS

TIFR, HYDERABAD, India

The Balloon Facility of Tata Institute of Fundamental Resarch (TIFR-BF), Hyderabad designed, fabricated small zero pressure plastic balloons with volumes of 300 m3, 1200 m3 and 3000 m3. These balloons were launched from TIFR-BF to study the Asian Tropopause Aerosol Layer (ATAL) in collaboration with different research institutes and laboratories during Indian Summer Monsoon Seasons (ISMS). These are the first ever, balloon-borne experiments to study the chemical composition of the Upper Troposphere and Lower Stratosphere (UTLS) region in India. The balloons with volumes of 300 m3 and 1200 m3 were especially, designed in such a way that it can be floating at UTLS region for several hours. It is very crucial to maintain the required altitude in order to collect the aerosol samples at a very cold temperature region of tropics, for this we added a ballast module in these balloon experiments to get more data points at the same level. And also it is very difficult to conduct plastic balloon launches during ISMS due to high surface wind conditions, so we adopted to new hybrid static launch method for these launches. Balloon design, fabrication, launch and floating at designed altitude for these flights are discussed in this paper.

PSB.1-0037-18 DEVELOPMENT OF A SUPER-PRESSURE BALLOON WITH A DIAMONDSHAPED NET - GROUND INFLATION TEST OF AN IMPROVED MODEL BALLOON OF 2,000 CUBIC METERS

Currently, we have been developing a novel type of super-pressure balloon for ultra-long duration flight of which envelope is covered with a diamond-shaped net of high-tensile fibers. Thanks to tensile forces developed in the net, stresses in the balloon envelope are effectively reduced and consequently thin polyethylene film with a thickness of 10-20 µm will suffice for the envelope, thus improving the payload capability of the balloon compared to the lobed-pumpkin type super-pressure balloon. Our ultimate goal is developing a 300,000 m3 balloon with a payload capacity of 900 kg at the altitude of 37 km. The development of the proposed superpressure balloon commenced in 2010 with a 10 m3 prototype balloon. After the verification of the first prototype balloon, we have evaluated the performances of a series of model balloons of the proposed type gradually enlarging their volumes; some of the results were reported in the past COSPAR assemblies, including a flight test of a 3,000 m3 balloon in the tandem balloon configuration with a 15,000 m3 zero-pressure balloon carried out in 2012. The paper discusses the development progress of the proposed balloon that has been achieved since the previous reporting at the 2012 COSPAR assembly. Focuses are on results of a ground testing of a 2,000 m3 model balloon of which performance is enhanced by redesigning the gore shape and also by devising a new fixing method of the net onto the balloon envelope.

This work presents balloon-borne measurements from summer regional field campaigns in the western Mediterranean basin performed in the framework of the project ChArMEx (the Chemistry and Aerosol Mediterranean Experiment; 2010-2020; see special issue https://www.atmoschem-phys.net/special_issue334.html), and some ideas for new transoceanic campaigns.

Due to long-range transport from surrounding continents with contrasted emissions, the lower troposphere over this regional sea is subject to high levels of both aerosols including desert dust and gaseous pollutants such as ozone (O_3), with a maximum during the long dry and sunny Mediterranean summer season. Moreover, strong climate change in the region is expected to develop positive feedbacks on pollution levels (e.g., the net decrease in solar radiation by aerosols has been shown to reduce evaporation and subsequently regional precipitation that scavenge aerosols) and the Mediterranean type of climate is expected to expand over a large part of Europe.

Based on developments of boundary-layer pressurized balloons (BLPBs; Doerenbecher et al. (Bull. Amer. Meteor. Soc., 2016) and dedicated scientific payloads, we were able to perform original quasi-Lagrangian monitoring of O_3 and desert dust aerosols over the sea. The strategy included the combination of classical sounding balloons and drifting BLPBs to document both their vertical distribution and long-range transport. Three test flights

of a BLPB with O3 measurements, launched in June 2012 from Martigues on the French Mediterranean coast, and a total of 13 BLPBs with O3 measurements and 10 with dust measurements by the new Light Optical Aerosol Counter/sizer (LOAC), launched between mid-June and early August 2013 from Mediterranean islands, namely Minorca (Spain) or Ile du Levant (France), were successfully performed. Drifting altitudes ranged between 0.25 and 3.2 km above sea level for O3 measurements, and between 2.0 and 3.3 for mineral dust. The longest flight exceeded 1000 km and lasted more than 32 h.

We present the drifting balloon and its basic payload, and the instruments developed for ChArMEx: a modified electrochemical ozone sonde and the new optical particle counter/sizer LOAC with dual scattering angle measurements allowing identification of dust particles (Renard et al., Atmos. Meas. Tech., 2016a and b). Numerous tests and validations were performed, including comparisons with collocated airborne measurements, sounding balloons, and remote sensing measurements.

Ozone data are analyzed to examine O3 diurnal variations in the marine atmospheric boundary layer and in the free troposphere above. By selecting flight segments with the best probability of pure Lagrangian conditions, we report O3 photochemical production in both the boundary layer and the free troposphere, at rates of 1 2 ppbv/h, significantly lower than those previously reported over land in the same region. More details can be found in Gheusi et al. (Atmos. Meas. Tech., 2016).

Several desert dust events were monitored. LOAC data could be fitted by a 3-mode log-normal distribution at roughly 0.2, 4 and 30 µm in modal diameter. We did not observe any significant evolution of the size distribution during the flights. The presence of such large particles several days after emissions is unexpected given their theoretical sedimentation velocity. An indirect evidence of the presence of charged particles has been derived from the LOAC measurements and we speculate that electrical forces might counteract gravitational settling of the coarse particles. More details can be found in Renard et al. (Atmos. Chem. Phys., 2018).

Over the Mediterranean, the duration of measurements was limited by the size of the basin. However at least 4-5 days of measurements are in principle possible in the present configuration thanks to a programmable on-off procedure to save energy (and electrolyte in the case of O3), allowing, for instance, transatlantic flights from Africa in the desert dust loaded Atlantic tradewinds. On-going miniaturization of LOAC, and new mini sensors (e.g. for NO2) should allow 1-wk transpacific flights to study the very long-range transport of both dust and pollution from China across the North Pacific during springtime. Air mass trajectories suggest that up to 5-km ceiling altitudes of BLPBs should be targeted.

PSB.1-0039-18 FLIGHT TEST OF A SMALL-SCALE SUPER-PRESSURE BALLOON

Zhu Rongchen, zhurongchen@aoe.ac.cn

Academy of Opto-electronics, Chinese Academy of Sciences, Beijing, China Wang Sheng, shengwang@aoe.ac.cn

Academy of Opto-electronics, Chinese Academy of Sciences, Beijing, China

A small-scale super-pressure balloon was tested in north China in september, 2017. The test balloon was a prototype for long duration balloon in further flights. The volume of the balloon was around 7000 cubic meters and the payload was around 50 kilogram. The cruising attitude of the balloon was around 25 kilometers, which lay in the quasi-zero wind layer. The main purpose was to verify the design and fabrication of the super-pressure balloon with tendons attached to the envelope. The flight test also explored the possibility of achieving long duration flight within short distance by taking advantage of the quasi-zero wind layer. In the fight test, the cruising velocity maintained within 3 meters per second for several hours. Important data such as temperature and differential pressure of the balloon was obtained and analyzed. Design methods were revised and further tests were planned.

PSB.1-0040-18 THERMAL-DYNAMIC PERFORMANCE OF A SUPER-PRESSURE BALLOON IN ASCENDING AND FLOATING PROCESS

Chinese Academy of Sciences,AOE, BEIJING, China

A super-pressure balloon was successfully launched by the Academy of Opto-electronics, Chinese Academy of Sciences, on September 10, 2017. The volume of the super-pressure balloon was around 7,000 m3, with a suspended load of 100 kg. A total of 20 kg of ballast were carried on this flight to pressurize the balloon and adjust the ascending rate of the balloon. After a 110 min ascending process, the balloon reached its designed floating altitude at 25 km. During the ascending process, the ballast were dropped in several increments until all of it was expended. The balloon afloat at around 25 km for near 6 hours before the terminate command was executed and began to fell.

The thermal environment of the balloon varies greatly during the ascending and floating process, and the thermal and dynamic performance of the balloon coupled closely with each other, the coupled performance of the thermal and dynamic characteristics of the balloon is of vital importance to the safe flight and accomplishment of designed mission. A comprehensive understanding of the thermal-dynamic performance of the balloon could be useful for the guidance of balloon design, fabricate and flight experiment.

This paper will present an investigation into the thermal-dynamic performance of the superpressure balloon during ascending and floating process, through theoretical analysis, numerical calculation and analysis of the flight data from this launched super-pressure balloon.

PSB.1-0041-18 THE LARGE BALLOON REFLECTOR (LBR): ANALYSIS OF A 10M SUBORBITAL BALLOON-BORNE TELESCOPE

Ethan Chaffee, ethan.chaffee@swri.org

Southwest Research Institute, San Antonio, Texas, United States

The Large Balloon Reflector (LBR) is a 10m sub-orbital balloon-borne telescope suitable for operation from the radio to THz frequencies. LBR was developed by the team of Southwest Research Institute (SwRI) and the University of Arizona (UA) under funding for Phase I and Phase II of the NASA Innovative Advanced Concepts (NIAC) program. The telescope is itself a balloon, spherical in shape, metalized on one side and anchored to the top of a carrier balloon. The carrier balloon serves as both the launch vehicle and a radome for the telescope while also providing protection from the surrounding environment to stabilize the reflector. NASA's Zero Pressure (ZP) and Super Pressure (SP) balloons provide a means of transporting and maintaining payloads of 2-3 tons to near space where the telescope will be free of 99% of the Earth's atmospheric absorption to observe the far-infrared/THz spectrum. The analysis presented in this paper regards the thermal environment of the LBR and the shape fidelity of the sphere. The temperature variations of the LBR system throughout the diurnal cycle will impact the shape of the spherical telescope. The analysis demonstrated the extent of the temperature variations across multiple thermal environments, such as the polar region and midlatitudes, and suggests techniques for compensating for shape distortions across the surface of the sphere.

PSB.1-0042-18 NUMERICAL INVESTIGATION ON THE FLUID-STRUCTURE INTERACTION OF HIGH-ALTITUDE TETHERED BALLOON

Yanxiang Cui, yxcui@aoe.ac.cn

Academy of OPTO—Electronics,Chinese Academy of Sciences, Beijing, China Donghui Zhang, zhangdonghui225@163.com

Chinese Academy of Sciences,AOE, BEIJING, China

This paper presents the results of a study to determine the fluid-structure interaction of flying a tethered balloon at an altitude of 20 km. The vehicle is a spherically shaped, constant volume, helium filled balloon with a ballonet. The balloon is restrained with a tether during the launch, operation, and recovery phases of the mission. The high-altitude tethered balloon placed in the stratosphere flow field is a flexible body with low rigidity and so can be taken as an elastic membrane structure. The distribution of the flow field around the balloon is closely related to its shape. When the balloon is partly inflated or in case of strong wind, the balloon has a large deformation, resulting in the non-dynamic coupling of the peripheral flow field of the balloon and its deformation. For the solution of this problem, the iteration method was introduced, and the three-dimensional flow around the balloon was studied numerically by FLUENT software and means of SIMPLE method based on the Finite Volume Method. In the numerical simulation of the elastic deformation, the moment theory of thin shell was introduced. A comparison between the pressure distribution and aerodynamic parameters was provided, when the aeroelastic deformation was considered for static zero-pressure body. The relations between the deformation and the changes of flow parameters and aerodynamic loads were also analyzed.

The results show that the flexible deformation of the balloon changes the surrounding flow field, resulting in a significant change in the aerodynamic load distribution on the surface; causing a change in the pressure differential between the inner and the outer of the balloon, which in turn leads to a large change in the stress in the balloon. The static pressure at the upwind side of the head area of the balloon is higher, resulting in the head being dented, while the static pressure at the top is negative, causing the pressure differential to increase and the balloon skin to expand outward.

We will describe a system that was designed to locate, track and navigate an aircraft under a stratospheric balloon in flight. This system was designed for the Extreme Space Observatory (EUSO) balloon flights in order to place calibration light sources within the field of view of the EUSO instrument during its flight in order to perform an in-flight calibration.

The system consists of a radio beacon located on the balloon that transmits its GPS coordinates at a 5 second cadence. The radio signals from this beacon are received by a software-defined radio onboard the aircraft which is interfaced to a laptop computer. This computer runs a realtime program that displays the balloon coordinates and the coordinates of the aircraft from a second GPS receiver in the aircraft. Additionally, the program also actively propagates the position of both the aircraft and balloon forward in time, based on the most recent coordinates.

On the screen of the computer there is a coordinate display showing the position of the balloon relative to the location and heading of the aircraft and a second display giving the location of the aircraft in a projected geographic coordinate system centered on the balloon and oriented with the x axis being latitude and the y axis being longitude. The program also calculates and overlays the field of view of the EUSO instrument on both displays. The design and use of this navigation system will be explained. Both test and balloon flight results will be shown.

Balloon based telescopes represent an opportunity to observe science in an environment with almost no atmospheric effects. However, balloon based platforms include a wide range of thermal environments as well as pointing a lightweight telescope over a large elevation range. The Gondola for High Altitude Planetary Science (GHAPS) was designed to provide nearly diffraction limited performance observations over the visible and infrared spectrum with a 1- meter aperture. To achieve such performance, detailed Structural Thermal Optical Performance (STOP) was used to predict telescope performance. Software was built to automate the process of analysis, enabling thermal, structural and optical analyses to be executed quickly with less effort. The end results was the capability to analyze both generic operating conditions and Design Reference Mission conditions, producing predictions that could be used to evaluate the quality of science return.

The Balloon Facility of Tata Institute of Fundamental Research in India launches scientific balloons for research in the field of astronomy and atmospheric sciences. The balloon facility has the capability to design, fabricate and launch zero-pressure balloons upto stratospheric altitudes. The Control Instrumentation group for Balloon Augmentation (CIBA) at the balloon facility handles all electronics related to telemetry, telecommand, tracking, real-time data display and storage, air-safety and payload recovery. In the recent past, CIBA has also designed and developed several customized electronics to meet specific experimental objectives. In this paper, we present details of the recent developments in instrumentation and their performance in balloon flights. Our future up-gradation plans will also be discussed.

We will describe the design and testing of the solar power system for the Extreme Universe Space Observatory Super-Pressure Balloon (EUSO-SPB) experiment that was launched from Wanaka, New Zealand in the spring of 2017. The solar power system performed well during the 12 day flight. We also report on its performance during this flight.

The solar power system consisted of a 24 volt battery pack composed of Odyssey PC1200 batteries charged by SunSaver MPPT charging controllers connected to arrays of SunCat solar panels.

Because the high altitude winds could carry the balloon north near the equator or south to Antarctica, we simulated flights at latitudes ranging from 0 to -67 at times ranging from the vernal equinox to the summer solstice. Based on this simulation we then determined the size of the solar power system and the optimum tilt of the solar panels. The results of this study will be described.

Rather than flying a rotator to keep one plane array of solar panels pointed at the sun, EUSO SPB1 had arrays of solar panels on all four sides of the gondola. Each side was tilted 14 degrees to maximize the power produced by the solar panels. Each array was connected

its own charging controller. These controllers had to operate in lock step in order to de-conflict their control functions. We will describe how this was accomplished.

The charging controller outputs were connected to the battery pack in parallel. A shunt and voltage divider were used to monitor the battery voltage and the current flowing into and out of the battery through the CSBF Science Stack. An array of DPDT relays were used to distribute the power to the instrument's subsystems. One pole of each relay switched the power while the other monitored the state of the relay. These relays were operated and monitored with the CSBF Science Stack.

The batteries use absorbed glass mat valve regulated lead acid technology and are designed to provide the high currents needed for cranking engines. In our application these batteries must provide a much lower current over the night. Extensive testing was required to gain experience with the performance of the batteries operated in this way. We will show the test results.

PSB.1-0047-18 APPLICATION OF SOLAR CELLS ON A HIGH ALTITUDE STRATOSPHERE BALLOON

Zhang Yanlei, zhangyanlei@aoe.ac.cn China Academy of Science, Beijing, China Li Zhaojie, lizhaojie@aoe.ac.cn

Academy of Opto-electronics, Chinese Academy of Sciences, Beijing, China Xuwei Wang, wangxuwei@aoe.ac.cn

Academy of Opto-electronics, Chinese Academy of Sciences, Beijing, China

The use of solar cells can effectively reduce the stratosphere balloon load and increase its theoretical flight time. To guide the application of solar cells on the stratosphere balloon, a calculation model was developed. A configuration analysis model with the consideration of HIT solar cell parameters and the lithium-ion battery parameters was developed. It was based on the solar radiation model and the working model of the PV energy system. The influences of the balloon geometry, size and operation parameters, such as operation latitude, seasons, flight direction, and speed, etc. were analyzed. It can be used to analyze the energy balance of the balloon. A simulation was conducted to a specified balloon. The result indicated that the general design of the PV energy system could be easily determined with this calculation model. In order to study the practical performance of solar cells on the stratosphere balloon and verify the calculation model, a stratosphere balloon was designed to carry out a solar cell flight test experiment at an altitude of 20 km. The test used a 1-square-meter HIT solar module. In response to this, a dedicated circuit was designed to collect real-time battery voltage and current data, and access to the solar cell I-V curve. At the same time, the solar cell operating temperature and its corresponding solar radiation data was measured. According to this, the working efficiency of the solar cell on the stratosphere balloon was obtained, and the working performance data of the solar cell that varies with the flight of the stratosphere balloon was summarized. The experiment confirmed that the theoretical calculation model of solar cell performance was consistent with the measured results. This test provides practical data that support for the application of solar cells to stratosphere balloons.

PSB.1-0048-18 MOTION COMPENSATION, THERMAL CONTROL AND WAVEFRONT SENSING ON THE THAI-SPICE PAYLOAD

At altitudes of 33 - 38 km, balloon-borne telescopes occupy a regime in which the Fried parameter is greater than 2 m. Telescopes with apertures up to the Fried parameter should be able to achieve diffraction-limited images. THAI-SPICE (Testbed for High Acuity Imaging - Stable Photometry, Image-motion Compensation Experiment) is a NASA-sponsored balloon program that will address two factors that can degrade image acuity: thermal gradients across the telescope and stability of the focal plane.

To study thermal gradients, THAI-SPICE will model the effectiveness of sun-shields, earthshields and optical telescope assembly (OTA) enclosures. Preliminary modeling suggests that a telescope's day/night thermal excursions can be reduced from over 50 K (without shielding) to less than 2 K (with passive shielding) and achieve steady-state temperatures as low as 180

K. Given the prospects for 100-day super-pressure balloon missions, the ability to passively cool a telescope is critical for infrared observations, and the reduction of temporal and spatial gradients eliminates one of the most significant obstacles to maintaining telescope alignment and mirror figure. THAI-SPICE will fly several instrumented OTA enclosures to test thermal models in the stratosphere.

To address image stability, THAI-SPICE will fly a 50-cm aperture telescope with pointing stabilized at the few arc-second level. Image motion on the focal plane will be characterized with a combination of inertial and optical sensors. To stabilize the focal plane at the 50 mas level, THAI-SPICE will use a solid-state tip-tilt correction device.

THAI-SPICE will also demonstrate a curvature wavefront sensor (CWS) to monitor aberrations in the balloon-borne telescope in-flight. The immediate goal is to quantify alignment errors and mirror aberrations as a function of the elevation angle, temperature field and other factors. An eventual goal will be to control a secondary mirror on a hexapod (or possibly a deformable mirror) to reduce aberrations. We will report on lab experiments in which we compare a CWS and a Shack-Hartmann array in head-to-head tests. THAI-SPICE is expected to have its first flight from Ft Sumner, NM in September 2019.

PSB.1-0050-18 UV OBSERVATIONS FROM HIGH ALTITUDE BALLOON PLATFORM

Joice Mathew, joice@iiap.res.in

Indian Institute of Astrophysics, Bengaluru, India

Balloon experiments provide a great springboard for instrument development for future space missions. The lower cost and the flexibility in launch timings and flight duration make highaltitude balloon experiments a wonderful testbed for space technology. Wavelengths below 400 nm are difficult to observe from ground-based observatories, but at balloon floating altitudes observations above 280 nm, as well as between 200 and 220 nm, become possible, the latter due to the narrowing of O3 and O2 absorption bands. One of the major challenges for observations from the high altitude balloon platform is the platform stability and pointing accuracy of the platform. We have developed a pointing system to achieve observations from the balloon platform. The pointing and stability of the system are carried out as two-fold (coarse and fine pointing) operation, using inertial measurement sensors and a star sensor, respectively. The attitude sensor obtains the pointing information and corrects the position to an accuracy of

±0.24° using servo motors. The star sensor works in the inner loop, providing much finer accuracy of around 30". We have developed a UV telescope to fly on high altitude balloon platform which is a prime focus telescope to fly on a 5 kg payload capacity balloon. A fiber is used to fed the light collected by the telescope to the spectrograph. The spectrograph is based on Czerny-Turner design, to work in the wavelength range of 250 - 400 nm. The main science objective is to take the UV spectrum of bright objects. Here we will describe the instrumentation involved in the high altitude balloon experiment and the design and development of one of the UV payloads to fly on the balloon platform.

PSB.1-0051-18 UNINTENTIONAL IGNITION DURING A GROUND TEST OF A HEAVY LIFT HYDROGEN ZERO PRESSURE BALLOON FOLLOWING TERMINATION

John Straus, john@worldview.space

World View Enterprises Inc., Tucson, Arizona, United States

World View is leading the way in the emerging stratospheric economy, unlocking affordable new applications with the introduction of the un-crewed Stratollite flight vehicle, and pioneering new perspectives. World View is a Tucson based company that launches large balloons into the Stratosphere to test scientific payloads. Recently World View has been exploring the use of hydrogen to replace helium as the lift gas for stratospheric ballooning. An RD effort was undertaken to design the hardware and processes for a hydrogen-safe fill system, launch system, payload and balloon systems. A series of four ground tests using moored balloons with successively increasing lift (30 kgf to 11,000 kgf) were conducted to evaluate the safety and efficacy of these systems. The planned termination for each test balloon involved the venting of hydrogen by the tearing of one of the gore panels of the balloon. In all but the final test, the hydrogen vented as expected, safely ending each test. The balloon was successfully gored in the last test, but approximately 10 seconds after goring of the balloon, the hydrogen-air mixture just above the balloon ignited, which almost instantaneously capsized the balloon, and sent a strong pressure wave out from the center of the ignition. No personnel were harmed during the event (sufficient safety procedures were in place for the termination process), but there was some superficial damage to the nearby buildings. This paper will present the results of the findings from this test, so that the ballooning community can take our experience into account when looking at hydrogen as a lift gas alternative to helium.

PSB.1-0052-18 THE CNES AéROCLIPPER BALLOON CAMPAIGN OF GUAM 2017

Centre National d'Etudes Spatiales, Toulouse, France

The AeroClipper developed by the French Space Agency (Centre National d'Etudes Spatiales - CNES) is a quasi-lagrangian device drifting with surface wind at about 20-30m above the ocean surface. It is a new and original device for real-time and continuous observation of air-sea surface parameters in open ocean remote regions. This device enables the sampling of the variability of surface parameters in particular under convective systems toward which it is attracted. The AeroClipper is therefore an ideal instrument to monitor Tropical Cyclones (TCs) in which they are likely to converge and provide original observations to evaluate and improve our current understanding and diagnostics of TCs as well as their representation in numerical models. One experiment took place in October 2017 from Guam Island, American territory located in the Western Pacific Ocean, in the framework of a scientific project in cooperation with the CNES and the Laboratory of Dynamic Meteorology (LMD).The AeroClipper demonstrates its capability to be captured by an Ocean Indian cyclone, as two models have converged, without damages, in the eye of Dora cyclone during the 2007 VASCO campaign. This paper will present the improvements of this AeroClipper system as well as the results of the 2017 Guam campaign.

The Gondola for High Altitude Planetary Science (GHAPS) was an observing asset under development by NASA's Planetary Science Division that would be hosted on stratospheric balloon missions intended for use by the broad planetary science community. A balloon-borne observatory like GHAPS could complement other ground and space-based telescopes, by virtue of low-cost access to near space and long duration flights. As specified in the 2016 GHAPS SIDT Report [1], not all decadal-class science questions will be amenable to study from the stratospheric GHAPS telescope, but certain questions are well suited to the advantages afforded by long-duration balloon missions in the upper stratosphere. In

particular, the lower terrestrial water content above stratospheric altitudes allows unique studies of ocean worlds and comets, whose main composition is water, as well as studies of carbon dioxide, which is not possible from the ground. The versatility of the mission and potential to host a wide variety of science (backend) instruments would allow the study of any celestial body (planets, moons and small bodies), both through imaging and spectroscopy. The SIDT Report helped: (1) define the scope of science investigations, derive the science requirements and instrument concepts, (2) prioritize the instruments according to science priorities that address Planetary Science Decadal Survey questions, and (3) generate a report that is broadly disseminated to the planetary science community. The GHAPS team created and examined different design reference missions, and characterized the different instrument requirements and challenges to a successful mission. In this presentation, we discuss potential science goals with GHAPS at infrared wavelengths, sensitivity expected for low-resolution (icy features) and high-resolution (gas features) studies, trade studies, as well as the core challenges observed during the mission development.

Acknowledgements. The GHAPS team acknowledges support by the Planetary Science Division at NASA HQ.

This paper summarizes the approach and results from a NASA-sponsored study on Venus aerial vehicles with a focus on the buoyant platforms that were considered. This study consisted of two multi-day workshops with intervening time for science and engineering analysis and involved a cross-disciplinary team of scientists, engineers and technologists drawn from NASA centers, industry and universities. The purpose was to identify what science could be obtained from different platforms, quantify the resource needs of mass, power and volume, assess the technological maturity of those platforms and provide guidance on required technology development investments to achieve flight readiness. The specific platforms considered were superpressure balloons, different types of variable altitude balloons, airplanes and a hybrid vehicle where lift is generated by both aerodynamic and buoyant forces. A key finding of the study was that variable altitude platforms provide a significant increase in scientific data return compared to constant-altitude superpressure balloons while requiring a potentially modest increase in mass, power and complexity. This paper provides the quantitative science and engineering data that justifies this conclusion along with the analysis methodology and underlying assumptions. It concludes by presenting the technology development roadmap matched to future mission opportunities along with a discussion of key technical challenges for each buoyant vehicle option.

The scientific investigation of the interior of Venus has for long been rendered impossible by the presence of extremely high temperature and pressure conditions on the planet's surface. Such extreme conditions restrict the lifetimes of surface missions to a few hours at best, which is far from sufficient for a seismological investigation, a key requirement for understanding a planet's interior.

However, with a highly dense atmosphere (90 atmosphere surface pressure) and relatively benign conditions in the middle and upper atmosphere, Venus is an ideal candidate for scientific ballooning. The remote detection of seismic waves is a particularly novel application for scientific ballooning on Venus. Seismic disturbances are known to generate infrasonic waves (frequencies < 20 Hz) by coupling energy from ground motion into the atmosphere. These waves have already been detected from earthquakes and volcanic activity from terrestrial stations on

Earth. On Venus, the coupling between the solid planet and the atmosphere is 60 times better than on Earth, owing to its high surface pressure. Therefore, sensitive and highly-accurate barometers can be deployed from free-flying balloons to detect seismically generated infrasonic waves. This technology was recently demonstrated by the authors in Pahrump, Nevada in an experiment where infrasonic waves from artificially created seismic disturbances were detected on barometers suspended from balloons. The success of this initiative heralds the prospect of investigating Venus' interior without having to land on the surface and survive for extended periods of time.

In this presentation, we will present our technique for the detection and characterization of infrasonic waves from seismic activity. We will also describe our progress from sensor development and deployment to a comprehensive analysis campaign involving signal processing, fusion of ground motion and barometric data, and simulations. Finally, we will discuss our path forward, which includes the expansion of balloon-based infrasound to study climatological and surface-atmosphere interaction phenomena. Our results will clearly demonstrate that infrasound sensors are a prime candidate for performing high-impact scientific ballooning, especially in inaccessible and harsh terrestrial environments, such as Venus.

The location of "biopause", the upper boundary of the biosphere, and the biological flux across the biopause on Earth are the key to understand the universality and distribution as well as the origin and evolution of life in the universe. The most direct information to elucidate the biopause is the distribution and dynamicity of life in the middle atmosphere. We carried out a scientific project named "Biopause" using JAXA's scientific balloons in order to grasp the dynamics of biological flux in the stratosphere, i.e. the lower middle atmosphere, comprehensively. Our first balloon experiment was conducted on June 8, 2016 and collected aerosol particles in the stratosphere using a newly developed descending inertial impactor. We estimated the number density of the stratospheric microbes including the unculturable ones for the first time in the world. In this presentation, we report the new results of the balloon experiment in this year and the initial results of the sample analysis.

PSB.1-0057-18 ESTIMATION OF THE DEPTHS OF THE UPPER AND LOWER BOUNDARIES OF THE MAGNETOACTIVE LAYER OF THE LITHOSPHERE

Oleg Brekhov, obrekhov@mail.ru

Moscow Aviation Institute, Moscow, Russia Yury Tsvetkov, tsvetkov@izmiran.ru IZMIRAN, Troitsk, Moscow Region, Russia

Studies of the deep structure and structure of the earth's lithosphere, its geothermy, petrology, the depth of the lower boundary of its magnetoactive layer are relevant. There are ways to study the parameters of the lithosphere by interpreting the physical models of the solid Earth based on the thermal, magnetic and gravitational fields. The anomalous magnetic field (AMF) is particularly effective in studying the magnetoactive layer of the lithosphere, its upper and lower boundaries. The basic information about AMF was obtained as a result of aeromagnetic and satellite magnetic surveys. Satellite magnetic surveys do not contain signals generated by deep sources with dimensions smaller than the survey height. Aerial surveys are performed at low altitude (hundreds of meters) and because of the intense local magnetic anomalies, AMF maps do not take into account deep magnetic sources. This does not make it possible to determine the true depth of occurrence of the lower boundary of the magnetoactive layer from the AMF maps. However, the geomagnetic field of the upper boundary of the magnetoactive layer is well represented in aeromagnetic survey data (AMF maps), and the upper limit of the magnetoactive layer of the lithosphere is reliably determined from them. The geomagnetic field of the center of gravity of the magnetoactive layer is well represented by magnetic survey data at altitudes of 20-40 km and reliably determines the position of the center of mass of this layer. The lower boundary of this layer is reliably determined from the depth of the upper boundary of the layer and the obtained data of its center of mass. This is important for estimating the depth of the Curie isotherm, which is used to construct the temperature scale of the rocks of the lithosphere used in geothermy and petrology. The technique of balloon gradient magnetic surveys was developed and mastered in practice by means of stratospheric balloons at altitudes of 20-40 km.

The E3Tratos mission is a research project led by the School of Electrical, Electronic and Telecommunications Engineering of the Universidad Industrial de Santander (UIS) that seeks to launch the first stratospheric probe balloon from Bucaramanga (Colombia) with scientific instrumentation developed by researchers from the UIS university to monitor greenhouse gases in the atmosphere and obtain images of Santander region from the stratosphere. This work shows the progress and partial results obtained in the design and implementation of the communications system on board the balloon which is composed by 3 subsystems: 1. image transmission, telemetry transmission and atmospheric variables captured during the flight and 3. Payload geo-referenced position. The system is complemented by a ground station that will receive the data and will be supported by the local amateur radio network.

The functional model consists of four stages: data acquisition, power stage, communications and ground station. The communications stage operates in VHF, since it is the standard that is most used by radio amateurs, we will transmit GPS position and meteorological information measured by the stratospheric balloon payload.

The low-cost on-board communication system is designed according to a block structure consisting of a microcontroller, digital synthesizer, oscillator, RF amplifiers and filters. The microcontroller is implemented in an embedded system that has a four-core ARM processor with state-of-the-art features. The communication blocks are responsible for processing the signal and send it through an antenna. The ground station consists of an antenna designed and tuned to the frequency and bandwidth according to the recommendations ITU (International Teleconnections Unit), the remaining functional blocks of the ground station will be designed using software-defined radio (GNU Radio).

We show results on the different stages of the experiment design and implementation that lead us to validate the full communications system. Transmission results were obtained performing links with straight line sight at different distances, since a few meters up to 20 kilometers. These results are very promising to the success of the "ET3ratos" mission.

The twin satellites of the Gravity Recovery and Climate Experiment (GRACE), which were launched on March 17, 2002, operated for more than 15 years. The mission objectives are to sense the spatial and temporal variations of the Earth's mass through its effects on the gravity field at the GRACE satellite altitude. The 15-year record of GRACE measurements recorded the seasonal cycle of mass transport between the oceans, land, cryosphere and atmosphere; its inter-annual variability; and the climate driven secular, or long period, mass transport signals. The three axis accelerometer measurements have recorded atmospheric neutral density variations through two solar cycles and altitude change from 495 km at mission initiation to 300 km at mission end. The global perspective and the accuracy of the measurements provided paradigm shifting insight into the Earth system interactions. Following a loss of battery capability, the nominal mission ended on October 10, 2017, when efforts to return to the science operations mode on exiting from the latest solar occultation period were unsuccessful. The last data collected was for the month of June, 2017. This early mission end will dictate a break of approximately one year between the GRACE and GRACE FO Missions, whose launch date is April, 2018. This presentation will review the mission accomplishments, describe the issues that influence the operations philosophy during the late mission years and the impact on data quality, discuss the future actions regarding the mission data and discuss the issues related to establishing continuity with the GRACE FO mission.

PSD.1-0002-18 COMBINATION SERVICE FOR TIME-VARIABLE GRAVITY FIELD SOLUTIONS (COST-G) - TRANSITION FROM AN EGSIEM PROTOTYPE SERVICE INTO A PRODUCT CENTER OF THE IGFS

The European Gravity Service for Improved Emergency Management (EGSIEM) was a project of the Horizon 2020 Framework Programme for Research and Innovation funded for three years (2015 - 2017). One of the main objectives was to establish a prototype service to combine monthly gravity field solutions from the past GRACE mission in order to deliver improved gravity field solutions for applications in Earth and environmental science research. Five analysis centers have contributed to these prototype service activities, where combinations on the solution level and more rigorous combinations on the normal equation level were performed. We present the achievements made so far and report the successful transition from the prototype phase into regular operation. As a Product Center of the International Gravity Field Service (IGFS) of the International Association of Geodesy (IAG), the Combination Service for Time-variable Gravity Field Solutions (COST-G) will continue the activities initiated by the EGSIEM project for the upcoming GRACE Follow-On mission.

PSD.1-0003-18 MULTI-APPROACH GRAVITY FIELD MODELS FROM SWARM GPS DATA

Pieter N.A.M. Visser, p.n.a.m.visser@tudelft.nl Delft University of Technology, Delft, Netherlands Swarm DISC Gravity

Although the knowledge of the gravity of the Earth has improved considerably with the CHAMP, GRACE and GOCE satellite missions, the geophysical community has identified the need for continued monitoring of its time-variable component with the purpose of estimating the hydrological and glaciological yearly cycles and long-term trends. The GRACE mission stopped its observation of the time variable gravity field at the end of 2017. The currently foreseen launch of GRACE Follow-On will be early 2018, such that a gap arises. This project aims at providing high-quality gravity field models from Swarm data that constitute an alternative source of gravimetric data, which could help alleviate this gap, as well as the short gaps that are present in the final stages of the GRACE mission. Independent from the existence of gravimetric data from dedicated satellite missions, the gravity field models derived from Swarm GPS data constitute an independent source of information about Earth's gravity field for e.g. monitoring of large mass transport processes.

Recently, the geodetic community has realized that the combination of the different gravity field solutions is superior to any individual model. We intend to exploit this fact and deliver the highest quality gravity field models, resulting from the combination of four different gravity field estimation approaches. In addition, we intend to evaluate the possibly added value of kinematic baseline solutions for the lower pair of Swarm satellites, which fly in a pendulum formation. To this aim, two different kinematic baseline solutions will be studied. In addition, two different models of non-gravitational forces will be used as well as observed non-gravitational accelerations for Swarm-C to assess the importance of separating conservative from non-conservative forces.

PSD.1-0004-18 ABSOLUTE AND RELATIVE ORBIT DETERMINATION FOR THE CHAMPGRACE CONSTELLATION

Xinyuan Mao, x.mao@tudelft.nl

Delft University of Technology, Delft, Netherlands Pieter N.A.M. Visser, p.n.a.m.visser@tudelft.nl Delft University of Technology, Delft, Netherlands Jose Van Den IJssel, j.a.a.vandenijssel@tudelft.nl Delft University of Technology, Delft, Netherlands

This research investigates a satellite constellation consisting of two different missions, the CHAllenging Minisatellite Payload (CHAMP) satellite and the Gravity Recovery And Climate Experiment (GRACE) twin satellites. They provide us three dual-satellites formations: an in-line or along-track stable GRACE-A and -B formation for which two satellites are 220 km apart, and two high-dynamic CHAMP/GRACE formations whose baseline lengths could vary from about 120 km to 7500 km during the selected 24-hours orbit arcs. The three satellites are equipped with BlackJack space-borne high-precision dual-frequency Global Positioning System (GPS) receivers. They provide high-low satellite-to-satellite GPS tracking data to conduct Precise Orbit Determination (POD) and Precise Baseline Determination (PBD) for this constellation. A few impact factors are analyzed in this research. These factors include the large cross-talk interference on the CHAMP GPS main navigation antenna due to the functioning of its GPS occultation antenna, and quite different perturbation levels for high-dynamic and low-dynamic formations. The relative dynamics for two CHAMP/GRACE formations are stronger than for the stable GRACE twin satellites. To obtain precise POD and PBD solutions for this constellation simultaneously, an Iterative Extended Kalman Filter (IEKF) including a subset GPS carrier phase integer ambiguity fixing strategy is implemented. It can be set such that the ambiguities for GRACE twin satellites baseline are fixed with higher preference. Results indicate that the implementations of the so-called Code Residual Variation (CRV) patterns for CHAMP improves the GPS observations modeling accuracy on each tracking frequency. Tailored relative dynamics constraints are properly set for each formation. The use of external independent Satellite Laser Ranging (SLR) data for validating absolute orbits proves a line-of-sight orbit precision level of 2-3 cm for each satellite. Moreover, the relative dynamics constraints between CHAMP and GRACE and the ambiguity fixing for their baselines are also beneficial for further improvement of the absolute orbit for CHAMP. Eventually for the CHAMP/GRACE formation the consistency between kinematic and reduced-dynamic baselines is of the order of 1-3 cm in each individual direction when its length is within 4000 km. For the GRACE formation it is of the order of only a few mm. Comparison between GRACE reduced-dynamic baseline solutions and its on-board K-Band Ranging (KBR) system observations shows a good agreement of about 0.7 mm.

PSD.1-0005-18 THE COPERNICUS POD SERVICE: ARCHITECTURE, RESULTS AND IMPACT ON SCIENCE

Jaime Fernández Sánchez, jfernandez@gmv.com GMV (Tres Cantos, Spain), Tres Cantos, Spain Heike Peter, heike.peter@positim.com

PosiTim UG (haftungsbeschraenkt), Swisttal, Germany Pierre Féménias, pierre.femenias@esa.int

ESA/ESRIN, Frascati, Italy

The Copernicus POD (Precise Orbit Determination) Service is part of the Copernicus Processing Data Ground Segment (PDGS) of the Sentinel-1, -2 and -3 missions (part of the European Copernicus Programme). A GMV-led consortium has developed, and it is operating the Copernicus POD Service being in charge of generating precise orbital products and auxiliary data files for their use as part of the processing chains of the respective Sentinel PDGS.

Currently there are five Sentinel satellites in orbit (S-1 AB, S-2 AB and S-3A); S-3B is expected to be launched in April 2018, and it will complete the constellation of these three missions. Future CD satellites are not expected before 2020.

Sentinel-1 requires high accurate orbits for InSAR processing; accuracies of 10 cm (2D) RMS in less than 3 hours and 5 cm (3D) RMS in less than 20 days. Sentinel-2 is an optical mission, which does not requires high accuracy orbital products - 1 meter (2D) RMS in less than 30 minutes; however the goal of the Copernicus POD Service is to obtain the same accuracy as for Sentinel-1. Finally Sentinel-3 is an altimetry mission, which requires accuracies in the radial component of the order of 8-10 cm (radial) RMS in less than 30 minutes, 3-4 cm (radial) RMS in less than 36 hours and finally 2-3 cm (radial) RMS in less than 25 days.

These satellites are all equipped with dual frequency geodetic-grade GPS receivers (on future CD satellite it will be a GPS+GALILEO receiver). Additionally, Sentinel-3 is equipped with a laser retro reflector for Satellite Laser Ranging (SLR) and a receiver for DORIS tracking.

By using similar orbital parametrizations, processing schemes, and inputs, the architecture of the Copernicus POD Service maximizes the synergies among the different missions to simplify the design and operations, and to obtain similar accuracy results across the three missions.

Quality control of the CPOD orbits is done by direct cross-comparison with independent orbit solutions provided by the Copernicus POD Quality Working Group (AIUB, CNES, DLR, EUMETSAT, ESOC, TU Delft, TUM .), each of them using a different POD strategy. With

S-3, SLR and DORIS provide independent means to validate the orbit.

This paper presents the Copernicus POD Service in terms of architecture, operations and orbital accuracy achieved by the different orbit products of the different missions. In particular it describes the architecture of the system, interfaces with the different centres (including the provider of GPS orbits and clocks and with the ILRS community), the physical models and POD strategy used, and the experience from processing routinely these different missions. This description if complemented with recent developments to process the new L2C GPS signals, and the future needs to process Galileo signals which will be available on the future CD satellites.

Then it describes the accuracy assessment of the products, and the different methodologies used for this, including the role of the Copernicus POD Quality Working Group. Finally, it describes the products generated to support scientific studies in areas like orbit modelling, ionospheric research, InSAR, altimetry, etc.

GMV (Tres Cantos, Spain), Tres Cantos, Spain

One of the main objectives of the Sentinel-3 ESA Earth Observation Mission, jointly operated by ESA and EUMETSAT, is to measure sea surface topography in the frame of the Copernicus ocean and land observation services. It consists of the two satellites Sentinel-3A (launched on February 16, 2016) and -3B (expected launch in April 2018) in Sun-synchronous, near-polar orbits at an altitude of around 815 km. Altimetry measurements are conducted with a synthetic aperture radar altimeter and require the knowledge of precise and accurate satellite orbits.

