A0.1-0001-18 RESEARCH ON REMOTE SENSING IMAGE ON-BOARD TARGET RECOGNITION BASED ON LOCAL INVARIANT FEATURE

Yantong Chen, chenyantong1@yeah.net Dalian Maritime University, Dalian, China Ming Zhao, eachzhao@126.com

Dalian Maritime University, Dalian, China Tingting Yao, ytt1030@126.com

Dalian Maritime University, Dalian, China

With the development of satellite remote sensing technology, the resolution of satellite image is increasing. And the high resolution satellite image can apply to the civil and military fields. Especially in military field, satellite image recognition is an important way to obtain military information. As the remote sensing satellite has the poor on-board process ability, traditional recognition and processing work of satellite image is carried out mainly in the ground. By the reason of satellite data transmission ability and the influence of ground station distribution, image acquisition process is very complex. The data from acquisition to the ground station is about in one day, because of the different satellite orbit. However, on-board target recognition can process the satellite image on orbit, and transmit the processed data to the ground command center through relay satellite or telemetry system. By this way, the access time of the information is shortened greatly, which ensure the timeliness of the remote sensing information. In this paper, we proposed a satellite image on-board target recognition method. According to the characteristics of remote sensing images and the problems exist in the onboard processing, this method is proposed combined with the development trend of the target recognition technology. We also make a deep research with the step of target recognition, such as feature detection, feature description and match recognition. In addition, we design an onboard fast target recognition system based on the characteristic of proposed method. We expect the system will provide theoretical basis and suggestions for practical engineering application. Aiming at ensure the rapidity and accuracy of the target recognize, we proposed a fast feature point detection algorithm based on the scale space theory. The algorithm builds the scale space by down sampling the image, and detects the feature points with AGAST algorithm in every scale space. However, the scale space will lead the feature point translation. Considering this problem, we proposed a method based on the feature point local relocation to location of feature points. Experiment results show that the algorithm is robust to scale, viewpoint and illumination transform. What's more, the algorithm takes a shorter time, and higher precision of feature points detect. In view of the complex and changeable characteristics of remote sensing images, especially the problem of illumination changes, we proposed a FREAK description algorithm based on feature point intensity normalization. First, we adjust the FREAK sample model to make the sampling points pay more attention to the edge and contour feature. And then, we estimate the dominant orientation of the descriptor by sampling point's gradient. At last, we normalized the pixel intensity by the neighborhood of feature point. Experiment results show that

the performance of proposed algorithm is better than others in scale, rotation and illumination transform. And the performance of viewpoint transform can satisfy the onboard process. In addition, the algorithm takes a relatively short time and is suitable for fast processing of remote sensing image. Take consider with the large amount of satellite image data and the low processing ability on the satellite, we proposed a hybrid spill tree data search method for satellite image on-board target recognition. The algorithm redundant segments the data in feature data preprocessing stage. By give up the edge of the sparse data points, the algorithm can adopt segmentation method based on center point. In feature matching stage, the algorithm measure the distance between feature vectors using XOR operation. We also improve SIFT feature matching strategy by using K nearest neighbor distance instead the second nearest neighbor distance. Finally, we use RANSAC algorithm to eliminate false matching points. Experiment results show that using the proposed search algorithm to recognize the target in remote sensing image, which has higher efficiency, shorter processing time and higher matching accuracy. When the high angle of the sun is low, the satellite image will appear many shadow areas. And these shadow areas will lead to a low target recognition rate. Taking consider with this problem, we proposed a target matching recognition method based on super pixel segmentation and reconstruction. First, we need to estimate the orientation of aircraft by using histograms of oriented gradients. And then, an improved SLIC super pixel segmentation algorithm is provided. By comparing texture feature instead of color feature space, we cluster the pixels that with the same features. Last, through target template images and orientation we reconstruct the super pixels. And the lowest error matching ratio is the recognized target. The test results show that the algorithm is more accuracy with target segmentation and wipe off the shadow areas efficiency. Compared with the situation of before superpixel segmentation, our method is more exactly. In engineering application, we develop an on-board rapid target recognition system based on FPGA+DSP combination form. We adopt the ideas of OpenVPX bus design and dual DSP parallel pipelining to ensure versatility and scalability of the system. By this way, we can improve the processing efficiency of the algorithm and lay the foundation for the on-board rapid target recognition. In addition, high speed interface provides a strong guarantee to the transmission of large amount of remote sensing image data on satellite. At last, we show the result of target recognition based on original satellite image data, which verification the feasibility of on-board target recognition.

A0.1-0002-18 OCEAN OBSERVATION FROM SPACE USING MARINE TRAFFIC DATA

Yann Guichoux, yann.guichoux@e-odyn.com eOdyn, PLOUZANE, France

Our presentation focus on the description of a transformative technique allowing omni-situ ocean surface currents measurements relying on environmental data sets and ship motions data analytics. The technology makes it possible to retrieve real time and historical ocean surface currents information at a global scale. First the technique is introduced, how machine learning on environmental data sets and ship motions can produce omni-situ ocean surface currents. Performances are assessed showing results in different ocean dynamic conditions, comparing HF radar measurement, drfters and geostrophic currents derived from altimetry with eOdyn products. Technology' fields of application, as well as its limitations and development status are introduced. A one year omni-situ ocean surface currents climatology is compared to the bottom topography. At last, new possibilities allowed by this technique are highlighted.

A0.1-0003-18 JAGUAR MONITORING STORE-AND-FORWARD SATELLITE: JAGUARSAT

Yiğit Çay, yigitcay.34@gmail.com

JaguarSAT is a hypothetical 1U CubeSat proposed as a part of 5th Pre-Mission Idea Contest held in August 2017 in Japan to realize a store-and-forward approach in jaguar tracking in America's forests with trap cameras. Lowering number of the jaguars indicate the signs of the ecosystems in these forests are getting worse; hence the studies of these areas for jaguar tracking is not only for jaguar population but all the ecosystem in these locations. JaguarSAT is proposed in this paper to accelerate the scientific studies by providing availability data from these remote areas to the ground stations of the institutes or governments ready to collaborate. Ground and space segment of the project are detailed as well as the whole project budget and space system implementation plan.

A0.1-0004-18 THE ABERRATION EFFECT IN ORBITAL EARTH OBSERVATION

Yixing Ding, dingyx@radi.ac.cn

Institute of Remote Sensing and Digital Earth, Chinese Academy of Sciences, Beijing, China

When the satellite images from the Earth orbit, light will take an interval of time to travel between the source (the terrestrial surface) and the sensor. The higher the sensor flies, the longer the interval lasts. Thus, an obvious geolocation problem for orbital imaging emerges that the observation geometry is changing from the time when the light leaves the source to the time when the light arrives at the sensor. This phenomenon, called light aberration in astronomy, is resulted from the relative motion between the source and the sensor. In earth observation, the aberration effect can be divided into two parts. One comes of the motion of the sensor, and the other is caused by the earth's rotation. The aberration effect has seldom been taken into consideration in geometry modeling until the high resolution earth observation system is developed. Recently, some aberration compensation algorithms have been constructed for better understanding of the errors in high-precision geolocation. In this paper, we use a two-step method to describe the error caused by the aberration effect in the geocentric celestial reference system (GCRS) for earth observation. Based on the simulation, a comparison between different orbits, including low earth orbit, geostationary orbit, and lunar orbit, will be presented. The result shows how the orbit altitude impacts on the magnitude of aberration error.

A0.1-0005-18 DESIGNING A SPACECRAFT TO EXPLOIT SIGNALS-OF-OPPORTUNITY FOR EARTH SYSTEM SCIENCE

Anthony Freeman, anthony.freeman@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Rashmi Shah, rashmi.shah@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

RF Signals of Opportunity (SoOp) are signals generated by communication or navigation satellites in Earth orbit, whose interaction with the Earth's surface can be exploited to address a wide range of Earth system science measurements. The most commonly known SoOp signals are L-Band GPS reflections, which were measured systematically by NASA's CyGNSS mission to reveal ocean surface wind speeds beneath cloud cover generated by cyclones. SoOp are spread across the RF spectrum, from VHF to Ka-band, with more and more sources available every year. This is significant, because Earth scientists use microwave signals reflected off the Earth's surface to characterize a wide range of geophysical variables, including water vapor and ice column densities in the atmosphere, sea surface heights, currents, wind speeds and wave direction, ocean salinity, snow water equivalence, soil moisture, biomass and moisture content of vegetation canopies, freeze/thaw in arctic soils, sea ice extent, and surface deformation. Different wavelengths are better suited to each of these measurements.