The Sentinel-3 precise orbit determination (POD) relies on data tracked by the on-board geodetic-grade dual-frequency GPS receiver and the DORIS instrument. A laser retroreflector array allows validating the orbits by means of Satellite Laser Ranging (SLR). Within the Copernicus POD Quality Working Group (QWG) precise orbits from different agencies are routinely compared for validation purposes. All members of the QWG employ a reduced-dynamic POD scheme, involving models for gravitational and non-gravitational forces, as well as empirical and/or pseudo-stochastic orbit parameters to absorb modeling deficiencies.

The great demands on Sentinel-3 orbit accuracy require that empirical and pseudo-stochastic orbit parameters should be used

with utmost care as they might degrade the radial orbit leveling, directly affecting the derived altimetry measurements. This implies especially the need for sophisticated and detailed models of non-gravitational forces, including aerodynamic accelerations, solar radiation pressure and Earth radiation pressure. In this presentation the non-gravitational modeling details of different QWG members are compared for Sentinel-3A. Besides a direct comparison of the modeled accelerations, the impact on POD is analyzed by comparing empirical orbit parameters and by means of SLR.

PSD.1-0007-18 IMPROVED BOX-WING MODELLING FOR THE LOW EARTH ORBITING SENTINEL SATELLITES

Heike Peter, heike.peter@positim.com

PosiTim UG (haftungsbeschraenkt), Swisttal, Germany Jaime Fernández Sánchez, jfernandez@gmv.com

GMV (Tres Cantos, Spain), Tres Cantos, Spain Pierre Féménias, pierre.femenias@esa.int ESA/ESRIN, Frascati, Italy

The Sentinel-1,-2, and -3 mission are part of the European Copernicus Programme. The low Earth orbiting satellites are designed for specific Earth observation applications, e.g., InSAR, optical imaging, and radar altimetry. The satellites are all equipped with geodetic-grade GPS receivers allowing for precise orbit determination on the few cm level. Such high accuracies are strongly required in particular for Sentinel-1 (C-band SAR) and Sentinel-3 (radar altimetry).

Precise orbit products for all three missions are generated from the Copernicus POD (Precise Orbit Determination) Service as part of the Copernicus Processing Data Ground Segment (PDGS). A GMV-led consortium is operating the Copernicus POD Service and it is delivering the orbital and auxiliary products.

The precise orbit determination procedure relies on sophisticated models for the gravitational and non-gravitational forces acting on the satellites. Box-wing models for the satellites are commonly used to apply the non-gravitational forces based on the direction and area of the individual surfaces and if applicable of their optical properties. As long as the satellites have simple shapes the box-wing models are fully sufficient for a precise modelling. However, if a satellite has a complex shape where self-shadowing significantly impacts the resulting nongravitational accelerations the box-wing modelling is limited.

Compared to other low-Earth orbiting satellites Sentinel-1 has a quite complex shape with selfshadowing of, e.g., the solar panel on the back of the SAR antenna. In the case of Sentinel-2 the solar panel is also shadowing one side of the satellite. Therefore, an improved box-wing modelling taking the self-shadowing into account is proposed to improve the orbit parameter estimation and the orbit determination results. Affected satellite surfaces are scaled based on the incident angle of the sun or the angle of the atmospheric drag acting on the satellite.

The proposed improved box-wing modelling is presented in detail. Improved results for Sentinel1 and Sentinel-2 are shown in terms of estimated orbit parameters, cross-comparisons to other orbit solutions provided by the Copernicus POD QWG (Quality Working Group) and in terms of orbit extrapolations.

PSD.1-0008-18 NON-GRAVITATIONAL FORCES ACTING ON SPACECRAFT: IMPACT OF DIFFERENT ATMOSPHERIC MODELS ON LEO ORBITS.

Valère Girardin, valere.girardin@aiub.unibe.ch

Astronomical Institute, University of Bern, Bern, Switzerland Daniel Arnold, daniel.arnold@aiub.unibe.ch

Astronomical Institute, University of Bern, Bern, Switzerland Stefano Bertone, stefano.bertone@aiub.unibe.ch

Astronomical Institute, University of Bern, Bern, Switzerland Adrian Jäggi, adrian.jaeggi@aiub.unibe.ch

Astronomical Institute, University of Bern, Bern, Switzerland

Keywords: non-gravitational forces, LEO POD, atmospheric model, airdrag, atmospheric drag.

The current accuracy in the orbit determination of artificial satellites heavily depends on a detailed modeling of non-gravitational forces. Although the use of empirical orbit parameters may compensate for unaccounted forces, a direct modeling of the non-gravitational forces increases both the quality and reliability of the orbits.

Non-gravitational perturbations are caused by particles interacting with the spacecraft surface. The largest force acting on a Low Earth Orbiter (LEO) below 800 km is airdrag followed by direct solar radiation pressure, Earth radiation pressure (i.e. reflected solar light and emitted thermal radiation) and finally the spacecraft thermal re-emission. The modelling of these forces was first performed half a century ago, but has undergone substantial improvements during the last decades. Recent atmospheric models and a better knowledge of solar activity constitute important advances, while high precision horizontal wind models and a better understanding of the gas-surface interaction between the satellite surface and the atmosphere are key parameters of airdrag modelling. In addition, precise measurement of the Earth local albedo/emissivity from CERES mission and accurate optical properties of the spacecraft surface lead to realistic computations of the photon surface interactions.

Airdrag is the most unpredictable non-gravitational force. The uncertainties in the atmospheric models (especially the density) are considered the primary source of error in the computation of airdrag. Therefore, this contribution will focus on the impact of the atmospheric and horizontal wind models on LEO orbits. We use the Bernese GNSS Software to compute the aforementioned non-gravitational forces. We will assess the orbit quality of different LEOs (GOCE, Sentinel-3A and GRACE) for each of the three most recent atmospheric models (NRLMSISE-00, JB2008 and DTM2013), both with and without scaling factor estimation. In order to support our results, statistics of the reduced-dynamics orbit fit will be shown, as well as external validations based on K/Ka-band ranging and satellite laser ranging measurements.

PSD.1-0009-18 GPS-DERIVED THERMOSPHERIC DENSITY DATA FOR THE SWARM SATELLITES

Jose Van Den IJssel, j.a.a.vandenijssel@tudelft.nl Delft University of Technology, Delft, Netherlands Eelco Doornbos, e.n.doornbos@tudelft.nl

Delft University of Technology, Delft, Netherlands Elisabetta Iorfida, e.iorfida@tudelft.nl

Delft University of Technology, Delft, Netherlands

The Swarm constellation consists of three identical satellites which fly in low Earth orbits to study the dynamics of the Earth's magnetic field. To geo-locate the onboard scientific instrument observations, the satellites are equipped with high-quality GPS receivers for precise orbit determination at the few cm level. The Swarm payload also includes an accelerometer, in order to derive information about the atmospheric density and wind. Unfortunately, the Swarm accelerometer measurements suffer from a variety of unexpected disturbances, which severely affects their usefulness. An alternative approach has therefore been developed where the non-gravitational accelerations are estimated directly from the high-quality GPS data using a Kalman filter approach. These estimated accelerations are used to generate low resolution densities for all Swarm satellites, and to correct and augment the accelerometer observations, currently available for Swarm-C only, to generate higher resolution densities.

This presentation describes the strategy that is used to estimate thermospheric densities from the GPS observations and gives an assessment of the obtainable resolution and accuracy. The resulting GPS-derived densities for the entire mission are presented and compared with thermospheric density model observations. For the most recently derived Swarm density data, these comparisons suggest a new deep solar minimum, similar to the one in 2008.

PSD.1-0010-18 EFFECT OF IONOSPHERIC AERODYNAMICS ON THE MOTION OF LOW EARTH ORBIT OBJECTS

Christopher Capon, c.capon@unsw.edu.au

University of New South Wales Canberra, Canberra, Australia Melrose Brown, melrose.brown@adfa.edu.au

University of New South Wales Canberra, Canberra, Australia Brenton Smith, brenton.smith@student.adfa.edu.au

University of New South Wales Canberra, Canberra, Australia

An accurate understanding of all the forces affecting the dynamics of Low Earth Orbit (LEO) objects is essential for providing precise orbit prediction and determination capabilities that address some of the challenges posed by the modern space environment. A key force influencing the motion of LEO object is their aerodynamic interaction with the local space environment. An aspect of LEO aerodynamics often neglected is the force resulting from the charged interaction between objects and the ionosphere i.e. ionospheric aerodynamics. Based on Particlein-Cell (PIC) simulations and atmospheric model outputs, this work examines the significance of ionospheric aerodynamics to the motion of LEO objects. Results highlight the potential importance of including ionospheric aerodynamics in forces models; preliminary observations indicating ionospheric drag may cause a 5%-35% increase in net drag along an orbit for a -3V 3U CubeSat class object at approximately 460 km altitude. The implications of findings in this work to the active satellite control (formation keeping, de-orbit, etc) are briefly discussed.

PSD.1-0011-18 ACTIVE USE OF IONOSPHERIC AERODYNAMICS FOR THE CONTROL OF SATELLITES

Brenton Smith, brenton.smith@student.adfa.edu.au

University of New South Wales Canberra, Canberra, Australia Christopher Capon, c.capon@unsw.edu.au

University of New South Wales Canberra, Canberra, Australia Melrose Brown, melrose.brown@adfa.edu.au

University of New South Wales Canberra, Canberra, Australia Russell Boyce, russell.boyce@adfa.edu.au

University of New South Wales Canberra, Canberra, Australia

Aerodynamic accelerations in Low Earth Orbit (LEO) are becoming more popular as a propellantless means of controlling formations of miniaturised satellites. For example, Planet, a Silicon Valley based company, routinely use differences in the drag acceleration acting on their CubeSats to establish constellations.

However, the component of drag due to a charged object interacting with the ionosphere is commonly neglected. Recently, studies have shown that ionospheric drag may cause a net increase in aerodynamic force of 5%-35%. Furthermore, the influence of ionospheric aerodynamics increases with, and can be controlled by, the spacecraft's electrical potential relative to the surrounding plasma.

UNSW Canberra is driving research into ionosphere aerodynamics and this work is the first effort in implementing active use of ionospheric aerodynamics for the control of spacecraft.

High fidelity orbit propagation software with inputs from the GITM, NRLMSISE-00, and IRI2012 atmospheric models are used to assess ionospheric drag enhanced manoeuvring based on the time required to achieve rendezvous, planar rephrasing, collision avoidance, and re-entry over varying initial orbital and environmental conditions.

PSD.1-0012-18 THE EFFECT OF SOLAR FORCING INDUCED ATMOSPHERIC PERTURBATIONS ON LEO SATELLITES' NOMINAL AERODYNAMIC DRAG

Victor U.J. Nwankwo, victornwankwo@yahoo.com Anchor University, Lagos, Nigeria

Sandip Kumar Chakrabarti, chakraba@bose.res.in

George Mason University, United States

The upper atmosphere changes significantly in temperature, density and composition as a result of solar cycle and storm interval variations due to the amount of absorbed solar radiation from solar energetic events. Satellite orbits are consequently affected by this scenario, especially those in low Earth orbit (LEO). Atmospheric drag is the strongest force perturbing the motion of satellites in LEO, and could cause re-entry of satellites, difficulty in identifying and tracking of the satellites and other space objects, manuvering and prediction of lifetime and re-entry. In this paper, we present the model of atmospheric drag effect on the trajectory of hypothetical and real LEO satellites of different ballistic coefficients. We investigated long-term trend in atmospheric drag on LEO satellites (due to solar forcing induced atmospheric perturbations and heating) at different phases of the solar cycle, and during short interval of strong geomagnetic disturbances or storms. We also show the dependence of orbital decay on the satellites ballistic coefficients, severity of solar cycle and phase and the extent of geomagnetic perturbations.

The continuous record of sea surface height measurements was initiated in 1992 by the TOPEX/Poseidon (NASA/CNES) mission and continued in 2001, 2008 and 2016 with the successive launches of the reference Jason-1 (CNES/NASA), OSTM/Jason-2 and Jason-3 (CNES/NASA/EUMETSAT/NOAA) satellites, respectively. The complementary missions Envisat and CryoSat-2 (ESA), HY-2A

(CNSA), Saral/AltiKa (ISRO/CNES), Sentinel-3A/B (ESA) fly in different orbits with lower altitudes and higher inclinations. This altimeter constellation of 10 satellites will keep expanding in the future with the extension of the three families Jason-CS, Sentinel-3 and HY-2 with 11 more satellites by 2030, not counting the next generation radar altimeter U.S.-French SWOT mission. All these Low-Earth Orbiters (LEOs) are at least equipped with a DORIS (Doppler Orbitography and Radiopositioning Integrated by Satellite) receiver in addition to a laser retroreflector array, and most of them also carry a GPS (Global Positioning System) dual-frequency receiver, to support their Precision Orbit Determination (POD) requirements.

The CNES POD group delivers homogeneous precise orbit solutions for these independent altimeter missions. This paper presents our plans for updating our POD standards and investigating improvements to modeling or mitigating remaining sources of orbit error. In particular, we show results from independent validation of SLR station biases, long-wavelength time-variable gravity recovery before the GRACE era, as well as geocenter motion determination, leveraging the long-time history of LEO satellites that are tracked using DORIS measurements.

Precise orbits of altimetry satellites are a basis for global and regional sea level investigations, since they provide positions of an altimeter, from which the distance to the sea surface is measured. High accuracy is required for satellite orbits, since any radial error maps directly in sea level height. In this paper, we show the impact of some effects on the orbits of altimetry satellites Jason-1, Jason-2 and Jason-3. In particular, we show the impact of the new ITRS realisations ITRF2014, DTRF2014 and JTRF2014 on Jason-2 orbit, as compared to using a previous ITRS realization for SLR stations - SLRF2008. Additionally, the impact of the refined satellite attitude handling on orbits is exemplary shown for Jason-2. We investigate the advantage of using DORIS observations in addition to SLR measurements for precise orbit determination of Jason satellites. Improved macromodels of Jason satellites improve orbit quality additionally. Importance of non-tidal loading modelling is shown as well. Furthermore, we study the impact of various perturbing forces on Jason satellites. The impact of these effects on the root-mean-square and mean fits of observations, single-satellite sea surface height (SSH) crossover differences, mean and standard deviations of the radial errors, as well as geographically correlated mean SSH errors is investigated.

PSD.1-0015-18 CAN WE IMPROVE THE ATMOSPHERIC DELAY CORRECTIONS FOR SATELLITE LASER RANGING?

Rolf Koenig, koenigr@gfz-potsdam.de

Deutsches GeoForschungsZentrum, GFZ, Wessling, Germany Kyriakos Balidakis, balidak@gfz-potsdam.de

Florian Zus, zusflo@gfz-potsdam.de GeoForschungsZentrum Potsdam, Potsdam, Germany

Unlike in microwave-based techniques where weak tropospheric modelling can be compensated to a large extent by estimating residual delays, the observation geometry in satellite laser ranging (SLR) hinders such a treatment. Therefore the a priori tropospheric delays should be known as good as possible. We revisit the modeling of the atmospheric delay in SLR data analysis focusing on zenith delays, the mapping function and the gradients with the aim to improve orbit determination and parameter estimation. Firstly data from the model levels of ERA Interim reanalysis are employed to homogenize the in situ meteorological data recorded in the measurement data. Doing so several stations show up with non-negligible biases and jumps in their pressure series. Secondly by rigorous ray-tracing in ERA Interim, the so-called Potsdam Mapping Functions (PMF) for laser frequencies is determined. The differences between PMF and the latest standard in SLR mapping functions, FCULa, can be as large as 3 mm at 20 degree elevation. Thirdly gradient components of first and second order based on the ray-traced delays are estimated. As gradients from the tropospheric model are neglected in standard SLR analysis, errors as large as 30 mm at 20 degree elevation may be induced. The homogenized meteorological data, the PMF and the gradients are applied in Precise Orbit Determination for eight years of LAGEOS-1 and -2 SLR observations. The impact of these refinements in terms of orbital fits and their effect on reference frame and station coordinates are assessed.

PSD.1-0017-18 TEST OF PULSAR NAVIGATION WITH INSIGHT-HXMT

Shijie Zheng, zhengsj@ihep.ac.cn

Institute of High Energy Physics (IHEP), Beijing, China

Pulsar Navigation, which utilizes pulsar observations to determine the position or orbit of a spacecraft, has attracted more and more attentions. In this work we report our first results testing pulsar navigation with Insight-HXMT observations. Insight HXMT, which is launched in 2017, comprises of three x-ray telescopes covering the energy band 1-250keV. A new pulsar navigation algorithm has been proposed for orbit determination. With 5-day-long observations of the Crab pulsar, the orbit was determined successfully within 10 kilometres.

PSD.1-0018-18 AN INVESTIGATION INTO CUBATURE KALMAN FILTER PERFORMANCE FOR ORBIT DETERMINATION APPLICATION

Paula C P M Pardal, paulapardal@usp.br University of Sao Paulo, Lorena, Brazil Helio Koiti Kuga, hkk@dem.inpe.br

National Institute for Space Research, S, Brazil Roberta Veloso Garcia, robertagarcia@usp.br University of Sao Paulo, Lorena, Brazil

The purpose of this work is to discuss the Cubature Kalman Filter (CKF) performance when applied to a high nonlinear problem: artificial satellites orbit determination, using real Global Positioning System (GPS) data. The CKF is a discrete-time nonlinear Bayesian filter based on a third-degree spherical-radial cubature rule, which allows to numerically computing multivariate moment integrals in the Bayesian filter. In particular, it also provides a set of cubature points scaling linearly with the state vector dimension. As a result, the CKF yields a systematic solution for high dimensional nonlinear filtering problems, such as the orbit determination addressed here. In this work, the application consists of determining the orbit of an artificial satellite, using real data from the GPS receivers. This is a nonlinear problem, with respect to the dynamics and measurements equations, in which the disturbing forces are not easily modeled. The problem of orbit determination consists essentially of estimating values that completely specify the body trajectory in the space, processing a set of observations that can be collected through a tracking network grounded on Earth or through sensors, like space GPS receivers onboard the satellite. The GPS is a widespread system that allows computation of orbits for artificial Earth satellites by providing many redundant measurements. Throughout an onboard GPS receiver, it is possible to obtain nonlinear measurements (pseudoranges) that can be processed to estimate the orbital state. The standard differential equations describing the orbital motion and the GPS measurements equations are adapted for the nonlinear filter so that the CKF algorithm is also used for estimating the orbital state. The assessment to be presented will be based on the robustness of the filter, concerning convergence speed when the measurements are scattered. The results from CKF will be compared to the unscented Kalman filter (UKF) results for the same problem, in computational terms such as convergence and accuracy. Based on the analysis of such criteria, the advantages and drawbacks of the implementations are presented.

PSD.1-0019-18 OPTIMAL EARTH COVERAGE ANALYSIS OF SATELLITES IN FORMATION

Nor Affendy Yahya, fuisester@gmail.com University Putra Malaysia, Serdang, Malaysia

Optimal Earth Coverage Analysis of Satellites in Formation

Nor Affendy Yahya(1*),Renuganth Varatharajoo(1**),A. Salahuddin M. Harithuddin(1***)

1 Faculty of Engineering, Universiti Putra Malaysia, 43400 Selangor, Malaysia. * fuisester@gmail.com ** renu99@gmx.de ***asalahuddin@upm.edu.my

The concept of spacecraft flying in formation has indeed revolutionized the way satellite is being used today. Most often, a single fully-functional spacecraft is unable to cater for all the demands required by multi-hierarchical satellite operators and users especially when optimal Earth coverage region is desired. Formation flying spacecraft is capable of offering indigenous solutions to constraint Earth surface coverage problem while greatly improvised the applicability and their usability in the sense that longer satellite lifetime were possible, operational redundancy can be achieved and multi-tasking mission objectives could be accomplished. So far, there have been very few researches associated with the satellite formation flying for an optimal Earth coverage. In this paper, we conducted a performance measure analysis for two satellites flying as an example in close formation in low Earth orbit. Their respective ground track coverage areas were assessed and analysed in detail to extract valuable properties such as average instantaneous overlapping area (IOA), maximum coverage distance and formation altitude influence on satellite coverage performance measures in relation to different orbital configurations. Parametric studies involving effect of varying formation distance and altitude on the resulting overlapping coverage area were done in order to gain an understanding of the trend which later can be exploited to optimize the potential of optimal spacecraft formation flying for the purpose of Earth observation mission ground coverage. In the proposed model, a specific orbit inclination with no great perturbation effects were proposed together with the deduced spacecraft formation flying governing equations. Determination of overlapping coverage area parameter is numerically computed using the model of double overlap configuration type which is calculated for a period of one orbital cycle. Preliminary results showed significant influence of formation distance on the resulting overlap area if compared to the effect of changing altitude. However, there exists dynamic relationships between formation altitude and formation distance for the determination of overlapping coverage area. For instance, higher altitude formation flying with small separation between spacecraft resulted in larger overlapping area as compared to lower altitude with small separation spacecraft formation. The results were subsequently analysed using 3-dimensional graph to investigate each variable's trend towards acquisition of optimum Earth surface coverage region. Finally, the findings allow to establish the correlation between the deduced spacecraft formation flying governing equations and the optimal parametric ground coverage relations.

PSD.1-0020-18 FUEL-OPTIMAL CONTROL FOR SPACECRAFT FORMATION FLYING AND RECONFIGURATION PROPELLED USING ELECTROMAGNETIC FORCES.

With the development of small satellite technique, a spacecraft capable of producing higherthan-natural electrostatic charges may keep desired relative distances and orientations via the Lorentz-force interaction with a planetary magnetic field. This paper presented Hybrid combination of Lorentz forces provided by modulating spacecraft's electrostatic charge (magnetic and electric fields), using a Cartesian coordinates-based description of the spacecraft's relative states. Numerical simulation results are provided to demonstrate the functionality of the proposed controller to correct the drift due to J2 perturbations. We have used two different examples of formation flying satellites, the first example (TanDEM-X - TERRA SAR X) have relative poison about 3 km, the second (CLOUDSATCALIPSO) have about 600 km. The obtained results confirm that in the first case the effect off j2 on relative poison is about 3.9 km through 10 periods, and the magnitude of charge to mass ratio (q/m) must be -0.256 C/kg to correct about 3.7 km when used magnetic part of Lorentz force only. In addition, the rest of drift 0.2 km has been coerced after the electric part of Lorentz are considered. On the other hand, the drift of the second case for relative position due to J2 is about 2.1 km through 15 periods, and we need a charge to mass ratio + 0.185 C/kg to corrected 1.9, and 0.2 km using magnetic and electric parts of Lorentz force respectively. Finally, the required velocity increment (V) for controlling in both cases charged and uncharged spacecraft are presented.

PSD.1-0022-18 SOLVING THE MAIN PROBLEM IN SATELLITE THEORY THROUGH RECURRENT NEURAL NETWORKS

Davide Amato, davideamato@email.arizona.edu University of Arizona, Tucson, Arizona, United States Aaron Jay Rosengren, ajrosengren@email.arizona.edu University of Arizona, Tucson, Arizona, United States Roberto Furfaro, robertof@email.arizona.edu University of Arizona, Tucson, Arizona, United States

Machine learning techniques have turned out to be game-changers in several fields of engineering and applied sciences. However, their potential for the analysis and prediction of dynamical systems is only starting to be expressed. This work takes a decisive step in this direction by investigating the possibility of using Recurrent Neural Networks (RNNs) for the trajectory prediction of an orbiter subject to the gravity field of an oblate Earth (i.e., the main problem in satellite theory).

While previous works have applied static machine learning algorithms such as feedforward neural networks and Support Vector Machines (SVMs) to orbit propagation and prediction tasks, the trajectory evolution may best be represented through algorithms capable of representing sequential time series. RNNs, and, in particular, the specialized architecture called Long ShortTerm Memory (LSTM), model sequential data achieving success in a large variety of domains including natural language processing and genomic analysis. Importantly, LSTM can capture both long range dependencies as well as non-linear dynamics representing an ideal model to capture the behavior of systems with multi-scale dynamical structures. Once trained, the evaluation of a RNN/LSTM output is relatively inexpensive. This makes such algorithms attractive candidates for precise on-board orbit propagation and for large-scale simulations of the RSO catalog, inter alia. Moreover, the parallel programming paradigm can be exploited so as to further decrease the computational time required for training and prediction.

We adopt a supervised learning approach in which a RNN/LSTM is trained on data provided by reference trajectories computed with high-accuracy numerical integrations. The evolution of the trajectory provided by the trained RNN/LSTM is compared to the reference in order to tune its parameters by trial-and-error. Moreover, the correctness of the short-periodic and secular behavior of the RNN/LSTM solution is checked against known firstand second-order analytical approximations. We establish time boundaries in which the RNN solution is under an assigned error threshold, and compare its CPU time with respect to an efficient numerical orbit propagation technique.

PSD.1-0023-18 TWO-LINE ELEMENT ESTIMATION FROM SPACE CATALOG USING DEEP NEURAL NETWORK

Rasit Abay, r.abay@student.adfa.edu.au

University of New South Wales Canberra, Canberra, Australia
Sudantha Balage, s.balage@adfa.edu.au

University of New South Wales Canberra, Canberra, Australia
Melrose Brown, melrose.brown@adfa.edu.au

University of New South Wales Canberra, Canberra, Australia
Russell Boyce, russell.boyce@adfa.edu.au

University of New South Wales Canberra, Canberra, Australia

The US Space Catalog includes Two-Line Elements (TLEs) of resident space objects (RSO), and Joint Space Operations Center (JSpOC) publishes publicly available TLEs on its servers. Although TLEs are widely used for space research and space operations, the official estimation scheme of TLEs in the Space Catalog isn't available. The current method for estimating TLE is based on non-linear least squares and finite difference methods VC2008. Because this approach applies differential corrections to the initial conditions to reduce the sums of errors between the orbital data and associated propagation of Simplified General Perturbations #4 (SGP4) propagation to estimate TLEs, it requires good initial estimates of the TLEs to avoid local minima that end up with inaccurate TLEs. Keplerian elements at epoch are used as initial estimates for TLEs in the current method. However, this assumption leads to local minima for most orbits. Therefore, a novel method to estimate TLEs without requiring good initial estimates is needed. Because machine learning methods are basically universal approximation tools, they can be trained to learn to estimate TLEs from Space Catalog. Moreover, the estimations of a machine learning model can be near-real-time (NRT) once it is developed by training with data. Although there is no mathematical tool that can prove a neural network (NN), which is a machine learning method, don't get stuck in local minima, it is highly unlikely that they end up in local minima because the training data are very high-dimensional. In addition, there are empirical techniques to evaluate the performance by monitoring the progress of the search process during training, and improving the model by continuously iterating over training, development test, and test data sets to avoid local minima. For NN to discover the distribution of the information in the data, the data representation is essential. The orbital evolution is represented in osculating elements and mean elements that are corrected for each time step by differential corrections method. Two different NN architecture will be investigated, namely convolutional and fully-connected neural networks. The NN model that can accurately estimate TLEs will be beneficial not only for maintaining space operations but also for promoting space situational awareness by providing a robust tool that doesn't require intensive computations that might be more essential for other tasks.

PSD.1-0024-18 MGEX: STATUS UPDATE ON THE MULTI-GNSS PILOT PROJECT OF THE INTERNATIONAL GNSS SERVICE

Peter Steigenberger, peter.steigenberger@dlr.de

Deutsches Zentrum fuer Luftund Raumfahrt (DLR), Wessling, Germany Oliver Montenbruck, oliver.montenbruck@dlr.de

Deutsches Zentrum fuer Luftund Raumfahrt (DLR), Wessling, Germany

The major task of the Multi-GNSS Pilot Project (MGEX) of the International GNSS Service (IGS) is tracking, collating and analyzing all available GNSS signals. The final goal is the integration of the evolving global and regional satellite navigation systems Galileo, BeiDou, QZSS, and NavIC (IRNSS) into the IGS operational products. The backbone for these activities is a network of multi-GNSS tracking stations available at the IGS data centers. Currently six MGEX analysis centers generate precise multi-GNSS orbit and clock products on an operational basis. Further products include merged navigation data, a dedicated CNAV product for GPS and QZSS, as well as two multi-GNSS differential code bias (DCB) products.

This contribution presents the current status of the multi-GNSS tracking network and the MGEX analysis products. Progress in solar radition pressure modeling is demonstrated and evaluated by satellite laser ranging residuals and orbit comparisons. The GNSS providers of Galileo and QZSS have recently published metadata like antenna offsets, spacecraft mass, and transmit power. The impact of these data on the analysis products will be demonstrated. Furthermore, clock analysis of new satellites not covered by the current MGEX products will be presented, namely for the BeiDou-3 and QZSS geostationary satellites.

Determination of precise satellite orbits of the Galileo constellation constitutes one of the key prerequisites for obtaining high-quality geodetic products, such as station coordinates or Earth rotation parameters. Various external forces, such as direct solar radiation pressure, Earth's albedo and infrared irradiance, perturb Galileo orbits and limit the quality of estimated satellite positions. Galileo satellites are especially vulnerable to non-gravitational accelerations due to their relatively low masses when compared to other GNSS spacecraft. Recently, the European Space Agency published key characteristics and parameters describing surface properties of Galileo In Orbit Validation (IOV) and Full Operational Capability (FOC) satellites, which allow the users to properly account for albedo and Earth infrared irradiance in the process of precise orbit determination. In this study, we evaluate the impact of antenna thrust, albedo and infrared irradiance on Galileo IOV, Galileo FOC, and Galileo FOC launched into incorrect eccentric orbits as a function of the beta angle, the argument of satellite latitude with respect to the Sun position and the height of the satellite above the Earth's surface. We show to what extent the proper orbit modeling reduces the RMS of satellite laser ranging (SLR) residuals and to what extent the neglect of a proper albedo modeling can be absorbed by estimating empirical orbit parameters (ECOM).

All Galileo satellites are equipped today with laser retroreflector arrays dedicated to SLR. Using

SLR data to Galileo allows for estimating global geodetic parameters, such as Earth rotation parameters and geocenter motion. In this study, we evaluate the quality of global geodetic parameters estimated on a basis of SLR tracking of Galileo satellites and other new GNSS constellations. One of the Galileo IOV satellites, E20, has been transmitting the signal solely on one frequency due to a serious batter outage in 2014. Single-frequency signal does not allow for the precise orbit determination when employing ionospheric-free linear combination. Therefore, there are no MGEX orbits available for E20. In this contribution, we use SLR data to determine E20 orbits. The quality of SLR-derived Galileo orbits is then evaluated on the basis of the quality of orbit overlaps and a comparison to E19 which was launched into the same orbital plane as E20. Finally, we show first results from the combined SLR-GNSS solution and advantages of such a combination.

PSD.1-0026-18 AN APPROACH FOR PARAMETER DECORRELATION IN PRECISE DYNAMIC ORBIT DETERMINATION

Junping Chen, junping@shao.ac.cn

Shanghai Astronomical Observatory, Chinese Academy of Sciences, Shanghai, China

Orbits and clocks are two fundmental parameters for the global navigation satellite systems(GNSS). Coventionally, satellite orbits are obtained by the dynamic orbit determination(DOD) technique, which uses satellite's dynamics and perturbations as constrains. Precise GNSS satellite time information is also derived from the DOD technique among the international GNSS community. We find apparent orbit/clock offsets in the most precise estimations among the International GNSS Services(IGS) analysis centers. The offsets include constant and periodical terms.

And the periodical terms of satellite orbits and satellite clocks are highly correlated. These results reveal one problem in the current IGS DOD technique, i.e. the correlation between the orbital radial component and satellite clock. And this problem may limit the accuracy of the GNSS services and its contribution to the definition and maintanance of the International Terrestrial Reference Frame(ITRF). Different from the traditional DOD, we develop a two-step TWTT(Two Way Time Transfer) assisted DOD approach for the decorrelation of satellite orbit and clock parameters. In the first step,the typical technique for precise time transfer TWTT, which is un-affected of satellite orbits error, is used to estimate satellite clocks. Afterwards, the precise clocks are fixed as known in the DOD processing. We test the approach for the BDS precise orbit determination, where TWTT data is retrieved from the ground tracking antennas and the GNSS observations are from around 50 globally-distributed sites. Results show that the new approach improves the precision of orbit determination and orbit prediction by more than 15% and 70%.

PSD.1-0027-18 INTER-SATELLITE LINKS: A VERSATILE TOOL FOR GEODESY AND PLANETARY AND INTERPLANETARY NAVIGATION

With the use of low-low satellite-to-satellite tracking gravity field recovery made a big step forward. Based on this technique the Gravity Recovery And Climate Experiment (GRACE) mission delivers monthly gravity field with high precision, allowing to measure effects in Earth water storage basins and variations in ice mass in Greenland and Antarctica from space. GRACE is using a Ka-band inter-satellite ranging technique, GRACE Follow-On will in addition test optical ranging. In fundamental physics high-precision optical inter-satellite tracking will be used to detect gravitational waves in space, as a first step LISA Pathfinder was launched recently. Inter-satellite links are not only used for ranging, also data transfer in space is based on such links. ESA's European Data Relay System will be established in up-coming years to collect data from the low orbiting Sentinel satellites and transfer the high data rate to ground. The same link may be used for ranging, data transfer and time transfer, a functionality that is discussed for next generation Galileo satellites. But to exploit this synergy a common concept for all three tasks has to be developed. In this paper we show that with inter-satellite ranging techniques with µm accuracy the limited accuracy of GNSS based orbit determination of low Earth orbiters (LEO), which is due to the limitations of one-way microwave tracking (unsynchronized clocks, phase center variations and offsets of the sending and receiving antennas) can be overcome. In the ESA study GETRIS the following question is answered: How can a highly accurate and precise GEO-based two-way ranging method support GNSS tracking? The reduction of systematic errors in LEO precise orbit determination (POD) by exploiting the synergy between ranging, dataand time-transfer is assessed in a concept consisting of precise two-way GEO-LEO tracking (as used for data transfer) and an ultra-stable oscillator on-board of the geostationary satellite (GEO) synchronized from ground. We now want to get a step further and design a versatile concept for the use of this synergy in a satellite constellation based on existing and future planned ESA infrastructure and highlight the benefits in different disciplines from geodesy to interplanetary ranging, with emphasis on gravity field recovery, where a proposal for the ESA EarthExplorer 10 is based on a minimal constellation for gravity field determination.

PSD.1-0028-18 ORBIT DESIGN OF LUMIO, A LUNAR METEOROID IMPACT OBSERVER

Francesco Topputo, francesco.topputo@polimi.it Politecnico di Milano, Milano, Italy

Diogene Alessandro Dei Tos, diogenealessandro.deitos@polimi.it Politecnico di Milano, Milan, Italy

Ana Cipriano, ana.cipriano@esa.int ESA/ESTEC, Noordwijk, Netherlands

The Lunar Meteoroid Impact Observer (LUMIO) is a CubeSat mission to observe, quantify, and characterise the meteoroid impacts by detecting their flashes on the lunar farside. This complements the knowledge gathered by Earth-based observations of the lunar nearside, thus synthesising a global information on the lunar meteoroid environment.

The mission implements a sophisticated orbit design: LUMIO is placed on a halo orbit about Earth-Moon L2 where permanent full-disk observation of the lunar farside is made. This prevents having background noise due to Earthshine, and thus permits obtaining high-quality scientific products. Repetitive operations are foreseen, the orbit being in near 2:1 resonance with the Moon orbit. Innovative full-disk optical autonomous navigation is proposed, and its performances are assessed and quantified.

LUMIO is one of the two winner of ESA's LUCE (Lunar CubeSat for Exploration) SysNova competition, and as such it is being considered by ESA for implementation in the near future. In this presentation, emphasis will be put on the orbit design of LUMIO, which has been conducted following a hierarchical trade-off structure. The selected orbit will be described in relation to the scientific objectives of the mission.

For the exploration of the far side of the moon, it is necessary to tackle the challenges of navigation and communication as the far side is invisible to the Earth. This paper proposes a mission consisting of four CubeSats in an Earth-moon L2 (EML2) halo orbit to assist the positioning of an asset on the far side of the moon, as EML2 halo orbits are always visible from the Earth and the lunar far side. Being miniature, CubeSats can be carried by a mother spacecraft aimed at the moon and deployed during the mid-course.

On the other hand, CubeSat missions are generally constrained by the very limited communication and propulsion capacity. A previous study has given a low-Δv deployment strategy for forming constellations in halo orbits. To further access the practical feasibility, this paper addresses the mission and system design, the accuracy of positioning related to the configuration of CubeSats, and optimal deployment trajectories in the continuous-thrust full-ephemeris model as well as the propulsion system options.

Key findings include 1) small halo orbits are favorable in terms of far-side coverage and positioning accuracy; 2) a low thrust as small as 0.7 mN can meet the requirement of deployment almost regardless of the reference Julian Date, and 3) the positioning accuracy is 3 km for a maneuvering object and 800 m for a ballistic object.

PSD.1-0030-18 IMPROVING THE GEOMETRY OF KAGUYA EXTENDED MISSION DATA THROUGH REFINED ORBIT DETERMINATION USING LASER ALTIMETRY DATA

National Astronomical Observatory of Japan, Iwate, Japan Takahiro Iwata, iwata.takahiro@jaxa.jp

Japan Aerospace Exploration Agency (ISAS/JAXA), Sagamihara, Japan

The Japan Aerospace Exploration Agency's (JAXA) SELenological and ENgineering Explorer (SELENE) mission to the Moon was launched in September 2007 and consisted of 3 spacecraft: a main satellite and two sub-satellites. The Kaguya mission, as it was also known, was the first of several late 2000's missions that marked a return to the exploration of the Moon and achieved many firsts. Today, Kaguya data are of fundamental importance and are highly complementary to data acquired by several earlier and later instruments, including of the Apollo Metric and Panoramic Cameras, the Chandrayaan-1 Moon Mineralogy Mapper (M3), and the Lunar Reconnaissance Orbiter's (LRO's) Wide and Narrow Angle Cameras (WAC and NAC). Kaguya's primary mission (PM) lasted from October 20, 2007 until October 31, 2008, and the extended mission (XM) lasted from November 1, 2008 until the controlled impact of the main satellite on the lunar surface on June 10, 2009. The main satellite's average altitude was 100 km during the PM and it was lowered to 50 km during the XM, with some periods having an even lower altitude. As a consequence, Kaguya science products using XM data have an increased spatial resolution. However, the geodetic position quality of these products is much worse than that of those acquired during the PM: radio tracking of Kaguya (necessary for determining the spacecraft's orbit precisely) was reduced after the PM, and the loss of momentum wheels resulted in frequent thrusting to maintain attitude, which further degraded the orbit determination accuracy. As a result, the degraded orbit quality during XM (at a level of several km compared to 10-30 m during PM) severely limits the scientific value of these high-resolution data.

Here, we show how making use of recent advances in lunar knowledge can improve the geometry of the Kaguya XM data. We redetermine the XM orbits for the main satellite by using improved gravity field models of the Moon, derived from data of the Gravity Recovery and Interior Laboratory (GRAIL) mission, and by using a novel data type for orbit determination, based on improved knowledge of the lunar topography from laser altimeter data of the Lunar Orbiter Laser Altimeter (LOLA) onboard LRO. We use the Kaguya Laser Altimeter (LALT) data directly in our orbit determination software GEODYN II, by comparing the LALT ranges to a high-accuracy LOLA topography basemap. As a result, the main satellite's orbit will be geodetically accurate and directly tied to the LOLA/LRO frame. We show that by using the GRAIL models in combination with the LALT data, we can improve the XM orbits from the level of several km to several tens of meters or better. Such improved orbits will greatly enhance the analysis of the entire Kaguya XM data set.

PSD.1-0031-18 IMPROVED NON-GRAVITATIONAL FORCE MODELING FOR MAGELLAN ORBIT DETERMINATION

One of the main objectives of the Magellan mission to Venus (1990-1994) was to map the Venusian gravity field. The spacecraft was continually tracked at periapsis, during gravity cycles, by using X-band Doppler links from the Deep Space Network. With a near-circular orbit (during phases 5-6, 1993/94) and periapsis altitude as low as 150-220 km, Magellan tracking data still constitute the main source of information to develop high resolution gravity field models for Venus.

Nevertheless, the reference Venusian gravity field model (MGNP180U - Konopliv et al, 1999) is now almost two decades old and shows its limitations when used to constrain increasingly precise geophysical models of Venus' interior and surface processes. This is motivating the development of a new high-resolution gravity field model for Venus, that could be potentially used for planning future missions and to study Venusian geodynamics. A crucial aspect to be considered for the reprocessing of Magellan data is a more accurate modeling of non-gravitational forces acting on the spacecraft, i.e., solar and planetary (albedo and IR) radiation pressure and aerodynamic accelerations. In particular, because of lacking knowledge of Magellan's attitude and material properties, past and ongoing orbit analysis have limited the spacecraft modeling to a simple cannon-ball, eventually corrected by a set of scaling factors.

We will present our advances in the setup of a reliable macro-model for the Magellan spacecraft, constituted of multiple plates. Material properties are based both on the (very limited) available literature and on a detailed analysis of Doppler residuals and resulting orbit quality, e.g., orbit overlaps, for a given set of tests. Moreover, the amplitude of the estimated dynamical and empirical parameters (including scaling factors for each force) shall allow to evaluate the accuracy of the tested setups. Regarding the attitude law, the knowledge of which is also required when using an extended macro-model, we will base our initial analysis on limited information available in the literature and then refine it.

This work shall support ongoing Magellan reprocessing efforts. Moreover, it could constitute a guideline to improve non-gravitational force modeling (and hence, the quality of the recovered orbits) when limited or no information is available on the probe geometrical and optical properties and/or its attitude, which is often the case for (old and sometimes recent) planetary missions.

PSD.1-0032-18 GEODESY, RELATIVITY AND SPACE NAVIGATION WITH THE MORE EXPERIMENT OF THE MISSION BEPICOLOMBO TO MERCURY

Luciano Iess, luciano.iess@uniroma1.it

Università degli Studi di Roma "La Sapienza", Roma, Italy

In October 2018 the joint ESA-JAXA mission BepiColombo will start a six year cruise to Mercury, its ultimate destination. With its suite of 16 instruments on two spacecraft (the Mercury Planetary Orbiter, MPO, and Mercury Magnetospheric orbiter, MMO), the mission aims at further extending the already extraordinary results from MESSENGER and answering many open questions on the planet, its formation and interactions with the space environment.

The Mercury Orbiter Radio-science Experiment (MORE) onboard the MPO has been designed to provide an accurate estimation of the spacecraft orbit, the gravity field and rotational state of Mercury, and to carry out classical and new tests of relativistic gravity. The space probe will act as a test mass in near free fall in the gravity field of Mercury and the other solar system bodies. The orbit of the spacecraft will be determined by means of an advanced multifrequency tracking system entailing three separate, coherent, simultaneous, two-way links at X and Ka band (7.2-8-4 GHz, 34-32.5 GHz). This configuration effectively suppresses the noise from the solar corona at nearly all solar elongation angles, providing range-rate accuracies up to 0.003 mm/s at 1000 s integration time. A 24 Mcps pseudo-noise code in the Ka/Ka link enables two-way range measurements with an accuracy of 20 cm after just 1 s integration. The strong non-gravitational accelerations caused by the harsh environment of the inner solar system will be measured and accounted for in the dynamical model by means of a high accuracy accelerometer (ISA), whose sensitivities are about 10-9-10-8 m/s2 in the frequency band 10-4-10-1 Hz. The spacecraft range and range rate observables will be combined with the ISA measurements in the orbit determination process to mimic a drag-free environment in software. This will be the first use of an accelerometer in a planetary geodesy and relativity experiment.

With 12 superior solar conjunctions in the cruise phase, BepiColombo offers the opportunity to carry out excellent determinations of the Post Newtonian parameter γ. The combined accuracy from all conjunctions is expected to improve by about a factor of ten the result obtained by the Cassini mission. In the orbital phase around Mercury, MORE will provide a significant improvement in the hermean gravity field (both static and tidal) and rotational state (obliquity and physical librations in longitude). Thanks to the novel ranging system, the motion of Mercury in the solar system will be determined with unprecedented accuracy, enabling improved tests of general relativity (including the precession of perihelion and the strong equivalence principle), and a direct, dynamical determination of the solar oblateness and mass loss.

PSD.1-0033-18 TRAJECTORIES IN THE NEIGHBORHOOD OF PHOBOS AND DEIMOS AIMING COVERAGE AND APPROACHING

Rodolpho Vilhena De Moraes, rodolpho.vilhena@gmail.com

INPE - Instituto Nacional de Pesquisas Espaciais, São José Dos Campos, Brazil Evandro Marconi Rocco, evandro_mr@yahoo.com.br

National Institute for Space Research (INPE), São José Dos Campos, Brazil

Due to some interesting physical and orbital characteristics of Phobos and Deimos, satellites of Mars, research involving these moons has grown. These moons have a highly irregular shape and their orbits are close to Mars. In addition, Phobos and Deimos have a high potential to provide important information about the evolution of the Mars system as well as to contribute to a future manned mission to Mars. There have been some attempts to visit Phobos, none of them successfully and, to this day, no mission has been sent to Deimos. This work presents a detailed study of the main perturbations capable of altering the orbit of a spacecraft that orbits Mars, Phobos and Deimos, in order to understand the dynamics of spacecraft movement in the proximity of such bodies and seek cases where it is possible to find stable or near stable orbits around Phobos and Deimos for the maximum possible time. Strategic trajectories are presented that allow the spacecraft to visit both moons on a regular cadence, to approach or to cover the moons. All trajectory simulations are performed using the Spacecraft Trajectory Simulator (STRS). The considered perturbations on the orbital motion of the spacecraft are: the gravitational potential of Mars, expanded in spherical harmonics up to degree and order 80, the gravitational attraction of the Sun, the gravitational potential of Phobos and Deimos and the solar radiation pressure. For the perturbations due to Phobos and Deimos is used a polyhedral model to define the shape and mass distribution of these bodies.

PSD.1-0034-18 CONCEPTUAL DESIGN OF A REVERSED SOLAR SAIL FOR AN ENHANCED PASSIVE PROPULSION

Sevuga Karthick Murugan, sevugakarthick@protonmail.com Kumaraguru College of Technology, Coimbatore, India

Presenting author: Rashickha Devarajulu Srinivasan, rashickha.16ae@kct.ac.in Kumaraguru College of Technology, Coimbatore, India

Indian Space Research Organisation, Coimbatore, India

The science of solar sail is well proven but the technology for utilizing the momentum transfer for the passive propulsion is challenging. Note that if the radiation is totally reflected, the radiation pressure is doubled, which is prudently utilized herein for the conceptual design of a reversed Solar sail with better performance. This paper puts forth the idea of propelling the solar sail towards the source, which is termed herein as a reversed Solar sail. An idealized physical model of a square Solar sail is selected for the parametric analytical studies. The electromagnetic spectrum emitted by the source can hit on the Be/Si/Al multi-layered mirrors. The augmented pressure exerted by the reflected photons on the sail helps in the forward motion of the sail towards the source with high payload capability. In this paper an attempt has been made for the numerical simulation of Sails performance aiming for comparing the system's abilities of both conventional and the reversed Solar sail based on the Scholz's model [2011 COSPAR].

PSD.1-0035-18 ON THE LISSAJOUS AND HALO ORBITS IN THE RESTRICTED THREE BODY PROBLEM WITH OBLATE PRIMARIES

Ram Kishor, kishor_math@curaj.ac.in

Central University of Rajasthan, Kishangarh, Ajmer, India, Kishangarh, India

We compute Lissajous and Halo orbits in the neighbourhood of collinear Lagrangian points L1 and L2 of the spatial circular restricted three body problem under the frame of Sun-Earth system, by using Lindstedt-Poincare method. We consider both the primaries as oblate spheroid. We analyse the effect of oblateness on the orbits (Lissajous and Halo) and it is found that oblateness has a considerable impact on the motion of infinitesimal mass. The results are applicable to extend the study under the influence of perturbation.

Keywords: RTBP; Oblateness; Lissajous Orbit; Halo Orbits; Lindstedt Poincare Method

PSD.1-0036-18 DESIGN AND DEVELOPMENT OF COMPACT VERSIONS OF PERMANENT MAGNET HALL THRUSTERS FOR BRAZILLIAN MICROSATELLITES

Jose Leonardo Ferreira, leo@fis.unb.br Universidade de Brasília UnB, Brasilia DF, Brazil Alexandre Martins, labfisplasma@gmail.com Universidade de Brasilia, Brasília, Brazil

Universidade de Brasília UnB, Brasília, Brazil Alvaro Queiroz, labfisplasma@gmail.com Universidade de Brasília UnB, Brasília, Brazil

Electric propulsion is, nowadays, a very successful method for primary and secondary propulsion systems. It is essential for station keeping of several existing satellites and for deep space and long term missions within the solar system. Permanent magnet Hall Thrusters (PHALL) have been developed at the Plasma Physics Laboratory at the University of Brasilia since 2004, as part of a space activity program held by the Brazilian Space Agency (AEB). Now, applications of compact versions of Permanent Magnet Hall Thrusters on future Brazilian space missions are needed and foreseen for the coming years, beginning with the use of small Divergent Cusp Field Hall (DCFH) Thrusters on CUBESATS (5-10 kg, 1-5 W) and Microsatellites (50-100 kg, 10-100W). Brazilian (AEB) and German (DLR) space agencies and research centers have been developing new rockets dedicated to small satellite launching known as the VLM - Microsatellite Launch Vehicle.

One of the main advantages of PHALL thrusters is the production of a steady state magnetic field by permanent magnets providing electron trapping and Hall current generation with a significant decreased load on the electric power supply. This advantage turns the PHALL thruster into an especially good option when it comes to space usage for longer and deeper space missions, where solar panels and electric energy storage on batteries is a limiting factor. The development of more compact versions of PHALL can also be very important for the ongoing Brazilian Geostationary Satellite (SBG) program that is being currently developed by an international consortium of Brazilian and foreign space industries.

Electric propulsion is now a key feature for spacecraft exploration of small bodies in the Solar System. It has been done by several countries with increasing frequency in the past twenty years. Since their historical beginning in the sixties, most of the Solar System missions were based on gravity assisted trajectories, which depended heavily on planet orbit positioning relative to the Sun and the Earth. The consequence of such dependence was always the narrowing of the mission launch window. Nowadays, the in situ exploration of icy bodies in the Solar System requires less dependence on gravity assisted maneuvering and needs new high precision and low thrust navigation methods. The main difficulty to reach these minor bodies is related to their specific orbits with high eccentricity and inclination. A good example is the case for sample return missions to NEOs - Near Earth Objects. They are small bodies consisting of primitive leftover building blocks of the Solar System formation. Such missions can be accomplished with the usage of low thrust trajectories with spacecraft's propelled by plasma thrusters.

In this work, we will show the improvements on PHALL II working conditions in a new vacuum facility, and its important contribution to test the development of new design and more compact versions of permanent magnet Hall thrusters. PHALL III is being designed with a DCFH like model and foreseen to be used in future cubesats and on microsatellites, including possible applications in geostationary attitude control systems and on low thrust trajectory missions to the Near Earth Asteroids region. We will show a particular new permanent magnetic field design for PHALL III, together with computer simulations, using a particle-in-cell methodology that predicts thrust performance characteristics and erosion lifetime expectations for these types of thrusters. Based on the successful results that were reached with PHALL II, we believe we will be able to develop a more compact and efficient plasma thruster. This will allow not only its use on microsatellites with small size and limited electric power consumption, but also the necessary performance improvements for future Brazilian spacecrafts on long term space missions.

PSD.1-0037-18 PARTICLE IN CELL NUMERICAL SIMULATIONS OF A TWO DIMENSIONAL MODEL OF CYLINDRICAL HALL PLASMA THURSTERS WITH PERMANENT MAGNETS

Jose Leonardo Ferreira, leo@fis.unb.br Universidade de Brasília UnB, Brasilia DF, Brazil Rodrigo Miranda, rmiranda@unb.br

University of Brasilia, 70910-900, Brazil Alexandre Martins, labfisplasma@gmail.com Universidade de Brasilia, Brasília, Brazil

The cylindrical Hall thruster (CHT) is a propulsion device that offers high propellant utilization and performance at smaller dimensions and lower power levels than traditional Hall thrusters. In this paper we present first results of a numerical model of a CHT. This model solves particle and field dynamics self-consistently using a particle-in-cell approach. We describe a number of techniques applied to reduce the execution time of the numerical simulations. The specific impulse and thrust computed from our simulations are in agreement with laboratory experiments. This simplified model will allow for a detailed analysis of different thruster operational parameters and obtain an optimal configuration to be implemented at the Plasma Physics Laboratory at the University of Brasília.

PSD.1-0038-18 PARAMETERIZATION AND DATA REDUCTION OF LUNISOLAR EPHEMERIDES

Jingshi Tang, jstang@nju.edu.cn Nanjing University, Nanjing, China Haishuo Wang, 1009185423@qq.com Nanjing University, Nanjing, China Hanyang Liu, 875716913@qq.com Nanjing University, Nanjing, China Guanshan Pu, 596693039@qq.com Nanjing University, Nanjing, China Lin Liu, lliu@nju.edu.cn

Nanjing University, Nanjing, China

Ephemerides of natural celestial bodies are needed in space missions, especially in computing the gravitations from the perturbing bodies, among which the Moon and the Sun are of great importance.

To obtain the lunisolar positions, one can use the conventional analytical formulas derived from Celestial Mechanics, which generally has a concise form but is relatively poor in accuracy. Alternatively, numerical ephemeris, such as JPL DE series or the INPOP series, offers highly accurate results. However, these products are always exhaustive for all the major bodies in the Solar System and are ready to be used in the "as is" form. The excess data significantly increases the size of the ephemerides and limits its portability for on-board application even sometimes for ground applications.

The work in this paper is set in the background of orbit propagation (OP) on board the GEO satellite. Every 4 hours, the orbit is updated with solutions from precise orbit determination and onboard OP is responsible to propagate the orbit during the period. The parameters of lunisolar ephemerides are designed to be updated from ground stations every 180 days. Our job is to design proper parameterization for lunisolar ephemerides, which are to be used in onboard OP. The performance is measured by the OP accuracy within 4 hours and the data storage within 180 days.

We use two methods to re-parameterize the lunisolar ephemerides. One method involves spectrum analysis on the lunisolar orbits, which are generated with a reasonable time interval. A full ephemeris spanning approximately 180 years is first analyzed using the conventional Fourier transformation (e.g., FFT). The frequencies are handpicked based on certain rules. These frequencies, once determined, are fixed throughout all 180-day intervals. The amplitudes and phases are fitted for each interval.

The second method is more straightforward, in terms that the raw ephemeris files are directly processed. Excess data are removed from the original files and only the lunisolar parameters are retained. Numerical ephemerides are fitted with Chebyshev polynomials, with carefully designed polynomial order and fitting span. By adjusting these two arguments, we manage to further reduce the parameter size, at the cost of reasonably lower accuracy.

These data reduction strategies are tested individually, regarding fitting accuracy and consistency between different numerical ephemerides. They are also tested in the orbit propagation to find out the impact of the reduced lunisolar ephemerides on the accuracy of the propagated orbits.

PSD.1-0039-18 PRELIMINARY GRAVITY STUDIES FOR A PHOBOS QSO MISSION

Jean-Charles Marty, jean-charles.marty@cnes.fr CNES/GRGS, TOULOUSE, France

Julien LAURENT-VARIN, julien.laurent-varin@cnes.fr CNES/GRGS, TOULOUSE, France

The ambitious MMX mission, lead by JAXA (Japan Aerospace Exploration Agency), aims to study the moons of Mars Phobos and Deimos. One major objective is to return a sample from the surface of Phobos. CNES is involved in some preliminary studies, especially for mission analysis and trajectory design. Phobos has a particular gravity environment, and trajectories around this moon are strongly curved by the proximity of Mars. Therefore, trajectory design is done in a specific rotating frame with the three bodies formalism, which leads to QSO (Quasi Satellite Orbit) for the probe. These results were presented in [R1]. Landing the probe requires accurate knowledge of the gravity. The accuracy one can reach with the different options of trajectory will be presented. The presentation is dedicated to investigate the accuracy of gravity field restitution that can be achieved for 9 candidate orbits (2D or 3D, with various distances to Phobos). A synthetic gravity field deduced from its shape is used in the simulation. Different hypotheses on Doppler (DSN) type and Laser altimetry measurement are tested. The second part of the presentation will propose a strategy for gravity field modeling consistently with a preliminary mission schedule approach. [R1] Elisabet Canalias, Laurence Lorda, and Julien Laurent-Varin. "Design of realistic trajectories for the exploration of Phobos", 2018 Space Flight Mechanics Meeting, AIAA SciTech Forum, (AIAA 2018-0716)

PSD.1-0040-18 ANALYTICAL AND SEMI-ANALYTICAL STUDIES OF DYNAMICAL EVOLUTION OF RETROGRADE GEOSYNCHRONOUS ORBITS

Ming-Jiang Zhang, mjzhang@pmo.ac.cn

Purple Mountain Observatory, Chinese Academy of Sciences, Nanjing, China Chang Yin Zhao, cyzhao@pmo.ac.cn

Purple Mountain Observatory, Chinese Academy of Sciences, China

Although retrograde geosynchronous orbits are not employed for the launched satellites currently, the concept of retrograde geosynchronous orbit is known long ago. It is possible that the retrograde geosynchronous orbits may be employed in some missions in the future. Dynamical evolution of retrograde geosynchronous orbits is studied through theoretical analysis and semi-analytical calculations in this paper. Based on the reasonable and simplified perturbation model, long-term evolution of orbital plane of retrograde geosynchronous orbits is particularly analyzed. The dynamical characteristics of orbital plane evolution are presented, which are markedly different from those of prograde geosynchronous orbits. In accordance with the dynamical characteristic of orbital plane evolution, the theoretical variation range and period of orbital inclination are further derived. Based on the averaged perturbation model, a series of semi-analytical calculations are carried out to discuss the effects of orbital parameters on the long-term dynamical evolution of retrograde geosynchronous orbits, and some conclusions are summarized. The reliability of the results derived from theoretical analysis and semi-analytical calculations is validated by numerical calculations with precise perturbation model finally. Moreover, the subtrack of an object in the retrograde geosynchronous orbit is also plotted through numerical calculation.

PSD.1-0041-18 NONLINEAR FILTERING FOR SEQUENTIAL SPACECRAFT ATTITUDE ESTIMATION WITH REAL DATA: CUBATURE KALMAN FILTER, UNSCENTED KALMAN FILTER AND EXTENDED KALMAN FILTER.

Roberta Veloso Garcia, robertagarcia@usp.br Universidade de Sao Paulo, Lorena, Brazil Paula C P M Pardal, paulapardal@usp.br University of Sao Paulo, Lorena, Brazil

Helio Koiti Kuga, helio.kuga@inpe.br

National Institute for Space Research (INPE), SAO JOSE DOS CAMPOS, Brazil

The purpose of this work is to analyze the performance of the Cubature Kalman Filter, Unscented Kalman Filter and Extended Kalman Filter estimators in the attitude estimation problem when submitted to real attitude sensors data. The Extended Kalman Filter (EKF) is the most used nonlinear filtering algorithm for the attitude estimation in real time. The EKF is the nonlinear version of the Kalman Filter which linearizes about an estimate of the current mean and covariance. However, when the filter is subjected to poor conditions, the linearization of the system may not be efficient and lead to an estimation of low accuracy and divergence of the filter. The Unscented Kalman Filter (UKF) is an algorithm that was developed in order to avoid the linearizations required by the EKF. Basically, the UKF uses a set of points chosen deterministically, called "sigma-points", to capture the probability distribution and generalizes to nonlinear system without the burdensome analytic derivation as in the EKF. More recently, the Cubature Kalman Filter (CKF) was proposed as an alternative estimation algorithm for general nonlinear systems. The CKF, which builds on the numerical-integration perspective of Gaussian filters, employs a third-degree spherical-radical cubature rule to compute Gaussianweighted integrals, derivative-free nonlinear filtering algorithm with improved performance over the UKF in terms of estimation accuracy, numerical stability and computational costs. In this work, the application uses the real measurement data for orbit and attitude of the CBERS-2 (China Brazil Earth Resources Satellite) satellite. The attitude dynamical model is described by nonlinear equations involving the Euler angles. The attitude sensors available are two DSS (Digital Sun Sensors), two IRES (Infra-Red Earth Sensor), and one triad of mechanical gyros. The analyzes are based on the robustness of the filter, in relation to the precision, computational cost and convergence speed in attitude estimation. As the use of real data makes it impossible to compare the estimated results with the real attitude of the satellite, then the results obtained via EKF are taken as reference for comparison with the UKF and CKF. The results in this work show that, for the case studied in this article, the filters are very competitive and present advantages and disadvantages that should be evaluated according to the need of each problem.

PSD.1-0042-18 MULTI-OBJECTIVE TRAJECTORY OPTIMIZATION FOR THE SPACE EXPLORATION VEHICLE

Xiaoli Qin, 37650788@qq.com

China Academy of Launch Vehicle Technology, BEIJING, China

The research determines temperature-constrained optimal trajectory for the space exploration vehicle by developing an optimal control formulation and solving it using a variable order quadrature collocation method with a Non-Linear Programming (NLP) solver. The vehicle is assumed to be the space reconnaissance aircraft that has specified takeoff/landing locations, specified no-fly zones, and specified targets for sensor data collections.

Vehicle control is accomplished by controlling angle of attack, roll angle, and propellant mass flow rate. This dynamics model is incorporated into an optimal control formulation that includes constraints on both the vehicle and mission parameter, such as avoidance of no-fly zones and exploration of space targets.

In addition, the vehicles models include the environmental models (gravity and atmosphere). How these models are appropriately employed is key to gaining confidence in the results and conclusions of the research. Trajectory optimization techniques have been developed steadily with the advances in optimal control and numerical computations. Optimal trajectories are developed using several performance costs in the optimal control formation, minimum time, minimum time with control penalties, and maximum distance. The resulting analysis demonstrates that optimal trajectories that meet specified mission parameters and constraints can be quickly determined and used for large-scale space exploration.

PSW.1-0001-18 FORECAST VERIFICATION ACTIVITY IN RWC JAPAN

Yuki Kubo, kubo@nict.go.jp

National Institute of Information and Communications Technology, Tokyo, Japan

A need of space weather forecast information is getting bigger and bigger. Many organizations in the world have issued the forecast information. However, the forecast information alone is not enough for users because the users cannot know the accuracy of the forecast. The forecast will be valuable information when issued together with verification information. Therefore, Regional warning center Japan (RWC Japan) have performed forecast verifications for issued forecast with long history. As the RWC Japan's forecasts are deterministic forecasts of various kinds of space weather parameters, we have already performed verification study of deterministic forecast on solar flares and geomagnetic disturbances. Recently, many probabilistic forecast models have developed around the world. As a probabilistic forecast may be more useful for users than deterministic one, a probabilistic forecast is recent trend. Therefore, we have also investigated verification techniques of probabilistic forecast. In this presentation, I will briefly present recent forecast verification activities performed in RWC Japan.

PSW.1-0002-18 VERIFICATION OF MET OFFICE SPACE WEATHER OPERATION CENTRE FORECASTS

Suzy Bingham, suzy.bingham@metoffice.gov.uk UK Met Office, Exeter, United Kingdom

Trinity College Dublin, Dublin, Ireland

M. Leila Mays, m.leila.mays@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States

The Met Office Space Weather Operations Centre (MOSWOC) has provided a 24/7 service to a range of government and commercial users in the UK since 2014. Forecasters produce timely alerts and warnings, along with space weather guidance issued at midnight and midday. The space weather forecasts disseminated by MOSWOC include solar flare and geomagnetic storm forecasts out to 4-days ahead. Terrestrial weather verification systems, originally developed for example to verify shipping forecasts, have been adapted to verify solar flare and geomagnetic storm forecasts. An overview of these adapted verification systems and preliminary results will be presented. Adaptation of the flare verification system to verify the NASA CCMC Flare Scoreboard will also be discussed; challenges in implementing the system for non-standardised forecasts will be outlined.

PSW.1-0003-18 SSA SWE NETWORK USER TEST CAMPAIGNS: VALIDATING SSA SPACE WEATHER PROTOTYPE SERVICE PERFORMANCE TOGETHER WITH END USERS

Sophie Chabanski, sophie.chabanski@aeronomie.be

Royal Belgian Institute for Space Aeronomy, Brussels, Belgium Erwin De Donder, erwin.dedonder@aeronomie.be

Belgian Institute for Space Aeronomy, Brussels, Belgium Jesse Andries, jesse.andries@oma.be

Royal Observatory of Belgium / Solar Terrestrial Center of Excellence, Brussels, Belgium Chris Perry, chris.perry@stfc.ac.uk

Rutherford Appleton Laboratory, Oxford, United Kingdom

In this presentation we summarize the preparation, execution, results and conclusions of user test campaigns run by the SSA Space Weather Coordination Centre (SSCC) for validating and improving the products and services of the SSA Space Weather Service Network.

In the frame of the Space Weather (SWE) Segment of its Space Situational Awareness (SSA) programme, the European Space Agency (ESA) is developing the SSA Space Weather Service Network which now provides access to 21 prototype end-user driven services through its SWE Portal (http://swe.ssa.esa.int/). These services are built upon a pool of around 150 products provided to the Network by 40 Expert Groups who themselves are organised into five expert service centres: Solar Weather, Heliospheric Weather, Space Radiation, Ionospheric Weather and Geomagnetic conditions. The Network also includes a Data Centre and the SSA Space Weather Coordination Centre (SSCC) located at the Space Pole in Brussels which provides first line end-user support via the SWE Service Helpdesk and overall service availability monitoring.

The SWE services are distributed over eight different service domains: Spacecraft Design, Spacecraft Operation, Human Space Flight, Trans-ionospheric Radio Link, Space Surveillance Tracking, Non-space System Operation, and General Data Services.

To demonstrate and validate the services and gain further insight into end users' needs, the SSA Space Weather Coordination Centre (SSCC) has run a number of dedicated user test campaigns in

specific high priority domains such as Spacecraft Operations, Aviation and GNSS services. The results of these campaigns are then analysed and the resulting recommendations utilised by ESA in the context of future service improvements.

After a brief description of the context and organisation of the test user campaigns, this presentation will give examples of the resulting tailored SWE bulletins and describe some of the key findings from these campaigns.

PSW.1-0004-18 QUANTIFYING MODEL PERFORMANCE FOR SPACE WEATHER

Steven Morley, smorley@lanl.gov

Los Alamos National Laboratory, Los Alamos, New Mexico, United States Daniel Welling, dwelling@umich.edu

University of Michigan, Ann Arbor, Michigan, United States

Approaches to quantifying model performance vary widely across the space weather domain. Model validation activities can be computationally expensive and need to be targeted at specific model outputs. Any given model may be able to predict multiple quantities of interest to different levels of fidelity, and key performance indicators will be required for each predictand. Accuracy and bias metrics are required for understanding how close the predictions are to observation, while skill metrics are required to describe relative performance and track improvements in model performance. The uncertainty on a prediction is also important and can be challenging to assess. Prediction of continuous quantities brings a different set of challenges than the prediction of discrete events, yet both are required across the space weather domain. We will present a discussion of understanding and quantifying different aspects of model performance, including uncertainty quantification, illustrated by examples using both operational models and models at a lower readiness level.

PSW.1-0005-18 USING SATELLITE IMPACTS TO INFORM SPACE WEATHER SENSOR AND MODEL REQUIREMENTS

Paul O'Brien, paul.obrien@aero.org

The Aerospace Corporation, Houson, Texas, United States

In situ sensors and environment models can provide valuable space weather information to satellite situational awareness and anomaly resolution. We examine how the nature and uncertainty of different kinds of environmental information lead to successful or unsuccessful assessment of the space weather hazard during satellite anomalies. Starting from impacts on high altitude spacecraft, we develop simple statistical models of anomaly hazard as a function of environmental parameters. We then demonstrate how the outputs of those hazard models are affected by nature and uncertainty of the parameters provided by an environmental sensor or model. This allows us to understand the accuracy and performance requirements for space weather sensors and models that provide those environmental parameters.

PSW.1-0006-18 FROM RESEARCH TO OPERATIONS: HOW THE OPERATIONAL COMMUNITY INFLUENCED THE DEVELOPMENT OF THE WSA MODEL

Charles Arge, charles.n.arge@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States

The Wang-Sheeley-Arge (WSA) model began as basic research model first developed by Yi- Ming Wang and Neil Sheeley at the Naval Research Laboratory back in the late 1980s. In the early 1990s the model became capable of predicting solar wind speed at Earth, and a major push was then made to further develop and operationalize it at NOAA starting in 1996. Fifteen years later the coronal portion of the WSA model was fully coupled to the advanced Enlil solar wind model forming the hybrid WSA-Enlil model. It was transitioned to operations at the National Weather Service's National Centers for Environmental Prediction in 2011. The transformation of the basic Wang-Sheeley research model to today's operational WSA-Enlil model resulted from the frequent interplay between the operational communities and model developers. In this talk I focus on the development of the WSA model and how operational needs and feedback from forecasters helped transform the model into the basic research and applied space weather model it is today.

An operational solar wind prediction system is presented. The system is an outcome of the collaborative efforts of scientists from the research community and forecasters from a space environmental operation center in China. This system is mainly composed of three modules: (1) a photospheric magnetic field extrapolation module, along with a Wang-Sheeley-Arge (WSA) empirical method, to obtain the background solar wind speed and the magnetic field strength on the source surface, (2) a modified Hakamada-Akasofu-Fry (HAF) kinematic module for simulating the propagation of solar wind structures in the interplanetary space, and (3) a module for coronal mass ejection (CME) detection and parameter derivation using the ice-cream cone model based on coronagraph images. By bridging the gap between fundamental science and operational requirements, this system is finally capable of predicting solar wind conditions near Earth, especially the arrival times of the co-rotating interaction regions (CIRs) and CMEs, which are major triggers for geospace environmental disturbances such as geomagnetic storms. The research to operation (R2O) effort reveals that the capability of operational space weather services can be significantly improved through collaboration between science and operation communities. It is also learned that in the R2O process, sustainable interactions between forecasters and research scientists are needed, to adjust the model parameters and to determine the best running scheme of the system through performance verification.

PSW.1-0008-18 SWIFT-FORECAST: PHYSICS-BASED FORECASTS THE SOLAR WIND IN REAL TIME

Rui Pinto, rui.pinto@irap.omp.eu

IRAP - Institute of Research in Astrophysics and Planetology, Toulouse, France Alexis Rouillard, alexis.rouillard@irap.omp.eu

IRAP/CNRS, Toulouce Cedex 4, France Vincent Genot, vincent.genot@irap.omp.eu

IRAP, University of Toulouse / CNRS, Toulouse, France

We present a new real-time solar wind forecasting pipeline named SWiFT (Solar Wind FluxTube)-FORECAST developed at IRAP. SWiFT is meant to perform quick and robust simulations (forward modelling) of the whole chain of processes that determine the state of the solar wind from the surface of the Sun to the helipshere. The pipeline couples a series of modules derived from mature research models: determination of the background coronal magnetic field, computation of many individual solar wind acceleration profiles (1 to 30 solar radii), propagation across the heliosphere and formation of CIRs (up to 1 AU or more), estimation of synthetic diagnostics (white-light COR/HI and EUV imaging, in-situ time-series) and comparison to observations and spacecraft measurements. The multiple flux-tube approach allows for very significant gains in computation time in respect to the full 3D MHD problem. SWiFT currently uses a combination of existing surface magnetograms and PFSS extrapolations but the interface is ready to include different combinations of magnotograms sources (WSO, SOLIS, GONG), flux-transport and data assimilation techniques (ADAPT), coronal field reconstruction methods (NLFFF, Solar Models), wind models (MULTI-VP), and heliospheric propagation models (CDPP/AMDA 1D MHD, ENLIL, EUHFORIA). I will discuss an implementation of this modeling chain that is able provide continuously a full set of bulk physical parameters (wind speed, density, temperature, magnetic field, phase speeds) of the solar wind based solely on physical principles up to 6-7 days in advance, and at a time cadence and a forecast compatible with space weather applications. The method benefits from multi-point observations and in-situ measurements and can use several intermediate control points for calibration and forecast validation. This is work is supported by the CNES.

PSW.1-0009-18 PERFORMANCE ANALYSIS OF GEOMAGNETIC STORM FORECASTING SERVICE STORMFOCUS

Tatiana Podladchikova, t.podladchikova@skoltech.ru

The Skolkovo Institute of Science and Technology, Skolkovo, Russia Anatoli Petrukovich, apetruko@iki.rssi.ru

Space Research Institute (IKI), Russian Academy of Sciences, Moscow, Russia Yuri Yermolaev, yermol@iki.rssi.ru

Space Research Institute, Moscow, Russia

Operational forecasting of geomagnetic storms is of great importance for many space weather applications. A new online geomagnetic storm forecasting service StormFocus was implemented in 2011 at SpaceWeather.Ru. StormFocus provides the warnings on the expected geomagnetic storm magnitude for the next several hours on an hourly basis using L1 solar wind and IMF measurements. In this study we present the performance analysis of StormFocus over the years of real-time operation and verification of the prediction algorithm. We also analyze the sources of prediction errors and identify the errors that can be fixed by improving the prediction algorithm and those that cannot be removed in real-time. This source of error is related with the missing data and the calibration-related differences between the real-time and the final data. These latter errors are often not recognized, but actually account for a significant part of the forecast uncertainty. StormFocus provided the successful real-time forecast of 87% storms, while the reanalysis running on final OMNI data predicted successfully 97% of storms. The prediction of the actual final peak Dst using the real-time input was provided successfully for 90% of storms, that proves the practical usefulness of the real-time forecast. These results confirm the general reliability of StormFocus service to provide the advance warnings of geomagnetic storm strength and space weather conditions in the near-Earth environment in real-time.

During space weather events, geomagnetically induced currents (GIC) can be induced in high voltage transmission networks, damaging individual transformers within substations. One of the risks to power systems is transformer failure, and hence it seems reasonable to consider transformers individually in modelling. However, a common approach to modelling a transmission network has been to assume that every substation can be represented by a single resistance to Earth. We have extended that model by building a transformer-level network representation of New Zealand's South Island transmission network. Our modelling makes use of Transpower

New Zealand provided values of resistances for transmission lines, transformers, and earth ground connections. Using this transformer-level network representation significantly changes the GIC hazard assessment, compared to assessments based on a substation-level assumption. These transformer-level GIC calculations show variation in GIC between transformers within a substation due to transformer characteristics and connections. The transformer-level GIC calculations alter the hazard assessment (in terms of peak GIC amplitude) by up to an order of magnitude at some locations.

New Zealand is unusual, in that we have access to an unusually long and spatially detailed set of Geomagnetically Induced Current (GIC) measurements. Near continuous archived DC current data exist since 2001, starting with 12 different substations, expanding over time to presently include about 20 different substations. There are large numbers of examples where multiple different transformers have been monitored in the same substation. These GIC observations show that different transformers in the same substation can have very different peak GIC during the same geomagnetic storm, confirming the need for this transformer-level detail.

In addition, we will present initial results of validating the modelled GIC against observations for a given geomagnetic storm (St Patricks Day 2015). This validation analysis will include an examination of the sensitivity of the modelled results to different areas of uncertainty, in particular the geomagnetic field changes, ground electrical conductivity and structure, and network properties.

PSW.1-0011-18 FORECAST VERIFICATION IN THE FRAMEWORK OF THE EU FLARECAST PROJECT

Manolis K. Georgoulis, manolis.georgoulis@academyofathens.gr Academy of Athens, Athens, Greece

Shaun Bloomfield, shaun.bloomfield@northumbria.ac.uk University of Northumbria, Newcastle, United Kingdom Mark Worsfold, mark.worsfold@metoffice.gov.uk

Anna Maria Massone, annamaria.massone@cnr.it CNR-SPIN, Genova, Italy

Michele Piana, piana@dima.unige.it Università di Genova, Genova, Italy Cristina Campi, campi@dima.unige.it CNR-SPIN, Genova, Italy

Federico Benvenuto, benvenuto@dima.unige.it Università di Genova, Genova, Italy Konstantinos Florios, cflorios@aueb.gr Academy of Athens, Athens, Greece

We describe the main practices and results of the comprehensive forecast verification effort undertaken in the framework of the EU FLARECAST project for solar flare prediction. In discussing FLARECAST, we compare between previous verification efforts of solar flare forecasting products or services and the potential advances brought by the FLARECAST project, that served as a uniform platform for testing numerous and diverse flare forecasting meth- ods. Results shown include major skill score values and extensive ranking of flare-predictive parameters. We further advocate for a robust error assessment of the scores and parameters involved in the verification process, that would provide the basis of a much-needed, continuous assessment of solar flare forecasting capabilities. In concluding, we list the discussion areas and recommendations addressed by the COSPAR - ILWS Roadmap, indicating the locations where the FLARECAST project has been contributing and providing feedback, potentially enabling further advances in the verification of forecasting activities of solar and heliospheric weather.

This work has received support by the EU Horizon-2020 FLARECAST project (grant agreement no. 640216).

PSW.1-0012-18 DEFINING METRICS AND TRACKING PROGRESS FOR PREDICTING CME ARRIVAL AND PARAMETERS AT L1: HIGHLIGHTS FROM THE INTERNATIONAL FORUM ON SPACE WEATHER CAPABILITIES ASSESSMENT

The Coronal Mass Ejection (CME) arrival time and impact working team has made efforts over the past year to decide upon a set of metrics with regard to the modelling and prediction of CMEs in order to quantify and track progress. Both user and science needs are taking into account when defining these metrics. This working team is part of the CCMC-led community-wide international forum for space weather modeling capabilities assessment including a workshop in April 2017. Our team focuses on the assessment of how successfully different models and techniques can predict CME arrival time and impact. After open communication with the scientific and user community, we have established a set of metrics for the quantification of the model performance. Current and future models have and will be tested for their CME arrival time and impact forecasting capabilities, based on these metrics and a selected set of events. The event set consists of a variety of different types such as false alarms, hits, and misses. We present here the current status of the CME arrival time and impact team.

The international forum on space weather capabilities assessment aims to quantify scientific progress in the area of space weather. More specifically it aims to deliver a framework for the application of metrics in order to measure performance/progress of space weather modelling and to construct a library of metric and validation techniques which may be used thereby harmonizing comparisons and validations which are made. One of the working groups acting under this umbrella focusses on space plasma and radiation environments and effects.

In this domain there are clearly established standards for defining an environment which spacecraft must survive. Each major agency has its own standards which drive requirements. This is less mature in the domain of commercial aviation. The aim of the working group is to connect the space weather modelling community with experts on environment specification in order to define environmental quantities (scientific predictands) which are representative of the environment driving an effect thus addressing user needs. The effects covered by the working group include surface charging, internal charging, total (ionizing and non-ionizing) dose, single event effects and effects on aircraft. In addition to the scientific (or environmental) predictand an associated effect quantity (and associated timescale) is defined for which tools are readily available to transform quantities from the environment to the effect. Finally, a set of statistical metrics are defined to evaluated the accuracy of model outputs.

The acceptance of quantities will simplify to task of space weather modelers in validating their model and provide an objective comparison between models to show which are more reliable for a given effect over a given timescale. This talk presents the progress of the working group thus far to define concrete quantities which shall constitute space weather metrics in this domain.

PSW.1-0014-18 DEFINING METRICS AND TRACKING PROGRESS FOR GEOMAGNETIC ENVIRONMENT MODELING: HIGHLIGHTS FROM THE INTERNATIONAL FORUM ON SPACE WEATHER CAPABILITIES ASSESSMENT

Daniel Welling, dantwelling@gmail.com

University of Michigan, Ann Arbor, Michigan, United States

The International Forum for Space Weather Capabilities Assessment workshop, held in April of 2017, brought together representatives from across the space modeling community to discuss how to improve systematic validation of our existing models. Working teams formed to focus on specific tasks and regions of interest. Working team members met before, during, and after to Гassess current validation practices, identify needs, and define goals for improving community standards. The ongoing efforts are reported at the Community Coordinated Modeling Center's website and in a special collection in AGU's Space Weather journal.

This talk highlights some of work performed by the International Forum's working teams. Focus is placed on the dB/dt metrics working team, which was tasked with updating standards previously used to select models for transition to operations. Early results from applying new standards on output from the Space Weather Modeling Framework are shown.

PSW.1-0015-18 DEFINING METRICS AND TRACKING PROGRESS FOR IONOSPHERE DISTURBANCES MODELING: HIGHLIGHTS FROM THE INTERNATIONAL FORUM ON SPACE WEATHER CAPABILITIES ASSESSMENT

Ioanna Tsagouri, tsagouri@noa.gr

CUA/NASA GSFC, Greenbelt, Maryland, United States Maria Kuznetsova, maria.m.kuznetsova@nasa.gov

NASA Goddard Space Flight Center/Heliophysics Science Division, Greenbelt, Maryland, United States

The ionospheric prediction models are relevant to a variety of needs. These include the reliable performance of critical engineering systems that operate within or through the ionosphere (e.g. satellite and ground based communication and geolocation applications), as well as scientific challenges in geospace investigations. Since both, the operational needs and our scientific understanding change dynamically with time, the systematic assessment of the performance of new and/or improved models and tracking of progress over time are essential requirements for both the establishment of our knowledge and the effective transition of the scientific achievements to reliable operational services. In this framework, the Ionosphere team was formed within the International Forum Space Weather Modeling Capabilities Assessment (https://ccmc.gsfc.nasa.gov/assessment/) to help the efforts on the assessment of ionospheric prediction capabilities with special emphasis in the ionospheric disturbances. Disturbances into consideration apply to the total electron content (TEC), the F2-layer characteristics (e.g. the peak electron density NmF2 or the critical frequency foF2 and the height of the peak electron density, hmF2), as well as to ionospheric scintillation. The team aims at establishing community agreed metrics that address specific user needs and the evaluation of existing ionospheric modeling capabilities based on the selected metrics in order to provide a benchmark against which new models can be assessed. The work plan is established on experiments performed over of a number of models that assume a wide range of formulations (i.e. empirical, physics-based and data assimilation) and includes the assessment of the uncertainties that accompany datamodel comparison tests (e.g. data quality, sensitivity to models' drivers). This presentation aims to highlight the results of the team's activities as a solid basis for further developments.

PSW.1-0016-18 DEFINING METRICS AND TRACKING PROGRESS FOR THERMOSPHERE DENSITY MODELING: HIGHLIGHTS FROM THE INTERNATIONAL FORUM ON SPACE WEATHER CAPABILITIES ASSESSMENT

Sean Bruinsma, sean.bruinsma@cnes.fr

Centre National d'Etudes Spatiales, Toulouse, France

In order to track the progress over time of thermosphere models, both first principle and semi-empirical, appropriate metrics are required. Secondly, neutral density data sets of good qualities and preferably with high-spatial resolution covering long intervals of time (i.e. years, and ideally a complete solar cycle) are needed. The neutral density observations can then be used to verify model accuracy with respect to latitude-longitude-local time variations, and solar and geomagnetic activity levels and seasonal variations, respectively. Data and metrics together allow benchmarking of the models and detailed quantification of the improvement.

In this presentation, the metrics agreed upon at the International Forum on Space Weather Capabilities Assessment will be discussed. The selected data for comparison with the models, and in particular the high-resolution accelerometer-inferred densities from CHAMP-GRACEGOCE, but also daily-mean densities (because that is the unique data source at 700-900 km altitudes), will be presented and shortly reviewed. Both long periods (entire years in order to cover high-medium-low solar activity conditions) as well as short-lived storm events of a few days were selected for the comparisons. Results of semi-empirical model-data comparisons will be shown to illustrate the adopted model performance metric, which is not carved in stone. The same test data and metric will be used by CCMC in the evaluation of selected first principles models.

PSW.1-0017-18 A FRAMEWORK FOR TRACKING PROGRESS TOWARDS USABILITY: APPLICATION USABILITY LEVELS.