The advent of low-cost, yet capable spacecraft platforms in cubesat form factors present an opportunity to develop LEO constellations of SoOp missions that can dramatically increase the temporal frequency of the above-mentioned Earth System Science measurements. To truly be cost-effective, such a constellation must be capable of receiving signals in multiple bands, adapting to the available sources from above. This will involve a considerable degree of autonomous operation. Depending on the underlying terrain (e.g. ocean, ice, desert, forest, agriculture), different algorithms may be used in onboard processing to retrieve surface properties of interest. This paper will describe the challenges involved in designing a spacecraft targeting multiple SoOp and multiple science measurements.

The research described in this paper was carried out by the Jet Propulsion Laboratory, California Institute of Technology, under a contract with the National Aeronautics and Space Administration.

A0.1-0006-18 MATCHING SCIENCE QUESTIONS AND TECHNOLOGY CAPABILITIES FOR FUTURE INFRARED SOUNDING MEASUREMENTS

Eric Fetzer, eric.j.fetzer@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Thomas Pagano, tpagano@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Current operational infrared (IR) atmospheric sounders including the Atmospheric Infrared Sounder (AIRS) on Aqua, the Crosstrack Infrared Sounder (CrIS) on JPSS, and the Infrared Atmospheric Sounding Interferometer (IASI) on MetOp measure the upwelling spectrum in the IR from about 3.8 to 15.4µm with very high spectral resolution (Λ/ΔΛ 1000) with spatial resolution of about 14 km and wide swath (>1500 km). AIRS, IASI and CrIS all have had high impact on operational forecasts, despite clouds limiting the forecast use of IR information to mostly clear areas and to the upper troposphere. Current sounders have also demonstrated skill in observing weather-related metrics appropriate for decision making applications, including drought and vector-borne disease indicators. However, as global and regional weather forecast models move to spatial resolution finer than about 10 km, information about processes at the smallest scales necessitates finer spatial resolution observations. This paper will discuss the operational, applications, and science research requirements of future IR sounders, how they fit into the 2017 NRC Decadal Survey, and the instrument requirements that result from the other requirements. We will also show instrument concepts developed at JPL that address these requirements. Finally. we will identify challenges in technology, measurement approach, and retrievals as we move ahead.

A0.1-0007-18 GRACE FOLLOW-ON: THE NEXT CHAPTER OF TIME-VARIABLE GRAVITY OBSERVATIONS FROM SPACE

GFZ German Research Centre for Geosciences, Wessling, Germany

The GRACE Follow-On mission is set to continue the successful data record from the original GRACE mission, which ended in mid-2017 after 15 years of successful operations and science discoveries. GRACE has provided a unique data record of subannual to decadal temporal variations in the Earth's gravity field that has become indispensable for climate-related studies and critical measurements of Earth's time varying mass distribution. These measurements enable key and revolutionary observations of the global water cycle, including ocean dynamics, polar ice mass changes, and global ground water changes.

In 2010, NASA (US) and GFZ (Germany) agreed to jointly develop and support the GRACE Follow-On mission to ensure data continuity, as well as to demonstrate a new Laser-Ranging Technology to further improve the spacecraft-to-spacecraft ranging measurements for nextgeneration gravity missions.

In the lead-up to launch, the GRACE Follow-On project has performed extensive simulations of the expected GRACE Follow-On performance on-orbit, including intersatellite ranging (both microwave and laser interferometer), accelerometer, thermal variability and deformation, and other instrument errors. The simulated data have been used for fully integrated end-to-end Science Data System testing, and to improve ground analysis software.

In this presentation, we will provide a review of the GRACE Follow-On project integration and tests before launch, the expected science performance, and a first status update of the postlaunch checkout and early operations phases and science payloads. We will also discuss science data continuity from GRACE to GRACE Follow-On, as well as to future potential successor missions.

A0.1-0008-18 SMALL SATELLITES FOR SPACE SCIENCE (4S) COSPAR ROADMAP

Rudolf Von Steiger, vsteiger@issibern.ch

International Space Science Institute, and University of Bern, Bern, Switzerland Robyn Millan, robyn.millan@dartmouth.edu

Dartmouth College, Hanover, New Hampshire, United States Maurice Borgeaud, maurice.borgeaud@esa.int

Klaus Schilling, schi@informatik.uni-wuerzburg.de University of Wuerzburg, Wuerzburg, Germany The 4S Roadmap Committee

Meir Ariel, Sergey Bartalev, Maurice Borgeaud, Stefano Campagnola, Julie Castillo-Rogez, René Fléron, Volker Gass, Anna Gregorio, Timothy Horbury, Kirsti Kauristie, David Klumpar, Bhavya Lal, Malcolm Macdonald, Robyn Millan, James Park, V. Sambasiva Rao, Klaus Schilling, Graeme Stephens, Alan Title, Rudolf von Steiger, Ji Wu

In 2016 COSPAR commissioned an international scientific roadmap on Small Satellites for Space Science (4S), focusing particularly on CubeSats and CubeSat-technology enabled small satellites. The report is motivated by recent progress and results summarized in a published paper (Zurbuchen, von Steiger et al., Performing High-Quality Science on CubeSats, Space Research Today, Vol. 196, pp. 10-30, August 2016) and a study by the US National Academies (Zurbuchen, Lal, et al., Achieving Science with CubeSats: Thinking Inside the Box, The National Academies Press, Washington, DC, 2016).

The roadmap has been developed by a study team that covers a broad range of scientific disciplines, from Earth to planetary science and from solar system science to astronomy. The team is composed of scientists and engineers working in universities, public research institutions and industry.

The report is structured into three main parts: I. Our Neighborhood: current status and scientific potential of small satellites and CubeSats II. Visions for the Future: potential ideas for what small satellites could be in the future III. Challenges to Further Development and Progress, and Ways to Overcome Them: roles of agencies, industry, policies, international collaboration and exchange

In this presentation, members of the study team will give an overview of the roadmap and summarize the findings of the study team with emphasis on the parts relating to Earth observation in particular. The final report is intended to be of value to space agencies, key actors, industries, and governments involved in Small Satellites

A0.1-0009-18 AUTONOMOUS SCHEDULING REQUIREMENTS FOR AGILE CUBESAT CONSTELLATIONS IN EARTH OBSERVATION

Sreeja Nag, sreejanag@alum.mit.edu

NASA Ames Research Center, Moffet Field, California, United States Sujay Kumar, sujay.v.kumar@nasa.gov

Goddard Space Flight Center, Greenbelt, Maryland, United States

Distributed Space Missions such as formation flight and constellations, are being recognized as important Earth Observation solutions to increase measurement samples over space and time. Cubesats are increasing in size (27U, 40 kg) with increasing capabilities to host imager payloads. Given the precise attitude control systems emerging commercially, Cubesats now have the ability to slew and capture images within short notice. Prior literature has demonstrated a modular framework that combines orbital mechanics, attitude control and scheduling optimization to plan the time-varying orientation of agile Cubesats in a constellation such that they maximize the number of observed images, within the constraints of hardware specs. Schedule optimization is performed on the ground autonomously, using dynamic programming with two levels of heuristics, verified and improved upon using mixed integer linear programming. Our algorithm-in-the-loop simulation applied to Landsat's use case, captured up to 161% more Landsat images than nadir-pointing sensors with the same field of view, on a 2-satellite constellation over a 12-hour simulation.