Leads: A. Halford, Steven Morley, Adam Kellerman, B. Thompson

As our community continues to grow and become more intertwined with industry and other fields, there is a need for a framework that can allow researchers and end users to identify applications for the research, quantify metrics for each specific application, and enable communication between the researchers and end users. To this end, the Assessment of Understanding and Quantifying Progress International Forum for Space Weather Capabilities Assessment working group has developed the Application Usability Level (AUL) framework. The AUL framework was developed by implementing lessons learned from Technology Readiness Levels (TRLs) used by the instrument community and Application Readiness Levels (ARLs) used by the Applied Science program in NASA's Earth Science Division, as well as modifying the levels and their milestones to better suit the needs of the Space Weather and Heliophysics communities. In this talk we will introduce the AUL framework and show examples of how it can be applied to research for the Space Weather and Heliophysics communities. For more information on the AULs and other work being done by the Assessment of Understanding and Quantifying Progress International Forum for Space Weather Capabilities Assessment working group, please see our website at the CCMC https://ccmc.gsfc.nasa.gov/assessment/topics/trackprogress.php

PSW.1-0018-18 TOWARDS COMMON VALIDATION AND VERIFICATION PROCEDURES IN THE ONGOING SSA SPACE WEATHER SERVICE NETWORK

Claudia Borries, claudia.borries@dlr.de

Manolis K. Georgoulis, manolis.georgoulis@academyofathens.gr Academy of Athens, Athens, Greece

In the framework of the Space Situational Awareness Programme (SSA) of the European Space Agency (ESA), the Space WEather (SWE) segment aims to help end-users in a wide range of SWE affected sectors to mitigate the effects on their systems, reducing costs and improving reliability. In the SWE segment, five Expert Service Centres (ESCs), the SSA Space Weather Coordination Centre (SSCC) and the SSA Space Weather Data Centre (SWE-DC) form the SSA SWE network. This network is providing SWE services to users dependent on space weather conditions. The SWE services are composed of an extensive number of products provided by numerous contributing expert groups. Each product is delivered to the SSA SWE network with a full package of documentation and user guidance. This includes results of validation and verification procedures helping the end-user to identify the appropriate products for each application. The currently diverse procedures for product validation and verification hamper the comparison and evaluation of different products. Therefore, the SWE network aims to harmonize these procedures. Here, an overview of the ESCs product validation assessment and planning for the current activity will be given, including examples of best practice and approaches for common validation and verification procedures.

PSW.1-0019-18 TERRESTRIAL WEATHER FORECAST VERIFICATION: METHODS AND TOOLS RELEVANT FOR SPACE WEATHER

Tara Jensen, jensen@ucar.edu

National Center for Atmospheric Research, Boulder, Colorado, United States Barbara Brown, bgb@ucar.edu

National Center for Atmospheric Research, Boulder, Colorado, United States John Halley Gotway, johnhg@ucar.edu

National Center for Atmospheric Research, Boulder, United States Tressa Fowler, tressa@ucar.edu

National Center for Atmospheric Research, Boulder, Colorado, United States Randy Bullock, bullock@ucar.edu

National Center for Atmospheric Research, Boulder, Colorado, United States

Verification and validation activities are critical for the success of modelling and prediction efforts at organizations around the world, including the National Oceanic and Atmospheric Administration (NOAA) and the National Aeronautics and Space Administration (NASA) in the U.S., the European Center for Medium Range Weather Forecasts (ECMWF), the Met Office in the United Kingdom, and others across the globe. Over many decades, methods have been developed, tested and applied to evaluate terrestrial forecasts and to track their performance over time. Because different methods are required for different types of forecasts, and users have different requirements for verification information, the methods cover a broad spectrum of tools and approaches. For example, categorical methods are used to evaluate event-based forecasts and probabilistic methods are used for ensemble and probability forecasts. A wide variety of display and summary approaches - including line graphs, box plots, reliability diagrams, performance diagrams, and score cards - are used to track and compare performance across time, model, and region. Advanced spatial methods developed and applied in recent years provide enhanced information about forecast performance beyond point-by-point comparisons.

More recently, comprehensive community tools have been developed and applied to provide consistent evaluations and to track terrestrial forecast performance. In particular, the Model Evaluation Tools (MET) developed at NCAR is being applied under the auspices of the U.S.'s Next Generation Global Prediction System (NGGPS) program to create an advanced unified terrestrial verification system (MET+). The MET+ system consists of several components, including a C++/Fortran code-base (MET), for the computation of verification statistics based on gridded forecasts and either a gridded analysis or point-based observations. The system also incorporates a database and display system (METViewer) for aggregating statistics and plotting graphical results. These tools are designed to be highly flexible to allow

for quick adaption to meet additional evaluation and diagnostic needs. A suite of python wrappers have been implemented to facilitate a quick set-up and implementation of the system, and to enhance the pre-existing plotting capabilities.

It is envisioned that this effort will expand to development of a unified verification system that will encompass a variety of spatial scales and provide a basis for evaluation of individual earth system component models (including atmosphere, atmospheric composition, land, ocean, ice and waves) and of the entire earth system model including coupling among system components and the evaluation of critical space weather fields and forecast products. This presentation will provide an overview of the current state-of-the-art in terrestrial forecast verification and the MET+ unified verification system, and will highlight how the system might be used within the space weather community. Some of the challenges associated with realizing this ambitious goal will also be considered.

PSW.1-0020-18 PSW1 DISCUSSION: COORDINATED SPACE WEATHER VALIDATION AND VERIFICATION ACTIVITIES: PROGRESS AND NEXT STEPS

Alexi Glover, alexi.glover@esa.int

European Space Agency, Darmstadt, Germany Maria Kuznetsova, maria.m.kuznetsova@nasa.gov

NASA Goddard Space Flight Center/Heliophysics Science Division, Greenbelt, Maryland, United States

The COSPAR-ILWS Roadmap made several recommendations in the area of verification and validation. These were framed in terms of teaming different communities active in space weather towards ensuring a coordinated collaborative environment leading to improved capability. Specific recommendations included the development of standard data and product metrics, ensuring harmonised access to data and model archives for the purposes of validation and definition of datasets needed to test models and forecast systems. This discussion will address progress made in these areas since the publication of the roadmap and consider what next steps could be supported within the framework of COSPAR's Panel on Space Weather. This discussion slot will build on the presentations given earlier in the event. All PSW1 presenters and interested panel participants are encouraged to participate in the discussion. The results of this discussion will be summarised and presented as part of PSW5: Space Weather Initiatives and Coordinated International Efforts to Implement the COSPAR-ILWS Roadmap Recommendations.

The high-energy protons from solar energetic particle (SEP) events present hazard to space systems: damage to science instruments/electronics/materials or to astronauts. A reliable estimate of the high-energy proton environment is critical to assure the mission success. Important characteristics of an SEP event are fluence, peak flux, energy spectrum, and time to reach the peak flux after an event starts. All of these characteristics are important to understand in order to design space missions properly whether it is a robotic mission or a human mission. For example, an estimate of the mission fluence spectrum from SEPs is needed to design the spacecraft shielding to ensure that the system survives the total mission fluence environment; the peak flux information is used to estimate single event effects to electronics devices. Another example may be that the knowledge of the time to reach the peak

flux could be used to provide an advanced warning to astronauts during an extravehicular activity (EVA) to take a shelter from an incoming SEP event. Because of unpredictable and sporadic nature of SPEs, statistical models are often used to represent the SEP parameters described above. For example, Feynman and her colleagues (Feynman et al., 1993; Feynman et al., 2002) used a log-normal distribution and Xapsos (Xapsos et al., 2000) used a truncated power laws to describe the statistics of the historical SEP event fluences. In a previous study, the statistics of event fluences, durations, and time intervals between events were investigated using the then-available historical SEP dataset obtained from the instruments onboard the IMP-8 spacecraft (Jun et al., 2007). It was found that (1) the event fluences can be approximately fit to a log-normal distribution and (2) the distributions of event durations and time intervals between the events can be represented by Poisson distributions. Since then, more comprehensive SEP dataset called Reference Data Set Version 2.1 (RDSv2.1) has become available covering the SEP events up to Year 2015 under a framework of the European Space Agency's (ESA's) Solar Energetic Particle Environment Modelling (SEPEM) project (Jiggens et al., 2017). The main objectives of this paper are twofold: First, the statistics of event fluences, durations, and time intervals will be re-visited by using the RDSv2.1; Second, the statistical analyses of peak fluxes and times to reach the peak fluxes will be performed using the same dataset RDSv2.1. The results of this study will address the statistical properties of all key parameters for designing a spacecraft or a mission where the SEP environment is an important consideration.

PSW.1-0023-18 VALIDATING SPACE ENVIRONMENT MODELS USING BOTH SCIENCE AND APPLICATION METRICS: A CASE WITH SURFACE CHARGING

Yihua Zheng, yihua.zheng@nasa.gov

NASA/GSFC, GREENBELT, Maryland, United States Yiqun Yu, yiqunyu17@gmail.com

Maria Kuznetsova, maria.m.kuznetsova@nasa.gov

NASA Goddard Space Flight Center/Heliophysics Science Division, Greenbelt, Maryland, United States

To make space science and space weather models useful for application purposes, it is important to validate them using proper metrics. Working with the community, the Community Coordinated Modeling Center (CCMC) has initiated the International Forum for Space Weather Modeling Capability Assessment. The space plasma and radiation effects group stemmed from this effort has discussed and come up with a set of science and engineering metrics for several types of effects that are relevant to spacecraft and/or other space assets (https://ccmc.gsfc.nasa.gov/assessment/topics/radiation-all.php). In this presentation, initial validation results of a few models in producing surface charging effect during two events/intervals (Event 1: from 16 March to 20 March 2013; Event 2: from 31 May to 2 June 2013) will be shown. The goal of such validation effort is to be able to track model performance over time and at the same time to provide feedback and stimulate improvement of models. The two events occurred during geomagnetic time periods where the former was due to a CME and the latter was likely caused by the flank impact of a slow CME followed by a high speed stream. Therefore, different solar drivers' influence on the near-Earth region and on surface charging can be analyzed as well.

PSW.1-0024-18 ANALYTICAL REPRESENTATIONS FOR CHARACTERIZING THE GLOBAL AVIATION RADIATION ENVIRONMENT BASED ON MODEL AND MEASUREMENT DATABASES

W Kent Tobiska, ktobiska@spacenvironment.net

Space Environment Technologies, Pacific Palisades, California, United States Christopher Mertens, christopher.j.mertens@nasa.gov

NASA Langley Research Center, Hampton, Virginia, United States Yihua Zheng, yihua.zheng@nasa.gov

NASA/GSFC, GREENBELT, Maryland, United States

Two major sources of radiation hazards at commercial aviation altitudes have been known for decades and those are galactic cosmic rays (GCRs) as well as solar energetic particles (SEPs). GCRs are produced outside the solar system in high-energy explosive events and consist mostly of energetic protons slowly modulated by the strength of the Sun's interplanetary magnetic field (IMF). SEPs come from either solar coronal mass ejections (CMEs) related to flaring events or from IMF shocks. In the latter case fast CMEs plow through a slower solar wind creating a shock front to produce energetic protons. Recently, a third radiation source has been identified that originates from relativistic electron precipitation (REP) associated with the Van Allen radiation belts and have been called radiation clouds although a physical perspective is likely to be flight through a -ray beam. This ensemble radiation field creates safety concerns for aviation. In human tissues, radiation can cause atoms and molecules to become ionized, dissociated, or excited. Cell death can result from higher doses and at extremely high doses, an organ's cell population can drop so rapidly that cells cannot be replaced quickly enough resulting in the tissue failing to function normally. Epidemiological studies in occupational groups have been conducted for several decades, usually with a focus on radiation-associated cancer, and there continues to be a broad discussion in this field of study. Because of this safety hazard, a broad community is seeking to i) define the requirements for real-time monitoring of the charged particle radiation environment to protect the health and safety of crew and passengers during space weather events; ii) define the scope and requirements for a real-time reporting system that conveys situational awareness of the radiation environment to orbital, suborbital, and commercial aviation users during space weather events; and iii) develop or improve models for the real-time assessment of radiation levels at commercial flight altitudes. While benchmarks for ionizing radiation related to aviation have included characterizing an occurrence frequency of 1 in 100 years and an intensity level at the theoretical maximum for radiation events, it is also important to develop a baseline radiation environment for GCRs, SEPs, and REPs against which events can be compared. We describe functional, analytical baselines for describing the ionizing radiation environment for commercial aviation based on observations and modeling as part of the NAIRAS, ARMAS, and RADIAN programs.

PSW.1-0025-18 IMPROVEMENTS TO THE NOWCAST OF ATMOSPHERIC IONIZING RADIATION FOR AVIATION SAFETY (NAIRAS) MODEL AND COMPARISONS WITH MEASUREMENTS FROM THE RADIATION DOSIMETRY EXPERIMENT (RAD-X) FLIGHT CAMPAIGN

Christopher Mertens, christopher.j.mertens@nasa.gov

NASA Langley Research Center, Hampton, Virginia, United States

The NASA Nowcast of Atmospheric Ionizing Radiation for Aviation Safety (NAIRAS) model is a real-time, global, physics-based model for predicting exposure to cosmic radiation to air travelers from both galactic and solar sources. Tabular and graphical data products from the prototype operational NAIRAS model are available via its public web site. The transport of cosmic radiation through the atmosphere is modeled in NAIRAS using the High Charge (Z) and Energy Transport (HZETRN) code. The transport procedures in NAIRAS have been recently updated by transitioning from HZETRN version 2010 to version 2015. The most important update in HZETRN2015 for the application of the NAIRAS model is the inclusion of pion-initiated electromagnetic cascade processes. The improvements to the NAIRAS model predictions, as a result of updating to the HZETRN2015 code, are quantified by comparing to the measurements obtained from the Radiation Dosimetry Experiment (RaD-X) flight campaign. The RaD-X campaign provided high-precision measurements of dosimetric quantities at seven altitudes ranging from the lower altitudes of commercial aircraft flight levels to altitudes above the Pfotzer maximum where the contributions from cosmic ray primaries are discernable in the dosimetric quantities. These comparisons between the NARIAS model predictions and the RaD-X measurements are shown for the first time.

PSW.1-0026-18 CROSS-VALIDATION OF TEC MAP PRODUCTS FROM IGS AND ESA SWE DURING QUIET AND DISTURBED CONDITIONS

Per Hoeg, per.hoeg@fys.uio.no University of Oslo, Oslo, Norway
Tibor Durgonics, tibdu@space.dtu.dk

DTU Space, Technical University of Denmark, Kgs. Lyngby, Denmark

TEC map products and their forecasts are increasingly used for assessing space weather impacts on infrastructures in our society and in decisions, where GNSS positioning and timing are an integrated element. Within communication, aviation, maritime safety, and leisure, precise knowledge of space weather impacts plays a growing importance. This cross-validation study addresses a comparison of the ESA ESC-I TEC map products with similar IGS data products for the European sector and the globe as well. Two monthly test periods were identified from 1995, describing the evolution of geophysical phenomena for quiet and disturbed conditions. The latter where dominated by CMEs (Coronal Mass Ejections) and HHS (High Speed Streams) originating from coronal holes hitting the magnetosphere of the Earth. The exact periods for the validations are: 1) March 1st - March 31st, 2015 (primarily dominated by disturbed conditions), and 2) October 15th - November 15th, 2015 (a quiet period with shorter lived disturbance periods). The metrics of the cross-validation was based on establishing statistical values of correlation, mean, mean model error, standard deviation, bias, and skill score for TEC cell values in the ESA and IGS data products. To resolve the spatial and temporal resolution issues in the two data products (ESA and IGS), all global data were transformed into similar grid-cell resolution in latitude and longitude, using a time resolution of one hour. The longitude and latitude resolution were 5.0 x 2.5 degrees, respectively. The ESA TEC maps over Europe had a smaller grid cell-size (2 x 2 degrees) than the datasets from IGS and CODE (5 x 2.5). To reduce truncation errors and unrealistic geophysical TEC gradients, mapping the products to a uniform resolution, a 2D-surface polynomial interpolation scheme (in longitude and latitude) was applied. The ESA now-casting products had a grid cell resolution of 1 x 1 degrees. In the cross-validation the above-mentioned interpolation scheme was applied here too. Spatial resolutions were obtained through a 7th order polynomial spline to the one-hour calculated standard deviations. Results were compared to a cubic spline during periods of data gaps. Only distribution functions, representing the hourly developments in the standard deviation for each separate period (March and October/November), showing a functional relation similar to a normal distribution, were considered in the estimates. The cross-validation gave for the global data set a mean and standard deviation averaged estimate for disturbed conditions of 4.3 and 3.4 TECU, respectively. Around 2 -2.5 TECU was related to differences in background models and mapping functions, giving rise to model-driven TEC gradients. During the main phase of the observed geomagnetic storms the mean of TEC differences shows a sudden positive bias, however during calm periods this bias tends to be slightly negative. For the quiet time period the mean squared error difference amounted to 3.4 TECU with a mean squared deviation of 3.1 TECU. For the European sector the number became for the same unbiased mean squared error estimator 5.3 (disturbed) and 4.7 (quiet) TECU with smaller standard deviations (from 0.7 to 1.0 TECU). Further insight into these differences and a discussion of the causes will be given in the presentation.

PSW.1-0027-18 ASSESSING AN APPROACH TO IONOSPHERIC TOTAL ELECTRON CONTENT FORECASTING USING PHYSICS-BASED MODELS

Xing Meng, xing.meng@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States Anthony Mannucci, anthony.mannucci@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, United States Olga Verkhoglyadova, olga.verkhoglyadova@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Bruce Tsurutani, bruce.tsurutani@jpl.nasa.gov JPL, Pasadena, California, United States

A goal of space weather forecasting is to predict conditions in the upper atmosphere (ionosphere and thermosphere) based on forecasted solar wind conditions, that might be available with a few day's lead time. To explore the forecast capabilities of state-of-the-art ionospheric and thermospheric models, we conduct ionospheric simulations with three first-principles models for multiple geomagnetic storms via the Community Coordinated Modeling Center (CCMC). The models we consider are the Coupled Thermosphere Ionosphere Plasmasphere Electrodynamics Model (CTIPe), the Global Ionosphere-Thermosphere Model (GITM), and the Thermosphere Ionosphere Electrodynamics General Circulation Model (TIE-GCM). The simulations are set up such that they are driven exclusively by quantities that could be forecasted, such as solar wind parameters, as might be available from a solar wind forecast. Specifically, we drive the models with a forecasted F10.7 solar flux index based on time series regression, and calculated hemispheric power indices based on empirical relationships with solar wind data. Observed interplanetary conditions are used to drive the models, in effect assessing the models as if a perfect solar wind forecast were available. These "forecast-mode" simulations are conducted for approximately 40 representative storm events, including storms caused by high-speed solar wind streams and coronal mass ejections, storms occurring at different phases of the solar cycle, and storms with various intensities. The simulated ionospheric total electron content (TEC) is analyzed with a metric that quantifies the global and local TEC responses during storms. By comparing to the TEC responses derived from Global Positioning System observations, we assess the potential of the three ionospheric models CTIPe, GITM, and TIE-GCM to forecast upper atmosphere conditions. Our research provides insights into the model capabilities in forecasting ionospheric space weather.

PSW.1-0028-18 PREDICTION OF THE EQUATORIAL PLASMA BUBBLE USING THE LINEAR GROWTH RATE OF THE RAYLEIGH-TAYLOR INSTABILITY OBTAINED WITH GAIA

Hiroyuki Shinagawa, sinagawa@nict.go.jp

National Institute of Information and Communications Technology, Tokyo, Japan Hidekatsu Jin, jin@nict.go.jp

NiCT, Tokyo, Japan

Yasunobu Miyoshi, miyoshi@geo.kyushu-u.ac.jp Kyushu University, Fukuoka, Japan

Hitoshi Fujiwara, h_fujiwara@st.seikei.ac.jp Seikei University, Tokyo, Japan

In recent years, the prediction of the equatorial plasma bubble (EPB) has been one of the most important issues in space weather forecasting. Previous observational and theoretical stud- ies have indicated that EPBs can be generated through the Rayleigh-Taylor (R-T) instability in the ionosphere. To investigate the possibility of the EPB occurrence prediction using the R-T instability analysis, we evaluated the linear growth rates of R-T instability in the ionosphere using a whole atmosphere-ionosphere coupled model GAIA (Ground-to-topside model of Atmosphere and Ionosphere for Aeronomy). The effects of thermospheric dynamics driven by atmospheric waves propagating from below on the R-T growth rate were included in the model by incorporating meteorological reanalysis data in the region below 30 km altitude. The daily maximum R-T growth rates for the period of 2011-2013 were compared with the observed occurrence days of EPB determined by the Equatorial Atmosphere Radar (EAR) and Global Positioning System (GPS) in West Sumatra, Indonesia. We found that a high R-T growth rate tends to correspond to the actual EPB occurrence. Based on this result, we will discuss the predictability of EPB occurrences using GAIA.

PSW.1-0029-18 OPERATIONAL ANALYSIS OF THE EARTH'S RADIATION ENVIRONMENT DURING FEBRUARY 14 - MARCH 5, 2014

Internet-based system of Space Monitoring Data Center (SMDC) of Moscow State University has been developed to predict and analyze radiation conditions in the near-Earth's space. This system consists of satellite databases and operational models devoted to collect, store and process in the near-real time monitoring data. SMDC operational services acquire data from ACE, SDO, GOES, Electro-L, Meteor-M satellites and use them for forecasting, now-casting and post-casting of the radiation and geomagnetic conditions in the near-Earth's space. Period of high level solar and geomagnetic activity on 14 February - 5 March, 2014 has been considered to test and validate SMDC operational services. Solar sources of interplanetary space disturbances and their influence on geomagnetic and radiation state of the Earth's magnetosphere are described based on the data obtained from SMDC Web-based applications. Validation of the operational models developed at SMDC was performed based on the quality of description of the physical conditions in the near-Earth's space during series of events on 14 February - 5 March, 2014.

PSW.1-0030-18 WI SKILL SCORES FOR SOLAR ENERGETIC PARTICLE EVENT FORECASTS

Stephen Kahler, stephen.kahler@us.af.mil

AFRL, Kirtland AFB, New Mexico, United States

Some solar energetic particle (SEP) event forecasting tools yield binary (yes-no) forecasts of event occurrences based on defined SEP peak intensity thresholds. These tools typically take solar flare parameters and flare longitudes and latitudes as inputs and calculate SEP event parameters, such as peak intensities and onset and maximum times. When the calculated peak intensities exceed a target threshold, a SEP event is forecast; if not, no event forecast or warning is issued. The quality of the tool is evaluated using one of several skill scores, which require four kinds of predicted versus observed outcomes: (1) yes - yes (a hit), (2) yes - no (a false alarm), (3) no - yes (a missed event), and (4) no - no (a correct null). In cases (2) and (3) no account is taken of the disparity between the forecast and observed SEP intensities. Thus, for a 10 pfu (proton flux unit) at $E > 10$ MeV threshold, a forecast of 11 pfu with an event observation of 8 pfu is treated the same as a forecast of 1100 pfu with an observation of 0.8 pfu: both are false alarms and weighted the same in the skill score calculations. We introduce an alternative approach to skill scores (called WI skill scores) accounting for false alarms with observed events just below the threshold and for missed events with observed events just above the threshold. A recent data set of SEP forecasts is used to illustrate the technique.

PSW.2-0001-18 SPACE WEATHER AT MERCURY: ICME EFFECTS ON MERCURY'S MAGNETOSPHERIC BOUNDARIES AND NORTHERN CUSP REGION

Using observations from the MESSENGER spacecraft in orbit around Mercury, we conduct statistical analyses and detailed case studies of the large-scale processes in Mercury's magnetosphere during interplanetary coronal mass ejections (ICMEs). The dynamic nature of Mercury's small magnetosphere is pushed to its extremes during times of ICMEs. We study the motion of the bow shock and magnetopause boundaries, erosion of the dayside magnetosphere, the size, extent, and plasma pressure of the northern cusp region, and the plasma precipitation to the surface during extreme events. Our statistical ICME study gives us a glimpse of Mercury's average response to extreme forcing, while the case studies reveal the large variability in both the magnetospheric response and in the nature of the forcing. We find that the magnetopause is substantially compressed due to an increase in solar wind ram pressure at these times. On average during ICMEs, the subsolar stand-off distance from the center of the planet is reduced by 15% as compared with the value during nominal solar wind conditions, and the magnetopause reaches the surface of the planet 30% of the time. On the other hand, the bow shock under these conditions is located farther from the planet than for nominal solar wind conditions, because of a decrease in Alfvén Mach number during the ICME passage. The cusp is observed to extend ~10° further equatorward and 2 h wider in local time. In addition, the average plasma pressure in the cusp is more than double that determined under nominal conditions. For the most extreme cases, the particle precipitation to the surface is an order of magnitude higher than average. The solar wind ram

pressure is found to be the dominant factor controlling these cusp characteristics, with the IMF BZ direction playing a small, but likely non-negligible role.

The surface of Mars, unlike Earth, is directly exposed to Space Weather as a result of it's lack of a global magnetic field and thin atmosphere. The Radiation Assessment Detector (RAD) on the Mars Science Laboratory(MSL) has been characterizing the Space Weather environment on the surface of Mars since landing in 2012 by providing measurements of the energetic particle radiation environment due to solar flares, coronal mass ejections (CMEs), and galactic cosmic rays (GCRs).

The synoptic measurements of the energetic particle environment provided by RAD will aid heliospheric modeling of space weather over solar cycle. These observations of SEP fluxes are contributing to a solar energetic particle (SEP) event database at Mars and the Martian surface to aid prediction of Solar Particle Events (SPEs), including onset times and size predictions.

This presentation will provide an overview of the RAD investigation and present measurements of the solar flare, GCR and radiation environment on the surface of Mars, and discuss the importance of providing broad heliospheric coverage for situational awareness of space weather as we plan to send humans out into deep space and to Mars.

RAD is supported by NASA (HEOMD) under JPL subcontract 1273039 to SwRI, and by DLR in Germany under contract with Christian-Albrechts-Universitat (CAU).

PSW.2-0003-18 ACCURATE PREDICTION AND TESTING OF CME ARRIVAL AND PROPERTIES FROM SUN TO EARTH

Iver Cairns, i.cairns@physics.usyd.edu.au University of Sydney, Sydney, Australia

IPS Radio and Space Services, Sydney, Australia

Most major space weather events are due to fast CMEs and their shocks interacting with Earth's magnetosphere. Accurate prediction of CME arrival, propagation, and properties is thus vital for prediction of space weather at Earth as well as elsewhere in the solar system. In particular, it is important to accurately predict the CME velocity, shape, and evolution as functions of position and time, as well as the flow velocity and magnetic field vector in the coronal and solar wind plasma, downstream of the CME shock, and inside the CME. We report the results of simulating 4 separate CMEs from the Sun to 1 AU with the Space Weather Modelling Framework (SWMF; 2015 and 2016 versions). The simulations are set up carefully using Wilcox photospheric magnetogram data and coronagraph images and height-time data below 10 solar radii from coronagraphs. Outstanding agreement between the observations and simulations is found for the CME on 29 November 2013 that was directed primarily towards STEREO A. In particular, the CME's arrival at STEREO A, deceleration of the CME in agreement with the Gopalswamy et al. [2011] model, and the time-varying plasma and field (including Bz) agree extremely well. from upstream of the CME shock to within the CME. Similarly, the results of the simulations to the Earth-directed CMEs of 4, 6, and 7 September 2017 range from excellent to very good for the arrival time and for the 1-hour averaged density, radial speed, Bz, and magnetic field strength from the shock to well into the CME. These results provide strong evidence that we have the capability with the Space Weather Modeling Framework, when sufficiently carefully initialized, to accurately predict the properties and

evolution of CMEs and the interplanetary magnetic field and plasma from the Sun to 1 AU. This suggests that we are very close to being able to accurately predict the triggers for CME-driven space weather at Earth.

PSW.2-0004-18 PREDICTIVE REANALYSIS-DRIVEN OPERATIONAL AND VERSATILE ELECTRON RADIATION BELT MODEL

Adam Kellerman, akellerman@igpp.ucla.edu UCLA, Los Angeles, California, United States

The Earth's radiation-belt environment is a dynamic region of harmful radiation driven by a complicated competition between external and internal drivers. Understanding the recent state, and predicting the changes in the radiation environment has seen increased societal interest due to the ever increasing reliance on space-based assets for navigation, communication, and surveillance. Numerous past models have been developed to forecast fluxes at and inside of geosynchronous orbit, however they typically rely on observed particle fluence or flux observations, often integrated or averaged over a daily period. Such models, although useful, can not accurately reproduce flux observations globally, and thus are not able to provide spacecraft operators what they really require, fluence on a given trajectory, whether that be at low-Earth orbit, mid-Earth orbit, geosynchronous orbit, or a transfer between orbits, where radiation belt electrons may damage or destroy components that are not sufficiently radiation hardened.

Presented is an operational, data-assimilative, physics-based radiation belt forecast model capable of producing a recent 8-day hindcast and 2-day forecast of inner magnetospheric electron fluxes, globally, and at 1-hour temporal resolution from 100's of keV to several MeV. The model has been running in real time since February 2015. With the presented model, comes the ability to estimate daily fluence for any inner-magnetospheric satellite trajectory, and thus a significant step towards providing a monitor for safe access to space. The presentation includes a review of model performance over the past 2 years of operation, including an analysis of future directions to improve accuracy and reliability.

Skobeltsyn Institute of Nuclear Physics, MSU, Moscow, Russia

Solar wind propagation from L1 point to the Earth orbit has been realized in terms of simple convection model taking data from DSCOVR and ACE as input. Data from the two spacecraft were processed since 1st of March, 2017 and solar wind parameters measured by spacecrafts at L1 point were compared. Solar wind parameters calculated at the Earth orbit were compared to that collected in OMNI database.Subsolar distance has been calculated using Shue, Suvorov-Kuznetsova, Sibeck, Petrinek-Russel, Kalegaev-Lutov models of the magnetopause. The obtained results were compared for several quiet and disturbed periods.

PSW.2-0006-18 SYSTEMATIC ANALYSIS OF MACHINE LEARNING TECHNIQUES FOR KP PREDICTION IN THE FRAMEWORK OF THE H2020 PROJECT 'SWAMI'

GFZ German Research Centre for Geosciences, Potsdam, Germany

The Kp index is a global measure of geomagnetic activity and it represents short-term magnetic variations driven by solar particle dissipation into near Earth's space. The Kp index is used as the most important indicator for space weather alerts and serves as input to various models, such as for the thermosphere and the radiation belts. It is therefore crucial to predict the Kp index accurately. Previous works in this area have mostly employed artificial neural networks to nowcast Kp and based their inferences on the recent history of Kp and solar wind data. In this study, we systematically test how other machine learning techniques apart from neural networks perform on the task of nowcasting and forecasting Kp for longer prediction horizons up to 72 hours. Additionally, we investigate the longer time history inclusion into the models and the influence of the 27-day recurrency and persistence on the predictive performance during disturbed and quiet times. We also test performance with solar wind predictions from WSAEnlil model. Finally, we evaluate and report the optimal combinations of machine learning models with the 27-day recurrency and persistence for different levels of geomagnetic activity.

PSW.2-0008-18 SPACE WEATHER FORECASTING: A DATA-DRIVEN AND PHYSICS-BASED CHALLENGE

Stefania Bucchi, b_steffi.geo@yahoo.com Colorado, United States

Giovanni Lapenta, giovanni.lapenta@wis.kuleuven.be

Centre for Plasma Astrophysics - KU Leuven, Leuven, Belgium

Predicting is not the same as understanding. We can understand in depth the physics behind a process but without data on the state of the system we can't make predictions. We know perfectly well the laws of physics regulating fluid dynamics, yet we can't predict whether it will rain in one week. Unless, like us, you live in Belgium and then it will surely rain. And we can say that because weather forecast is data-driven. We know that statistically in Belgium it rains almost every day. So much so that we go to Scotland for a break of sunshine. For space we do not have the same level of knowledge of statistics of past event nor a wealth of information from the current conditions. Predicting space weather than means making the best use of the coarse, partial and limited availability of data and using the incomplete understanding of the physical mechanisms behind it. To this end we need to develop methods that are best suited to work on small amounts of data. If we like to understand in depth a CME we need to use highly resolved simulations that include all physics processes. But that does not help us much in predicting if what is happening right now on the sun is leading to a Carrington-type event. For that we need a quicker simpler model that can be run many times using data assimilation to constrain the outcome as best as possible. We present a new approach, part of the AISA H2020 project and based on tools developed via funding by the US AirForce. The new tools are a Lagrangian MHD model of the solar wind plasma and its embedded disturbances and a statistical technique based on the representer technique to identify the best strategy for data assimilation.

PSW.2-0009-18 INVESTIGATION OF EXCEPTIONAL SOLAR ACTIVITY IN SEPTEMBER 2017: G4 GEOMAGNETIC STORM (07-08.09) AND GLE72 (10.09) IN MINIMUM OF SOLAR CYCLE 24

Lev Dorman, lid010529@gmail.com

University of Oulu, Oulu, Finland Dimitrinka Tomova, dimi16@abv.bg Bulgaria

Lachezar Mateev, lnmateev@bas.bg

Space Research and Technology Institute - Bulgarian Academy of Sciences, Sofia, Bulgaria

The exceptional solar activity in early September 2017 at minimum of solar cycle 24 is analised. The beginning of the intensive solar-terrestrial disturbances was the Active Region AR2673, which produced four powerful eruptions class X, including the strongest flare X9.3 of Solar Cycle 24 on September 6, 2017, after which began G4 - Severe geomagnetic storm on 07-08.09.2017 with Ap = 106, and also - the second strongest flare 8.2 of Solar Cycle 24 on September 10, 2017, which generated instantly the Ground Level Enhancement (GLE) of cosmic rays. This is GLE72 with increase of solar cosmic ray flux 6% in Oulu Station (Finland) (effective vertical geomagnetic cutoff rigidity: 0.8 GV), and increase 9% in DOMC Antartica and 14% in DOMB Antartica (in the latter case - lead free neutron monitors with effective vertical cutoff rigidity

<0.01 GV). h GLE72 develops under the conditions of a deep Forbush decrease (around 15%) in South Pole cusp caused by September 7th Coronal Mass Ejection. The three space regions of impact are investigated and analised in the present work: 1) Sun - photosphere and solar corona; 2) Interplanetary space with solar wind and its basic parameters - velocity V, density (or concentration N), temperature Tp and intensity of the magnetic field B; 3) Earth and its magnetosphere. Calculations of the solar wind parameters from measurments by SOHO and DSCOVR space probes in the point of Lagrange are made: the kinetic (dynamic) energy density Ek, thermal energy density Et and magnetic energy density Em during the investigated period September 2-15, 2017. We found two interesting phenomena in the investigated period: 1) tunnel effect in the Earth's environment, and 2) specific distribution of the solar wind energy density during and after the series of Coronal Mass Ejections. It is likely that both kinetic and magnetic energies can be used as predictors of strong geomagnetic storms. Besides

the investigation of GLE72 as second GLE in the current solar cycle 24 (after GLE71 on 17 May 2012 during the solar maximum) represents special interest.

PSW.2-0010-18 SOLAR WINDSOCKS - A SERVICE TO DERIVE ESTIMATES OF SOLAR WIND SPEEDS FROM COMETS' ION TAILS

Geraint Jones, g.h.jones@ucl.ac.uk

University College London, Mullard Space Science Laboratory, Dorking, United Kingdom Yudish Ramanjooloo, yudish@hawaii.edu

University of Hawaii, Honolulu, Hawaii, United States Robert Bentley, rdb@mssl.ucl.ac.uk

University College London, Dorking, United Kingdom

Comets' ion tails show material being carried away from cometary nuclei by the solar wind. As we know where each comet is, how fast it's moving, and in what direction, we can use the orientation of the tail to estimate the solar wind speed at the comet. Solar Windsocks is based on the assumption that the solar wind flow is radial, i.e. that it flows directly away from the Sun. This is known to not quite be true, with the solar wind often deviating a few degrees from the radial direction, but this assumption is necessary in order to derive solar wind speed estimates from comet images. The service takes a user's image, and projects it onto the comet's orbital plane. The position of the ion tail is then identified manually in the image, and the solar wind speed corresponding to each marked position in the tail is calculated. Using this technique, several solar wind speed estimates can be provided from each image. It is hoped that amateur and professional comet observers will donate their images and the resultant solar wind speed estimates to the project, to build up a database of point measurements of the flow speed in the inner heliosphere. The Solar Windsocks project is only possible through the financial support of the Europlanet-2020 Research Infrastructure, funded by the European Commission. Solar Windsocks is part of the Europlanet Planetary and Space Weather Services activity.

PANELS (P)

FROM IONOSPHERIC INDICES TOWARDS STANDARDISED ACTIVITY SCALES FOR SPACE WEATHER SERVICES (PSW.3)

PSW.3-0001-18 AN OPERATIONS PERSPECTIVE ON AN IONOSPHERIC INDEX

Robert Steenburgh, robert.steenburgh@noaa.gov NOAA-NWS, Boulder, Colorado, United States

Forecasters at the National Oceanic and Atmospheric Administration's (NOAA) Space Weather Prediction Center (SWPC) are charged with

. assessing the current and forecast space weather situation, including devising and formulating all necessary warning and forecast products . with emphasis on meeting the needs of the users.

In order to meet the needs of the GNSS community, consideration is given to the establishment of an ionospheric index to augment the existing NOAA scales: (R)adio blackout, (S)pace radiation storm, and (G)eomagnetic storm. The latitudinal stratification of ionospheric disturbances suggests an approach to developing an index. The concept will be explored from the perspectives of user needs, operational implementation and the associated complexities, including the need for consistency between existing and proposed scales. The adequacy of current operational ionospheric monitoring and modeling to support watch, warning, and alert capabilities will also be discussed.

PSW.3-0002-18 A REPORT ON DISCUSSIONS AT PAST SPACE WEATHER WORKSHOPS REGARDING THE NEED FOR AN IONOSPHERIC SCALE

Tim Fuller-Rowell, tim.fuller-rowell@noaa.gov

University of Colorado, Boulder, Colorado, United States

This is a report of the discussions at previous side meetings held during the Space Weather Workshop in Boulder over the past 3 years. We began by addressing basic questions such as: Do we need an ionospheric scale? What customer base is currently not served well by existing NOAA Space Weather Scale G, R, and S? What form should the scale take? What real-time data stream should drive it? Do we need both regional and global scales? Is more than one scale needed to address different customer sectors impacted by the ionosphere? At previous meetings the group was tending towards using the GNSS L1 and L2 phase data sometimes referred to as Along the Arc TEC Rate (AATR); e.g., hourly RMSE of 30 sec weighted TEC data. The target user group was GNSS because of the huge market, and since the existing scales already partially addressed the needs of some of the other user groups, such as HF propagation. The thought was to quantify the variability of AATR in different longitude and latitude sectors, and correlate with things like geomagnetic storms, Kp, solar flares, sudden stratospheric warnings, TIDs, MSTIDs, or other geophysical events. Assemble data over one solar cycle and multiple latitude and longitude sectors. The plan was to develop both regional and global "indices" or Scales. Other questions raised: Can it be forecast? What level of disturbance in AATR affects GNSS signals and has impact on users? How many stations would we need to monitor to define a global 1 to 5 scale? What is the relationship of AATR with S4 and sigma phi scintillation indices, and ROTI. What temporal cadence is needed? What is the impact of cycle slips? This paper will review some of this discussion and conclusions reached.

PSW.3-0003-18 SYNERGY BETWEEN THE DEVELOPMENT OF IONOSPHERIC DISTURBANCE INDICES AND MEDIUM-RANGE IONOSPHERIC FORECASTING

University of Southern California, Los Angeles, California, United States

At this time, there does not exist a widely used index that describes the magnitude of ionospheric space weather disturbances, despite the potential for significant user impacts. Yet, geomagnetic activity indices compiled over decades have had enormous scientific and practical value in characterizing the geomagnetic storm environment. Related to geomagnetic indices are the space weather scales (e.g. G1-G5) defined by NOAA's Space Weather Prediction Center, which are used both for space weather characterization and in medium-range forecasts (forecasts with a few days lead time). We are currently engaged in research on medium-range ionospheric forecasting, with the goal of predicting ionospheric conditions arising from both coronal mass ejections and high speed solar wind streams. Such upper atmosphere forecasts are based on forecasted solar wind values at 1AU that could be available a few days in advance. We consider both first-principles and data-driven approaches to forecasting, and place emphasis on improved scientific understanding that can arise from forecast-centric research. Due to the inherent complexity of the upper atmosphere response to space weather,

we are finding it advantageous to define metrics that characterize space weather conditions over large regions or globally. Such metrics could have a high degree of overlap with ionospheric disturbance indices, which are the focus of this session. We will describe ionospheric disturbance metrics relevant to forecasting that could also inform on the development of ionospheric indices. Initial forecast experiments using the Space Weather Forecast Testbed (SWFT) tool will be shown.

PSW.3-0004-18 THE DERIVATION AND VERIFICATION OF A REGIONAL IONOSPHERIC TEC DISTURBANCE INDEX

Yanhong Chen, chenyh@nssc.ac.cn

National Space Science Center, CAS, Beijing, China

A regional ionospheric disturbance index (RIDI) derived from the regional TEC map was introduced in this paper. The RIDI index can give a clear description for the disturbed phase (positive or negative) and strength of the ionospheric perturbation. The comparison between indices and the regional TEC disturbance suggested RIDI can represent the regional TEC well. Further verification using the multidimensional scaling suggested the RIDI is more correlated with TEC disturbance. The RIDI index can be used in global coverage. In addition, a Ns index was used to describe the disturbance range and it had a good relationship with Dst index. The RIDI and Ns can be used in space weather operational services to give the disturbance strength and influence range, which is convenient for users to know about ionospheric current conditions.

PSW.3-0005-18 ABOUT NEW IONOSPHERIC INDICES FOR SPACE WEATHER SERVICES

Alexander Rakhlin, rakhlin.alex@nirfi.unn.ru

Radiophysical Research Institute Nizhny Novgorod State University, Nizhny Novgorod, Russia Olga Sheiner, rfj@nirfi.unn.ru

Radiophysical Research Institute Nizhny Novgorod State University, Nizhny Novgorod, Russia Fedor Vybornov, vybornov@nirfi.unn.ru

Nizhny Novgorod State University, Nizhny Novgorod, Russia Aleksander Pershin, pershinalv@rambler.ru

Radiophysical Research Institute Nizhny Novgorod State University, Nizhny Novgorod, Russia

Strong and, as a rule, sudden perturbations in the near-Earth space (magnetosphere and ionosphere of the Earth) cause numerous disruptions in the operation of systems of radio navigation and telecommunications, global information networks, tracking and warning devices on the Earth, can lead to malfunctions in the operation of powerful energy systems. As a rule, information on the characteristics of ionospheric disturbances is based on geomagnetic data, such as Kp, Ap, Dst, calculated from ground-based observations. It is known that solar radiation affects the parameters of the ionosphere and the ionization processes in it, and an indicator of the level of ionized particles can be a relatively easily recorded critical frequency of the reflection of a radio signal during ionospheric sounding f0F2. The study of the influence of the total level of solar activity on the state of the ionosphere can be reduced to a study of the characteristic deviations Δf0F2 in the behavior of regular ionogram parameters over a large interval of observations. Assuming that the observed deviations are a consequence of other characteristic phenomena in quasiregular processes on the Sun, we are looking for possible cross-correlation relations and primary parameters that ensure the maximum correlation coefficients between the processes. For example, the data measured on satellites in geostationary orbits is considered: particle fluxes, X-ray radiation (GOES-13, 15). At the same time, a joint analysis of the characteristics of solar activity recorded in the immediate vicinity of the Sun, for example, on the ACE device located in the front libration point, and the frequency deviations

Δf0F2 showed the existence of correlation links between the parameters of high-speed solar wind flows and the response of ionospheric characteristics. Thus, according to the results of measurements of the solar wind velocity, magnetic field, plasma concentration, the information on the origin and degree of ionospheric disturbance can be obtained much earlier than the data of events near the Earth are used. The report presents the results of a joint analysis of the behavior of the parameter of the mid-latitude ionosphere of the Earth at the F2 layer heights

(Δf0F2) and its relation to the characteristics of coronal mass ejections and high-speed solar wind fluxes in various phases of solar activity to determine prognostic probabilistic relationships between the parameters of the indicated solar phenomena and variations in the parameters of the mid-latitude ionosphere.

PSW.3-0006-18 THE RATE OF TEC INDEX AND GLOBAL IONOSPHERIC IRREGULARITY MAP

Xiaoqing Pi, xiaoqing.pi@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

The rate of total electron content (TEC) index (ROTI) [Pi et al., 1997] characterizes random fluctuations of ionospheric TEC, which occur when the radio signals traverse ionospheric irregularities. The index can be derived from dual-frequency carrier phase data of Global Navigation Satellite System (GNSS) signals tracked using geodetic-type GNSS receivers. Compared to the traditional ionospheric scintillation measurements, major characteristics of ROTI include: (1) measurements of integrated ionospheric irregularities; (2) not susceptible to receiver local oscillator error; (3) applicable to detection of irregularity-induced phase fluctuations at different carriers; (4) applicable to GNSS-based systems to mitigate the effects of ionospheric scintillation. ROTI data can be obtained from thousands of existing geodetic survey stations. ROTI measurements have been applied to the assessment of GNSS positioning degradation due to scintillation effects [Pi et al., 2017]. Using ROTI, global ionospheric irregularity maps (GIIMs) can be generated at 5-minute cadence. GIIMs capture global and regional activities of ionospheric irregularities under nominal geophysical conditions and during space weather storms. Prototype systems for global and regional nowcast of ionospheric irregularities using ROTI and GIIM have been developed and tested with real-time GNSS networks. This presentation will give an overview of ROTI and GIIM, discuss pros and cons of the ROTI vs. the traditional ionospheric scintillation measurements, and report the development of prototype nowcast systems. Highlights of science investigations and technology applications using ROTI and GIIM will also be presented.

PSW.3-0007-18 AATR AN IONOSPHERIC ACTIVITY INDICATOR SPECIFICALLY BASED ON GNSS MEASUREMENTS AND TAILORED FOR GNSS USERS

Jaume Sanz, jaume.sanz@upc.edu

Universitat Politecnica de Catalunya, Barcelona, Spain

J. Miguel Juan, jose.miguel.juan@upc.edu

Universitat Politecnica de Catalunya, Barcelona, Spain Adria Rovira-García, adria.rovira@upc.edu

Universitat Politecnica de Catalunya, Barcelona, Spain Guillermo Gonzalez-Casado, guillermo.gonzalez@upc.edu Universitat Politecnica de Catalunya, Barcelona, Spain Deimos Ibáñez, deimos.ibanez@upc.edu

Universitat Politecnica de Catalunya, Barcelona, Spain Raul Orus-Perez, raul.orus.perez@esa.int ESA/ESTEC, Noorwdijk, Netherlands

This work reviews an ionospheric activity indicator useful for identifying disturbed periods affecting the performance of Global Navigation Satellite System (GNSS). This indicator is based in the Along Arc TEC Rate (AATR) and can be easily computed from dual-frequency GNSS measurements.

The AATR indicator has been assessed over more than one Solar Cycle (2002-2017) involving about 140 receivers distributed world-wide. Results show that it is well correlated with the ionospheric activity and, unlike other global indicators linked to the geomagnetic activity (i.e. DST or Ap), it is sensitive to the regional behaviour of the ionosphere and identifies specific effects on GNSS users.

Moreover, from a devoted analysis of different Satellite Based Augmentation System (SBAS) performances in different ionospheric conditions, it follows that the AATR indicator is a very suitable mean to reveal whether SBAS service availability anomalies are linked to the ionosphere. On this account, the AATR indicator has been selected as the metric to characterise the ionosphere operational conditions in the frame of the European Space Agency (ESA) activities on the European Geostationary Navigation Overlay System (EGNOS). The AATR index has been adopted as a standard tool by the International Civil Aviation Organization (ICAO) for joint ionospheric studies in SBAS.

In this contribution, we explain how the AATR is computed, paying special attention to the cycle slip detection, which is one of the key issues in the AATR computation, not fully addressed in other indicators such as the Rate Of change of the TEC Index (ROTI). Furthermore, we present the advances towards the real-time implementation of the AATR index. These improvements focus on the timely monitoring and warning of Space Weather events. The main conclusions about the ionospheric activity that extracted from the AATR values during the above mentioned long-term study are: (a) the different spatial correlation related with the MOdified DIP (MODIP) which allows to clearly separate high, mid and low latitude regions, (b) the large spatial correlation in mid latitude regions which allows to define a planetary index, similar to the geomagnetic ones, (c) the seasonal dependency which is related with the longitude and (d) the variation of the AATR value at different time scales (hourly, daily, seasonal, among others) which confirms most of the well-known time dependences of the ionospheric events, and finally,

(e) the relationship with the space weather events.

PSW.3-0008-18 ESTIMATING THE DEGREE OF IONOSPHERIC PERTURBATIONS USING AN IONOSPHERIC INDEX

German Aerospace Center (DLR), Neustrelitz, Germany

Space weather can strongly influence trans-ionospheric radio signals depending on the frequency used. To assess the intensity of a space weather event from its origin at the sun to its influence on the ionosphere, there is a number of physical quantities which must be derived from scientific measurements, such as the solar flux density F10.7, interplanetary magnetic field and geomagnetic indices. In combination with additional classification systems, all these parameters provide orientation in a physically complex environment. Therefore, indices are used for a brief communication of simplified but adequate situation awareness to users. Space weather driven ionospheric phenomena can heavily affect customers in the communication and navigation domain, but they are still served inadequately by the existing indices. We present a new robust index, based on ground based real time GNSS measurement data from several GNSS reference networks,that is able to properly characterize temporal and spatial ionospheric variations on small to medium scales. The proposed ionospheric disturbance index can overcome several drawbacks of other ionospheric measures and might be a suitable candidate as potential driver for an ionospheric space weather scale.

The present work shows the preliminary results from the analysis for developing the ionospheric scales based on Disturbance Ionospheric Index (DIX). This index aims to target all the different user groups affected by ionospheric disturbances, e.g. the navigation, positioning and satellite communication users, in a simple and straightforward approach. Therefore, we used the Vertical TEC (VTEC) over South America to calculate the Total Electron Content Maps covering latitudes from 60°S to 20°N and longitudes from 90°W to 30°W, with 5 x 5 degrees resolution. Afterwards, the DIX Maps are obtained to reveal the variation of the TEC over an average quiet ionosphere background. Among the results, we have different methodology for achieving the average quiet ionosphere background and disturbances in the DIX at different latitudinal sector.

PSW.3-0010-18 AN ANALYSIS OF IONOSPHERIC SCINTILLATION INDICES

Yannick Beniguel, beniguel@ieea.fr IEEA, Courbevoie, France

This paper will review the ionospheric indices used to quantify the ionosphere scintillation levels. It will start with a review of observations both at low and high latitudes. The low latitudes observations will include years of major solar activity, this being the main driver of the equatorial scintillation activity. The high latitudes scintillation data set will include an analysis of the major magnetic storms which occurred in the last two years.

In both cases, low and high latitudes, the main indices and the algorithms to derive them will be analysed. This concerns in particular the phase and scintillation indices, the signal correlation characteristics and the spectra parameters.

The ability of a scintillation model to reproduce these scintillations will be investigated in the two cases.

PSW.3-0011-18 NEW CAPABILITIES FOR PREDICTION OF HIGH-LATITUDE IONOSPHERIC SCINTILLATION: A NOVEL APPROACH WITH MACHINE LEARNING

Ryan McGranaghan, ryan.mcgranaghan@colorado.edu

NASA Jet Propulsion Lab / California Institute of Technology, Pasadena, California, United States

Anthony Mannucci, anthony.mannucci@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, United States

Space weather has a wide-reaching impact on technological systems. Among the critical affected technologies are those dependent on radio signals propagating through the complex, variable ionosphere, especially those from Global Navigation Satellite Systems (GNSS). Complexity and multi-scale variability (in both time and space) characterize the ionosphere and threaten the integrity of GNSS signals. However, these signals also provide better spatial coverage at a higher cadence than any single ionospheric data set. We present a new data-driven approach to the prediction of ionospheric disturbances to GNSS signals, specifically scintillation, by taking advantage of years of GNSS scintillation data. These data are used to train a supervised machine learning classification model known as a support vector machine (SVM) [1]. We focus for the first time on high-latitudes, where space weather effects are most direct and no prediction capability currently exists. We show through robust quantitative metrics (i.e., beyond the conventional visual assessment) that this method produces a high degree of accuracy in predicting high-latitude scintillation with one-hour lead times based on the current state of the ionosphere, geomagnetic environment, and solar wind.

We discuss the use of this new predictive capability as a predictive benchmark and a much more robust means of characterizing ionospheric effects on radio signals than global indices, thereby fulfilling the role of an ionospheric index. This work embodies the future of space weather as outlined by the COSPAR roadmap [2], placing focus on prediction, taking a data-driven approach, and leveraging state-of-the-art techniques that can evolve traditional approaches in lieu of the growing and complex space weather observational system.

PSW.3-0012-18 FORECASTING GNSS SCINTILLATION USING A NEW PROXY SCINTILLATION INDEX (ROBI) DERIVED FROM ALL SKY IMAGERS

Sajan Mushini, smushini@ucalgary.ca University of Calgary, Calgary, Canada Susan Skone, shskone@ucalgary.ca University of Calgary, Calgary, Canada Emma Spanswick, elspansw@ucalgary.ca University of Calgary, Calgary, Canada Eric Donovan, edonovan@ucalgary.ca University of Calgary, Calgary, Canada

Global Navigation Satellite System (GNSS) signals propagating through structured ionosphere such as aurora may be scintillated causing observation and possibly positioning errors. It is advantageous to determine the magnitude of GNSS signal scintillation associated with a given level of auroral brightness observed around the signal's ionospheric pierce point (IPP). Such information would enable the exploitation of auroral image observations in space weather monitoring and impact assessment. Many previous studies have observed a general correlation between auroral luminosity and GPS phase scintillation but not a defined one-to-one relationship. Consistent with such findings, in this study a relatively low correlation coefficient of 0.38 is observed between the phase scintillation and the level of brightness around the GPS signal's ray path for a dataset of 292 events in the Canadian sector. Alternatively, a new pseudoscintillation index, Rate of change of Brightness Index (ROBI), is introduced in this study which is derived from the changing auroral brightness around the satellite's IPP. This ROBI is highly positively correlated (correlation coefficient: 0.77) with GPS phase scintillation (σϕ). Forecasting scintillation in GNSS signals when these signals pass through auroral arcs is also an important capability to have for high precision positioning and navigation applications in the auroral regions. In this study we also demonstrate the capability of artificial neural networks to forecast scintillation due to auroral using ROBI from an ASI and σϕ for that satellite obtained from a GPS receiver as inputs. This study demonstrates that neural network forecasted phase scintillation (σϕ) clearly follows the σϕ index reported by the receiver with a correlation of 75%

PSW.3-0013-18 THE USE OF REAL-TIME POLAR CAP (PC) INDICES FOR SPACE WEATHER MONITORING

Peter Stauning, pst@dmi.dk

Danish Meteorological Institute DMI, Copenhagen, Denmark

The Polar Cap (PC) indices, PCN (North) and PCS (South), reflect the transpolar plasma convection driven by the interaction of the solar wind with the magnetosphere. The standard PC indices based on geomagnetic observations at Qaanaaq (Thule) and Vostok, respectively, have been used in a variety of solar-terrestrial investigations relating to magnetic storm and substorm conditions. In their real-time versions, the indices could be useful for power grid protection by enabling warning an hour or more (Stauning, 2013) ahead of violent events of geomagnetically induced currents (GIC) that may threaten high-voltage power grids in the vicinity of the auroral zones. The PC indices, furthermore, might help the forecast of auroral substorms with their colourful and impressive display of vivid auroras for the benefit, among other, of polar winter tourism. The presentation shall consider such applications and shall also discuss the available methods to derive real-time PC index values as well as the quality of presently provided indices (Stauning, 2015, 2018). Furthermore, the potential use of alternative locations in the northern and southern polar caps to provide data for PC indices (Stauning, 2018) shall be considered.

We use results on the trajectory calculations of planetary distribution CR penumbra function (equal to 1 for allowed CR trajectories and 0 for forbidden trajectories) and calculations of corresponding variations of CR effective cutoff rigidities Rc for each 5 years during 1950 - 2050 (1950, 1955, and so on, up to 2050) with taking into account changes of primary rigidity GCR spectrum due to modulation in the Heliosphere. Based on these results we determine how changed the flux of GCR and corresponding ionization rate in low ionosphere (where GCR is the one of main sources of ionization) due to time variations of Rc for the same each 5 years during 1950 - 2050 in dependence of latitude and longitude. Obtained results are important for more exact determining influence of GCR on ionosphere and radio-wave propagation in 1950

2015 and forecasting of expected influence up to 2050. For solar CR events (with different primary energetic spectrums) obtained results give possibility to calculate and forecast more exactly their influence on ionosphere and radio-wave propagation finally caused by processes on the Sun, by Space Weather effects, and by processes deep inside the Earth.

PSW.3-0015-18 IONOSPHERIC DISTURBANCE SCALES TO SUPPORT AERONAUTICAL COMMUNICATIONS, NAVIGATION, AND SURVEILLANCE SYSTEMS

Susumu Saito, susaito@mpat.go.jp

National Institute of Maritime, Port, and Aviation Technology, Chofu, Tokyo, Japan

In the civil aviation, different communications, navigation and surveillance (CNS) systems are used to support aircraft operations and air traffic control. Radio waves from HF to L-band radio waves are for communications between ground and air and between air and air. In navigation, conventional ground navigation aids such as VOR (VHF Ommnidirectional Range) or ILS (Instrument Landing System) use VHF. Recently Global Navigation Satellite Sytem (GNSS) using L-band is getting more widely used. In surveillance to monitor the airplanes, ADS-B (Automatic Dependent Surveillance - Broadcast) where airplanes broadcast their information such as position or direction is getting widely used. The source of the position is the GNSS. These systems use radio waves and are often influenced by ionospheric activities. However, since the frequencies are different, ionospheric phenomena that have impacts on each system is different.

Considering the increasing air traffic and importance of space weather effects, International Civil Aviation Organization (ICAO) is standardizing the space weather information service for aeronautical operations. As the information provided for aeronautical operations, they have to be simple and concise. Therefore, physical quantities have to be interpreted into scales that is related to the relevant operations.

In this study, GNSS is taken as one of the examples. Currently, GPS and GLONASS signals at the L1 frequency are standardized and available for aviational use. Therefore, ionospheric delay variations associated with ionospheric disturbances are serious error sources and their impact needs mitigated. However, ionospheric disturbances have different scale sizes corresponding to different physical mechanisms behind them. This study discusses the contents of the relevant information and their necessary spatial granularity. In the next generation GNSS, more constellations and a second frequency (L5) will be available. For this multi-constellation and multi-frequency (MC-MF) GNSS, ionospheric delay (or equivalently total electron content) effects will almost disappear. However, effects of scintillations will become more important. Instead, frequency dependent information will be necessary. Thus, space weather information necessary for the next generation MC-MF GNSS will also be discussed in this study.

PSW.3-0016-18 APPLICATION-ORIENTED INDICES FOR DESCRIBING TEMPORAL AND SPATIAL VARIATIONS OF THE IONOSPHERIC IONIZATION

Norbert Jakowski, norbert.jakowski@dlr.de

Deutsches Zentrum fuer Luft-und Raumfahrt (DLR), Neustrelitz, Germany

Mainul Hoque, mainul.hoque@dlr.de

Deutsches Zentrum fuer Luft-und Raumfahrt (DLR), Neustrelitz, Germany

Ionosphere can adversely affect accuracy, continuity, availability, and integrity of modern Global Navigation Satellite Systems (GNSS) in different ways. Hence, reliable information on key parameters describing the perturbation degree of the ionosphere is helpful for estimating the potential degradation of the performance of these systems. So, to guarantee the required safety level in aviation, Ground Based Augmentation Systems (GBAS) and Satellite Based Augmentation Systems (SBAS) have to detect and mitigate ionospheric threats in particular due to ionospheric gradients. In this talk we investigate two approaches for estimating temporal and spatial gradients of the Total Electron Content (TEC) in near real time. The approaches allow estimating the current perturbation degree of the ionosphere with high temporal resolution. The capabilities and accuracy of the approaches are demonstrated by a simulation study using a 3D electron density model of the ionosphere and plasmasphere in conjunction with realistic GNSS constellations. The potential of these approaches to serve as objective ionospheric indices for scaling horizontal TEC gradients and rapid solar flare effects has been investigated. The results are presented focusing on their use in precise dual frequency GNSS applications.

PSW.3-0017-18 IONOSPHERIC STORM EFFECTS ON GNSS PRECISE POSITIONING

Michael Terkildsen, m.terkildsen@bom.gov.au

Space Weather Services / Bureau of Meteorology, Sydney, Australia
German Olivares, g.olivares@bom.gov.au

Cooperative Research Centre for Spatial Information, Sydney, Australia

Dynamic changes in ionospheric electron content and structure, commonly referred to as ionospheric space weather, have the potential to affect the performance and availability of GNSSbased positioning applications. Further, the impact is largely dependent on how the positioning algorithm mitigates the effects of GNSS signal delay through the ionosphere. This varies considerably across positioning platforms. Developing a simple index that adequately captures the impact of ionospheric space weather on all GNSS positioning platforms is therefore a challenging task. We evaluate the impact of an ionospheric storm on a number of positioning algorithms, including both PPP-AR and PPP-RTK. Multiple performance metrics are used to relate GNSS-based positioning performance to ionospheric space weather conditions.

PSW.3-0018-18 AN ASSESSMENT OF THE IONOSPHERE RESPONSE TO FIVE THE MOST INTENSE GEOMAGNETIC SUPERSTORMS DURING 60 RECENT YEARS

Iwona Stanislawska, stanis@cbk.waw.pl

Space Research Centre of the Polish Academy of Sciences, Warsaw, Poland Tamara Gulyaeva, gulyaeva@izmiran.ru

Institute of Terrestrial Magnetism, Ionosphere and Radio Wave Propagation of the Russian Academy of Sciences (IZMIRAN), Moscow, Russia

Oksana Grynyshyna-Poliuga, ogp@cbk.waw.pl Space Research Centre PAS, Warsaw, Poland Lubov Poustovalova, pustoval@izmiran.ru IZMIRAN, Moscow, Russia

An assessment of the ionosphere perturbations can be made through the construction of the global instantaneous maps of the foF2 critical frequency (GIM-foF2) and the ionospheric weather index maps GIM-Wf(foF2). These maps can offer a potentially useful tool to provide users with the prevailing tracking conditions over a certain area and also be used to help mitigate the effects of the disturbances on HF communication and GNSS positioning. This paper presents results of reconstruction of the ionospheric weather during five the most intense superstorms observed since IGY (1957, 1958, 1959, 1989, 2003) with the instantaneous global maps of the F2 layer critical frequency, GIM-foF2, and the ionospheric weather index maps, GIM-Wf. The intensity of the ionospheric superstorm is characterized by the planetary Wfp index derived from GIM-Wf maps. Model relationship is established between mean Wfp profile and geomagnetic superstorm profiles demonstrating saturation of the ionospheric storm activity towards the peak of geomagnetic storm. Superposed epoch analysis of five events has shown delay of the ionospheric superstorms regarding the geomagnetic superstorms. Time lag of Wfpmax is found equal to 9 h after AEmax, 6 h after apmax and aamax, 2 h after Dstmin which allows model forecast of the ionospheric superstorm when geomagnetic superstorm is captured with one or more of geomagnetic indices.

PSW.3-0019-18 THE RELATIONS OF POLAR CAP (PC) INDICES TO SOLAR WIND PARAMETERS AND GEOSPACE MAGNETIC DISTURBANCES

Peter Stauning, pst@dmi.dk

Danish Meteorological Institute DMI, Copenhagen, Denmark

The Polar Cap (PC) indices are based on geomagnetic observations at Qaanaaq (Thule) and Vostok, respectively. To derive index values, the geomagnetic variations are projected to the direction considered to be perpendicular to the noon-midnight transpolar plasma convection and scaled with respect to the solar wind merging electric field. The PC indices measure the transport of plasma and magnetic fields from the front of the magnetosphere to the tail region and are considered to represent the input of energy from the solar wind to the Earth's magnetosphere. With appropriate time shifts and integration of samples, PC indices could be used to predict auroral (AL), mid-latitude (Kp) and ring current (SYM, ASYM, Dst) geomagnetic disturbance indices (e.g., Stauning, 2012). In addition to their inherent relations to the solar wind electric fields and thereby to the solar wind velocity and the transverse components of the interplanetary magnetic fields, the PC indices respond to density changes related to impulsive variations in the solar wind dynamical pressure (Stauning, 2008). The general solar wind density level, however, has little effect on the PC index values. The presentation shall discuss the relations of PC indices to further disturbance parameters and provide insight in PC index dependencies of importance for the proper interpretation of index variations at space weather monitoring applications.

PSW.3-0020-18 POLAR CAP (PC) INDICES BASED ON MULTIPLE SOURCES ENSURING CREDIBILITY AND OPERATIONAL RELIABILITY

Peter Stauning, pst@dmi.dk

Danish Meteorological Institute DMI, Copenhagen, Denmark

To establish reliable Space Weather forecasts based on Polar Cap (PC) indices, and also to ensure credibility of their use for scientific analyses of solar wind-magnetosphere interactions, additional sources of data for the PC indices have been considered (Stauning, 2018). In the search for alternative index sources, objective quality criteria were established to be used for the selection among potential candidates and also for control of the quality of PC index series in current use. In the Canadian region, the data from Resolute Bay magnetometer, as will be shown, may provide alternative PCN indices of adequate quality. In Antarctica, the data from Concordia Dome-C observatory are shown to provide an alternative basis for qualified PCS indices. Examples to be presented shall document the usefulness of these alternative index sources. Thus, PCN indices in a real-time version based on magnetometer data from Resolute Bay could have given 6 hours of early warning, of which the last 2 hours were "red alert", up to the onset of the strong substorm event on 13 March 1989 that caused power outage in Quebec. The alternative PCS indices based on data from Dome-C have helped to disclose that presently available Vostok-based PCS index values are corrupted throughout most of 2011

PSW.3-0021-18 SPACE-TIME DISTRIBUTION OF IONOSPHERE IONIZATION RATE DURING GLE AND SEP EVENTS BY SOLAR COSMIC RAYS (SCR): THEIR CHANGING FROM 1950 UP TO EXPECTED AT 2050 DUE TO VARIATIONS OF CR PENUMBRA FUNCTIONS AND CUTOFF RIGIDITIES WITH TAKING INTO ACCOUNT TIME VARIATIONS OF SCR SPECTRUM DURING GLE AND SEP EVENTS.

The effective cutoff rigidity is determined not only by the penumbra function (equal to 1 for allowed CR trajectories and 0 for forbidden trajectories), but also by rigidity/energy spectrum of SCR, which changed with time during GLE and SEP events (caused by dependence of propagation parameters from rigidity/energy of SCR). We use results on the trajectory calculations of planetary distribution CR penumbra functions for each 5 years during 1950 - 2050 (1950, 1955, and so on, up to 2050). Based on these results we determine how changed the flux of SCR and corresponding ionization rate in low ionosphere (where SCR and GCR are main sources of ionization) due to time variations of Rc for the same each 5 years during 1950 - 2050 in dependence of latitude and longitude. For solar GLE and SEP events (with different primary rigidity/energy spectrums) obtained results give possibility to calculate and forecast more exactly their influence on ionosphere and radio-wave propagation finally caused by processes on the Sun (generation SCR and ejection from solar corona into solar wind), by Space Weather effects during SCR propagation from the Sun to the Earth), and by processes deep inside the Earth (changing the main magnetic field).

Department of Earth, Planetary, and Space Sciences, University of California, Los Angeles, California, United States

The Space Physics Archive Search and Extract (SPASE) Metadata standard is a communitydeveloped standard that is being supported and used by the NASA-funded space and solar physics community. It is also in use by the international community and by other U.S. agencies (NOAA). SPASE metadata has long been used to describe experimental data, software, documents and more. The most recent additions to the SPASE information model are extensions to support describing a simulation or model and the results generated from a run. These extensions are based on the work done by the EU's Framework 7 Integrated Medium for Planetary Exploration (IMPEx) project. In addition to IMPEx, these extensions have been adopted by the multi-agency Coordinated Community Modeling Center (CCMC) to describe supported models and run results. These extensions, along with the core SPASE metadata, enable the discovery of related observational and theoretical data resources through search portals such as NASA's Heliophysics Data Portal. In addition, SPASE provides a variety of tools and services related to generating and validating resource descriptions. One new service is that SPASE now provides support for issuing Digital Object Identifiers (DOI) for resources that are described with SPASE. The SPASE Metadata Working Team (SMWT) will work with data producers who lack other avenues for producing DOI so that their registered data may be referenced in publications. SPASE also provides generated landing pages based on the content of SPASE resource descriptions which can be used for any DOI. Overall SPASE metadata is capable of providing the infrastructure to connect data, documents, people, software, services and published works. And when SPASE metadata is harvested by a portal an ability to have rich discoverability.

PSW.4-0002-18 THE SMWT: A CONCERTED EFFORT TO PRODUCE SPASE-BASED METADATA FOR HELIOPHYSICS AND SPACE WEATHER DATA TO ENABLE UNIFORM ACCESSIBILITY

Shing Fung, shing.f.fung@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States The SPASE Metadata Working Team

Aaron Roberts, Todd King, Reine Chimiak, Lee Bargatze, Chuck Dolan, Leonard Garcia, James Weygand

Heliophysics measurements have been made over the years by both space-based and groundbased instruments, which are typically supported or funded by various international and national agencies. As a result, data repositories are globally distributed across geopolitical and agency boundaries. The data themselves have also been obtained by a large variety of observing platforms and instrument types, thus the resulting measurement types, data types and data attributes are diverse and the heliophysics data environment is fundamentally heterogeneous. As such, users of heliophysics data have to become accustomed to and utilize different pathways and tools to access, search, and use the data they need to analyze. While discipline-specific data services and tools have so far served the heliophysics research community adequately, the recognition of the importance and emphasis in recent years on heliophysics systems science and space weather research, however, have brought new requirements for data services to serve interdisciplinary and diverse user communities. This presentation will describe a concerted undertaking by the SPASE Metadata Working Team (SMWT) in identifying all electronically accessible heliophysics data products (space-based and ground-based) and describing them by using the same metadata model, SPASE, so that they can be uniformly accessed and searched by a common protocol, e.g. the Heliophysics Applications Programming Interface (HAPI). The SMWT undertaking will help implement the recommendations from international bodies, such as the COSPAR-ILWS Space Weather Roadmap and the International Space Weather Initiative (ISWI), so that effective international data coordination can foster successful space weather research.

PSW.4-0003-18 METADATA EFFORT AT THE COMMUNITY COORDINATED MODELING CENTER (CCMC)

The Community Coordinated Modeling Center (CCMC) at NASA GSFC is home to one of the largest and an ever-growing collections of space weather models, simulation runs, and simulation results. Members of the Space Science community regularly rely on these unique collections of data for space weather forecasting, validation efforts, space science research, and education purposes. Starting in 2016, as part of the Information Architecture for Interactive Archives (IAIA) working team, the CCMC began implementing a new metadata system for models, model runs, and model outputs that is compliant with the SPASE metadata standard. This metadata system will be an important component in our Comprehensive Assessment of Models and Events Based on Library tool (CAMEL) framework, which is currently under development. It will also be the major backbone of the Runs-On-Request Next Gen system. By adding metadata to CCMC hosted models and data, it will allow CCMC to develop sophisticated search functionality to aid in harvesting our unique collections of data. To support data accessibility and interoperability, the CCMC plans to implement application programming interfaces (APIs) following the Heliophysics Application Programmer's Interface (HAPI) protocol whenever possible starting with the integrated Space Weather Analysis (iSWA) system time series API. Allowing the space science community to take full advantage of our unique collections of data is one of the primary goals at the CCMC.

The Heliophysics Application Programmer's Interface (HAPI) is a new interface specification that both large and small data centers can use to expose time series data holdings in a standard way. It is a REpresentational State Transfer (REST) or RESTful web service that provides a method to stream digital time series information from data providers to data users. The HAPI concept relies on data products that have been organized in consistently formatted files with increasing, though not necessarily uniformly increasing, time tags. The data product files must be uniform in terms of parameter content but may have any number of parameters and the individual parameters may be any assorted collection of scalars, vectors, tensors, or generalized arrays.

HAPI requires four endpoints to allow clients to evaluate and provide access to the contents of a data server. The four endpoints all specify the HAPI server version number and the HAPI server response status. The set of endpoints that the HAPI server requires are: 1) Capability - defines the output stream format, either comma-separated values, binary, JSON, or custom, 2) Catalog - a list of the available datasets, 3) Info - a data header in JSON format that provides at least the minimum required information to automate streaming of the data; this endpoint may include information for data set attributes and parameter attributes, and 4) Data - specifies the time range, parameter selection, and format for the data streaming request.

The HAPI specification is available at Github, where projects are also underway to develop reference implementation servers that data providers can adapt and use at their own sites. Also in the works are data analysis clients in multiple languages (IDL, Python, Matlab, Javascript and Java). Institutions which have agreed to adopt HAPI include Goddard (CDAWeb for data and CCMC for models), LASP at the University of Colorado Boulder, the Planetary Plasma Interactions node of the Planetary Data System (PPI/PDS) at UCLA, the Plasma Wave Group at the University of Iowa, the Space Sector at the Johns Hopkins Applied Physics Lab (APL), and the timeseries.org site maintained at George Mason University. Over the next year, the adoption of a uniform way to access time series data is expected to significantly enhance interoperability within the Heliophysics data environment.

PSW.4-0005-18 SPACE WEATHER JHELIOVIEWER IN A HETEROGENEOUS WORLD

The Space Weather JHelioviewer project aims to augment the freely available services of the Helioviewer project with space weather relevant capabilities. As such, it merges the output of several networked software services by combining the display of 1D data (timelines), 2D data (solar images and spectrograms), 3D data (multispacecraft imaging, magnetic field lines modelling), solar event detections (e.g., HEK), and space weather alerts. This talk will highlight the experiences gathered while incorporating this system with several diverse datasets and services.

PSW.4-0006-18 SDDS - YET ANOTHER DATA WAREHOUSE SYSTEM FOR SPACE EXPERIMENTS

Minh Duc Nguyen, nguyendmitri@gmail.com

Scobeltsyn Institute of Nuclear Physics, Moscow, Russia Ludmila Mukhametdinova, lucymu@gmail.com

Skobeltsyn Insnitute of Nuclear Physics, MSU, Moscow, Russia

This work introduces the Satellite Data Downloading System (SDDS) developed at SINP MSU in 2016. SDDS is a fully automatic, flexible, and scalable data warehouse system that accumulates data from Russian and foreign space crafts, and also ground stations in near real-time. SDDS monitors all its components and visualizes their activities in real-time. If an error occurs, the monitoring system will immediately deliver the error description to satellite operators using the Telegram messenger service. For data acquisition, SDDS provides a user-friendly web interface, a Python library, and a REST API. Using the built-in Python library, one can easily compose data from available in SDDS space experiments into a dataset (NumPy arrays, Pandas data frames) and use it in different machine learning models. The web interface provides the possibility to retrieve data and save them to a local computer in text format. It also supports creating customizable plots on the fly with retrieved data and saving the results as images.

PSW.4-0007-18 ENHANCED INTEROPERABILITY THROUGH AUTOMATED DATA ARCHIVE PRODUCT TRACKING, ADAPT, OF SPACE WEATHER DATA PRODUCTS

Lee Bargatze, lfb@igpp.ucla.edu

Department of Earth, Planetary, and Space Sciences, University of California, Los Angeles, California, United States

The Automated Data Archive Product Tracking, ADAPT, effort is a project that addresses the need to enable seamless discovery and access of Heliophysics data products. ADAPT consists of a collection of software composed mainly of BASH shell scripts and IDL routines, that automate the production of SPASE metadata files. SPASE, which is an ontological XML schema, has been designed by Heliophysics researchers to generate metadata documents that describe data products down to the parameter level. And, SPASE is the NASA accepted standard for the description of heliophysics and space weather data products. Once SPASE data product descriptions are generated, they are ingested into metadata GIT registries, which are then leveraged by the Heliophysics Virtual Observatories, VxOs, for data product search and download with interoperability across many data servers that are distributed worldwide. It is important to recognize that the heliophysics and space weather data environment is highly dynamic with thousands of data products involved. Access to data is clearly facilitated via the VxOs but routine access is possible only if the VxO SPASE metadata registries contain accurate and up to date information. The track record until now has clearly demonstrated that the ADAPT method is a highly prolific means of producing SPASE metadata descriptions in a timely, uniform fashion and with a high degree of quality control. As of January 2018, nearly half of all SPASE data product descriptors that are registered in the Heliophysics VxO GITs have been produced by various versions of the ADAPT tool set. Currently, ADAPT has been used primarily to describe data products that are stored on the NASA GSFC CDAWeb data server by using the Common Data Format, CDF. Over 1,000 such data product descriptors have been generated via ADAPT and submitted for VxO registration. An early version of the ADAPT, then called the SPASEnator, was used to generate data product descriptions for World Data Center ground magnetic field and other data sets. ADAPT is not limited in terms its ability to skim metadata out of variously formatted self-describing data products. It has been constructed in a modular fashion that allows the harvesting such metadata by substitution of a single routine. And, another valuable aspect of ADAPT is its ability to provide detailed data parameter attribute information. The parameter information is crucial to enable value-added services that rely on leveraging the SPASE metadata information. Finally, well-documented SPASE descriptions can also be used to ease the archiving of space weather data products.

PSW.4-0008-18 VOEVENT FOR SUN-EARTH AND PLANETARY SPACE WEATHER

GEOPSUniv paris Sud 11, Orsay, France

With its Planetary Space Weather Service (PSWS), the Europlanet-H2020 Research Insfrastructure (EPN2020RI) project is proposing a compelling set of databases and tools to that provides Space Weather forecasting throughout the Solar System. We present here the selected event transfer system (VOEvent). We describe the user requirements, develop the way to implement event alerts, and chain those to the 1) planetary event and 2) planetary space weather predictions. The service of alerts is developed with the objective to facilitate discovery or prediction announcements within the PSWS user community in order to watch or warn against specific events. The ultimate objective is to set up dedicated amateur and/or professional observation campaigns, diffuse contextual information for science data analysis, and enable safety operations of planet-orbiting spacecraft against the risks of impacts from meteors or solar wind disturbances.

The Europlanet H2020 Research Infrastructure project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 654208.

PSW.4-0009-18 THE ESA VIRTUAL SPACE WEATHER MODELLING CENTRE - PART 2

Daniel Heynderickx, dhconsultancy@skynet.be DH Consultancy, Leuven, Belgium

Robbe Vansintjan, robbe.vansintjan@oma.be Royal Observatory of Belgium, Ukkel, Belgium Andrey Kochanov, andrey.kochanov@gmail.com KU Leuven, Heverlee, Belgium

VSWMC

Stefaan Poedts (KU Leuven), Andrea Lani and Herman Deconinck (VKI), Ngoc-Diep Ho and Fabien Diet (SAS), Daniel Heynderickx (DH Consultancy), Johan De Keyser, Erwin De Donder, Norma B. Crosby and Marius Echim (BISA), Luciano Rodriguez, Andy Devos, Freek Verstringe and Benjamin Mampaey (ROB), Richard Horne, Sarah Glauert and John Isles (BAS), Piers Jiggens, Ralf Keil, Alexi Glover, Alain Hilgers and Juha-Pekka Luntama (ESA)

The goal of the ESA ITT project AO-1-8384-15-1-NB VSWMC-Part 2 is to further develop the Virtual Space Weather Modelling Centre (VSWMC), building on the Phase 1 prototype system and focusing on the interaction with the ESA SSA SWE system. The objective and scopes of this project include:

The efficient integration of new models and new model couplings, including a first demonstration of an end-to-end simulation capability.

The further development and wider use of the coupling toolkit and the front-end GUI which will be designed to be accessible via the SWE Portal.

Availability of more accessible input and output data on the system and development of integrated visualization tool modules.

The consortium that took up this challenge involves: 1) the Katholieke Universiteit Leuven (Prime Contractor, coordinator: Prof. S. Poedts); 2) the Belgian Institute for Space Aeronomy (BIRA-IASB); 3) the Royal Observatory of Belgium (ROB); 4) the Von Karman Institute (VKI); 5) DH Consultancy (DHC); 6) Space Applications Services (SAS); 7) British Antarctic Survey (BAS).

The VSWMC-Part 2 project started in February 2016. At the time of the meeting, the project will be finished, which means that all the models (EUHFORIA, CTIM, CTAN2, BAS-RBM, COOLFluiD, GUMICS, etc.) and all the model couplings will be installed and operational in the VSWMC. Hence, after a short description of what and how, several models and model couplings will be demonstrated, including a full Sun-to-Earth scenario simulation of a CME evolution and impact at Earth.

The VSWMC system is being developed under ESA's Space Situational Awareness (SSA) Programme and is intended to become an operational system as part of the ESA SSA SWE system.

PSW.4-0010-18 DEVELOPING GUIDELINES FOR TRANSPARENT DATA DISCOVERY, ACCESS AND DISTRIBUTION

Daniel Heynderickx, dhconsultancy@skynet.be DH Consultancy, Leuven, Belgium

Ralf Keil, ralf.keil@esa.int

European Space Agency (and Rhea System), Darmstadt, Germany

The panel event will conclude with a half hour round table discussion, with the aim of identifying guidelines for improving access to data holdings and querying of existing metadata standards. Participants are invited contribute to the discussion and to prepare questions and (very) short presentations beforehand.

PSW.4-0011-18 OPERATIVE PRODUCTS OFFERED BY LAMP (LABORATORIO ARGENTINO DE METEOROLOGíA DEL ESPACIO) IN ARGENTINA

Vanina Lanabere, vaninalanabere@gmail.com Universidad de Buenos Aires, Argentina, Argentina Sergio Dasso, sdasso@iafe.uba.ar

Instituto de Astronomía y Física del Espacio (IAFE), Buenos Aires, Argentina Adriana Gulisano, sdasso@iafe.uba.ar

IAFE, Buenos Aires, Argentina

Viviana Lopez, vivianaelisa23@gmail.com

Servicio Meteorológico Nacional, Buenos Aires, Argentina

The number of countries developing operative Space Weather (SWx) activities has significantly increased during the last years. Several international institutions, as for instance the World Meteorological Organization (WMO), the International Civil Aviation Organization (ICAO), the United Nations Office for Outer Space Affairs (UNOOSA), have began to develop programs and activities on Space Weather, some of them with the aim of having answers to the negative effects of extreme SWx events. At the beginning of 2016, our laboratory on SWx in Argentina (LAMP: Laboratorio Argentino de Meteorología del esPacio) started to develop activities on operative SWx. These activities are being developed by four institutions: Departamento de Ciencias de la Atmósfera y los Océanos at Universidad de Buenos Aires (DCAO-UBA), Instituto de Astronomía y Física del Espacio (IAFE), Instituto Antartico Argentino (IAA), and Servicio Meteorológico Nacional (SMN). These SWx activities started in 2014 with a programme of courses on operative SWx. In 2015, a website at DCAO started to offer the first operative products in Space Weather (spaceweather.at.fcen.uba.ar), offering information about the current conditions of the energetic proton flux arriving to the terrestrial environment, online information about the flux of radiation at two X-rays bands near Earth (GOES), and also information of the Kp index. A forecasting service of SWx is also provided. Since 2016, we started to develop a daily monitoring of real-time information on the SWx conditions, in particular, the conditions of the Sun, the interplanetary medium, the magnetosphere, and the ionosphere. The information is analyzed by each participant and discussed later on, during monthly briefings. A weekly report is done as a resume of the space weather activity and it is posted on the website. Also from a collaboration between DCAO and EMBRACE-INPE, a product showing the total electron content in the Argentine ionosphere is also include in the portal. We present here an example of the activities on operative Space Weather developed in Argentina and a summary of the products we develop in the LAMP group.

PSW.4-0012-18 FACILITATING ADVANCEMENTS IN SPACE WEATHER DATA AVAILABILITY THROUGH A SPACE WEATHER TESTBED AND DATA PORTAL

Christopher Pankratz, chris.pankratz@lasp.colorado.edu

LASP / University of Colorado, Boulder, Colorado, United States

Society has grown reliant on complex and highly interconnected technological systems, which makes us increasingly vulnerable to the effects of space weather events. An extreme space weather event today could conceivably impact many of the crucial systems we rely on, including disrupting operating earth-orbiting satellites, potential collapse of electrical grids, and impairing navigation, communication, and remote sensing capabilities. Thus, it is imperative that the scientific community address the question of just how severe events might become and to ensure stakeholders have access to the essential data needed for research and decision making. Stakeholders include policy makers and public safety officials who need to be informed by the facts on what might happen during extreme conditions. This requires essentially extremely timely up-to-the-minute alerts, warnings, and also forecasts of severe space weather events, which in turn demands measurements, models, and associated data products to be available via the most effective data discovery and access methods possible.