In this paper, we will derive the requirements for the above algorithm to run onboard small satellites such that the constellation can make time-sensitive decisions to slew and capture images autonomously, without ground support. We will apply the above autonomous algorithm to a time critical use case - monitoring of precipitation and subsequent effects on floods, landslides and soil moisture, as quantified by the NASA Unified Weather Research and Forecasting Model. Since the latency between these event occurrences is quite low, they make a strong case for autonomous decisions among satellites in a constellation. The algorithm can be implemented in the Plan Execution Interchange Language - NASA's open source technology for automation, used to operate the International Space Station and LADEE's in flight software

- enabling a controller-in-the-loop demonstration. The autonomy software can then be integrated with NASA's open source Core Flight Software, ported onto a Raspberry Pi 3.0 for a software-in-the-loop demonstration. Future use cases can be time critical events such as cloud movement, storms or other disasters, and in conjunction with other platforms in a Sensor Web.

A0.1-0010-18 CUBESATS FOR ASTROPHYSICS: THE STAR-PLANET ACTIVITY RESEARCH CUBESAT (SPARCS)

Arizona State University, Tempe, California, United States Daniel Jacobs, dcjacob2@asu.edu

Arizona State University, Tempe, Arizona, United States

The observational problems in Astrophysics are fundamentally different from those in Earth Science. Interesting Astrophysics generally takes place at the limit of detectability, requiring long exposures, sensitive instruments, and very stable platforms.

Here we describe the landscape of scientifically competitive Astrophysics missions using CubeSats and compare it with the Earth Science one. We identify potential science opportunities, discuss technological bottlenecks, and identify ways to overcome the unique challenges imposed by Astrophysics. As case studies, we review the four funded Astrophysics missions, with a special emphasis on the Star-Planet Activity Research CubeSat (SPARCS).

SPARCS' mission is to study the ultraviolet (UV) environment of exoplanets around low-mass stars. Low-mass stars are the most common type of stars in the Universe and host the most exoplanets. UV radiation from the star modifies the atmospheres of exoplanets, impacts their habitability, and limits our ability to determine their composition. However, little is known about the UV behavior of the stars over time: SPARCS seeks to fill this gap.

SPARCS will be a 6U CubeSat hosting a 9 cm telescope and an ultrasensitive 2-band UV camera (160 nm and 280nm). The spacecraft will fly on a sun-synchronous 6 pm orbit and stare continuously at 12 targets over a period of one year. The telescope has been designed to minimize the impact of the expected pointing jitter (7″-10″ over 10 minutes). The camera will carry a JPL-developed delta-doped detector, which offers high efficiency (5-10x GALEX), high stability and durability (no flooding required unlike HST-WFC), and tailorable response in the entire UV spectral range. Autonomous on-board software will track the development of flares in the target stars, and produce postage stamps for downlink.

Slated to fly in late 2021, SPARCS is led by Arizona State University (ASU). ASU will perform payload integration and testing and manage the project. JPL will fabricate and test the camera. Funding for SPARCS is provided by NASA's Astrophysics Research and Analysis program, NNH16ZDA001N.

A0.1-0011-18 VISTA+ INSTRUMENT: A NEW MICRO-THERMOGRAVIMETER DEVICE FOR IN-SITU MEASUREMENTS IN PLANETARY ENVIRONMENTS AND IN-SPACE OUTGASSING MONITORING

Fabrizio Dirri, fabrizio.dirri@iaps.inaf.it INAF - IAPS Rome, Roma, Italy

E. Palomba, F. Dirri, A. Longobardo, D. Biondi, A. Boccaccini, E. Zampetti, B. Saggin, D. Saccabarozzi, A. Galiano

The proposed instrument, VISTA+, is a follow-up of the VISTA (Volatile In-Situ Thermogravimetry Analyzer) instrument [1] that was studied for Phase A of different Cosmic Vision Space missions, such as the M2 Marco Polo and the M3 MarcoPolo-R [2] and during Contamination Assessment Microbalance Project (CAM-ESA) which aimed to develop a Quartz Crystal Microbalance-device able to monitor the contamination due to materials outgassing in space environment [3]. VISTA: is a micro-thermogravimeter able to measure dust and water ice and to search for volatiles (such as hydrated and organic compound) possibly present in the collected dust. The core of the instrument is a Piezoelectric Crystal Microbalance (PCM) in which the temperature can be changed by a built-in heater and performing Thermogravimetric cycles (TGAs). An improvement of VISTA would be 1) the identification of grain size distribution, especially for the particles <20 µm that are more affected to clinging and charging and can be more dangerous in the perspective of the future human exploration and 2) the capability to perform TGA at temperatures up to 773 K (500°C), allowing the desorption of organics. Besides, knowing the grain size distribution would be also useful to detect and monitor the contaminants that are going to deposit on critical spacecraft surfaces, such as optical systems, solar panels, thermal radiators and thermal management systems [4]. Thanks to VISTA heritage, VISTA+ will include the following units: 1) Sensor Head 1 (SH1), consisting in an array of three quartz crystal microbalances, devoted to grain size measurements and water ice detection; 2) Sensor Head 2 (SH2), based on a GaPO4 crystal, devoted to TGA at high temperatures to measure water and organic amount in the dust; 3) Proximity electronic, 4) Main Electronic Unit (MEU) to acquire data, to control the temperature for TGA measurements and to supply the power to the two sensor heads; 5) User interface. The SH1 mass should not exceed 100g, whereas 40g is the expected mass of SH2. These characteristics makes it a competitive instrument for landers or rovers as well as for an orbiters/spacecrafts to detect and characterize the contaminants produced in space and their outgassing rates [5] by means of TGA.

A0.1-0012-18 CARBON NANOTUBES: APPLICATIONS IN SATELLITES

Ajay Prasad, ajay.sedsvit@gmail.com VIT University,Vellore, VELLORE, India Anto Godwin, anto@nopo.in

NoPo Nanotechnologies India Private Limited, Bengaluru, India

Space Exploration is one of the industries where the advancement of technology is at its peak, It helps us gain insights to the universe, explore new frontiers and also the technology that are developed leads to the invention of modern products and gadgets which are used in everyday life. One of the major objectives of space missions is to deliver payloads. The payloads are Satellites which is an artificial object that is placed in an orbit to do a certain job, this covers a wide range of activities including weather monitoring, natural calamities prediction, ocean surveillance, voice communication, navigation systems and others. The technology that is used in these satellites is updated with the latest in technology. Therefore, presenting a massive opportunity for consumer-focused space technology is Nanotechnology. Carbon Nanotubes are an advanced Nanotech material that is ideal for space usage. It exhibits high strength, conductivity, radiation resistance and unique properties such as ballistic electron conduction and low-voltage field emission. Carbon Nanotubes have been studied thoroughly for 25 years. Several laboratory breakthroughs and prototypes particularly for use in space have been demonstrated. This review intends to detail about the applications of SWCNTs in various components of satellites, the change in efficiency of each subsystem. The article explains how each property of nanotubes is being used in different applications. The electrical conducting property of the nanotubes is being used in antennas which increases the performance 20 times compared to those of the conventional ones, The same property is being utilized for Electromagnetic Radiation shielding. Batteries that use nanotubes as their electrode increases the energy density by 10 times as well as withstanding the extreme temperature. CNTs are used as an additive material along with a variety of materials to make space ready structures. Because of their high thermal conducting property, the nanotubes are being used as a black hole forming material which absorbs the light 99.965% which are further used to prevent stray light, the same coating is being used on solar panels to increase the light absorbing capacity. The critical element in the satellites is considered to be the thruster that propels the satellite. The nanotubes offer a great solution for their field emitting property. The current density is found to be as high as 4 A/cm^2 which also produces the electric field as low as 2 V/µm. By improving the performance of each subsystem, It increases the efficiency of the satellite as a whole.The special nanotube properties and applications have been thoroughly reviewed in this work.

A0.1-0013-18 OBSERVATIONS OF MULTI-DIRECTIONAL PARTICLE DETECTOR FROM HXMT

Chunqin Wang, wcq@nssc.ac.cn

National Space Science Center, Chinese Academy of Sciences, Beijing, China

Hard X-ray Modulation Telescope(HXMT) was Chinese first space astronomy satellite, which launched into 550km with inclination of 43 °on June 2017. The Multi-directional Particle Detector on HXMT was designed to provide measurements of energetic protons and electrons. The detector is an all solid-state system that can make 16-directional flux measurements of electrons with energy 200KeV and protons with energy 1.5MeV, and can also measure the differential energy spectra of electrons from 0.4>1.5MeV and protons from 3300MeV with 7 channels separately from single direction. The detector can characterize particles distribution for detail especially in SAA which is important for low earth orbit missions. Here, we give brief induction of the instrument and show the primary observation results from the Multi-directional Particle Detector and evaluate the effect of anisotropy on flux measurements.