Similarly, advancement in the fundamental scientific understanding of space weather processes is also vital, requiring that researchers have convenient and effective access to a wide variety of data sets and models from multiple sources. The space weather research community, as with many scientific communities, must access data from dispersed and often uncoordinated data repositories to acquire the data necessary for the analysis and modeling efforts that advance our understanding of solar influences and space

physics on the Earth's environment. The University of Colorado (CU) is a leading institution in both producing data products and advancing the state of scientific understanding of space weather processes, is well positioned to address many of these issues. CU is inaugurating a dedicated Space Weather Technology, Research, and Education Center (SWx TREC) that will serve many of these needs, including implementation of an interoperable data portal intended to more effectively serve the needs of the Space Weather research community, as well as facilitating the advancement of models into production/operational use. In this presentation, we will outline the motivating factors for effective space weather data access and present plans and methods for meeting model testing/incubation needs, as well as the data management and access needs of the disparate communities who require space weather data and information.

PSW.4-0013-18 OPEN SOURCE DATAHUBSYSTEM: FROM SENTINELS DATA ACCESS TO AN AGNOSTIC DATA DISTRIBUTION TOOL

Calogera Tona, calogera.tona@serco.com Serco S.p.A., Frascati, Italy

Raffaele Bua, raffaele.bua@serco.com Serco S.p.A., Frascati, Italy

Cristina Arcari, cristina.arcari@serco.com Serco S.p.A., Frascati, Italy

Arturo Montieri, arturo.montieri@serco.com Serco S.p.A., Frascati, Italy

Barbara Borgia, barbara.borgia@serco.com Serco S.p.A., Frascati, Italy

Keywords: Open Source Data Hub System (OS DHuS), data access, dissemination, Sentinels, Copernicus, Earth Observation, European Space Agency (ESA), Landsat-8, Cosmo-Skymed, Pleiades.

Today we are assisting to an increasing amount of heterogeneous and distributed Earth Observation data. These data allow to investigate better our Earth from different perspectives and to monitor and observe its environment and security. In this challenging context, the European Union's Earth Observation Programme Copernicus [1], plays an important role looking at our planet promoting free and open access policy to data, creating new services and benefits for all users (e.g. data scientists, researchers, service providers and decision policy makers). This work describes the Data Hub System, an open source software developed by a European consortium (lead by Serco-Gael companies) to guarantee ESA Copernicus data access. The OS DHuS is used to disseminate all Sentinels data products via two different access mechanisms: Graphical user interface (GUI) and Application Program interface API. [2].The DHuS, being open source is online in GitHub public repositories [3]. This paper will show in particular how OS DHuS modularity allows to create plug-in components dedicated to the management of heterogeneous set of data (e.g. EO data, maps, etc.). We'll illustrate the developed modules, called add-ons, to handle also non-sentinel missions. Landsat-8, Cosmo-Skymed, and Pleaides add-ons represent some of these examples available in our public GitHub repositories [4]. This approach demonstrates how the OS DHuS can be considered an agnostic Earth Observation and geospatial information data access and dissemination tool. The software can be easily extended and enriched with new modules, to manage dispersed datasets from heterogeneous fields like in situ data

(i.e. ground stations, airborne sensors and sea-borne sensors). [1] http://www.copernicus.eu/

[2] https://scihub.copernicus.eu/dhus/ [3] http://sentineldatahub.github.io/DataHubSystem/

[4] https://github.com/SentinelDataHub?tab=repositories

PSW.4-0014-18 NGSAT - A FRAMEWORK FOR SPACE EXPERIMENT DATA WAREHOUSE

Minh Duc Nguyen, nguyendmitri@gmail.com

Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia

This work introduces the NgSat framework developed at SINP MSU in 2016. NgSat provides tools, libraries, and routines that significantly ease the process of developing automatic systems for space experiment data downloading, processing, storage, and distribution. NgSat automates the whole satellite data processing cycle which consists of the following steps: connecting to satellite data sources, downloading new data, extracting scientific data from the downloaded data, inserting processed data into a database, and moving data to a storage. The approach proposed in NgSat was evaluated through real-world scenarios and addressed the challenges related to space experiment data warehouse. NgSat can potentially be adapted to a wide range of data warehousing scenarios in other fields of physics.

PSW.4-0015-18 INTEGRATED SYSTEM TO HANDLE AND VISUALIZE AURORAL OVAL DATA

Anatoli Petrukovich, apetruko@iki.rssi.ru

Space Research Institute (IKI), Russian Academy of Sciences, Moscow, Russia Ivan Uvarov, uvarov@d902.iki.rssi.ru

Space Research Institute of RAS (IKI), Moscow, Russia Oleg Nikiforov, gelokin2201@gmail.com

Space Research Institute of the Russian Academy of Sciences, Moscow, Russia Tatiana Podladchikova, t.podladchikova@skoltech.ru

The Skolkovo Institute of Science and Technology, Skolkovo, Russia

Space Weather is an integrated science, encompassing the full cause and effect chain of physical processes from Sun to Earth surface. Data handling and access tools available now usually concentrate on some specific data type,like solar images or time-sequences of spacecraft plasma data. Our prime interest is Earth auroral region, described with a very wide variety of heterogeneous data, including auroral spacecraft and ground imaging, magnetic and electric current vector maps, radars, etc. Currently a tool able to integrate, visualize and process the whole variety of available data is absent. We are developing such a system for auroral data storage, access, visualization and analysis. It is based on a Geo-information Web-based System, used in IKI for remote sensing data, and currently handling more than 2 PB data online, including data computations. This system driver is now updated to include geomagnetic coordinate transformations, real-time solar wind data, geomagnetic indices, etc. Currently the system includes DMSP UV data, auroral oval models, and is rapidly filled with other sources. The bonus of using standard remote sensing GIS is availability of real-time weather data for any location. Having in mind huge data volumes typical to remote sensing data, this auroral system is capable to handle almost unlimited amounts of any existing auroral data. The Web-site will be shown at poster.

PSW.5-0001-18 ACTIVITIES AT THE NATIONAL SCIENCE FOUNDATION IN SUPPORT OF SPACE WEATHER RESEARCH

Michael Wiltberger, mwiltber@nsf.gov

National Science Foundation, Alexandria, Virginia, United States

NSF's primary role in developing space weather readiness for the nation is in the support of basic research that advances fundamental understanding of space weather and related processes. This includes the generation of solar storms, their propagation through the interplanetary medium, and their impact on the near-Earth space environment. NSF-supported community members draw upon that research in the development of models for these space weather processes. These models often utilize observations from NSF's persistent ground-based observational platforms, among others, to test and further refine our community's understanding of space weather. Among the goals of these NSF-funded research activities are to benefit society and contribute to the achievement of specific desired societal outcomes, such as improving space weather predictive capabilities.

PSW.5-0002-18 ESA SSA SPACE WEATHER ACTIVITIES AND COSPAR-ILWS ROADMAP

Juha-Pekka Luntama, juha-pekka.luntama@esa.int ESA, Darmstadt, Germany

Alexi Glover, alexi.glover@esa.int

European Space Agency, Darmstadt, Germany Stefan Kraft, stefan.kraft@esa.int

European Space Agency, Darmstadt, Germany

One of the objectives of the ESA Space Situational Awareness (SSA) Programme is to develop a European Space Weather (SWE) System that can provide operational space weather services to support protection of European space and ground based assets against adverse effects from space weather. Service provision in the system is based on a federated network of Expert Groups (EGs) within ESA Member States grouped into five thematic Expert Service Centres (ESCs). EGs are responsible for the processing of the space weather measurement data into products. These products are combined into services to the end users by the SSA SWE Coordination Centre (SSCC).

The Programme is currently in its third phase focussing on strategic objectives that have been defined together with stakeholders and the ESA member states. Current ESA SSA space weather activities are focussing on verification and validation of the available precursor services and targeted developments of new service capabilities. These development activities are addressing for example developments of physics based space weather models and enhanced services targeting critical user domains including satellite operations, ground based power system operations and aviation.

ESA SSA Programme's main objective is to develop operational space weather service capability. This means that many of the activities within the programme are related to Researchto-Operations (R2O) developments based on European scientific expertise. COSPAR-ILWS Roadmap provides a reference that supports the dialogue between the Programme and the scientific community about research that is needed for new building blocks for operational space weather services. ESA SSA Programme is continuously collecting feedback from the end users to improve the understanding of the user needs and to enhance the already available space weather services. COSPAR-ILWS Roadmap offers a global framework for this Operations-toResearch (O2R) discussion. ESA is also actively participating coordination of space weather activities in many international forums including UN COPUOUS, WMO, CGMS, ISES and

COSPAR PSW.

This presentation will address the status and prospects of the Space Weather System in ESA's SSA Programme, the international collaboration framework and how ESA SSA Programme is approaching international space weather coordination within Europe and at global level.

PSW.5-0003-18 SUPPORTING SPACE WEATHER OPERATIONS-TO-RESEARCH ACTIVITIES

Terrance Onsager, terry.onsager@noaa.gov

NOAA Space Weather Prediction Center, Boulder, Colorado, United States Elsayed Talaat, elsayed.t.talaat(at)nasa.gov

NASA Headquarters, Washington, District of Columbia, United States Michael Wiltberger, mwiltber@nsf.gov

National Science Foundation, Alexandria, Virginia, United States Howard Singer, howard.singer@noaa.gov

NOAA Space Weather Prediction Center, Boulder, Colorado, United States Brent Gordon, brent.gordon@noaa.gov

NOAA Space Weather Prediction Center, Boulder, Colorado, United States

The COSPAR/ILWS Space Weather Roadmap recommends actions to advance international preparedness to space weather. This involves identifying the highest priority research areas to address space weather service needs. In the United States, the National Space Weather Action Plan addresses the need to improve the understanding of, forecasting of, and preparedness for space weather events. In response to the need to advance and coordinate space weather research and operations capabilities, NASA, NOAA, and NSF are supporting research to promote space weather operations-to-research (O2R) activities. O2R activities can broadly be defined as the joint pursuit of improvements of operational capabilities and advancements in related fundamental research. The focus of an initial pilot research opportunity is the improvement of forecasts of the background solar wind, solar wind structures, and coronal mass ejections. This presentation will describe the multi-agency effort to promote operations-to-research and research-to-operation activities and discuss future goals, including the possibility of internationally coordinated efforts.

PSW.5-0004-18 ISAS/JAXA HELIOPHYSICS PROGRAM

Masaki Fujimoto, fujimoto.masaki@jaxa.jp

Institute of Space and Astronautical Science, Kanagawa, Japan

There has been multiple Heliophysics missions by ISAS/JAXA that served the world-wide scientific community by providing it with high-quality data. The good examples for large missions are Geotail (launch in 1992, still operative) and Hinode (launch in 2006, still operative). Two small missions launched by the Epsilon rocket, Hisaki in 2013 and ERG/Arase in 2016, are good examples showing that small missions of this class can be useful to Heliophysics research. That is, there are multiple platforms that ISAS can offer to the world-wide community to deepen the space weather research. What mechanism is missing in order to make a necessary international collaboration utilizing an ISAS platform to happen? I would like to disclose the dialogue I have been having with the community members and discuss what should be the next step in this line.

PSW.5-0005-18 CHINA ACTIONS TO THE SPACE WEATHER ROADMAP

Ji Wu, wuji@nssc.ac.cn

National Space Science Center, Chinese Academy of Sciences, Beijing, China

In response to the COPSAR/ILWS Roadmap recommendations, China has recently approved several projects aiming at enhance the abilities of understanding and monitoring space weather. The major projects are: ASO-S (Advanced Space-borne Solar Observatory), MIT (Magnetosphere - IonosphereThermosphere Coupling Exploration), and the ESA-China joint space weather science mission SMILE (Solar wind - Magnetosphere - Ionosphere Link Explore), a new mission to image the magnetosphere. Compared to satellites, ground-based monitors are cheap, convenient, and provide continuous real-time data. The new projects on the ground are: Chinese Meridian Project II (CMP-II), a ground-based program fully utilizing the geographic location of the Chinese landmass to monitor the geo-space environment, the International Meridian Circle Program (IMCP) for space weather hopes to connect chains of ground-based monitors at the longitudinal meridians 120 deg E and 60 deg W. In these short presentation, all the above will be mentioned briefly.

PSW.5-0006-18 SPACE WEATHER IN THE UK

Richard Harrison, richard.harrison@stfc.ac.uk

Rutherford Appleton Laboratory, Didcot, United Kingdom Mario M. Bisi, mario.bisi@stfc.ac.uk

Rutherford Appleton Laboratory, Oxford, United Kingdom Mike Hapgood, mike.hapgood@stfc.ac.uk

Science and Technology Facilities Council, United Kingdom

The UK Government's inclusion of severe space weather on the National Risk Register (NRR) of Civil Emergencies in recent years has led to a somewhat co-ordinated, yet wide-ranging set of activities that is attempting to tackle space weather threats at the national level, but incorporating active engagement on the international scene. Two immediate responses to the Government's decision in managing the space weather risk are: (a) the setting up of a UK space weather forecasting centre at the Met Office, in Exeter (UK) - which is only one of two civil forecasting centres world-wide that are manned 24 hours a day, 7 days a week; and (b) the formation of the Space Environment Impacts Expert Group (SEIEG), chaired by Prof. Mike Hapgood from STFC RAL Space, that advises the UK Cabinet Office and the Government Department of Business, Energy and Industrial Strategy. These activities have come about from active partnerships between agencies, industrial groups, and the science community to ensure that the wide range of issues involved are fully covered. In parallel, the UK Space Agency (UKSA), in responding to these activities and engaging with key institutes such as the STFC Rutherford Appleton Laboratory (RAL) and the Met Office, has become a major supporter of the emerging ESA Space Situational Awareness (SSA) space weather programme, which ultimately ensured that the UK has taken leadership roles in the instrument development activities for the planned Lagrange L5 space weather mission as well as in service activities such as the Heliospheric Expert Service Centre. All of these activities, and more, have come about because of extensive dialogue between the academic community, the industrial community, the relevant agencies, and Government in the UK, as well as with international groups such as ESA and NOAA. The strategic approach in the UK has been particularly successful and continues to evolve. Of particular interest in the coming years is the development of the role of the UN COPUOS and COSPAR, with which the UK will be fully engaged.

PSW.5-0007-18 UNOOSA VIEW ON COSPAR/ILWS ROADMAP AND GLOBAL COORDINATION FOR SPACE WEATHER

Simonetta Di Pippo, simonetta.dipippo@un.org

United Nations Office for Outer Space Affairs, Vienna, Austria

Space weather monitoring, prediction and research have become essential pillars of the global response to advance space weather science, thereby advancing the development of improved operational space weather services and improving resilience against adverse space weather effects and impacts.

There are many instruments to be included in coordination efforts. Among the most important is providing decisionand policy-makers with relevant information by awareness-raising about hazards and risks related to space weather. When risks are identified, the steps to mitigate them could be taken more effectively. Improving resiliency to address them is a process in which coordination and communication of best possible designs and engineering could lead to improved mitigation or complete avoidance of adverse effects. When infrastructure is better protected, data can be gathered more reliably and through increased coordination, open-data sharing and real-time data accessibility the stakeholders can avoid duplication of efforts and help each other in forecasting hazardous events.

There is a need to monitor progress in field of space weather, a task that could be delivered by already established relevant stakeholders, including UNOOSA, COSPAR, ICAO, WMO, ISES, IAU, or SCOSTEP to name a few.

PSW.5-0008-18 WMO'S INITIATIVE FOR PROMOTING SPACE WEATHER IN OPERATION

Toshiyuki Kurino, tkurino@wmo.int

WMO Space Programme, Geneva, Switzerland Robert Rutledge, robert.rutledge@noaa.gov

NOAA Space Weather Prediction Center, Boulder, Colorado, United States

The space weather observations include the following domains: the Sun, interplanetary space, near-Earth space, magnetosphere, ionosphere, thermosphere, geomagnetic field. The required space weather data are obtained by a numerous types of instruments, both in space and on Earth. These platforms are operated by different organizations, in many cases not associated with meteorological services.

In May 2015, the World Meteorological Congress (Cg-17) agreed that WMO should undertake international coordination of operational space weather monitoring and forecasting with a view to support the protection of life, property and critical infrastructures and the impacted economic activities in an optimized overall effort. In June 2016, the Executive Council (EC-68) approved the Four-year Plan for WMO activities related to Space Weather in 2016-2019, and requested to establish Interprogramme Team on Space Weather Information, System and Services (IPT-SWeISS) who will pursue the work and achievement of the former expert team on Space Weather, the Interprogramme Coordination Team on Space Weather (ICTSW) with 23 WMO Member Countries and 6 UN and Intergovernmental Organizations as of 10 January 2018.

Ad hoc Task Team on Aviation (TT-AVI) was established in IPT-SWeISS to assist WMO in the conducting of site assessments and audits of prospective space weather information at the request of the International Civil Aviation Organization (ICAO). Consistent with the working arrangements between the two Organizations, ICAO has officially requested WMO to undertake such site assessments and audits between October 2017 and February 2018 in view of ICAO's intention to introduce an operational space weather information service for international air navigation by November 2018.

In this talk, the present status of WMO's initiative for promoting space weather will be presented with its difficulties and problems.

PSW.5-0009-18 SCOSTEP EFFORTS IN THE GLOBAL COORDINATION FOR SPACE WEATHER SCIENCE

Nat Gopalswamy, nat.gopalswamy@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States

The scientific committee on solar terrestrial physics (SCOSTEP) is an interdisciplinary body of the International Council for Science (ICSU) collaborating with five scientific unions unions (IAMAS, IAU, IUGG/IAGA, IUPAP, URSI) and three interdisciplinary bodies (COSPAR, SCAR, and WDS). SCOSTEP is actively involved in the science, capacity building, and public outreach activities related to solar terrestrial physics. By design, space weather is a significant part of solar terrestrial physics dealing with the short-term variability of the Sun and how it affects Earth's space environment. The space weather activities of SCOSTEP are conducted via the scientific programs such as the current VarSITI (variability of the Sun and Its Terrestrial Impact). Of particular interest for space weather is the ISEST (International Study of Earthaffecting Solar Transients) project directly deals with the two sources of space weather at Earth, viz., coronal mass ejections and high speed solar wind and their consequences (geomagnetic storms and solar energetic particle events). As part of this project, daily alerts are issued whenever a space-weather causing feature such as a filament or a coronal hole appears near the disk center of the Sun. SCOSTEP also collaborates with COSPAR, URSI, and the International Space Weather Initiative (ISWI) to run Space Science Schools for PhD students and young postdocs. These capacity building activities enhances space weather literacy among researchers in developing countries. SCOSTEP also runs a visiting scholar program that provides shortterm (1-3 months) training in solar terrestrial relationship in advanced laboratories for students from developing counties.

PSW.5-0010-18 GLOBALLY COORDINATED SPACE WEATHER EDUCATION AND OUTREACH INITIATIVE: UNOOSA SCHOOLS AND OUTLOOK ON COORDINATED EDUCATIONAL AND OUTREACH OPPORTUNITIES

Simonetta Di Pippo, simonetta.dipippo@un.org

United Nations Office for Outer Space Affairs, Vienna, Austria

The Office for Outer Space Affairs, in its central role of fostering capacity-building in the use of space science and technology and their applications for the benefit of all countries, in particular developing countries, has organized several hundred training courses, workshops, seminars and meetings for the benefit of Member States, including in the area of space weather.

The International Space Weather Initiative (ISWI), which grew out of the International Heliophysical Year 2007 (IHY), is an international cooperation programme to advance space weather science by combining the deployment of instruments with the analysis and interpretation of space weather data obtained from those instruments in conjunction with space data, and to advance education and capacity-building in space weather science and communicate the results to the public.

IHY and ISWI have contributed to the development of space science schools that encourage students to consider a career in space science. In that context, the Office for Outer Space Affairs is organizing discussion forums to educate the public and policy-makers about space weather phenomena, as well as training courses and seminars for students and professionals in space weather data analysis and prediction. Those activities bring together a large number of experts every year, including experts from developing nations.

PSW.5-0011-18 COMMUNITY COORDINATED MODELING CENTER: BRINGING SPACE WEATHER AWARENESS TO THE NEXT GENERATION

Anna Chulaki, anna.chulaki@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States Community Coordinated Modeling Center

Maria Kuznetsova, Sarabjit Bakshi, Justin Boblitt, Darren De Zeeuw, Peter Macneice, Leila Mays, Michelle Mendoza, Richard Mullinix, Kiran Patel, Asher Pembroke, Lutz Rastaetter, Ja Soon Shim, Aleksandre Taktakishvili, Tina Tsui, Yari Collado-Vega, Chiu Wiegand, Yihua Zheng

Community Coordinated Modeling Center (CCMC) is a multi-agency partnership aimed at enabling, supporting and performing research and development for next-generation space science and space weather models. Additionally, over the past decade we have become an international hub for raising generations of young space scientists and engineers by providing multifaceted opportunities for hands-on learning, supporting graduate education and research, and spreading space weather awareness worldwide. CCMC hosts an expanding collection of models developed by the international Heliophysics community and has built web-based tools, including interfaces for model execution and analysis of simulation results, an online space weather awareness system (iSWA), a database of space weather phenomena and multiple space weather learning and analysis tools.

These unique assets and services stand ready to support graduate summer schools worldwide, including ones in remote locations. CCMC's portable computer systems have enabled student interactive learning during schools as far as India and Siberia. Our hands-on exercises and tailored simulation modules are a staple of Heliophysics summer schools. We are always happy to develop new materials on your request!

Our more recent educational effort is focused on the firstand second year college undergraduates (including students from two year colleges) and could possibly become a component of the new millennium core education. The CCMC has developed a hands-on space weather forecaster training package, Space Weather Bootcamp, aimed at igniting young people's enthusiasm for space physics by involving them in an active, real life project. The training provides space environment awareness, an understanding of the fundamentals of the Sun-Earth system and of the impacts of space weather on humans and technological systems. Our undergraduate experimental research forecasters get an exciting opportunity to work with the CCMC team engaged in prototyping the latest state-of-the-art space weather forecasting capabilities and to actively contribute to the NASA missions through real time analysis and forecasting. The Bootcamps are also open to graduate students, mission operators, interested researchers and educators.

Our experience shows that to build space weather capacity we can start promoting space weather awareness to students in their very first year in college, in a way that helps recruit and retain young people in science. We can reach wider audiences by building more interactive tools for space weather learning (including citizen science applications) and by organizing training for teachers and college educators. At the moment, the CCMC is the sole hub for this kind of space weather awareness training. With international help, multiple forecaster training hubs can be established at different locations over the world, with students from different countries in different time zones collaborating on round-the-clock, real time space weather forecasting.

PSW.5-0012-18 SPACE WEATHER WITHIN THE FRAMEWORK OF COSPAR'S PANEL ON CAPACITY BUILDING

Alexi Glover, alexi.glover@esa.int

European Space Agency, Darmstadt, Germany

Through its Panel on Capacity Building, COSPAR organises a series of capacity building workshops with various partners. The workshops aim to convey practical knowledge in areas addressed by COSPAR's Commissions and Panels and build lasting bridges between scientists. The typical workshop aims to provide practical training based on currently operating missions and extensive online data archives. In 2016 and 2017 3 and 4 workshops were organised respectively, covering a range of areas including Space Weather.

The first COSPAR Capacity Building Workshop focusing on Space Weather took place in 2016 in Kamchatka, Russia led by IKIR RAS and the second will take place later in 2018 in Sao Jose dos Campos, Brazil led by INPE's Embrace Programme. Space Weather is by definition a highly cross-disciplinary topic and the COSPAR framework provides an excellent opportunity to develop a training format which combines scientific excellence with operational awareness and practices. Current experience will be presented along with possible future directions.

PSW.5-0013-18 INPUTS AND OUTLOOK ON ROADMAP AND I-SWAT FROM PSW.1,4 EVENTS:

Maria Kuznetsova, maria.m.kuznetsova@nasa.gov

NASA Goddard Space Flight Center/Heliophysics Science Division, Greenbelt, Maryland, United States

Updates from PSW.1: Metrics and validation needs for space weather models and services (Alexi Glover) - Updates from PSW.4: Coordinated Information dissemination and interoperability (Daniel Heynderickx)

PSW.5-0014-18 INPUTS AND OUTLOOK ON ROADMAP AND I-SWAT FROM PSW.2-3 EVENTS:

Maria Kuznetsova, maria.m.kuznetsova@nasa.gov

NASA Goddard Space Flight Center/Heliophysics Science Division, Greenbelt, Maryland, United States

Updates from PSW.3 Towards standardized ionospheric activity scales (N. Jakowski) - Updates from PSW.2: Space weather in solar system and beyond (M. Grande)

PSW.5-0015-18 INPUTS TO AMBIENT SOLAR WIND MODELING: PLANS FOR INTERNATIONAL SPACE WEATHER ACTION TEAMS

Jon Linker, linkerj@predsci.com

Predictive Science, Inc., San Diego, California, United States

As part of the COSPAR Space Weather Roadmap study (Schrijver et al. 2015), several observational, computational, and theoretical needs were identified, which in turn require improvements to our understanding in specific areas. One such area is the ambient corona and solar wind, which form the backdrop for eruptive events like coronal mass ejections. A key input is the solar magnetic field, which structures the corona and solar wind; a related input is coronal heating, which is strongly correlated with the magnetic field and is also important for solar irradiance. The roadmap also identifies the challenge of transforming the cohort of spaceweather researchers into an effectively functioning global research community. In this talk, I will briefly outline how the concept of International Space Weather Action Teams (ISWAT) may be brought to bear in improving space-weather related capabilities for understanding and modeling the ambient corona and solar wind.

PSW.5-0016-18 IDEAS AND PLANS FOR ISWAT CLUSTERS FOCUSED ON PROPAGATION OF TRANSIENTS THROUGH EVOLVING AMBIENT HELIOSPHERE AND INPUT TO GEOSPACE

Manuela Temmer, manuela.temmer@uni-graz.at Institute of Physics, UNI Graz, Austria, Graz, Austria

Space Weather is an important issue of global matter, but needs coordinated efforts. Many international groups perform research on the propagation of transients and based on that develop Space Weather forecasting services. In order to avoid duplication and to efficiently improve the performance of currently available models, they need to become better visible and to undergo scientific peer-review qualification. iSWAT is an international, community driven effort and provides the required platform to challenge propagation models and to exchange experience with peers. iSWAT is also a network that fosters collaboration among interdisciplinary group members, like from geospace, that are potential users of propagation models. Coordinated international cooperation will offer new perspectives and will make models more efficient and progress them efficiently towards operational tools. Operational tools are not only meant to be used by (industrial) end-users, but particularly by peers in order to get a more complete understanding of the physical processes underlying CME propagation.

PSW.5-0017-18 IDEAS AND PLANS FOR ISWAT CLUSTERS FOCUSED ON SOLAR ENERGETIC PARTICLES THROUGHOUT THE HELIOSPHERE

Robert Wimmer-Schweingruber, wimmer@physik.uni-kiel.de Christian-Albrechts-Universität zu Kiel, Kiel, Germany

Different from photons or energetic neutral atoms, charged solar energetic particles are tied to the local magnetic field which governs their transport throughout the heliosphere. In the last decade, measurements of energetic particles accelerated at the Sun have shown us that these particles can be observed to regions of the heliosphere which are not believed to be magnetically connected to the acceleration site. These humbling observations underline the need for coordinated efforts in the following areas: 1) determination of the global solar and heliospheric magnetic field, 2) measurements of the turbulent properties of the inner heliosphere,

3) multi-point measurements of energetic particles throughout the heliosphere, 4) modeling of particle acceleration and transport through this background. These efforts are not as difficult as they may seem. We stand at the eve of a "Golden Age" for in-situ investigations of the inner heliosphere with a concurrent international fleet of spacecraft distributed in many regions of space. Ensuring free exchange of scientific and other data from these missions will allow us to understand particle acceleration and transport and to use solar energetic particles as a tool to probe the magnetic structure of the inner heliosphere.

PSW.5-0018-18 IDEAS AND PLANS FOR THE DEVELOPMENT OF I-SWAT CLUSTERS FOR NEAR-EARTH RADIATION AND PLASMA ENVIRONMENT AND IMPACTS ON (AERO)SPACE ASSETS

Ian Mann, imann@ualberta.ca

University of Alberta, Edmonton, Canada

The COSPAR-ILWS Roadmap (2015-25) "Understanding space weather to shield society" identified three impact pathways, including "Pathway II: Dynamic radiation belt modeling". To address Pathway II, and "to understand the particle environments of (aero)space assets leading to improved environmental specification and near-real-time conditions", the Roadmap recommends that community should "Combine spaceand ground-based observations of solar wind, particle populations within the magnetosphere, and ground-based magnetometer and ionospheric networks into radiation-belt models." Towards this goal, this talk will provide an initial overview of elements of the activities of International Space Weather Action Teams (I-SWAT) and clusters relating to the near-Earth space radiation and plasma environment, focussing on applications for understanding their impacts on (aero)space assets. Such I-SWAT activities include modelling efforts to advance our understanding of the fundamental processes responsible for space radiation dynamics, and improving our understanding of the linkages and between the highly coupled elements of the solar wind-magnetosphere-plasmasphere-ionosphere system. Such activities are essential to address one of the highest priority COSPAR-ILWS research areas to improve space weather information and forecasting to: "Understand the radiation belts through dynamic observation-based modeling".

PSW.5-0019-18 ATMOSPHERIC VARIABILITY AND SATELLITE DRAG

Sean Bruinsma, sean.bruinsma@cnes.fr

Centre National d'Etudes Spatiales, Toulouse, France

The global COSPAR-ILWS roadmap for 2015-2025 mentions satellite drag, but user needs, research (ongoing and opportunities), and recommendations are not discussed in the paper. The first task of the "Neutral Density and Orbit Determination at LEO" cluster is therefore consolidating a list of user needs for satellite drag forecasting capability in order to evaluate which items require improvement. This concerns not only the obvious candidate, the thermosphere model, but also the solar and geomagnetic drivers (often proxies) and the quality of their forecast, as well as the satellite model (shape, mass, material, etc).

To track progress of a thermosphere model appropriate metrics are required, as well as highquality and high-resolution data over many years. The 2017 International Forum on Space Weather Capabilities Assessment produced both metrics and test data, and models are currently being evaluated with help from CCMC. Pure model performance, i.e. using observed solar and geomagnetic input, is not constant but a function of time scale (solar cycle to minutes), solar and geomagnetic activity levels, and location. When forecasting density, thermosphere model errors increase due to the error in the forecast of the drivers. Forecast horizons vary from a few days to months, to years, to complete solar cycles in mission design. It is essential that solar and geomagnetic activity forecast models and thermosphere models are improved in concert, and this is foreseen in the present I-SWAT cluster design. Scoreboards for thermosphere models, solar and geomagnetic activity forecast models will be created.

The third component, satellite model, is the most problematic one. Standard models, such as CIRA for the atmosphere, do not exist. Our ultimate goal is satellite drag forecasting; improvement can be quantified too by means of precise orbit determination, i.e. scorecards can be produced. However, computation of satellite shape and aerodynamic coefficients must be harmonized first, either through applying identical models, or for example through scaling.

PSW.5-0020-18 IDEAS AND PLANS FOR ISWAT CLUSTERS FOCUSED ON IONOSPHERE VARIABILITY AND IMPACT ON COMMUNICATIONS AND NAVIGATION

Anna Belehaki, belehaki@noa.gr

National Observatory of Athens, Palaia Penteli, Greece Ioanna Tsagouri, tsagouri@noa.gr

National Observatory of Athens, Penteli, Greece

Masha M. Kuznetsova, maria.m.kuznetsova.1@gsfc.nasa.gov NASA GSFC, Greenbelt, Maryland, United States TechTIDE Consortium http://techtide.space.noa.gr/?page_id=1073

The ionospheric variability is the result of major processes that occur within the coupled atmosphere-ionosphere-magnetosphere system. Short-wavelength solar radiation, magnetospheric energetic particles, and magnetospheric convection are the key drivers that trigger enhancement of the ionospheric conductance at high latitudes and modify the electrical currents that flow between the ionosphere and magnetosphere. These injections of energy drive a global thermospheric circulation, exciting a spectrum of waves that redistribute energy both locally and globally. Planetary waves, tides, and gravity waves from the lower atmosphere propagate upwards, deposit momentum into the mean circulation, and generate electric fields via the dynamo mechanism in the lower ionosphere. Neutral winds and electric fields from these combined sources redistribute plasma over local, regional, and global scales and sometimes create conditions for instability and production of smaller-scale structures in neutral and plasma components of the system. The resulting large scale ionospheric effects, travelling ionospheric disturbances, scintillations and bubbles constitute a threat for operational systems using predictable ionospheric characteristics, such as GNSS, SBAS, HF communications, geolocation systems and for scientific observations such as the radio astronomy. Because of the strong local time and latitudinal character of the perturbations, the development of a global monitoring and prediction system for all scales of ionospheric disturbances is extremely challenging. This requires, at first, continuous improvements in the models' prediction capability to match users' requirements. Another major challenge is the users' awareness. This must be primarily addressed through the setup of a Research-to-Operations (R2O) validation framework which is the main mission of the CCMC at NASA and it is also attempted in the framework of the ESA SSA SWE programme for the European assets. Another important activity, which is implemented for the needs of the EC H2020 TechTIDE project, is the specification of the impacts with one-to-one correspondence between the type of ionospheric phenomena and the imposed perturbations in each affected system. This is attempted through the establishment of an open dialogue with the users that can lead to a database of effects, and through joint actions between scientists and users for the developments of mitigation technologies. The talk reviews ongoing efforts worldwide and provide recommendations for teaming and collaboration activities.

PSW.5-0021-18 ADDRESSING LONG-TERM SOLAR VARIABILITY AND CLIMATE CONSEQUENCES THROUGH THE ISWAT INITIATIVE

Dibyendu Nandi, dnandi@iiserkol.ac.in

Center of Excellence in Space Sciences India, IISER Kolkata, Mohanpur, India

.Abstract: In this talk, I will briefly summarize the current state of understanding of the solar magnetic cycle and its long-term variability. In the context of the international space weather roadmap, I will highlight outstanding issues in translating our understanding to forecasting of long-term solar activity and its space weather and climate consequences. We will discuss coordinated action plans under the umbrella of the International Space Weather Action Teams to address these challenges.

The LOFAR for Space Weather (LOFAR4SW) is an international project the aim of which is to deliver the full conceptual and technical design for creating a new leading-edge European research facility for space weather science. The project will engage with stakeholders to prepare a facility which produces unique research data with key impact on advance predictions of space weather events affecting crucial technological infrastructures of today's society.

The objective of LOFAR4SW is to prepare for a large scale high-end research facility in which completely simultaneous, independent observing modes and signal paths provide continuous access to two research communities: radio astronomy and space weather research.

Space weather science aims, through observation, monitoring, analysis and modelling, at understanding and ultimately predicting the complex state of the solar wind - magnetosphere - ionosphere - thermosphere system, and the potential impact on biological and technological systems on Earth. Increased fundamental knowledge, coupled to large-scale monitoring programs, is needed for much more advanced predictions of the impact of space weather events on Earth.

A fully-implemented LOFAR4SW system will enable a wide range of solar and space weather research topics to be tackled and have unique strengths in several high-impact science areas: tracing the initial launch of a CME; detailed tracking of the solar wind and CMEs through interplanetary space; in-depth studies of micro-structure in the Earth's ionosphere. This facility will uniquely provide the missing link of measurements of the interplanetary magnetic field on global scales - a key parameter in forecasting the severity of geomagnetic storm on Earth. The LOFAR4SW will allow scientists to to answer many important questions with regard to the solar corona, the heliosphere, and Earth's ionosphere.

The action was started on December 2017 and the aim of this presentation is to show the main goals of the project and the initiated activities

PSW.5-0024-18 THE CONTRIBUTION OF THE IONOSPHERE PREDICTION SERVICE PROJECT IN SUPPORTING THE MITIGATION OF THE IONOSPHERIC EFFECTS ON GNSS

Claudio Cesaroni, claudio.cesaroni@ingv.it

INGV, Institute Nazionale di Geofisica e Vulcanologia, Roma, Italy IPS team

L. Spogli, F. Rodriguez, G. De Franceschi, M. Aquino, F. Berrili, M. Hutchinson, S. V. Veettil,

V. Romano, R. Ronchini, S. Di Rollo and D. Del Moro.

The Ionosphere Prediction Service (IPS) is an on-going project funded by the EC (project 434/PP/GRO/RCH/15/8381; 2016-2018). IPS is led by TELESPAZIO (IT) in collaboration with the Istituto Nazionale di Geofisica e Vulcanolgia (INGV-IT), the University of Nottingham (UNOTT-UK), the University of Tor Vergata (UTOV-IT), the Nottingham Scientific Ltd (NSL,- UK) and TELESPAZIO VEGA (DE). The scope of this project is to design and develop a service prototype capable of providing different products to GNSS users and service providers that can assist with early warnings and predictions on the state of the ionosphere. Such products are fine-tuned to match the needs of the different communities (aviation, mass market, critical infrastructures monitoring etc.) to which the service is targeted. The core scientific contribution of the project is represented by the research activities carried out by the project's research collaborators (i.e., INGV, UNOTT and UTOV) with the aim to go beyond the state of the art in understanding the impact of significant ionospheric-related geophysical events on today's technology-based society. The outputs of the research activities are nowcasting and forecasting tools, dealing with different topics that can be divided into three blocks: "Solar and Space-Weather Monitoring" (UTOV), "Ionosphere weather monitoring and forecasting" (INGV) and "Receiver and user positioning performance" (UNOTT). TELESPAZIO is in charge of integrating all the products into a Central Processing and Storage Facility (CPSF) as a chain of processors. These are capable of describing the Space-Weather phenomena from the sun Sun to the ionosphere affecting the GNSS service provider and user community. This paper presents the nowcasting and forecasting algorithms developed in the frame of the research activities, their validation as well as the web portal in which the user can setup customized alerts and warnings.

PSW.5-0025-18 SPACE WEATHER SERVICE IN MEXICO. GROUND BASE INSTRUMENTAL NETWORK, WARNING SYSTEM AND SCIENTIFIC STUDIES.

The Mexican Space Weather Service (www.sciesmex.unam.mx) was created in 2014 in response of changes in the Civil Protection Law in Mexico. These modifications included space hazards and space weather events as national risks. The SCiESMEX comprises several products including a warning system, and weekly and special reports. SCiESMEX became a Regional Warning System of the International Space Environment Services (ISES) in June 2015. The SCiESMEX instrumental network includes real time data from a radio telescope to perform interplanetary scintillation (IPS) observations of solar wind conditions, two CALLISTO systems, cosmic rays observatory, a total magnetometer, and maps of the total electron content (TEC) using data from local networks of GPS receivers. This year we are deploying a network of five ionosondes, and a network of five magnetometers. The data from these instrumental networks will allow us to perform studies in Mexico to evaluate the regional responses to different space weather events. The SCiESMEX is also collaborating with National Civil Protection authorities to develop protocols to react to intense or extreme space weather events. These efforts in Mexico are also in agreement with COSPAR and United Nations recommendations to impulse international collaboration in space weather studies.

PSW.5-0026-18 GLOBALLY COORDINATED SPACE WEATHER EDUCATION AND OUTREACH INITIATIVE

Maria Kuznetsova, maria.m.kuznetsova@nasa.gov

NASA Goddard Space Flight Center/Heliophysics Science Division, Greenbelt, Maryland, United States

Dibyendu Nandi, dnandi@iiserkol.ac.in

Center of Excellence in Space Sciences India, IISER Kolkata, Mohanpur, India

Convener: Dibyendu Nandi, CESSI / IISER Kolkata

Description: This panel discussion will bring together diverse organizations involved in space weather education and outreach activities, provide brief summaries of ongoing activities and discuss a new initiative of the COSPAR Space Weather Panel towards global coordination in space weather awareness, education and outreach.

Plan: I plan to kick this off with a brief introduction highlighting the importance of global coordination in developing a framework for space weather education and outreach and COSPAR's Space Weather Panel's role in enabling this. Subsequently, speakers would be asked to present the activities of their organizations (5 minutes each, with slides if necessary).

PSW.5-0027-18 NATIONAL/REGIONAL AGENCIES VIEW ON COSPAR/ILWS ROADMAP AND GLOBAL COORDINATION FOR SPACE WEATHER.

Maria Kuznetsova, maria.m.kuznetsova@nasa.gov

NASA Goddard Space Flight Center/Heliophysics Science Division, Greenbelt, Maryland, United States

Questions to be addressed by the panelists: - How roadmap guidelines are correlated with national/regional/international programs, action plans and policies? - Are there any focused space weather programs and upcoming missions run by the agencies that will aid in understanding the origin of space weather, its assessment and forecasting? - What are major challenges in global coordination on space weather? How we should address those challenges? - What should be the role of COSPAR PSW in global coordination efforts and how the Roadmap should be updated to enable/facilitate this role?

CSES PRELIMINARY RESULTS ON IONOSPHERIC VARIABILITY AND ITS CONNECTION WITH SEISMIC ACTIVITY AND SOLAR FORCING (S.1)

S.1-0001-18 THE 1ST CHINA SEISMO-ELECTROMAGNETIC SATELLITE MISSION

Xuhui Shen, shenxh@seis.ac.cn

Institute of Crustal Dynamics, CEA, Beijing, China Xuemin Zhang, zhangxm96@126.com

Institute of Earthquake Science,CEA, Beijing, China Jianping Huang, xhhjp@126.com

Institute of Crustal Dynamics, CEA, Beijing, China

The 1st China Seismo-Electromgnetic Satellite (CSES) launched at Feb.2, 2018 after 15 year's research and developing and currently it sounds good status onboard. CSES mission was proposed to be the first satellite of space-based geophysical fields observation system in China with a lot of application prospect in earthquake science, geophysics, space sciences and so on. And coincide with the mission objective, the satellite decides to use the Circular Sun Synchronous Orbit with altitude about 500km and descending node time at 14:00LT. The payload assemble includes 8 instruments, Search-Coil Magnetometer, Electric Field Detector, High precision Magnetometer, GNSS occupation Receiver, Plasma Analyzer, Langmuir Probe, Energetic Particle Detector, and Three-frequency Transmitter, in which, we have an effective cooperation with Italian Space Agency on Energetic Particle Detector and Austrian Institute of Space on High precision Magnetometer. At this moment, the satellite and the launching vehicle shipped to and have passed different test in the launching site. Before their shipment, CSES have done a series of test and calibration both in China and Italy, most of the test results accord with the designing requirement and is due to very useful for the coming scientific application. According to the schedule, CSES will have its life time of 5years with the first six months for commission test and then deliver to CEA for regular operation. The CSES data will open for global scientists with few class of authorization. And at this moment, we may expect that CSES primary result will be issued during the conference.

With the exploration of the near Earth magnetic field, the internal structure of Earth, the Earth geomagnetic distribution and spatial environment can be studied. CSES will be the first Chinese satellite of this kind in a near Earth orbit. Its scientific goal is the real-time monitoring of electromagnetic changes by studying the Earth system, especially the ionosphere and other spheres' mutual actions. The magnetic field is one of the most important physical parameters for monitoring the ionosphere. And the High Precision Magnetometer (HPM) will be responsible for the accurate measurement of magnetic field vector components from DC to 15Hz in orbit. Considered the magnetic environment of the spacecraft and the vector value accuracy requirement for magnetic field detection. The HPM consists of two fluxgate sensors and a CDSM scalar sensor. The fluxgate sensors will provide the vector components of the magnetic field but with limited accuracy and long-term stability. The CDSM sensor measures the scalar of the magnetic field with high accuracy and stability and will be therefore used to calibrate the vector data. With the help of two fluxgate sensors, the satellite remanence magnetic interference can be reduced. Several ground data processing methods used to get the real accuracy vector magnetic field data have been considered, include the physical calibration of the single sensor, the absolutely vector correction algorithm, the remanence magnetic interference elimination and coordination conversion method. And several ground calibration tests have been operated to get the real excellent performances of each sensor. The CSES will be launched in early 2018, after several month's in orbit operation, it will be a good opportunities to show the geomagnetic data get by CSES-HPM to all attendants during the COSPAR.

CSES (China Seismo-Electromagnetic Satellite) is a scientific program developed in the framework of a collaboration between the China National Space Administration (CNSA) and the Italian Space Agency (ASI). The CSES satellite mission is developed by China Earthquake Administration (CEA), together with several Chinese institutes, in collaboration with Italian universities and research institutes lead by the National Institute for Nuclear Physics (INFN). CSES is the first satellite of a space monitoring system proposed in order to investigate the topside ionosphere and designed in order to gather world-wide data of the near-Earth electromagnetic environment.

The main objectives of the mission are to investigate the near-Earth electromagnetic, plasma and particle environment and for studying the seismo-associated disturbances in the ionospheremagnetosphere transition zone, the anthropogenic electromagnetic noise as well as the natural non-seismic electromagnetic emissions, mainly due to tropospheric activity. In particular, the mission aims at confirming the existence of possible temporal correlations between the occurrence of earthquakes for medium and strong magnitude and the observation in space of electromagnetic perturbations, plasma variations and precipitation of bursts of high-energy charged particles from the inner Van Allen belt.

In this framework, the High Energy Particle Detector (HEPD) of the CSES mission has been developed by the Italian Limadou Collaboration. HEPD comprises a double-sided microstrip silicon tracker, a layer of plastic scintillators for trigger and a calorimeter, made of a tower of plastic scintillators and a matrix of inorganic crystals, surrounded by plastic scintillator veto planes. The detector is capable to provide good energy and angular resolution and a wide angular acceptance, for electrons of 3 - 100 MeV, protons of 30 - 200 MeV and light nuclei up to the oxygen.

The CSES satellite, launched on February 2nd 2018 from the Jiuquan Satellite Launch Center (China), was placed in a sun-synchronous orbit at an altitude around 500 km.

S.1-0004-18 HIGH-ENERGY PARTICLE DETECTOR ONBOARD CSES: THE DESCRIPTION AND FIRST RESULTS

Wei Chu, chuwei4076@126.com

Institute of Crustal Dynamics, CEA, BeiJing, China Shen Xuhui, shenxuhui@vip.sina.com

Institute of Crustal Dynamics, CEA, BeiJing, China Xu Song, xusongicd@126.com

Institute of Crustal Dynamics, CEA, BeiJing, China

This paper gives a description and the first results of the high-energy particle detector(HEPP) placed onboard the CSES satellite. This detector include three independent detectors namely HEPP-H, HEPP-L and HEPP-X. The HEPP-H and HEPP-L are aimed to measure energetic particle fluxes in the energy range from 100keV to about 50MeV for electron and 2Mev to about 200MeV for proton in order to provide information on the energetic particles which can interaction with the low frequency waves. The energy resolution, better than 10keV, and the 256 energy channels allow to obtain insights on the radiation belt structure. The HEPP-X can provides information of the Solar X ray in the energy range from 1keV to about 35keV which can bu used to evaluate the effects of solar activity to the Earth. The satellite was launched on Feb 2 of 2018. The data received during orbit test show for the first time that the detector work well and the detector data can be used to study the variation of the energetic particles during the magnetic storm and substorm and also the relationship between the earthquake and the energetic particles at the lower ionosphere.

S.1-0005-18 IDEAS AND SOLUTIONS FOR A NEXT GENERATION HIGH ENERGY PARTICLE DETECTOR FOR THE CSES MISSION

Roberto Iuppa, roberto.iuppa@unitn.it University of Trento, Trento, Italy

The High Energy Particle Detector is one of the instruments on board the China Seismic Electromagnetic Satellite, designed, constructed and operated by the Italian Limadou collaboration. The HEPD is sensitive to 10-100 MeV electrons, as well as 30-300 MeV/n nuclei, to be detected in the latitude range 65°. Observing MeV electron precipitations to study seismic phenomena is newer and less consolidated than traditional approaches, focused on measuring electric and magnetic field variability, as well as plasma features in the ionosphere. The Limadou collaboration took advantage of the experience gained from currently-flying CSES mission to improve the design of a new 1-100 MeV particle detector, lowering the energy threshold, distinguishing electrons and nuclei already at trigger level and tracking particle trajectories online. Ideas for an upgraded HEPD are discussed and details are given about technical solutions envisaged to put them into effect.

S.1-0006-18 A HIGH-PERFORMANCE ELECTRIC FIELD DETECTOR FOR SPACE-BORNE MEASUREMENTS

Piero Diego, piero.diego@iaps.inaf.it IAPS/INAF, Rome, Italy

In the framework of the CSES-Limadou collaboration a prototype of a new Electric Field Detector (EFD) for space applications has been developed. The instrument has been conceived for space-borne measurements to investigate electromagnetic phenomena in the ionosphere in order to improve the knowledge of lithosphere-ionosphere coupling. The proposed instrument can measure electric field as a potential difference between probes pairs. The instrument measures electric field in a wide band of frequencies extending from quasi-DC up to about 4 MHz. The resolution in the ULF band is better than 1 µV /m with a dynamic range of 120 dB. With this bandwidth and precision, the described electric field detector represents a very performing and updated device for electric field measurements in space. The detector consists of four spherical probes to be installed on four booms deployed from the 3-axes stabilized satellite. Ranges of expected probe potentials have been obtained by studying the various currents collected by the sensors along a simulated orbit. Plasma data of Demeter mission measurements have been analyzed to evaluate the proper bias current to be injected. Cross-calibration with Langmuir probe data of CSES will be performed for better comprehension of the EFD measurements.

S.1-0007-18 PRELIMINARY RESULTS OF EFD ON CSES

Jianping Huang, xhhjp@126.com

Institute of Crustal Dynamics, CEA, Beijing, China Wenjing Li, xhhjp@163.com

Institute of Crustal Dynamics, CEA, Beijing, China Shen Xuhui, shenxuhui@vip.sina.com

Institute of Crustal Dynamics, CEA, BeiJing, China

On February 2, Chinese first geophysical satellite, China Seismo-Electromagnetic Satellite, was launched successfully. Following the DEMETER, this satellite is a new satellite with the main aim to look for the earthquake-related ionosphere precursor. On CSES, there are 8 payloads, including Electric Field Detector (EFD), High Precise Magnetometer (HPM), Search Coil Magnetometer (SCM), Plasma Analyzer Package (PAP), Langmuir Probe (LAP), High Energetic Particle Package (HEP), GNSS Occultation Receiver (GOR) and Tri-Band Beacon (TBB). The EFD payloads, including the Probe, pole and electrician, will detect the electricity with the frequency DC-3.5MHz, which is divided into 4 bands, ULF (DC-16Hz), ELF (6Hz2KHz), VLF (1.8kHz-20Khz) and HF (18Khz-3.5MHz). For ULF and ELF, the waveform series are produced. For VLF, it is produced in waveform with burst mode and in spectrum with survey mode. For HF, it is produced in spectrum. Here some results are shown to see variation around the magnetic storm, earthquakes and Hiss.

S.1-0008-18 ACTUAL AND VIRTUAL CONSTELLATIONS FOR PROBING THE IONOSPHERE AND MIT COUPLING - THE CASE OF SWARM

Rune Floberghagen, rune.floberghagen@esa.int ESA, Frascati, Italy

The European Space Agency's three-satellite Swarm constellation was launched in November 2013 to carry out absolutely calibrated multipoint observations using a multiple payload philosophy. Its suite of instruments include dual magnetometers, a thermal ion imager, Langmuir probes, accelerometers and state-of-the-art GNSS receivers, all of which contribute to measurements of both the electromagnetic and neutral environment. Four years later the mission has become a catalyser for the interaction between the geophysical and space science communities, for one. But even more importantly, the constellation has proven to provide conclusive, high temporal and spatial resolution information on energy transport, current and turbulence in the MIT system, worldwide and in all sorts of geomagnetic conditions.

This paper describes the role of the Swarm mission in the context of geospace research, specifically targeting the MIT system, and including plans for the future. Moreover, in 2015 a strategic collaboration initiative between the European Space Agency and the Chinese National Space Administration regarding the joint exploitation of the CSES and Swarm missions, supported by the successful launch of CSES-01 on 2 February 2018, now offers the possibility to address common research objectives in a virtual constellation approach. This pertains to the MIT system, but also to calibration and validation of the payload suites as well as our common research objectives in terms of ionospheric earthquake precursor detection.

S.1-0009-18 GEOMAGNETIC FIELD DATA IN SUPPORT OF THE ELECTRIC FIELD DETECTORS ANALYSIS ON CSES.

Maurizio Candidi, maurizio.candidi@iaps.inaf.it INAF - IAPS Rome, Roma, Italy

Igor Bertello, igor.bertello@iaps.inaf.it INAF, Roma, Italy

Giuliano Vannaroni, giuliano.vannaroni@iaps.inaf.it INAF-IAPS, Rome, Italy

The measurement of ionospheric static electric fields on board CSES will require exact knowledge of various contributions due to ambient and instrumental effects. An order of magnitude evaluation of several such effects has been performed, including vxB, in order to model corrections to sensor readings which may significantly improve the identification of geophysical parameters. It is shown that very precise measurements of flight and ambient parameters and detailed modeling of the configuration of probes and satellite, will be necessary for the appropriate inference of external geophysical electric field and its dynamics. Data from the DEMETER mission are used to simulate the environment around CSES.

S.1-0010-18 IONOSPHERIC ELECTRIC FIELD MEASUREMENTS ON CSES FOR VARIOUS PLASMA CONDITIONS.

Igor Bertello, igor.bertello@iaps.inaf.it INAF, Roma, Italy

Maurizio Candidi, maurizio.candidi@iaps.inaf.it INAF - IAPS Rome, Roma, Italy

Giuliano Vannaroni, giuliano.vannaroni@iaps.inaf.it INAF-IAPS, Rome, Italy

Igino Coco, igino.coco@ingv.it

Istituto Nazionale di Geofisica e Vulcanologia, Roma, Italy

The precise measurement of ambient DC electric fields in the ionosphere with the technique of double probes requires the removal of several effects from the floating potentials measured by the sensors, in relation with the ambient plasma parameters, the geometrical configuration of the probes and boom system and the flight parameters. In addition, the plasma parameters will have to include measurements from the plasma motion instrument. Detailed analysis of the influence of such external parameters on the final measurement of the DC ambient electric field is provided, and requirements on the precision of intercalibration from other CSES instruments are assessed. Data from the DEMETER and Swarm missions are used to simulate the environment around CSES.

S.1-0011-18 MINIATURIZED FUV IONOSPHERIC PHOTOMETER

Peng Ruyi, pengry2011@163.com

National Space Science Center,CAS, Beijing City, China Fu Liping, fuliping@nssc.ac.cn

National Space Science Center,CAS, Beijing City, China

As a space-based optical remote sensing method, Miniaturized FUV Ionospheric PhotoMeter with small size, low power consumption, high sensitivity is an important means to detect physical parameters of the ionosphere. Using the Miniaturized FUV Ionospheric PhotoMeter to detect the ionospheric 135.6nm night airglow can obtain the ionospheric TEC, F layer peak electronic density(NmF2), which can be used to study ionospheric space environment change information, the impact of the ionosphere on the radio communications, etc.; The ionospheric 135.6nm day airglow and the LBH radiation radiance can be used to obtain the ionospheric O / N2 ratio information, which can be used to study the space weather events and monitor the electromagnetic environment changes in the Earth's space. The FY3-D Ionospheric PhotoMeter(IPM), launched on November 15, 2017, has a detection sensitivity which is greater than 150 counts / s / Rayleigh and a spatial field of view of 1.6×3.6 ° with high horizontal spatial resolution that helps to achieve more accurate ionospheric exploration.This report will introduce several features of the FY3-D IPM. Key Word:FUV,ionosphere,photometer,135.6nm airglow,LBH radiation radiance

CSES mission will investigate the structure and the dynamics of the topside ionosphere, the coupling mechanisms between upper atmosphere, ionosphere and magnetosphere and the temporal variations of the geomagnetic field, in quiet and disturbed conditions. Data collected by the mission will also allow to studying solar-terrestrial interactions and phenomena of solar physics, namely coronal mass ejections, solar flares and cosmic ray solar modulation. Anyway, the main objective of the mission is to study the existence of possible (temporal and spatial) correlations between the occurrence of earthquakes (EQs) and the observation of iono-magnetospheric perturbations with a particular focus on the precipitation of particle bursts (PBs) from the inner Van Allen belts. The claimed PBs-EQs correlations ask for a confirmation based on a careful rejection of the large background of the natural non-seismic geomagnetic perturbations due to solar activity, tropospheric e.m. emissions and artificial emitters. We present: i) the details of the High-Energy Particle Detector (HEPD) of the CSES mission, conceived for optimizing detection of energetic charged particles precipitating from the inner Van Allen belts and built by the italian LIMADOU Collaboration; ii) the general method for investigating such a PBs-EQs correlations that has been developed by analyzing data from the SAMPEX mission and that will be extended to study HEPD data.

S.1-0013-18 THE DEFINITION OF INSTRUMENTAL AND ENVIRONMENTAL BACKGROUNDS IN THE ELECTROMAGNETIC EMISSIONS ABOVE SEISMIC REGIONS.

Mirko Piersanti, mirko.piersanti@aquila.infn.it IAPS/INAF, Rome, Italy

Igor Bertello, igor.bertello@iaps.inaf.it INAF, Roma, Italy

Piero Diego, piero.diego@iaps.inaf.it IAPS/INAF, Rome, Italy

Maurizio Candidi, maurizio.candidi@iaps.inaf.it INAF - IAPS Rome, Roma, Italy

Pietro Ubertini, pietro.ubertini@iaps.inaf.it INAF - IAPS Rome, Roma, Italy

To define a background for the electromagnetic emissions above seismic regions, it is necessary to consider the statistical distribution of wave energy in absence of seismic activity. N˘emec et al. [2008], built a map of electromagnetic emissions containing the statistical description of the intensity of electromagnetic waves obtained from the entire DEMETER satellite data set. Then, they estimated the frequency of occurrence of a signal during a seismic event with a different intensity then the background level defined by the map. In this work, we applied a completely new method to determine both the environmental and instrumental background. Our technique is based on a new data analysis tool called ALIF (Adaptive Local Iterative Filtering, [Cicone et al. 2016 and 2017; Piersanti et al. 2017]); through a time-frequency analysis, this method can identify and quantify the variations across different scales for nonstationary signals due to the complexity and non–linearity of the system that generated them. To evaluate the instrumental noise, we applied the SMT method (Standardized Mean Test) proposed by Alberti and Piersanti (2016) and we performed a multiscale statistical analysis (MSA). The MSA calculated the variance σ, the skewness S, the kurtosis excess Kex = K 3,

the relative energy rel and the Shannon Information Entropy I for each ALIF mode (IMF). To evaluate the environmental noise, a background map of 1° 1° latitude/longitude cells, showing the averaged Erel (Er¯el), has been constructed; the geomagnetic activity, the presence of seismic activity and the local time sector were used as a parameters. Any signal exceeding by a certain threshold both the instrumental and environmental backgrounds will be considered as a case event to be investigated. Here we show the results obtained for the entire DEMETER satellite data set (2004 - 2011) for both the electric and magnetic field instruments. The same analysis is ongoing with the recently collected CSES data.

S.1-0014-18 LITHOSPHERE-ATMOSPHEREIONOSPHERE COUPLING STATISTICAL VALIDATION BY MEANS OF 3.5 YEARS OF SWARM SATELLITE ELECTROMAGNETIC DATA ANALYSIS

Claudio Cesaroni, claudio.cesaroni@ingv.it

INGV, Institute Nazionale di Geofisica e Vulcanologia, Roma, Italy SAFE team

SAFE ("Swarm for Earthquake study") project (funded by ESA in the framework of "STSE Swarm+Innovation") deals with the integrated analysis of more physical parameters whose abnormal variations have been found to be possibly associated with impending earthquakes. These observations are mainly: electromagnetic variations, total electron content and the electron density in the ionosphere, measured both from Swarm satellites and ground-based observatories. We show here the results of a systematic analysis of around 3.5 years of magnetic and electron density satellite anomalies in the whole space-time interval of interest, avoiding high magnetic latitudes (1 Jan 2014-31 Aug. 2017, |geomagnetic latitude|50o) which are correlated with earthquakes by means of a superimposed epoch approach. Both data analyses show that the anomaly concentrations are superior with respect to random anomaly distributions by more than 2.5, supporting the hypothesis for a lithosphere-atmosphere-ionosphere coupling in the preparation phase of earthquakes. The recent launched CSES satellite mission with dedicated scientific payload for pre-earthquake anomaly detection will let us available more electromagnetic data for applying the same techniques for searching precursors of future earthquakes.

This work is partly funded by the European Space Agency under "SAFE" Project and by the Italian Space Agency under "Limadou-Science" Project.

S.1-0015-18 CHANGES IN IONOSPHERE DUE LARGE EARTHQUAKES AFFECT: A PERSPECTIVE

Sohan Lal, sohangeokuk@gmail.com

Indian Institute of Technology Roorkee, Uttrakhand, India Anand Joshi, anushijos@yahoo.co.in

Indian Institute of Technology Roorkee, Uttrakhand, India

Abstract: In the present study a detailed study has been done and observes, it is somehow that great and major earthquakes affect the ionospheric current. And from the some research it is found that the anomalies occurred near the epicentres take place before two or one days which will be help in short term prediction. This study highlight the use of Ionospheric changes in the atmosphere will help to predict the earthquake and how big data analysis present a better scenario in study the relation between the earthquake and ionosphere changes. Foreshocks also generate the anomalies in the region of epicentre as foreshocks are indicator of major shocks, so anomalies due to fore shocks can be used in the prediction of earthquake to save the casualties. In the present work from all the study it is concluded that using the ionospheric changes give a advancement in prediction of the earthquake. For example the study of Nepal earthquake also reveals that there is changes in the ionospheric current before the main shock and foreshock. Using the observations of Global positioning system (GPS) and movement of the crustal plate and global ionosphere map (GIM) given by the centre for orbit determination (CODE) in Europe, it is found that major earthquake occurred in Nepal of magnitude 7.9 (Mw) has been affected the ionospheric changes including its before and after shocks. There are more researcher suggest that gravity wave at ionosphere causes anomaly Hayakawa (1999).

S.1-0016-18 EARTHQUAKESPREDICTION TO PRECURSOR

Suryanshu Choudhary, csuryansh@gmail.com AISECT University, Bhopal, India

Ashok Kumar Gwal, ak_gwal@yahoo.co.in Barkatullah University, 462026, India

Earthquake is one of the deadliest occurrences on earth that is destroying the entire human societies. There were many studies that took place from predictions until the precursor, but still scientists do not have a precise scientific theory about earthquakes. Through this research, efforts have been made to explain the changes in the environment before the earthquake and what's the principle behind that changes. Present study also provides possible explanation about how to get the earthquakes waves in the atmosphere and affect the ionosphere layers.

S.1-0017-18 AN INTERACTIVE STUDY OF LITHOSPHERIC - IONOSPHERIC - MAGNETOSPHERIC COUPLING THROUGH POES SATELLITE ENERGETIC PARTICLE BURST DURING AND PRIOR TO NEPAL EARTHQUAKE

Ionospheric Magnetospheric transition region and the time correlation of particle rate fluctuation and earthquake is a subject of interest for various authors for last few decades. Van Allen Radiation Belt is a zone of energetic charged particle originated from solar wind that is captured by earth's magnetic field line. Van Allen radiation belt is consisted of two part outer belt and inner belt. Outer Van Allen radiation belts variation depends on solar cycle variation, semi-annual variation and solar rotational variation. Inner Van Allen radiation belts variation depends on solar cycle only. There are several low earth orbital satellite to observe count rate of energetic particle in Van Allen Radiation Belt. In our study we use Medium Energy Proton and Electron Detector (MEPED) instrument data which is on-board in NOAA 15 satellite to study particle flux and burst correlated with earthquake. MEPED consisted of 6 proton channel collecting data for 30-80 keV, 80-240 keV, 240-800 keV, 800-2500 keV, 2500-6900 keV, >6900 keV respectively and 3 electron channel collecting data for >30 keV, >100 keV,

>300 keV respectively. These 6 proton channels and 3 electron channels also collect data in 0 degree and 90 degree direction simultaneously. MEPED on-board NOAA 15 satellites collects particle count rate on its orbital path and then it can be interpolated over global circumstance. We present the electron count rate data collected by MEPED on its path and the interpolated result of the data showing particle burst associated with Nepal earthquake on May 12, 2015. As the upcoming Chinese Seismic-Electromagnetic Satellite (CSES) deals with the similar study of deposition of energetic charge particle in the radiation belt due to seismic activities, it will be an unique opportunity to corroborate our previous findings during Nepal earthquake with newly coming outputs for other future earthquake. This comparison will also provide sufficient scope to understand the physical process behind LAIC mechanism.

S.1-0018-18 ELECTROMAGNETIC FIELD OBSERVATIONS BY THE DEMETER SATELLITE IN CONNECTION WITH THE 2009 L'AQUILA EARTHQUAKE.

Mirko Piersanti, mirko.piersanti@aquila.infn.it IAPS/INAF, Rome, Italy

Piero Diego, piero.diego@iaps.inaf.it IAPS/INAF, Rome, Italy

Igor Bertello, igor.bertello@iaps.inaf.it INAF, Roma, Italy

Maurizio Candidi, maurizio.candidi@iaps.inaf.it INAF - IAPS Rome, Roma, Italy

Pietro Ubertini, pietro.ubertini@iaps.inaf.it INAF - IAPS Rome, Roma, Italy

On April 6, 2009, at 01:33 UT, a 6.2 Mw earthquake stroke the city of L'Aquila (=42,21;

=13,23). An intense preseismic activity (3<M<5) had been observed for several months. The DEMETER satellite was operational and flew within 1 hour in local time (LT) over L'Aquila twice a day (10 LT and 22 LT). Electromagnetic field data from DEMETER, experiments ICE and IMSC, have been analyzed during periods in which waveform data collection was available to retrieve possible signals, connected with the earthquake and possible precursor activity. The data analysis was performed based on a new technique (ALIF, Cicone et al. 2016 and Piersanti et al. 2017). The statistical background was evaluated over four months (January - April) in 2009 and 2010 when geomagnetic activity was very low (0<Kp2; Sq). On April 4, 2009, when DEMETER flew exactly over L'Aquila at UT=20:29, an intense signal was observed at 333 Hz, whose characteristics seem to be related to a rotation of the electromagnetic field, giving rise to a different ionospheric plasma circulation.

S.1-0019-18 MAGNETIC FIELD FLUCTUATIONS FEATURES IN THE IONOSPHERE

Ionosphere-Magnetosphere system is recognized as a complex and active element of space weather and as a region where important science questions can be answered. In this framework, a high priority has the understanding how local, regional, and global-scale phenomena couple to produce observed responses across scales. Turbulence provides one pathway by which energy moves across scale sizes from large to small where energy can be dissipated in the form of heating. Swarm mission, which is a true multi-point and multi-purpose constellation, represents a unique opportunity for address some of these science questions. In detail, it gives us a chance of investigating the nature and the scaling features of magnetic field fluctuations for different geomagnetic activity levels and of unveiling the role played by turbulence on ionospheric plasma medium. In particular, using the magnetic field data recorded on board of Swarm, the local scaling indices of the 1st and 2nd order structure functions of the external field fluctuations are evaluated, showing its capability both to give new insights about the ionosphere-magnetosphere coupling and to provide information of the ionospheric turbulence. The results presented are an example of the capability of the Swarm data to generate new insights on the ionospheremagnetosphere coupling and, at the same time, to develop new applications where the changes in scaling features can be used as a local indicator of the magnetosphere conditions. This information can also give new key clues for the development of more actual physical models and could be relevant also for similar studies with data from CSES mission.

The dynamics of the Earth's ionosphere is strongly influenced by the changes of the current systems flowing in the Earth's magnetosphere. Although this is particularly true in the case of high latitude and polar regions, the increase of the equatorial ring current systems causes some dynamical changes in the status of the ionospheric plasma and field conditions. Here, using data collected by the ESA-Swarm constellation, we investigate the features of the magnetic field and plasma parameter (electron density and temperature) fluctuations in the ionosphere at middle and low latitudes, as well. In particular, we investigate the spectral/ scaling features of these fluctuations and their changes with the geomagnetic activity, as monitored by AE and Sym-H indices. A close view of the features of these fluctuations along the CSES trajectory is also presented.

Pietro Ubertini, pietro.ubertini@iaps.inaf.it INAF - IAPS Rome, Roma, Italy

Geomagnetic cutoff rigidities are a quantitative measure of the shielding provided by the Earth's magnetic field. Their estimation allows to predict the energetic charged particle transmission through the magnetosphere to a specific location as a function of direction. The tracing-particle method has been applied to determine the particle trajectories and asymptotic directions by assuming the Tsyganenko 1989 model for the geomagnetic field. Different states of the magnetosphere corresponding to different levels of geomagnetic activity have been considered. Finally, grids of cutoff rigidities distributed over the Earth have been computed at the altitudes of the CSES orbit in order to characterize the penetration through the geomagnetic field of both galactic cosmic rays and large solar energetic particle events.

This work is partly funded by the Italian Space Agency under grant ASI-INFN "Limadou Scienza".

S.1-0023-18 IONOSPHERIC AND GEOMAGNETIC BACKGROUND CHARACTERIZATION FROM GROUND-BASED AND SPACE-BORNE MEASUREMENTS: PRELIMINARY RESULTS FROM LIMADOU-SCIENCE PROJECT ACTIVITIES

Claudio Cesaroni, claudio.cesaroni@ingv.it

INGV, Institute Nazionale di Geofisica e Vulcanologia, Roma, Italy Limadou INGV Team

Definition of an ionospheric and geomagnetic background is essential to catch anomalies possibly related to lithosphere-atmosphere-ionosphere coupling (LAIC) but a universally accepted method to define "quiet" ionosphere and magnetic field is not established at present time. Ground-based (ionosonde and GNSS) instruments provide large datasets that can be used to define a background ionosphere and magnetic field under different conditions. On other hands, space-borne measurements by Langmuir probe and vector magnetometer installed on board of CHAMP and Swarm satellites need models to define a reference background. In this paper, a first attempt to highlight anomalies in ionospheric electron density and magnetic field components under different solar conditions is presented to support future study that will be performed by using measurements from CSES mission. Results suggest that IGRF-12 describes very well the magnetic field in the considered period (2014-2017) while IRI-2016 overestimates electron density at the altitude of the CHAMP satellite (about 350 km) during the solar minimum (2007-2009). Some possible alternative solutions are proposed in order to mitigate the latter problem.

The evaluation of the external origin contribution (BEXT and EEXT) in geomagnetic field satellite observations in the near Earth location (1.2 RE<R<1.5 RE; RE being the Earth radius) during active magnetic conditions is one of the key problem in the Space Weather context. We propose an innovative algorithm able to discriminate the external from the internal origin (BINT) contributions in immediate post-processing of the one time series under exam. Differently from the currently implemented procedure, which relies on models based on statistics of several months of data, the proposed algorithm will generate directly from Level 1 magnetic data time series a Level 2 product made up of BINT and BEXT. The algorithm is based on the Adaptive Local Iterative Filtering (ALIF) technique [Cicone et al., 2016; Piersanti et al., 2017]. ALIF is able to decompose non-stationary time series into several intrinsic mode functions (IMFs) which are functions oscillating around zero, but not necessarily with constant frequencies and amplitudes. Then, by applying the statistical test described in Alberti and Piersanti [2016] and by a multiscale statistical analysis, the algorithm discriminates between the different intrinsic "macro-scales" of LEO satellite observations. Consequently, the algorithm is able to separate BINT from BEXT with high efficiency. We applied this algorithm to SWARM, DEMETER and CSES magnetic field data. We compared the evaluated BINT with both IGRF and CHAOS-6 model obtaining comparable results, leading the possibility to validate the IGRF model coefficients and increase the accuracy of CHAOS-like models. Concerning BEXT, our results lead to the identification

of different magnetospheric current systems across which each satellite orbits (such as the Ring Current, the Tail current and the Magnetopause current). Finally, the correct identification of the magnetospheric field in LEO satellite is of crucial role for the identification of the ionospheric origin field contribution.

Istituto Nazionale di Geofisica e Vulcanologia, Roma, Italy Virgilio Quattrociocchi, virgilio.quattrociocchi@iaps.inaf.it Istituto Nazionale di Astrofisica, Roma, Italy

The Earth's ionosphere is a very dynamical system whose dynamics is controlled by both the Earth's atmosphere and magnetosphere, and the solar irradiation. In particular, the geomagnetic activity which is driven by the changes of the magnetic field and plasma conditions in the interplanetary medium, affects the condition of the ionospheric plasma in terms of composition and dynamics. In this presentation, we investigate the changes of the ionospheric electron density and temperature as a function of the geomagnetic activity level, using data collected by the ESA-Swarm mission. The analysis is done by applying the Natural Orthogonal Composition (NOC) approach, capable of identifying the different patterns in terms of Empirical Orthogonal Functions (EOF) and Principal Components (PC).

S.1-0026-18 ASSESSING THE IONOSPHERIC ELECTRIC FIELD: COMPARISON BETWEEN CSES EARLY DATA AND SWARM MEASUREMENTS.

Pietro Ubertini, pietro.ubertini@iaps.inaf.it INAF - IAPS Rome, Roma, Italy

The deep knowledge about the electric fields ruling the ionospheric electrodynamics is of crucial importance to understand both the ionospheric physics and the lithosphere-atmosphereionosphere coupling (LAIC). In particular, the occurrence of electromagnetic anomalies possibly related to the preparatory phases of large earthquakes requires disentangling it from those due to the forcing from the geospace, like those driven from solar events, or other phenomena of anthropogenic origin. The China Seismo-Electromagnetic Satellite (CSES), recently launched on 2 February 2018, has been designed to provide high quality data to characterize the electromagnetic environment in the ionospheric plasma. In the specific, it offers the possibility to measure the variation of electric field at the CSES altitudes (500 km), by means of an Electric Field Detector (EFD). To provide the first validation of such measurements in flight mode, we compare the early EFD data with the electric field estimation provided by the data and products of Swarm ESA constellation. Waiting for the coincidence between the local times of CSES and Swarm orbits, we exploit the 4.5 years of measurements by Swarm to obtain a climatological assessment of the ionospheric electric field to be compared to the CSES EFD measurements.

S.1-0027-18 IN FLIGHT PERFORMANCE OF THE ELECTRONICS OF THE HIGH ENERGY PARTICLE DETECTOR ONBOARD CSES

Valentina Scotti, scottiv@na.infn.it INFN, Napoli, Italy

Giuseppe Osteria, osteria@na.infn.it INFN - Napoli, Naples, Italy

CSES-Limadou Collaboration http://cses.roma2.infn.it/node/53

In this paper we will present a description of the electronics of the High Energy Particle Detector (HEPD) onboard the China Seismo Electromagnetic Satellite (CSES) and its in flight performance. CSES is a scientific mission dedicated to monitoring electromagnetic, plasma and particles perturbations of atmosphere and inner Van Allen belts caused by solar and terrestrial phenomena and to the study of the low energy component of the cosmic rays (5 - 100 MeV for electrons and 15 - 300 MeV for protons). The satellite, launched on February 2nd, 2018 from the Jiuquan Satellite Launch Center (Mongolia), hosts several instruments onboard. The HEPD, built by the Italian "Limadou" collaboration, is able to separate electrons and protons and identify nuclei up to Iron. The HEPD comprises the following subsystems: detector, electronics, power supply and mechanics. The electronics can be divided into three blocks: silicon detector, scintillator detectors (trigger, energy and veto detectors) and global control and data managing. The trigger system allows switching between several configurations. Each trigger configuration corresponds to different field of view of the apparatus. It is possible to change the trigger configuration along the orbit to cope with different fluxes encountered.

S.1-0028-18 OVERVIEW OF THE CSES (CHINA SEISMO-ELECTROMAGNETIC SATELLITE) MISSION

Piergiorgio Picozza, piergiorgio.picozza@gmail.com INFN and University of Rome Tor Vergata, Rome, Italy on behalf of

The CSES Collaboration

CSES (China Seismo-Electromagnetic Satellite) is a mission in collaboration between CNSA (Chinese National Space Administration) and ASI (Italian Space Agency). Realized by CEA (China Earthquake Administration) together with several Chinese Institutions and INFN (Italian National Institute of Nuclear Physics) in cooperation with IFAC-CNR, INAF (Italian National Institute of Astrophysics), INGV (National Institute of Geophysics and Volcanology) and other Italian institutions, it is in orbit since February 2nd 2018. The main objectives are the investigation of the near-Earth electromagnetic, plasma and particle environment and the study of the seismo-associated disturbances in the ionosphere-magnetosphere transition zone, the anthropogenic electromagnetic noise as well as the natural non-seismic electromagnetic emissions, mainly due to tropospheric activity. In particular, the mission aims at confirming the existence of possible temporal correlations between the occurrence of earthquakes of medium and strong magnitude and the observation in space of electromagnetic perturbations, plasma variations and precipitation of bursts of high-energy charged particles from the inner Van Allen belt. On board of the CSES satellite, orbiting Sun-synchronous at about 500 km of altitude with an inclination of 97.4°, there are installed two Particle Detectors, a Search Coil Magnetometer, a High-Precision Magnetometer, an Electric Field Detector, a Plasma Analyzer, two Langmuir probes, a GNSS Occultation Receiver and a Tri-Band Beacon. The multi-instrument payload allows, by measuring simultaneously several different parameters, a more reliable identification of the signature of the studied phenomena. The in-flight performance of the scientific payload and some preliminary results will be presented at the conference.

In the mid-1980s, as NASA planetary exploration expanded, it became apparent that a national archive that could handle digitized data was needed. NASA launched the Planetary Data System (PDS) in 1989 after considerable planning and development. Because most of the early planetary data originated from NASA missions, the international scientific community became familiar with PDS standards. Thus, when the European Space Agency (ESA) began producing planetary science data they adopted components of the PDS standards and developed the Planetary Science Archive (PSA). This occurred under version 3 (PDS3) of the PDS Standards. The PDS and PSA worked closely together to develop standards and share data. As additional agencies began developing unique missions of interest to the international community, two needs were identified: increased cooperation and collaboration to facilitate access to the individual archives, and modernization and implementation of standards.

A group of individuals involved in mission archiving within the international planetary community met in 2006 to develop a mechanism for enhancing international access and collaboration [1]. The goal of this meeting was to develop an approach that would: 1) Give scientific communities world-wide access to data archives built upon similar standards; 2) Reduce cost of archiving and distributing science data by collaborating and sharing standards; 3) Ensure reusability of science data across agency/mission/instrument boundaries; 4) Coordinate archiving processes and plans; and 5) Improve and increase access to tools and services offered.

As a result of these interactions, the International Planetary Data Alliance (IPDA) was founded. Over the past decade, the IPDA has

grown significantly, with shared projects focused on achieving the goals. Over twelve agencies have joined the IPDA and participate in the Steering Committee. These agencies have supported a major upgrade of the Planetary Data System standards called “PDS4”. NASA and ESA are now operationally using PDS4 and all future planetary missions are adopting or planning to adopt it for archiving their data. Over the next decade, this will lay a foundation by which improved and increased access, tools, and services can be realized at a global scale.

This talk will provide an overview of the IPDA and discuss opportunities to increase use, access, and interoperability as an international data science platform for planetary science research.

University of Maryland, College Park, College Park, Maryland, United States

In recent years, Earth and space science funding agencies worldwide have come to understand that publication of funded scientific results is only part of their mandate, they must also preserve and provide access to the data from which those results were derived. As a result, many new data systems and data archives have been created. Scientists are now frequently required to archive the data that they acquire, and to describe their archive plans in a data management plan (DMP) as part of the proposal process. Here we present the elements of a good data management plan, regardless of the funding agency. These elements include: beginning the planning process early, selecting the right archive, understanding the standards and practices of that archive, developing a realistic work plan (and budget), and allowing schedule margin for inevitable slippage. A key to creating a quality DMP is to start planning early and leave plenty of time to write the DMP. Even scientists who are experts in the archiving process may find that the archive they have delivered data to in the past has modernized or otherwise updated their standards or practices. Often it is not obvious where data should be archived, or even if an appropriate data system exists. Once the target archive or data system has been determined, it is important to learn that system’s standards and practices, including acceptable data formats, metadata requirements, nomenclature, and any additional required documentation. A clear understanding of the system requirements is required in order to develop a credible work plan and budget for the funding agency. The work plan should include a list of tasks, due dates, and should identify who will perform each task. Data must be documented clearly and completely. The documentation task should be assigned to a scientist who fully understands the data, its acquisition, and its processing and calibration. Some archives require external review of data and documentation. If required, the plan should include time for both the review and the response to the reviewer’s comments. Even if an external review is not required, having a Co-Investigator or colleague review the data set makes sense.

Data preparers are often so close to the data that they forget to document some of the details of the acquisition or processing that are required for others to use the data correctly. Some archives require or encourage inclusion of software used in the data processing. Well-documented software can be included with the archive documentation and/or uploaded to a public software repository such as GitHub (or NASA GitHub for NASA planetary data). Archiving should immediately follow data processing and not deferred to the end of the performance period. Documenting and archiving the data promptly insures that details of the process will not be lost in the interim. All of these components should be covered in the DMP. Lastly, given the long list of items that need to be determined prior to writing and then discussed in the DMP the value of starting the process early cannot be over stated.

S.2-0003-18 BUILDING THE DATA MANAGEMENT PLAN OF OBSERVATOIRE DE PARIS

Aurélie Kasprzak, aurelie.kasprzak@obspm.fr Observatoire de Paris, Paris, France

Frédéric Saconnet, frederic.saconnet@obspm.fr Observatoire de Paris, Paris, France

Carlo Maria Zwölf, carlo-maria.zwolf@obspm.fr Observatoire de Paris, Meudon, France

During the last decade, the production of science data increased in parallel with the decreasing cost of digital storage and the increase of data processing and computation capabilities. Science institute have to find a way to manage and preserve this data inflow. Most of the calls of funding agencies now require to provide a description of how the data produced in the projet will be managed (archiving, curation, distribution.) and published. This usually takes the form of a Data Management Plan. Funding agency also required more and more to select open source licences for any production of the project, for instance by enforcing FAIR (Findable, Accessible, Interoperable, Reusable) principles.

Founded in 1667, the Observatoire de Paris is the largest French national research center for astronomy. Nearly a third of all French astronomers are working in its five laboratories and institute. Located in Paris, Meudon and Nançay, they are all associated with CNRS (National Center for Scientific Research) and with the major scientific universities in the Paris and Orléans area. The research conducted at the Paris observatory covers all the fields of contemporary astronomy and astrophysics: the study of the Sun and Sun-Earth relations, planets and planetary systems, star formation, the interstellar medium, the formation and evolution of galaxies, astroparticles and cosmology, time and space metrology as well as the history and philosophy of science. The Library of the Observatoire is a service entirely devoted to research. Its two missions are to provide scientists with the most complete and pertinent documentation, and to enrich a 350 year old heritage, while at the same time thinking about what today's heritage will be, and what the future will bring. Although mainly destined for the scientists of the Observatoire, it is nevertheless also open to others: scientists from different disciplines and all countries, students, school children, the general public, who are welcome and for whom it organizes scientific and technical outreach activities.

Observatoire de Paris has listed a few services that needed to set up a way to formally manage their data more formally: the Informatics Department of the Observatory (DIO), which is hosting scientific computing servers and data storage facilities for the sciences teams of the observatory; the Paris Astronomical Data Centre (PADC), which provides interoperable access on data collections produced within the observatory; the Library of the observatory. Several teams (linked with projects funded by EU or space agencies) showed interest as well.

Several actions have now been started by the working group: Identification of the various sources of data and data collection in each department of the Observatory; Identification of the needs in term of citation (data collections, artifacts, documents, software.) and licences; study of possible authoritative delegations (e.g., on DOI attribution, long term preservation.) and to whom; proposing a Data Management Plan template to support science teams when applying for fundings. Those actions are all aiming at building a generic Data Management Plan for the Observatory, that would propose rules and practices for preserving, distribution and sharing science products.

The PADC team is deeply involved in data-related international data alliances, such as the International Virtual Observatory Alliance (IVOA), the International Planetary Data Alliance (IPDA), and the Research Data Alliance (RDA). This is ensuring that: (a) this study is conducted with up-to-date technologies and concepts, and that (b) the results of the study will be discussed and advertised in those international contexts.

S.2-0004-18 AGILE SCIENCE DATA CURATION IN THE PLANETARY SCIENCES

J Steven Hughes, steve.hughes@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States
Daniel J. Crichton, daniel.j.crichton@jpl.nasa.gov

JPL, Pasadena, California, United States

The Planetary Data System (PDS) is an information model-driven service architecture that supports the capture, management, distribution, and integration of planetary science data captured in distributed data archives world-wide. The foundational principles of the PDS4 Information Model (IM), the core element of the architecture, were adopted from the Open Archival Information System (OAIS) Reference Model (ISO 14721) and the Metadata Registry Specification (ISO/IEC 11179) and were implemented in W3C XML (Extensible Markup Language). The PDS is unique in that the PDS4 IM drives the PDS4 infrastructure by providing the concepts, relationships, and constraints as a sharable, stable, and formally organized set of information requirements. These requirements are used to generate systems files for all aspects of PDS operations including XML Schemas for metadata collection and validation, data dictionaries, standards specifications, and configuration files for tools and services. Evolutionary change in the community is efficiently managed by a hierarchical governance scheme. This presentation will provide an overview of the roles played by the IM, principles of agile data curation, and how the IM enables agile data curation for the international Planetary Science community.