A0.1-0014-18 POSTER AUTHORS TO ADVERTISE THEIR POSTER (EG 1 SLIDE AND 1 MN MAX) + DISCUSSION

Ralph Kahn, ralph.kahn@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States

This will give an opportunity for poster authors who wish to advertise their poster to present 1 slide and speak for 1 minute, max.

The only way to measure the imbalance with sufficient accuracy is to measure both the incoming solar radiations (total solar irradiance) and the outgoing terrestrial radiations (top of atmosphere outgoing longwave radiations and shortwave radiations) onboard the same satellite, and ideally, with the same instrument. The incoming solar radiations and the outgoing terrestrial radiations are of nearly equal magnitude of the order of 340.5 W/m????2. The objective is to measure these quantities over time by using differential Sun-Earth measurements (to counter calibration errors) with an accuracy better than 0.05 W/m2. It is necessary to observe during a decade and to measure the global diurnal cycle with a dozen satellites. Solar irradiance and Earth Radiation Budget (SERB) is a potential first in orbit demonstration satellite. The SERB nano-satellite aims to measure on the same platform the different components of the Earth radiation budget and the total solar irradiance. Instrumental payloads (solar radiometer and Earth radiometers) can acquire the technical maturity for the future large missions (constellation that insure global measurement cover) by flying in a CubeSat. This presentation is intended to demonstrate the ability to build a lowcost satellite with a high accuracy measurement in order to have constant flow of data from space.

A0.1-0016-18 15 YEARS OF SORCE SOLAR IRRADIANCE MEASUREMENTS AND THE NEW TSIS OBSERVATIONS

The Spectral Irradiance Monitor (SIM), the SOLar STellar Irradiance Comparison Experiment (SOLSTICE), and the XUV Photometer System (XPS) instruments on board the Solar Radiation and Climate Experiment (SORCE) mission have been taking daily Solar Spectral Irradiance (SSI) measurements since April 2003.

We present the latest data releases from these instruments, describing the improvements in the new datasets and the trends measured during Solar cycles 23 and 24. An inter-comparison of the SSI over the overlapping wavelengths for SIM and SOLSTICE is presented as well as a comparison with the results of the first few months of Total and Spectral Solar Irradiance Sensor operations.

A0.1-0017-18 THE FY-3 GNOS II INSTRUMENT CONFIGURATION AND PERFORMANCE

Qifei Du, dqf@nssc.ac.cn

National Space Science Center, Chinese Academy of Sciences, Beijing, China Yueqiang Sun, syq@nssc.ac.cn

National Space Science Center, CAS, Beijing, China Weihua Bai, bjbwh@163.com

China

Introduction Global Navigation Satellite System (GNSS) Radio Occultation measurements can remote sensing Earth's neutral atmosphere and ionosphere. Meanwhile, another GNSS remote sensing technique named GNSS Reflectometry (GNSS-R) has been developed rapidly, which can retrieve sea surface wind speed. The GNSS Occultation Sounder (GNOS) instruments were designed for FY-3 series of meteorological satellites for sounding the Earth's atmosphere and ionosphere since the 2nd batch FY-3 satellites. After the launch of the European TDS-1 satellite and the American CYGNSS constellation, to measure the sea wind field using GNSSR technique is proved to be effective. The Chinese researchers propose to integrate these two GNSS remote sensing techniques in one sounder, a new instrument named GNOS II is designed, which will be a payload for the third batch FY-3 satellite.

GNOS II Configuration The GNOS II instrument includes six antennas, four RF front-end units and one signal processing unit (SPU). One antenna used for precise orbit determination (POD) is installed on zenith side. Two front viewing and two back viewing occultation antennas are configured for occultation tracking, which are used for atmosphere sounding and ionosphere sounding respectively. Four RF front-end units are installed close to the antennas, in order to reduce the loss of the cable between antenna and RF front-end unit.

The SPU is the major unit of the GNOS II which accomplished the GNSS signal down-convertor and baseband processing. There are three function modules inside the SPU. The navigation module receives GNSS direct signals by a POD antenna, and then calculates the real-time position and velocity information of the FY-3 satellite, also outputs the carrier phase data for the precise orbit determination in post processing. Based on the GNSS and FY-3 satellites' geometry information, the occultation module predicts and tracks the ionospheric and neutral atmospheric occultation signals using ionospheric and neutral atmospheric occultation antennas, respectively. Similarly, the reflection module generates Delay Doppler Maps (DDMs) of GNSS signals scattered from the ocean surface, which is used for wind speed retrieval.

Measurement accuracy and ability The precision of code and carrier phase and real-time navigation were analyzed in the lab, using a Spirent GSS9000 GNSS signal simulator. The simulator allows for a realistic modeling of FY-3 satellite trajectory. By using the double difference method, the satellite and receiver clock errors can be eliminated, and the accuracy of the receiver observations can be determined. The results showed that the carrier phase precisions were less than 1.0 mm (C/N0=48dB•Hz) for both GPS L1 and L2. We also estimated the precision of the pseudorange, the precisions were less than 10cm for both BeiDou Navigation Satellite System (BDS) and GPS.

The first GNOS II instrument has 8 occultation channels for GPS, 8 occultation channels for BDS and 4 occultation channels for Galileo. More occultation channels and wide coverage atmosphere occultation antenna will help increase the number and quality of occultation tracking. The distribution of GPS system radio occultation events received by GNOS II in one day, rising and setting occultation number is 590 times for only GPS system by simulation, up to 1700 times taking into account BDS and Galileo system.

The GNOS can receive GPS L1, BDS B1 and Galileo E1 sea surface reflected signals simultaneously and real time onboard process them into Delay Doppler Maps for sea surface remote sensing. The reflected signals in orbit respond to ocean surface roughness, from which wind speed is retrieved. There are 8 DDMs channels in total, 4 channels for GPS L1, 3 channels for BD B1 and 1 Channel for Galileo E1. The coherent integration time and incoherent times of each DDM are 1ms and 1000. So, one DDM channel can output 1 DDM per second. DDM's Delay and Doppler pixels are 122 and 20 with the resolution of 0.25 chips and 500Hz respectively.

Summary The GNOS II instrument is a payload on the third batch of FY-3 series satellites. The GNOS II can generate Delay Doppler Maps (DDMs) of GNSS signals scattered from the ocean surface, which is an important improvement compared with the first generation GNOS. The test results show that the GNOS II instrument has excellent performance in precision of code, carrier phase and real-time navigation.

A0.1-0018-18 SPACE-BASED RADIO IMAGING ISSUES FOR SYNTHESIS ARRAY DESIGN, EVALUATION, AND OPTIMIZATION

GA Shanmugha Sundaram, ga_ssundaram@cb.amrita.edu Amrita Vishwa Vidyapeetham University, Coimbatore, India Pradeep Kumar K A, sansam77@gmail.com

Amrita Vishwa Vidyapeetham University, Coimbatore, India Rajagopalan T, t_rajagopalan@cb.amrita.edu

Amrita Vishwa Vidyapeetham University, TN, India Radio interferometry site configuration

GA Shanmugha Sundaram

Configuration study for large arrays involves several aspects pertinent to synthesis imaging, that in turn identify an optimization to the topology. These include identification of the most appropriate locations (in terms of hostile interference signals), picking an appropriate subset among them for locating a reasonable performance array, and the setting up of basic characteristics of the configuration with the establishment of terrain specific masks. The resultant array layout has the potential to create several artefactual morphologies in the synthesised radio map. Application of potent deep learning algorithms provides the much needed insight on the nature of such morphologies. Optimization of the array layout can then be pursued, considering parameters such as dynamic range, fidelity index, radio map dimensions, spatial resolution, distributed radio source location vis-a-vis the phase center of the array, and a few other operational and image reconstruction techniques, towards a reconfigured array that minimizes the occurrence of these artefacts, which shall otherwise contribute erroneous information regarding various physical phenomenon in space-based radio wavelength imaging and surveys.