S.2-0005-18 THE EMIRATES SPACE DATA CENTER

Alexandria DeWolfe, alex.dewolfe@lasp.colorado.edu

Laboratory for Atmospheric and Space Physics, Boulder, Colorado, United States Sarah Amiri, sarah.amiri@mbrsc.ae

Mohammed Bin Rashid Space Centre, Dubai, United Arab Emirates

As part of the UAE's Emirates Mars Mission (EMM), we are constructing a data archive to preserve and distribute science data from this and future missions. The archive will be publicly accessible and will provide access to Level 2 and 3 science data products from EMM, as well as ancillary data such as SPICE kernels and mission event timelines. As a member of the International Planetary Data Alliance (IPDA), the UAE has committed to making its archive PDS4-compatible, and maintaining the archive beyond the end of the mission. EMM is scheduled to begin collecting science data in spring 2021, and the archive is expected to begin releasing data in September 2021.

S.2-0006-18 INTERNATIONAL SUPPORT FOR SPACE MISSION GEOMETRY CALCULATIONS

Charles Acton, charles.h.acton@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena CA, California, United States

An important but often overlooked element of conducting engineering and science activities for a space science mission is the provision of means to compute a wide assortment of "observation geometry" calculations-items such as range or altitude; latitude and longitude of an instrument's boresight intercept with a surface; and phase, incidence and emission angles at the place of an observation. Such calculations are not generally easy to make, especially if high accuracy is required, but the algorithms and methods for doing so can be standardized and applied across all missions. With this in mind, NASA has implemented the Navigation and Ancillary Information Facility (NAIF)-a small group that has developed a multi-mission scheme named SPICE [1] for making these kinds of calculations.

First deployed during the Magellan mission to Venus in 1989, SPICE has become a widelyused method within NASA for providing engineers and scientists the geometry parameters needed for conducting portions of mission operations, for planning scientific observations, and for analyzing the science data returned from those observations. Observing its technical success and its freedom from export and licensing restrictions, and desiring consistent, reusable means for computing observation geometry, space scientists and space agencies around the globe have adopted the SPICE methodology [2].

This first-ever SPICE presentation at COSPAR outlines the kinds of calculations possible using SPICE and describes the various tools, services and data freely provided to its users.

The research described in this publication was carried out at the Jet Propulsion Laboratory, California Institute of Technology, under a contract with the National Aeronautics and Space Administration.

University of Arizona, Tucson, Arizona, United States Alex Pires, ajpires@email.arizona.edu

University of Arizona, Tucson, Arizona, United States

While large, homogenous scientific fields often have repositories and existing data standards (e.g. GenBank), for small communities in multidisciplinary fields (e.g. astrobiology) publishing and sharing data can be challenging. In development for nearly four years, the Open Data Repository's (ODR) Data Publisher software has been designed as a collaborative data publication tool for small groups of independent researchers who usually have few options for publishing data that can be utilized within their community.

ODR's Data Publisher aims to provide an easy-to-use software tool that will allow researchers to create and publish database templates and related data. The end product will facilitate both human-readable interfaces (embedded images, files, and charts) and machine-readable interfaces utilizing semantic standards. The web-based interface allows researchers to enter data, view data, and conduct analysis using any programming language supported by JupyterHub (https://github.com/jupyterhub/jupyterhub) or other cloud-based analytical tools (e.g. QAnalyze, https://www.qanalyze.com/about). This toolset makes it possible for a researcher to store and manipulate their data in the cloud from any internet capable device. Data can be embargoed in the system until a date selected by the researcher. For instance, open publication can be set to a date that coincides with publication of data analysis in a third-party journal.

The Data Publisher software runs on the standard LAMP (Linux, Apache, MySQL, PHP) stack to provide the widest server base available. The software is based on Symfony (www.symfony.com) which provides a robust framework for creating extensible, object-oriented software in PHP.

The software interface consists of a template designer where master database templates can be created and customized. A master database template can be shared by many researchers to provide a common metadata standard that will set a baseline for all derivative databases. Individual researchers can then customize the master template with specialized fields, file storage, or visualizations unique to their studies. This allows groups to create compatible databases for data discovery and sharing purposes while still providing the flexibility needed to meet the needs of scientists in rapidly evolving areas of research.

In conjunction with teams at NASA Ames and the University of Arizona, a number of pilot studies are being conducted to guide the software development so that it allows them to publish and share their data. These pilots include (1) the Astrobiology Habitable Environments Database (AHED), a central searchable repository designed to promote and facilitate the integration and sharing of all the data generated by the diverse disciplines in astrobiology; (2) a database containing the raw and derived data products from the CheMin instrument on the MSL rover Curiosity (http://odr.io/CheMin), featuring a versatile graphing system, instructions and analytical tools to process the data, and a capability to download data in different formats. Ongoing development will complete integration of third party meta-data standards and publishing data to the semantic web.

The Europlanet H2020 program started on 1/9/2015 for 4 years. It includes an activity to adapt Virtual Observatory (VO) techniques to Planetary Science data called VESPA. The objective is to facilitate searches in big archives as well as sparse databases, to provide simple data access and on-line visualization, and to allow small data providers to make their data available in an interoperable environment with minimum effort.

The VESPA system, based on a prototype developed in a previous program [1], has been hugely improved during the first two years of Europlanet H2020: the infrastructure has been upgraded to describe data in many fields more accurately; the main user search interface (http://vespa.obspm.fr) has been redesigned to provide more flexibility; alternative ways to access Planetary Science data services from VO tools have been implemented; VO tools are being improved to handle specificities of Solar System data, e.g. measurements in reflected light, coordinate systems, etc. Current steps include the development of a connection between the VO world and GIS tools, and integration of Heliophysics, planetary plasmas, and mineral spectroscopy data to support of the analysis of observations.

Existing data services have been updated, and new ones have been designed. The global objective is already overstepped, with 34 services open and 20 more being finalized.

A procedure to install data services has been documented, and hands-on sessions are organized twice a year at EGU and EPSC; this is intended to favour the installation of services by individual research teams, e.g. to distribute derived data related to a published study. In complement, regular discussions are held with big data providers, starting with space agencies (IPDA). Common projects with ESA and NASA's PDS have been engaged, with the goal to connect PDS4 and EPN-TAP. In parallel, a Solar System Interest Group has just been started in IVOA; the goal is here to adapt existing astronomy standards to Planetary Science.

The Europlanet 2020 Research Infrastructure project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 654208.

S.2-0009-18 A NEW SERVICE USING IPDA AND VIRTUAL OBSERVATORY TOOLS TO PROVIDE ABSOLUTE SOLAR SPECTRA AT GROUND

Alain Sarkissian, alain.sarkissian@latmos.ipsl.fr LATMOS / UVSQ - IPSL - CNRS, Guyancourt, France Mustapha Meftah, mustapha.meftah@latmos.ipsl.fr CNRS, Guyancourt, France

In the framework of the Sun-Earth relations, the SOLSPEC spectrometer embarked on the International Space Station allowed to obtain solar spectra at different periods of the solar cycle and in particular at its minimum. Spectra are currently accessible via various virtual observatory services including at CDS (Centre de Donnees de Strasbourg, France)

ftp://cdsarc.u-strasbg.fr/pub/cats/VI/152 and via http://vizier.u-strasbg.fr/viz-bin/VizieR?- source=VI/152

Our colleagues ask for an adaptation in spectral resolution depending on the use, and also absolute solar spectra observed at ground for many configurations: zenith view, limb, sky, etc. Many requests have been made to us in this sense, and this service via a virtual Observatory portal seemed to us the most adapted to our situation. This tool is the result of IPDA and IVOA (International Virtual Observatory Alliance) collaboration.

Markus Demleitner, msdemlei@ari.uni-heidelberg.de University of Heidelberg, Heidelberg, Germany

The MASER (Measuring, Analysing and Simulating Radio Emissions) project provides a comprehensive infrastructure dedicated to low frequency radio emissions (typically < 50 to 100 MHz). The four main radio sources observed in this frequency are the Earth, the Sun, Jupiter and Saturn. They are observed either from ground (down to 10 MHz) or from space. Ground observatories are more sensitive than space observatories and capture high resolution data streams (up to a few TB per day for modern instruments). Conversely, space-borne instruments can observe below the ionospheric cut-off (10 MHz) and can be placed closer to the studied object.

Several tools have been developed in the last decade for sharing space physcis data. Data visualization tools developed by The CDPP (http://cdpp.eu, Centre de Donnees de la Physique des Plasmas, in Toulouse, France) and the University of Iowa (Autoplot, http://autoplot.org) are available to display and analyse space physics time series and spectrograms. A planetary radio emission simulation software is developed in LESIA (ExPRES: Exoplanetary and Planetary Radio Emission Simulator). The VESPA (Virtual European Solar and Planetary Access) provides a search interface that allows to discover data of interest for scientific users, and is based on IVOA standards (astronomical International Virtual Observatory Alliance). The University of Iowa also develops Das2server that allows to distribute data with adjustable temporal resolution.

MASER is making use of all these tools and standards to distribute datasets from space and ground radio instruments available from the Observatoire de Paris, the Station de Radioastronomie de Nancay and the CDPP deep archive. These datasets include Cassini/RPWS, STEREO/Waves, WIND/Waves, Ulysses/URAP, ISEE3/SBH, Voyager/PRA, Nancay Decameter Array (Routine, NewRoutine, JunoN), RadioJove archive, swedish Viking mission, Interball/POLRAD. MASER also includes a Python software library for reading raw data.

The Europlanet H2020 Research Infrastructure project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 654208.

S.2-0011-18 COORDINATING PYTHON DEVELOPMENT FOR HELIOPHYSICS

Alexandria DeWolfe, alex.dewolfe@lasp.colorado.edu

Laboratory for Atmospheric and Space Physics, Boulder, Colorado, United States D Aaron Roberts, aaron.roberts@nasa.gov

NASA Goddard Space Flight Center/Heliophysics Science Division, Greenbelt, Maryland, United States

Python has become the programming language of choice of many researchers in Heliophysics. Many groups have developed analysis tools that are very useful, but up until now there has been little support for coordination between them. We have initiated a Python working group to bring together developers from all of these different projects, in order to share knowledge and lessons learned, develop standards and recommendations for best practices, and support existing Python libraries used by multiple projects. We are working with the SunPy, SpacePy, pysat, CDF, SPEDAS, and tplot projects, and anticipate reaching out to others as they are identified. In 2018 we plan to identify community needs for project support and new development, establish recommendations for coding standards and standard libraries, and build a team website to collect information and provide links to projects and documentation.

NASA and its partners maintain a watch for Near-Earth Objects (NEOs), asteroids and comets that pass within Earth's vicinity, as part of an ongoing effort to discover, catalog, and characterize these bodies and to determine if any pose an impact threat. NASA's Planetary Defense Coordination Office (PDCO) is responsible for:

Ensuring the early detection of potentially hazardous objects (PHOs) - asteroids and comets whose orbits are predicted to bring them within 0.05 astronomical units of Earth's orbit; and of a size large enough to reach Earth's surface - that is, greater than perhaps 30 to 50 meters; • Tracking and characterizing PHOs and issuing warnings about potential impacts; • Providing timely and accurate communications about PHOs; and • Performing as a lead coordination node in U.S. Government planning for response to an actual impact threat.

The PDCO collaborates with other U.S. Government agencies, other national and international agencies, and astronomers around the world. The PDCO also is responsible for facilitating communications between the science community and the public should any potentially hazardous NEO be discovered. In addition, the PDCO works closely with the United Nations Office of

Outer Space Affairs and the Committee on the Peaceful Uses of Outer Space to support international collaborations on Near Earth Objects. The PDCO is NASA's representative as a leading member of the International Asteroid Warning Network (IAWN) and the Space Missions Planning Advisory Group (SMPAG), multinational endeavors endorsed by the United Nations for an international response to the NEO impact hazard, established and supported by the space-capable nations. In this paper, we provide an overview of the office's many and varied planetary defense endeavors. We will also provide opportunity for more collaborations for a global and a national communications effort.

S.3-0002-18 DART ASTEROID THREAT MITIGATION TEST

Andrew Cheng, andrew.cheng@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States DART Team

A. S. Rivkin, J. Atchison, O. Barnouin, L. Benner, N. Chabot, C. Ernst, E. G. Fahnestock, D.

C. Richardson, A. M. Stickle, C. Thomas

The Double Asteroid Deflection Test (DART) will be the first space experiment to demonstrate the kinetic impactor method of asteroid impact hazard mitigation. DART is part of the AIDA international cooperation between ESA and NASA, where the NASA DART mission will impact the small moon of the binary asteroid 658034 Didymos in October, 2022 and change its orbit. This change will be measured by ground-based observatories to confirm the amount of deflection. The second component of AIDA is the ESA Hera mission which is planned to rendezvous with the Didymos binary asteroid, to measure the outcomes of the DART kinetic impactor test, particularly the size and depth of the DART impact crater, and the changes in the Didymos binary system orbital and rotational dynamics. These measurements will provide the first measurements of momentum transfer efficiency from a kinetic impact at full scale on an asteroid representative of the impact hazard, where the impact conditions of the projectile are known. The DART impact on the 160 m moon of Didymos will decrease the binary orbit period by 7 minutes, assuming momentum transfer efficiency of unity. The DART impact may induce librations of several degrees amplitude, depending on the moon's axial ratio. It will furthermore make a 7 m to 20 m diameter crater depending on target properties and other impact conditions, and it will release a volume of particulate ejecta that may be directly observable from Earth or even resolvable as a coma or an ejecta tail by ground-based telescopes.

S.3-0003-18 STATUS OF THE EUROPEAN CONTRIBUTION TO AIDA: THE HERA MISSION

The original proposal of the Asteroid Impact Deflection Assessment (AIDA) consisted of NASA's kinetic impactor, the Double Asteroid Redirection Test (DART), and ESA's Asteroid Impact Mission (AIM), a spacecraft with a sophisticated payload that would observe the binary asteroid Didymos before, during, and after the DART impact on the asteroid moon. However, while AIM received considerable interest by some ESA member states on the Ministerial Conference in 2016, it did not reach full funding. Since then, the European component has been redesigned. The new mission, called Hera, is optimized to reach the mission goals with a simplified spacecraft and a small baseline payload. The instruments are the Asteroid Framing cameras (flight spares of the Dawn Framing Cameras), a lidar, and a cubesat carrying the ASPECT imaging spectrometer. The design leaves ample margin for additional payload contributions by interested partners. We will present the status of the ongoing studies of the Hera mission, and the plans for the investigation of Didymos in cooperation with DART.

S.3-0004-18 BINARY ASTEROID (65803) DIDYMOS: OBSERVATIONS OF AND CONSTRAINTS ON THE BINARY SYSTEM

Petr Pravec, petr.pravec@asu.cas.cz

Astronomical Institute of the Academy of Sciences of the Czech Republic, 25165, Czech Republic

Peter Scheirich, petr.scheirich@gmail.com

Astronomical Institute, The Czech Academy of Sciences, 25165, Czech Republic

The binary near-Earth asteroid (65803) Didymos is a planned target for the Asteroid Impact Deflection Assessment (AIDA) mission. AIDA will be the first space experiment to demonstrate asteroid impact hazard mitigation by using a kinetic impactor to deflect an asteroid. It is an international cooperation, consisting of two mission elements: the NASA Double Asteroid Redirection Test (DART) mission and the ESA Hera rendezvous mission. The primary goals of AIDA are (i) to test our ability to perform a spacecraft impact on a potentially hazardous near-Earth asteroid and (ii) to measure and characterize the deflection caused by the impact. The AIDA target will be the secondary member (satellite) of the binary asteroid Didymos, with the deflection experiment to occur in late September or early October, 2022. The DART impact on the secondary at 7 km/s is expected to alter the binary orbit period by about 4 minutes and this period change will be measured by Earth-based observatories. The Hera spacecraft will characterize the asteroid target and monitor results of the impact in situ at Didymos. The DART mission is a full-scale kinetic impact to deflect a 150m diameter asteroid, with known impactor conditions and with target physical properties characterized by the Hera mission.

Remote (mostly Earth-based) observations of Didymos are an important part of the mission. Their two main goals are following: 1) A pre-characterization of the target binary asteroid, which is necessary for designing and planning the spacecraft mission. 2) Measurement of a change of the secondary orbital period caused by the DART impact, which provides a back-up for a case Hera does not happen or fails. In our talk, we will overview photometric observations of the Didymos system that were obtained in 2003 (discovery of the Didymos secondary), 2015 and 2017. We will present what constraints they place on parameters of the binary system, in particular the secondary's orbital period, relative semi-major axis and eccentricity, the secondary-to-primary mean diameter ratio, orientation of the secondary's orbit in space, primary's rotation period and albedo. We will also discuss how more observations planned to be taken in 2019-2022 will further improve our knowledge of the binary system, including determination of a drift of the secondary's orbit by the BYORP effect and estimation of the secondary's equatorial elongation and spin period.

S.3-0005-18 DIDYMOS BINARY SYSTEM DYNAMICS AND PHYSICAL PROPERTIES INVESTIGATIONS FOR THE DART MISSION, INCLUDING OUTCOMES OF THE DART IMPACT

The Double Asteroid Redirection Test (DART) mission concept currently under development is designed to be the first meaningful demonstration of a kinetic impactor for planetary defense against a small body impact hazard. Its mission target, the binary Near-Earth Asteroid (NEA) system 65803 Didymos, has been the subject of studies organized through the dynamical and physical properties working group of the DART Investigation Team. These studies have been aimed at: 1) characterizing the Didymos system's pre-impact dynamics, and un-perturbed and perturbed time evolution thereof, consistent with all observation data; 2) modeling changes to the system's dynamics that may be induced by the DART spacecraft's impact with the secondary during the system's October 2022 close approach to Earth; and 3) determining how physical properties can be inferred based on current knowledge. This talk focuses on the first two items.

For the first item, we have developed and maintained a Didymos Reference Model (DRM). This includes a radar and lightcurve derived primary shape model, but only has assumed axial ratios for an elongated ellipsoidal secondary, as available data doesn't support obtaining a secondary shape model. The primary diameter is 780 m ±10%, the secondary's mean equivalent volume diameter is 163 18 m. The primary rotation period and binary orbital period are well constrained from photometric lightcurve data, at 2.2600 0.0001 hr and 11.920+0.004/-0.006 hr, respectively. From the latter, and the mean separation of 1180+40/-20 m, a system mass of (5.278 0.54) 1011 kg is obtained. However, the individual component masses (and most critically, the secondary mass) are not yet distinguished. Derived bulk density is in turn only constrained to 2104 kg m−3 30%. Binary orbit eccentricity is bounded small (<3%) and the binary orbit pole is known within several degrees, but we currently assume on average synchronous rotation of the secondary and near-alignment of both body spin poles with the orbit pole. It is notable that depending on actual primary size, mass, and density values allowed within these constraints, the primary may be at or extremely close to spin disruption, meaning having equatorial regions with net outward acceleration, requiring cohesive strength.

As for long-term time evolution of the pre-impact dynamics, we have examined external tides, solar radiation pressure, and thermal re-radiation (BYORP) effects, and inter-component tidal energy dissipation. But greater focus has been on high fidelity simulation of the dynamics over shorter time frames appropriate to the mission duration, including planned post-impact ground-based observation. We have performed Full Two Body Problem (F2BP) simulations of Didymos instantiations consistent with the DRM. Example results show the expected modes of motion given full coupling between primary and secondary body rotation and binary orbit (e.g. spin-orbit co-precession, secondary libration). These modes are all expected to be as relaxed as possible pre-impact, but the minimum forced libration amplitude has been characterized given choice of secondary shape parameters/ shape model. Following detailed output comparison of two independent code implementations of the same symplectic integrator and polyhedral formulation of mutual gravitational potential of the components, we conducted a broader F2BP simulation benchmarking exercise. This used four test systems and involved participants with various numerical integrators and various force and torque models based on various other mutual potential formulations (e.g. higher-order inertia integrals, packed cubes/spheres). We compared metrics of both computational cost, and accuracy/precision loss with respect to conserved quantities and differential geometric properties of the underlying dynamics, to inform selection of the best simulation methodologies for different contexts.

For our examination of the potential effects of the DART impact on the dynamics, we obtained terminal approach and impact conditions from the mission design team. Nominally, the 500

kg DART spacecraft would impact at 6.0 km s–1 along a direction nearly opposed to (164°

from) the secondary's binary orbit velocity vector, tilted 16° out of the binary orbit plane, and with approach solar phase angle of 60°. This is expected to reduce the binary orbit period by a few minutes, with mission requirements to achieve >73 seconds period change, measured to accuracy of <7.3 seconds (1σ). An independent estimate of the secondary mass is also desired, to obtain a measure of the kinetic impactor momentum transfer

enhancement parameter β. However, currently β is highly uncertain and there also exists targeting dispersion about the nominal (optimal) impact location on the secondary. In light of this, we have conducted sparse raster sampling of β values and impact locations, and performed F2BP simulation of the postimpact dynamics in each case. This has allowed determination of which dynamical modes are excited and by how much, with particular focus on the induced libration amplitudes. It has also bounded the probability of breaking on-average synchronous rotation of the secondary.

S.3-0006-18 SIMULATING THE DOUBLE ASTEROID REDIRECTION TEST (DART): EFFECTS OF IMPACT PARAMETERS ON MOMENTUM ENHANCEMENT FROM A KINETIC IMPACTOR

Angela Stickle, angela.stickle@jhuapl.edu JHU/APL, Laurel, Maryland, United States Emma Rainey, emma.rainey@jhuapl.edu JHU/APL, Laurel, Maryland, United States Megan Bruck Syal, syal1@llnl.gov

J. Mike Owen, owen8@llnl.gov

Lawrence Livermore National Laboratory, Livermore, California, United States

The Double Asteroid Redirection Test (DART) is a NASA mission concept to test the kinetic impact deflection of an asteroid. DART would target the moon of the binary system Didymos ("Didymoon"), impacting at 6 km/s to change the moon's orbital period. DART represents the first direct test of the kinetic impactor theory for planetary defense. The momentum enhancement of Didymoon from the DART spacecraft is parameterized by and depends on the initial spacecraft momentum (pspacecraft) and the momentum of ejecta excavated during crater formation (pejecta): =1+(pejecta/pspacecraft), with momenta tracked in the direction of intended deflection. An important part of mission development is determining the expected outcome of the impact, including crater formation and momentum enhancement from the impact.

Impact modeling is one of the primary tools to be used to interpret the results of the kinetic impact deflection, to infer the physical properties of the target asteroid, and to advance our understanding of impact processes on asteroids. The DART team utilizes several state-of-the-art hydrocodes to simulate possible outcomes of the encounter. Target properties, including cohesion, porosity, and internal structure, may have significant effects on the momentum enhancement from a kinetic impact used to deflect an asteroid. Initial statistical analyses and modeling efforts suggest that the yield strength of the material, porosity, target cohesion and internal friction, and internal structure are the most important parameters to consider. Material porosity can come in the form of "microporosity" where there is void space among grains in the material, or "macroporosity" where the void space is along large-scale cracks or between large boulders if the asteroid is a "rubble pile". Both of these porosity types will affect the ejecta generated following impact, and thus the eventual momentum enhancement from the kinetic impact. Simulations of impacts into rubble piles show a wide range of momentum enhancements depending on the particulars of the internal structure, internal porosity, and where the impact occurs. Depending on the structure of the target (e.g., amount, size, and location of large boulders), impact outcomes can vary significantly. If the spacecraft were to impact onto a large, strong boulder, for instance, the cratering process and ejecta flow field will be significantly different than if the spacecraft were to impact into weaker granular matrix between boulders. In general, crater size and ejecta material (and thus, β) are dominated by boulder material and whether the impactor strikes matrix or boulder material first. The internal damage propagation within the target is also sensitive to the presence of boulders, which may imply that disruption behavior is different.

Further simulations are underway in order to fully explore this parameter space and map out the possible outcomes for the DART impact, and to estimate from the measured deflection of Didymoon.

Portions of this work were prepared by LLNL under Contract DE-AC52-07NA27344. LLNL-ABS746064.

S.3-0007-18 MOMENTUM ENHANCEMENT DUE TO HYPERVELOCITY IMPACTS INTO CONSOLIDATED AND POROUS ROCK

James Walker, james.walker@swri.org

Southwest Research Institute, San Antonio, Texas, United States Sidney Chocron, sidney.chocron@swri.org

We have been exploring the momentum enhancement that occurs when impactors strike metals, rock, and now pumice at hypervelocity [1-3]. Momentum enhancement is the effect that the crater ejecta created by the impact leads to more momentum transferred to the impacted body than solely the momentum of the projectile. It is desirable to quantifying momentum enhancement to provide needed information in the event hypervelocity impactors are considered in deflecting celestial bodies such as asteroids or comet nuclei. In momentum enhancement experiments it has been observed that the size scaling of momentum enhancement is not linear for impacts into consolidated materials. In particular, experiments clearly show for metals and suggest for consolidated rock that as the size of the impactor increases, the momentum enhancement increases more than would be expected based on impactor size. Experiments suggest, however, that this may not be the case for pumice. To understand the momentum enhancement and its potential size scaling behavior, we have performed impacts using the Southwest Research Institute range firing projectiles at speeds of 2 to 2.1 km/s. Aluminum projectiles had diameters of 2.54 and 4.45 cm, which is a relatively large scale based on most momentum enhancement studies which are performed with small caliber light gas guns. The targets impacted as simulants for asteroids were consolidated rock and pumice. We believe this scale is large enough that in working with the pumice we obtain a representative response and not an impact-location-specific response. This paper includes the previously published data as well as new data and presents new computations and discussion of momentum enhancement mechanisms to better understand the impact event. Porosities of asteroids range from 0 to >50%, with most >20%. Meteorites, which sample asteroids, have a similar range. Since porous targets react differently to hypervelocity cratering than non-porous targets, it is critical to measure the response of asteroid samples to impacts. To quantitatively determine the momentum transfer from hypervelocity impact cratering we suspended targets in front of a large rectangular grid in the vacuum chamber at the NASA Ames Vertical Gun Range. Each target was impacted by a 1/16" or 1/8" Al-sphere shot at 4 to 6 km/s. Using high-speed video images we measured the recoil speed of each target and determined the momentum multiplication factor (β), the ratio between the recoil momentum of the target and the momentum of the impactor. We impacted 5 samples of the CV3 carbonaceous chondrite Northwest Africa (NWA) 4502 with a mean porosity of 2.1%, 7 samples of the ordinary chondrite NWA 869 with a mean porosity of 6.4%, 4 samples of the ordinary chondrite Saratov with a porosity of 15.6%, a sample of terrestrial serpentine, one of the two clay minerals that dominate the composition of the hydrous CI chondrites, with a mean porosity of 18.8%, and 2 samples of terrestrial pumice with a mean porosity of 70%, to cover a wide porosity range. We found that for the anhydrous samples β decreased with increasing porosity, consistent with hydrocode modeling. However, the β values we measured are larger, with β = 3.37 for NWA 4502, 2.70 for NWA 869, 2.08 for Saratov, 4.93 for serpentine, and 2.15 for pumice, than results from hydrocode modeling for 5 km/s impacts into relatively strong, porous rock targets. The β value for the moderate porosity (18.8%) hydrous serpentine target (β = 4.93) is more than twice the β value for the anhydrous Saratov targets, which have comparable porosities. This result suggests that the hydration of the serpentine target substantially enhances the momentum transfer, likely by the jetting of water vaporized in the hypervelocity cratering event. Comets, with their high ice content, should be even more affected by vapor jetting. Even the most porous rock targets we impacted had substantial momentum enhancement from crater ejecta. For our most recent impacts we documented the target shape by 3D laser scanning, and measured the grain and bulk densities, porosity, and compressive strength of the targets to facilitate comparison with hydrocode modeling. The momentum enhancement due

to crater ejacta should be considered in design of kinetic impact deflection missions and modeling of the alteration of asteroid orbits by collisions.

Predicting the total momentum delivered onto a target asteroid constitutes one of the challenges of kinetic impactor-based orbit deflection methods. In spite of numerous laboratory experiments and considerable modeling efforts, uncertainties in the direction and magnitude of the momentum carrying material excavated during the impact remain uncomfortably large. Field-testing of kinetic impactors is, therefore, crucial to verifying ejecta models and credible momentum enhancement factor (β) predictions. The NEOTωIST mission concept could deliver such a validation by changing the spin state of the asteroid (25143) Itokawa. Targeting a well-characterized object off-center yields a change in the rotation state that is proportional to the momentum enhancement factor. Consisting of an impactor, a flyby vehicle and CubeSat chasers, the NEOTωIST concept would constrain β through direct observation of the ejected material, as well as through a complementary tracking of changes in the asteroid's spin state via ground-based observations. In this contribution, we show that the currently envisioned impact scenario would alter Itokawa's principle rotation period by several minutes - well above the detection limit of ground-based facilities. We, furthermore, present optimum potential impact locations on Itokawa that would allow for an accurate determination of the momentum enhancement factor. This information about the NEOTωIST concept is pre-decisional and is presented for planning and discussion purposes only.

S.3-0011-18 A NEW CONCEPT OF ASTEROID MITIGATION USING EXPULSION PAYLOAD IN SPACECRAFT SYSTEM

Sathiyavel C, directorapjarc@gmail.com

DR.A.P.J.Abdulkalam Research & development centre, Chennai, India

The recent studies by international space university identify Thermonuclear Devices; Directed energy system gives a set of recommendations for better preparation to mitigation of the asteroid. This study is highly drawback to develop experimental work in the future. This paper presents a suitable experimental work in real time model to mitigate of Asteroid and compares the performance with simulation work through Liquid Hydrogen Liquid Oxygen propellants. This principle can be achieved by spacecraft System that carries an explosive payload which is including liquid Hydrogen, liquid oxygen, laser beam, Arduino Controller. The trajectory dispenses the Spacecraft at a distance of a few asteroid diameter while doing this we have to control the radio frequency transmission in the earth so that the Arduino controller can be changed in active mode. The continuously liquid Hydrogen Liquid Oxygen onto the Asteroid surface, at this same time, ignite the liquid propellants throughout the laser beam in order to vaporize the surface material, hence transferring a continuous force to the Asteroid. We modify evaporation process so that vapor highly growth to demonstrate the function exits. Therefore a multi spacecraft system might be applicable to Asteroid with size > 200m.

S.3-0012-18 DEFLECTING LARGE AND MEDIUM SIZE ASTEROID TRAJECTORIES BY A NUCLEAR ARRAY (FEW-DOZEN) TRACTORS, EJECTING COHERENTLY AS FOUNTAINS, THE SAME SOIL MASS.

Daniele Fargion, daniele.fargion@roma1.infn.it

Physics Department, Rome University 1, INFN Rome 1,, Rome, Italy

Rarest large (km size) or more common medium (tens-hundred meter size) incoming asteroid may be deflected by their trajectories by the landing of an array of micro robotic nuclear engines tractors (ton sized), located and landed on the asteroid surfaces, able to dig the asteroid icy (or dust) surface while propelling it as an effective a mass momentum fountain jet array: the asteroids skin (ice, dust) ejections and their consequent bending might drive the asteroid easely far from the Earth impact target if a programmed pre-cursor landing occur years before. Eventual tuned planetary gravity bending may amplify the success. The need for mini and midi asteroid test capture and safe parking in nearby orbits, may guarantee a a wide array of stations, mostly in a robotic ibernated state, offering a safe and solid multi body system for an early and fast two body hit in deflection of a greater incoming asteroid The asteroid skin ejection system it is an ideal tool in future planetary defense. Catastrophic asteroid impacts are among the few natural disasters that can in principle be averted using current technology. Should an asteroid be discovered and predicted to impact our planet near a population center, humankind may have the option of sending a space mission to alter the potentially hazardous object's trajectory. A kinetic impactor spacecraft, for instance, could transfer momentum to the asteroid through a high-velocity collision, thus avoiding a future impact on our planet. Differences in asteroid shape and composition, however, cause the magnitude and direction of the delivered momentum to be to some degree uncertain. Without accurate information on where an asteroid is "parked" after a deflection attempt, the same object may become a concern for planetary defense at a later date. In the worst case, the target asteroid enters a so-called "gravitational keyhole," retaining a high probability to collide with our planet. In order to avoid such scenarios, we demonstrate how to best target an asteroid during a kinetic deflection maneuver so as to minimize the chances of an Earth impact in the foreseeable future.

The issue of protecting ground infrastructures and space assets from the hazards coming from space, i.e. space debris, Near-Earth-Objects (NEO) and Space Weather, has recently gained momentum. In Europe it is addressed by the Space Situational Awareness Programme (SSA) of the European Space Agency (ESA) as well as at European Commission level. Within this framework it is foreseen the deployment of a European network of sensors for the detection of space objects able to trigger and support impact monitoring activities. The so-called "Fly-Eye" telescope with its unique optical design guaranteeing a wide-field (6.7°x6.7° FoV) and a highsensitivity (down to 21.5 visual magnitude) is a key element to this end. In survey mode this telescope allows to timely detect small NEOs approaching the Earth and to efficiently catalogue space debris in a wide range of orbital regimes, from high LEO (Low-Earth Orbit) up to the geostationary ring. The first-light of the ESA SSA Fly-Eye telescope devoted to NEO survey is expected by end 2019.

In order to investigate observational sites in Italy which could satisfy the SSA observational requirements we have analyzed different locations taking into account sky pollution, cloud coverage and seeing values. Both space and ground-based data were used. Cloud coverage data have been obtained from Earth observation satellites at different scale resolution (MODIS ACQUA, MODIS TERRA, MSG) and epochs. Seeing evaluation is based on existing data and/or in-situ ground-based seeing monitor equipments. The sky brightness was estimated by using NOAA (VIIRS/DMSP) and World Atlas 2015 (F. Falchi et al. 2016) maps. Due to the peculiarity in which NEO and space debris survey

are expected to operate, logistic considerations were also taken into account. We present the outcome of the resulting trade-off analysis which shows the advantages and drawbacks of each site, eventually leading to identify those which could satisfy the technical and operational needs of running a NEO/space debris based on Fly-eye telescopes.

S.3-0015-18 ON-ORBIT MONITORING OF METEOR IMPACTS USING CUBESATS

The Chelyabinsk meteor event of 2013 showed the potential dangers of an asteroid impact. Luckily, the meteor resulted in airburst that released about 500 kilotons of energy (more than 30 times the explosive power of the nuclear bomb that hit Hiroshima). There were no known space or ground assets that were able to provide timely detection and early warning. This motivates the need for a early-warning surveillance system which can help us better prepare for such dangers.

Networks of spacecraft are necessary to characterize and constantly monitor near-Earth threats such as meteor impacts. Networks of CubeSats are ideally suited because of the low-development cost and for demonstrating continuous monitoring of rare phenomena. In this presentation, we propose development of a prototype, single spacecraft called, SWIMSat (Space-based Wideangle Impact of Meteors Satellite). The satellite will monitor meteor impacts. SWIMSat will be ideally located in Low Earth Orbit which enables rapid deployment for relatively low-cost. SWIMSat will be coupled with state of the ground assets managed by the University of Arizona including the Catalina Sky Survey The advent of newly available, low-cost CubeSat technology makes it feasible to start now, within the scope of a university program, and achieve sizable gains towards the security of near-Earth space within a low cost budget.

In this presentation, we present the latest design of SWIMSat. SWIMSat will be a 3U CubeSat with an onboard visible, wide-angle camera to perform autonomous imaging, detection and target tracking. Image processing will be performed on the CubeSat using state-of-the-art Field Programmable Gate Arrays. Furthermore, the spacecraft will use an off-the-shelf attitude control system

from Maryland Aerospace called MAI 400 to provide a few degrees of pointing stability. Continuous monitoring by a team of humans is not feasible. Hence the spacecraft will utilize a suite of smart, autonomous control software that will detect and track a meteor entry event. Meteor entry detection presents its own challenges as these events are relatively rare. Our work has focused on developing advanced-physics based simulations to recreate these entry events for use by our image detection algorithms.

Our simulation work show that by having swarms of CubeSats monitor these events from multiple locations it is possible to triangulate the position of the meteor in real-time, obtain readings on their size and possibly composition. Using this swarm, it maybe possible to measure the meteor in multiple wavelengths, including visible, near-IR,IR and hyperspectral camera to determine composition of the meteor and its potential for ground impact. Thanks to rapid advancement and miniaturization of electronics we are on pathway towards developing a lowcost on-orbit solution to meteor impact monitoring.

DISCOVERING EARTH'S RADIATION BELTS – SIX DECADES OF ASTONISHING ACHIEVEMENT (SIDL1)

SIDL1-0001-18 DISCOVERING EARTH'S RADIATION BELTS - SIX DECADES OF ASTONISHING ACHIEVEMENT

Mikhail Panasyuk, panasyuk@sinp.msu.ru

Moscow State University, Skobeltsyn Institute of Nuclear Physics, Moscow, Russia

Discovering Earth's Radiation Belts - Six Decades of Astonishing Achievement Daniel Baker and Mikhail Panasyuk 2017-18 marks the 60th anniversary of the dawn of the Space Age. The first artificial "moon" of our home planet, Sputnik (Russian for "companion"), was launched into low Earth orbit on 4 October 1957 by the then Soviet Union. While Sputnik 1 was little more than a radio beacon, it showed the entire world that Intercontinental Ballistic Missiles (ICBMs) - at the core of Cold War military arsenals - could also launch satellites into space. Shortly after the launch of Sputnik 1, Soviet scientists launched the second spacecraft into Earth's orbit on 3 November 1957. It was a much larger and more sophisticated vehicle. The satellite was the first to place into space a living creature - the dog Laika. Officially, Sputnik was launched in the framework of the International Geophysical Year. In addition to biological experiments, on board Sputnik 2 Soviet scientists under the leadership of Prof. Sergei Vernov of Moscow State University placed a detector for measurement of radiation in space - a Geiger-Muller counter. January 31, 1958, saw the launch by the United States of Explorer 1 into Earth orbit. James Van Allen and his team from the University of Iowa had radiation detectors on board Explorer I. It is interesting that Van Allen used the same type of radiation detectors as Vernov did: Geiger-Muller tubes as detectors for cosmic radiation measurements. The first results obtained by the pioneers of exploration of outer space was a truly epoch-making: they led to the discovery of new natural phenomena - the Earth's radiation belts - a phenomenon that was not predicted before the start of the space age. This discovery was the beginning of the formation of a new science - Space Physics. This presentation will describe the development of the first space missions and will provide a broad overview of the subsequent 60 years of radiation belt science.

INTERDISCIPLINARY LECTURES (SIDL)

LARGE-SCALE QUANTUM COMMUNICATION NETWORK WITH SATELLITES (SIDL2)

SIDL2-0001-18 LARGE-SCALE QUANTUM COMMUNICATION NETWORK WITH SATELLITES

Jian-Wei Pan, pan@ustc.edu.cn

University of Science and Technology of China, Hefei, China

Free-space quantum communication with satellites opens a promising avenue for global secure quantum network and large-scale test of quantum foundations. Here we report a serial of experimental progresses on free-space quantum communication over long distance. In the meantime, Chinese Quantum Science Satellite has been launched on August 16th 2016. Through nearly one year of efforts, we have achieved the three major scientific goals-satellite-based entanglement distribution over 1200km and test of quantum nonlocality under strict Einstein's locality condition, ground-to-satellite quantum teleportation, and satellite-to-ground quantum key distribution. Recently, we also realized satellite-relayed quantum secured communication between China and Europe at locations separated by 7600 km. Our work pays the way for global quantum network and ultimate test of quantum nonlocality in outer space.

SIDL3-0001-18 GAIA: THE GALAXY IN 6 DIMENSIONS

Elena Pancino, pancino@arcetri.inaf.it

Gaia was launched in 2013, and is now scanning the sky to accurately measure the positions and motions of about 2 10^9 point like sources of $3 < G < 21$ mag, with the main goal of reconstructing the 6D phase space structure of the Milky Way. The sky will be repeatedly scanned (70 times on average) for five years or more, adding the time dimension, and the Gaia data are complemented by mmag photometry in three broad bands, plus line-of-sight velocities from medium resolution spectroscopy. This impressive dataset will have an impact on various areas of astrophysics, from solar system objects to distant quasars, from unresolved galaxies to nearby stars, from binaries and extrasolar planets to light bending experiments. The second data release, DR2, is foreseen for the 25 of April 2018, therefore the COSPAR meeting is nicely timed to describe the release content and present some of the first results obtained with Gaia DR2 data.

SIDL4-0001-18 ECONOMIC VALUE OF A MORE ADVANCED CLIMATE OBSERVING SYSTEM

Bruce A. Wielicki, b.a.wielicki@nasa.gov

NASA Langley Research Center, Hampton, Virginia, United States

The climate science community has done a heroic job of using space based Earth observations to estimate climate change despite the fact that few of those observing systems were designed with climate change requirements, and most require substantial corrections and modifications. But what if we designed a global observing system specifically for climate change science, rather than using a collage of non optimal weather and research observations? How much faster could we unscramble anthropogenic climate change from natural variability and observation uncertainty? What would be the economic value to the world of such a system? What is the right amount for society to invest in climate research to narrow climate prediction uncertainties? What is the return on investment? How would we design such a system? The presentation will address these questions and demonstrate that the value of such a system is surprisingly large and is controlled by the accuracy of the observations.

The presentation will also suggest key elements needed in the design of an advanced climate observing system. Our current climate observations are extremely important, but they are far from optimal. Improved methods can better understand and communicate to society the right amount to invest in future climate observations.

INTERDISCIPLINARY LECTURES (SIDL)

SEARCHING FOR LIFE OUTSIDE THE EARTH, IN OUR SOLAR SYSTEM AND BEYOND (SIDL5)

SIDL5-0001-18 ASTROBIOLOGY FROM EARTH TO MARS AND BEYOND!

Penelope Boston, penelope.j.boston@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States

Astrobiology begins right here on Earth studying the extreme environments that our planet offers and testing hypotheses with modeling and laboratory analyses. Understanding from such investigations must then be translated to predicting where we may find life elsewhere in our Solar System and even beyond in our galaxy. We study unique lifeforms on Earth and the physical and chemical biosignatures, that is traces of life, that they leave behind. Such traces can be used to provide a “Field Guide to Unknown Organisms” for developing life detection instruments, ideas for space missions to find life, and insights into ancient life on Earth. Examples from the extensive work to date and that to come in the future illustrate the prospects for finding life in our Solar System and beyond.