A0.1-0019-18 THE GRACE FOLLOW-ON LASER RANGING INTERFEROMETER

Kirk McKenzie, kirk.mckenzie@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Robert Spero, spero@jpl.nasa.gov

JPL, Pasadena, California, United States

GRACE Follow-On will replace the Gravity Recovery and Climate Experiment (GRACE) mission, which has been measuring Earth's gravity field since 2002; with launch planned for spring 2018. Like GRACE, GRACE Follow-On will use a microwave link as its primary instrument to measure micron-level changes in the 200km separation of a pair of satellites in a following polar orbit. GRACE Follow-On will also include a 2-way laser-link, the Laser Ranging Interferometer (LRI), as a technology demonstrator package. The LRI is an NASA/German partnership and will demonstrate inter-spacecraft laser interferometry with a goal of 10 times better precision than the microwave instrument, or about 90 nm/rtHz between 10 and 100 mHz. This talk will present first results of the interferometer link.

A0.1-0020-18 NOVEL POLARIZATION IMAGING SPECTROSCOPY

Chunmin Zhang, zcm@mail.xjtu.edu.cn

Xi'an Jiao Tong University, Xi'an, Shaanxi, China Tingyu Yan, yantingyu2010@qq.com

Xi'an Jiaotong University, Xi'an, China

A novel principle and scheme of static Imaging Polarization Spectroscopy which can obtain the image, spectrum and polarization information of the target simultaneously based on Savart polariscope is presented. It can not only acquire the image of the target, but also get the spectrum and full Stokes parameters of each pixel. The experiment device of Interference Imaging Spectropolarimeter was developed and simulated spaceborne detection experiments was carried out, acquiring the long-range target image, spectrum and polarization information, realizing the static, same time, real-time acquisition of image, spectrum and polarization information. Novel Static Imaging Polarization Spectroscopy has the advantages of small size and light weight, wide field of view, high spatial and spectral resolution, high detection sensitivity, no moving parts, and the ability of acquiring image, spectrum and polarization information simultaneously. Its features go beyond any single camera (imager), spectrometer, or other devices which can obtain image and spectrum. It has important scientific significance and broad application prospects in space exploration, earth observation, aerospace, and detection of land surface, atmosphere and ocean remote sensing.

Key words: Novel Imaging Polarization Spectroscopy; Image, spectrum and polarization 4-D integration information acquisition technology; Novel principle, technology and equipment of hyperspectral remote sensing.

A0.1-0021-18 RESEARCH ON NEW HYPERSPECTRAL IMAGING TECHNIQUES FOR DEEP SPACE SCIENCE DETECTION

Linghua Guo, guolinghua@hotmail.com

China Academy of Space Technology, Beijing, China Jingping Zhu, zhujingping(at)mail.xjtu.edu.cn China

The depth and breadth of space science research depends on the breakthrough and support of a series of key technologies. Space probes can boldly go where no human has gone before, and obtain the space target information, such as the shape, size, surface form, mineral content, element and so on. The new scientific payload technology is one of the key technologies of space probes to obtain the above information. Based on the analysis of the characteristics of hyperspectral imager, this paper proposes a new system concept of hyperspectral imaging technology, with a large field of view of ±10º, high spectrum of 5nm-10nm, and spatial resolution which is better than 30m@500km. If needed, the field of view could increase to ±20º. Such new hyperspectral imaging techniques will be used to lay the technical foundation of deep space science detection.

DLR - German Aerospace Center, Wessling, Germany

The upcoming Environmental Mapping and Analysis Program (EnMAP) - German imaging spectroscopy mission - is a joint response of German Earth observation research institutions, value-added resellers and space industry to the increasing demand for accurate, quantitative information about the status and evolution of terrestrial ecosystems. EnMAP is currently in the construction phase with a launch planned in 2020. The project management is led by the Space Agency of DLR. The space segment consisting of instrument and bus will be established by OHB System AG.

The EnMAP satellite will be operated on a sun-synchronous orbit at 643 km altitude with a local time of descending node 11:00 to observe any location on the globe under defined illumination conditions featuring a global revisit capability of 21 days under a quasi-nadir observation. The satellite has an across-track tilt capability of ± 30° enabling a revisit time of four days. The hyperspectral instrument will be realized as a pushbroom imaging spectrometer. Its data acquisition over the broad spectral range from 420 nm to 2450 nm will be performed by a CMOS (Complementary Metal Oxide Semiconductor) detector array for VNIR (visible and near infrared) with 95 spectral channels, i.e. 6.5 nm spectral resolution, and by a MCT (Mercury Cadmium Telluride) detector array for SWIR (shortwave infrared) with 135 spectral channels, i.e. 10 nm spectral resolution. The ground pixel size is 30 m × 30 m at nadir at 48° northern latitude. In this context a pointing accuracy of better than 500 m is expected. The pointing knowledge and therefore the accuracy of image products will be better than 100 m and can be improved by ground processing, if a reference image is available, to approximately 30 m (i.e. 1 pixel) w.r.t. the used reference image. The sensors' 1000 pixels in spatial direction result in a swath width of 30 km. Regular on-board calibration measurements are performed to update the calibration tables for the processors.

EnMAP level 0 (L0) image products (raw data) will be long-term archived while L1B products (systematically and radiometrically corrected data), L1C products (geometrically corrected data) and L2A products (atmospherically corrected data) will be processed on demand. The L1B processor corrects the hyperspectral image cube for systematic effects of the focal plane detector array, e.g. radiometric non-uniformities, and converts the system corrected data to physical at-sensor radiance values based on the currently valid calibration tables. The L1C processor creates ortho-images based on direct geo-referencing techniques implementing a lineof-sight model, which uses on-board measurements for orbit and attitude determinations as well as the sensor look direction vectors based on the currently valid calibration values. Furthermore, it is foreseen to automatically extract ground control points from existing reference data sets by image matching techniques to improve the geometric accuracy better than one pixel size. The L2A processor performs atmospheric correction and haze detection of the images by estimating the aerosol optical thickness and the columnar water vapor. Output products will be the ground reflectance cube and masks of land, water, cloud, cloud shadow, haze, cirrus and snow.

A0.1-0023-18 RESEARCH ON TRACKING METHOD OF SPACE-BASED INFRARED SYSTEM FOR THE HIGT DYNAMICS TARGET IN ATMOSPHERE

Hao Guo, guohao_calt@163.com

Science and Technology on Space Physics Laboratory, Beijing, China Bo Tian, tianb_0131@163.com

Zhang Yechen, yexuan1008@qq.com

China Academy of Launch Vehicle Technology, Beijing, China

The characteristics of high speed and ultra maneuver for high dynamics target vehicles in atmosphere have brought great difficulties for maneuvering target localization and tracking. Traditional filtering algorithms obviously cannot give accurate target state estimation and the tracking performance has declined. In this paper, a tracking method to the high dynamic target in atmosphere is derived for spaced-based infrared system. By analyzing the radiation principle of a high dynamic target in atmosphere, the line of ray (LOR) algorithm for the infrared characteristics of the target affected by high temperature gas is given. And then its infrared intensity is calculated via the LOR algorithm. The coverage of space-based infrared system to the typical high dynamic and high altitude target in atmosphere is obtained by the formulas of the signal to clutter ratio (SCR) and detection range. Considering about large-scale maneuverability of high dynamics target in atmosphere, the algorithm of combining interacting multiple model (IMM) and multi-satellites passive location method are built for tracking for the target, the purpose of high precision tracking for high dynamic target in atmosphere is achieved. And then a novel single-satellite tracking algorithm is further proposed based on the multi-satellites passive location algorithm above. The superior accuracy on tracking for the high dynamic target in atmosphere of these two tracking algorithms are verified by simulation results, hence both multi-satellites and single-satellite passive location can obtain high precision target tracking data.

A0.1-0024-18 THE COHERENCE CHARACTERISTIC ANALYSIS FOR HIGH-RESOLUTION TERRASAR-X DATA - MAN-MADE OBJECTS AND NATURAL OBJECTS

Takashi Nonaka, nonaka.takashi@nihon-u.ac.jp Nihon University, Narashino, Chiba, Japan Tomohito Asaka, asaka.tomohito@nihon-u.ac.jp Nihon University, Narashino, Chiba, Japan Keishi Iwashita, iwashita.keishi@nihon-u.ac.jp Nihon University, Narashino, Chiba, Japan

We can gather different kinds of information due to the specific wavelength of SAR. The TerraSAR-X series (TerraSAR-X and TanDEM-X) are one of the high specification commercial X-band SAR satellites, and play significant roles especially for acquiring high spatial-resolution images of 1 m up to 25 cm at the highest. One of the promising application fields of SAR data is disaster monitoring, and many researchers have studied the estimation of the damaged area caused by the earthquake, flood, landslide eruption of the volcano, etc., by utilizing the change detection methodology. However, the difficulty of the method for most of the studies has several factors (land cover, acquisition times, orientation of the building, water vapor) except the damage related issue affect the image quality and the value of the threshold and the detection accuracy vary depending on the situation. One of the reasons is the insufficient understanding of the feature of the sensors, and the applicability for the methodology. The purpose of this study was to acquire the knowledge of the coherence value for TerraSAR-X due to the baseline, acquisition duration, and land cover. The study site was the central of Tsukuba in Ibaraki Prefecture. Tsukuba station built in 2005 was the center of the images. First, we classified the land cover into man-made objects and natural objects using the reference “High-Resolution Land Use and Land Cover map” produced by AVNIR-2 on ALOS satellite operated from 2006 to 2011. It is noted that the classification errors is occurred due to the errors of the products and the difference of the times of the acquisition. Both StripMap mode and High-resolution SpotLight mode data were acquired in 2008, and the orbit direction of these data was also different. We conducted the interferometric analysis and acquired the coherence maps of the 25 pairs of dataset. Finally, we evaluated the coherence value of man-made objects and natural objects for each pair of image. The result showed that the coherence value of man-made objects was higher from 0.12 to 0.26 than natural objects for all pairs (the deviation of the coherence in the same pair was about 0.15, and it did not depend on the land cover). The difference was neither related to the baseline nor the acquisition duration, however the difference of the coherence was highly related to the coherence value themselves (man-made, natural objects). This study showed that the coherence of the natural objects showed highly negative correlation with acquisition duration. On the contrary, that of the man-made objects was not related to the acquisition duration comparing with natural objects. However, as a result of the multiple regression analysis, the value was expressed using both baseline and acquisition duration. We also revealed that this tendency was not affected by the acquisition mode and orbit direction.

A0.1-0025-18 INTER-ANNUAL VARIABILITY OF THE MONSOON INVERSION OVER THE ARABIAN SEA AS INFERRED FROM SATELLITE MEASUREMENTS AND WRFARW MODEL SIMULATIONS

Sanjeev Dwivedi, sanjeev.esa@gmail.com

King Abdullah University of Science and Technology, Saudi Arabia, Thuwal, Saudi Arabia

A high resolution dynamical downscaling data for 38 years starting from 1980 to 2017 is used in this present study to identify the variability of the Monsoon Inversions (MI) that forms over Arabian Sea (AS) before the onset of Asian Summer Monsoon (ASM) season and persists through-out the ASM. As the MIs are mainly formed due to cross-equatorial winds and we have analysed the parameters that controls the formation and seasonal persistence of the MI. Weather Research and Forecast (WRF) model is used to generate long-term high-resolution data by adopting continues re-initialization method. This high-resolution data enables us to explore the long-term trends and intermittent atmospheric phenomena over the Arabian Sea for the extended period containing the entire solar cycle, many cycles of ENSO and Quasi - periodic phenomena. Along with the WRF data, we have also used the radiosonde data for five stations to explain the MI characteristics and frequency of occurrence. Further we have also used 10 years of MetOp onboard IASI sounder observations to study the MI characteristics.

The statistical analysis between WRF and observations at the coastal stations indicates a drift in temperature, humidity and winds in the altitude region of 1 - 2 km, which is the height of MI's. The statistical significance of MI analysis from WRF data is at 95 % confidence level as per Mann-Kendall and Sen's slope estimator over the study area. A long-term trend analysis is also carried out to identify the effect of winds and inter-annual variability of MI. The MI has been forming during the monsoon season over Salalah at an average altitude of 0.5 - 2 km. The core of the low-level jet (LLJ) is at the height of around 1.5 km. The climatological WAS winds at 950 and 850 hPa shows a decreasing trend in the winds, MI strength, frequency of occurrence and also the height of the MI. The trends computed from the spatial data clearly revealed that the negative trends over the central (high), western and eastern Arabian Sea (moderate values). The decreasing wind speed across the Arabian Sea is responsible for the decrease of the MI intensity, height and the frequency of occurrences. The variability of the MI for two epochs of 1980 - 1998 and 1998 - 2017 indicates that in the first epoch trend is constant and in the later epoch it is significantly decreasing.

A0.1-0027-18 PERFORMANCE EVALUATION OF A REGIONAL NWP MODEL COSMO DURING THE PASSAGE OF A VERY SEVERE CYCLONIC STORM

Space Physics Laboratory, VSSC, ISRO, Trivandrum, THIRUVANANTHAPURAM, India

In the first week of December 2017, a Very Severe Cyclonic Storm, namely - "OCKHI" made its landfall near the coast of south Gujarat and adjoining Maharashtra of the Indian sub-conenent. During its entire course of movement, this cyclonic storm caused severe damage to the structure and affected human lives as well in the Indian coastal regions. Here, we present a case study on the performance evaluation of a regional numerical weather prediction (NWP) model, COSMO (Conosrtium for Small-scale Modelling) during the passage of OCKHI cyclonic storm over the Arabian Sea. The COSMO model simulations are evaluated with a special emphasis on the predictability of three distinct aspects, namely: (i) lead-time required for prediction of such severe cyclonic storm; (ii) intensity of the cyclonic storm; and (iii) locations of the landfall. Results obtained from this case study indicate that the model is able to capture such severe weather events almost 18 hours ahead of its occurrence. The intensity of cyclonic storm and its track simulated by the model are compared with the observations. An attempt is also done to improve the leadtime in predictability of such severe weather events by introducing a new scheme of initialization in the COSMO model by providing a 24 hrs spin-up from the global model analyses fields.

A0.1-0029-18 INDUS RIVER MONITORING USING SATELLITE ALTIMETRY

The optimal management of water resources, or any other resource, requires, as a prerequisite, the availability of data. To bring into sustainable equilibrium the supply and demand for water, it is necessary, therefore, to have access to accurate and near real time data quantifying the supply and the consequent demand. The quantification of the supply of water in the Indus river basin has been a serious challenge for Pakistan to overcome. This has manifested itself as a grave problem in various sectors. First and foremost is the issue of efficient allocation of water to its users, mainly agriculture which utilizes almost 97% of the water. In addition, relations among the riparian provinces, principally Punjab and Sindh, and also among the riparian states in the Indus river basin have been adversely affected. Furthermore, given that there exists extreme variability in the flows of the Indus River, mainly due to majority of its water coming from the himalayan glaciers, the creation of a river management plan necessitates the availability of accurate and precise water level data. Therefore, combatting this critical issue requisites efficient monitoring of the available water level, and hence the total surface water supply. Targeting the supply side of this challenge,therefore, this research aims to explore the feasibility and the potential of Satellite Radar Altimetry (SAR) in monitoring the water level of the Indus river basin.

Magnetometry has a lot of tradition in space and planetary science. Among the first launched satellites altogether in history, Sputnik 3 and Pioneer 1 and 2 ferried magnetometers into orbit in 1958, as did most scientific exploration missions following them. The telltale magnetometer boom is one of the prominent recognizable features of an exploration spacecraft, nowadays carrying the spaceflight state-of-the-art fluxgate and vector helium√ magnetometers. These well-tried systems have excellent sensitivities in the range of 100 pT / Hz, but are intrinsically complex, requiring non-miniaturizable parts and electronics (fluxgate), or cryogenics and lasers (optically pumped atomic gas). We propose a new approach for a self-calibrating solid-state vector magnetometer, relying on spin-carrying quantum centers in silicon carbide semiconductor devices. We show a proof-of-concept miniature magnetom√eter using an off-the-shelf silicon carbide device, reaching a sensitivity on the order of 100 nT / Hz. We also discuss the potential increase of sensitivity by defect-engineering in both commercially available and homegrown devices. Additionally, we consider the notion of increasing sensitivity while reducing weight and volume footprint by placing multiple magnetometers on the spacecraft; to offset and negate the influence of the spacecraft's own field in relation of the desired background field.

JIANG Li, WU Tong, MEN Li-zhou, YIN Qing, LIU Ke

The requirement for ever-increasing-resolution space cameras drives focal length and diameter of optical lenses be increasing. High-frequency vibration in the process of launching and complex environmental conditions of the outer space generate micro deformation in components of space cameras. As a result, images from the space cameras are blurred. Therefore, it is necessary to measure the micro deformations in components of space cameras in various experiment conditions. This paper presents a high-accuracy micro deformation measurement method. The method is implemented as follows: (1) fix Invar balls onto a space camera being measured and measure the coordinate for each ball under the standard condition; (2) simulate high-frequency vibrations and environmental conditions like the outer space to measure coordinates for each ball under each combination of test conditions; and (3) compute the deviation of a coordinate of a ball under a test condition combination from the coordinate of the ball under the standard condition and the deviation is the micro deformation of the space camera component associated with the ball. This method was applied to micro deformation measurement for space cameras of different models. Measurement data for these space cameras validated the proposed method.

A0.1-0032-18 ADVANCED RETARDING POTENTIAL ANALYSER FOR MARTIAN IONOSPHERIC STUDIES

Ambili Kailasam Madathil, ambilisadasivan@gmail.com

Indian Institute of Space Science & Technology, TRIVANDRUM, India Anjusha Mathew, anjusha118@gmail.com

Indian Iinstitute of Space Science and Technology, Thiruvananthapuram, India

ARIS (Advanced Retarding potential analyser for martial Ionospheric Studies), an ionospheric plasma and electrostatic instrument used for the structural and compositional studies of Martial Ionosphere, is a payload in the upcoming MOM (Mars Orbital Mission)-2 of ISRO. ARIS uses a Dual-Retarding Potential Analyser (RPA) configuration which consist of two RPAs in its architecture, Ion mode-RPA(I-RPA) and Electron mode-RPA(E-RPA). RPA is a plasma diagnostic tool that measures ion/electron energy distribution, which consists of a collector shielded from the plasma by a series of biased grids. It acts as a high pass filter which allows particles with energy to charge ratios greater than the retarding potential to pass and reach the collector. The instrument is designed in such a way that it is capable of handling ion/electron concentration of 10 - 106 cm−3, ion/electron temperature 100 -25000 K, ion drift velocity of 0.01 - 2.0 km/s, solar wind electron temperature of 25000 - 5x105 K and solar wind electron concentration of 0.5 - 100 cm−3. A five-ion retarding grid configuration is used for obtaining a high energy resolution of 1 amu and to minimize retarding potential homogeneities. Other grids are used for reducing aperture fringe fields and eliminating focusing and defocusing effects. The I-V (Particle Current-Retarding voltage) curve that results from measuring current as a function of the retarding potential is related to the flux distribution of the incoming particles and can be used to infer the particle density, particle temperature, ion composition and the component of the velocity vector in the direction of motion normal to the instrument aperture plane.

A0.1-0033-18 ATTITUDE ESTIMATION OF SMALL SATELLITES IN CONSIDERATION OF GEOMAGNETIC FIELD ANOMALIES

Demet Cilden-Guler, dmtcldn@gmail.com Istanbul Technical University, Istanbul, Turkey Zerefsan Kaymaz, zerefsan@itu.edu.tr

Istanbul Technical University, Istanbul, Turkey Chingiz Hajiyev, cingiz@itu.edu.tr

Istanbul Technical University, Istanbul, Turkey

Low Earth orbiting small satellites commonly use magnetometers as an attitude determination instrument. The difference in the components of the magnetic field vectors or the angle between them (model and measurement data) affects the estimation accuracy of the satellite's attitude. For attitude determination system, IGRF model is used in most of the cases but the difference between the sensor and model increases when the geomagnetic activity occurs. On the other hand, geomagnetic field anomalies are treated like noises on the magnetometer measurements and estimated using one of the stochastic processes. However, the differences are not supposedly caused by the magnetometer noises but might be caused by the external magnetic field especially in magnetically disturbed days which is sensed by the magnetometer but not by an internal magnetic field model.

In this study, geomagnetic field model, T89 including the external variations in the Earth's geomagnetic field resulting from the solar wind and interplanetary magnetic field aside from the internal field is also considered. Those two models can be evaluated to see a noticeable difference on extraterrestrial field effects on satellite's attitude determination system changing with its height. The comparisons are made between the models and observations and between the models under various magnetospheric activities. Extended Kalman filter is implemented in order to estimate the satellite's attitude using different sensor configurations including one or more of the sensors, a combination of the magnetometer, sun sensor, and gyroscope for the nanosatellite's attitude determination system with IGRF and T89 on magnetically quiet and active times. It is concluded that magnetic field anomaly affects the satellite's attitude more or less depending on both the sensor configuration and the magnetic activity times.

A0.1-0034-18 PFL: A MODERN APPROACH TO SMALLSAT FLIGHT SOFTWARE

Steven Morad, smorad@email.arizona.edu

University of Arizona, Tucson, Arizona, United States

SmallSat flight software is usually proprietary, mission specific, and difficult to write for those unfamiliar with computing concepts. Projects like NASA's Core Flight Software and Kubos are headed in the right direction, but the methodology for flight software is still stuck in the 1970s. As processor power increases and component and launch costs decrease, scientist and engineer time becomes the most important resource. PFL's purpose is to drastically decrease development time and staff requirements for SmallSats by providing support for high-level languages, greatly increasing readability, and providing methods for code reuse between different missions and different bus configurations. We present an open-source, cross-platform, crosslanguage flight software platform named Python Flight Layer (PFL). Based on a microkernel architecture, PFL consists of subsystem servers that can be written in any language with socket support. By providing readable and accessible infrastructure, we enable those without flight software skills to easily and quickly write reliable code.

A0.1-0035-18 LIFE TESTING AND PERFORMANCE EVALUATIONOF 1.0 N THRUSTER FOR SATELLITE APPLICATIONS BASED ON GREEN PROPELLANT

Nadeem Ul Haq, nadeemulhaq.liu@gmail.com

Space and Upper Atmosphere Research Commission (SUPARCO), Karachi, Pakistan

Satellite propulsion and instrumentation is designed to provide capability to perform certain operations such as attitude control, orbit transfer, orbit maneuver and deorbiting at the end of life. Use of green propellants such as hydrogen peroxide (H2O2) in satellite propulsion is not new. Hydrogen peroxide was first used in the reaction control systems of US X-1 and X-15 space planes, also in SYNCOM series and early bird satellites. A significant amount of work was carried out in the 1960s at NASA laboratories on hydrogen peroxide decomposition and its applications but this effort was subsequently abandoned due to availability of effective hydrazine catalysts. Recently, hydrazine has been banned by European Union because of its toxic and carcinogenic nature. It is neither easy to handle nor its preservation is simple. In February 2008, US government showed its concerns over US navy launch of spy satellite towards its own satellite which could release hydrazine vapors at breathing level. Therefore, efforts are being carried out to search an alternate who could meet the propulsive performance of hydrazine along with environment friendly nature. One such alternative is highly concentrated hydrogen peroxide (high test peroxide, HTP), often referred as a 'Green' or low toxic propellant. H2O2 is an economically viable and simple solution to health and safety problems. The purpose of this research is to design an environment friendly, green propellant based thruster, which could work over a longer period of time without deterioration so that the thrusters could be mounted in future satellite as a reaction control system. To decompose HTP into high temperature and environment friendly product gases (i.e. oxygen and steam), a silver catalyst bed is developed as per experimental results already available. The testing has been conducted using highly pure 88% -90% HTP in conformance with the American MIL-P-16005E standards. The work presented in this paper is not only about brief discussion of design methodology to develop HTP based thruster but also focuses, in details, on performance and life testing of thruster for over 9000s in steady state mode. Extensive testing of the thruster has been performed and the performance and life of the thruster is evaluated. The results obtained i.e. the chamber pressure in particular, are presented and the thruster chamber roughness and chamber pressure degradation over time have been studied. Thruster has also been tested on thrust measurement bench and results are shown. Through this work, successful life testing of the thruster has been performed and the research work established and proved H2O2 a potential candidate to constitute green propellant thruster configuration along with other instruementation for use in reaction control system of future satellites.

A0.1-0036-18 A MULTI-PROPELLANT RADIO FREQUENCY PLASMA THRUSTER

Igor Matveev, ibmatveev@gmail.com

Applied Plasma Technologies, Corp., McLean, Virginia, United States Svetlana Matveyeva, ibmatveev@gmail.com

Virginia, United States

Applied Plasma Technologies, Corp. (APT) and International Plasma Technology Center, Corp. (IPTC), both US corporations, offer for discussion the results of preliminary modeling and tests of a Multi-Propellant 25 kW radio-frequency (RF) plasma thruster for deep space exploration. A list of plasma gases or propellants includes Ar, water steam, CO2, and could be extended by other gases and their blends. APT and IPTC have a line of commercial high power and high pressure RF plasma systems for a wide range of applications. Operation pressure - from 1 bar to 10 bar. A Multi-Propellant Thruster Concept is a result of significant progress in the RF plasma development and could be considered as a platform for other space needs, as space waste processing, CO2 decomposition, minerals processing, etc.

A0.1-0037-18 SPACE STUDIES OF THE EARTH'S SURFACE, METEOROLOGY AND CLIMATE

Zelalem Wudu, zolomlkt@gmail.com

ETIOPIAN SPACE SCIENCE AND TECHNOLOGY INSTITUTE, Addis Ababa, Ethiopia 1/15/ 2018 zolomlkt@gmail.com +251-918-312-314 ADDIS ABABA, ETHIOPIA ZELALEM WUDU TO: COSPAR ZARM

Dear Sir/Madam Recently I completed the requirements for the Bachelor of degree in Mechanical Engineering at Bahir-Dar Institute of Technology and working on Entoto Observatory and Research Center as a junior researcher. I am exploring potential opportunities with a well established firm that will lead me to become a great researcher on this field of study. I would like to participate in this program to develop my knowledge for further study and research work. I have an excellent communication skill and a strong background in Mechanical Engineering. I have good analytical, practical and sound knowledge in all major subject of my discipline. My personal characteristics such as poise, confidence, dependability patience, creativity etc are highly admirable. I am motivated to learn and perform best capacities. I spent most of my time in studying and trying to learn new techniques in the area of study. I have several strengths but my main strength is the motivation of further studying and research area. I work well with my colleagues and administration during my final year thesis project and I learn many things from them. Thank you for your consideration and the opportunity.

With Best Regards Yours Sincerely, ZELALEM WUDU

A0.1-0038-18 MICROCHANNEL THERMALIZATION INLET TO ELIMINATE MOLECULAR FRAGMENTATION IN ORBITAL CLOSED-SOURCE MASS SPECTROMETERS

Abraham De La Cruz, lehi.abraham18@gmail.com Brigham Young University, Provo, Utah, United States Daniel Austin, austin@chem.byu.edu

Brigham Young University, Provo, Utah, United States

Mass spectrometers for flybys and orbiters have been used to analyze neutrals which are sampled as they enter the instrument inlet at relatively high velocity. Two types of inlet designs used in the past are "open source" and "closed source". However, these inlet designs present some limitations. Open source inlets are not as sensitive as closed sources. On the other hand, molecular species can be altered in closed source inlets due to the high kinetic energy of impact. Sampled molecules are vibrationally excited upon impact, and subsequently can fragment. These fragments are, of themselves, not stable compounds and will only make it to the ionizer of the mass spectrometer after they combine with some other fragments. Radical-radical recombination on the surface of the closed source walls is a likely mechanism. Thus the altered original composition of the samples leads to incorrect interpretation of measurements. Calculations show that dissociation lifetimes after impact, for compounds and velocities relevant to some mission scenarios, occur at the order of microseconds-shorter than the time needed for thermalization due to multiple impacts inside the source. We are developing a source that overcomes the above problem by thermalizing or cooling the sampled molecules much more quickly than in a conventional source. Molecules are cooled faster than their dissociation lifetime. These quenched molecules remain intact during the sampling process and during introduction to the mass spectrometer. This source employs a microchannel array. Channels with diameter of tens of microns reduce the time between thermalizing impacts from tens of microseconds to tens of nanoseconds. Initial efforts focus on stainless steel channels, but in theory other materials will also work, such as ceramic. The channels allow ram pressure enhancement and the accompanying increase in sensitivity of an open source, without the fragmentation present in a closed source. This source would be beneficial to any flyby or orbiter mass spectrometer, including such instruments sampling plumes on ocean satellites in the outer solar system.

A0.2-0001-18 INTRODUCTION TO SCIENTIFIC EVENT A0.2

David Halpern, david.halpern@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Barbara Ryan, bryan@geosec.org GEO Secretariat, Geneva, Switzerland

COSPAR became a Group on Earth Observations (GEO) Participating Organization in 2007 and, since then, has focused its contributions towards advancement of understanding of the global integrated Earth system. GEO is building a Global Earth Observation System of Systems (GEOSS). In 2016, COSPAR prepared a 2016-2025 Roadmap on observations and modeling for global integrated Earth system science (Advances in Space Research, 57, 2037-2103) to contribute to the GEO 2016-2025 Strategic Plan for building GEOSS. GEO accomplishes its work through a variety of mechanisms that span thematic, as well as geographic domains. We shall hear about scientific and technological foundations of several of these efforts. The intent of this scientific event is to encourage broader participation of COSPAR Associates in GEO's global efforts to build a truly integrated global observing system.

A0.2-0002-18 GEOGLAM: EARTH OBSERVATION IN SUPPORT OF TIMELY, ACCURATE, AND ACTIONABLE DECISIONS FOR FOOD SECURITY & AGRICULTURE

Alyssa Whitcraft, akwhitcraft@geoglam.org

Group on Earth Observations Global Agricultural Monitoring Secretariat, Superior, Colorado, United States

Inbal Becker-Reshef, ireshef@geoglam.org

Group on Earth Observations Global Agricultural Monitoring Secretariat, College Park, Colorado, United States

Chris Justice, justice(at)hermes.geog.umd.edu

University of Maryland, College Park, College Park, United States

Agricultural markets have become increasingly volatile, threatening food security and human livelihoods. Access to timely, accurate, transparent, and actionable information about crop condition and production can help stabilize markets and provide early warnings of crop failure, thereby promoting food security. In 2011, the Group of Twenty (G20) Agricultural Ministers developed the G20 Action Plan on Food Price Volatility and Agriculture that includes the launching of the Agricultural Market Information System (AMIS; www.amis-outlook.org), and the Group on Earth Observations Global Agricultural Monitoring initiative (GEOGLAM; www.geoglam.org), the latter utilizing Earth observations (EO) for improved information about crop condition and production. In June 2016, the G20 reaf-firmed its support of GEOGLAM.

GEOGLAM's primary objective is to reinforce the international community's capacity to produce and disseminate timely, accurate, and actionable information on and forecasts of agricultural production at national, regional, and global scales through the use of satellite and in-situ Earth observations. Through the coordination of satellite, in-situ, and agrometeorological observations, and through the transparent sharing of methods and information, GEOGLAM aims to strengthen national, regional, and global monitoring systems and improve access to timely, accurate, and actionable information.

This presentation will highlight GEOGLAM's successful application of satellite data to empower science-based decision making in main producer countries as well as in countries at risk of food insecurity.

A0.2-0003-18 MONITORING EARTH'S CHANGING MOUNTAINS WITH THE GROUP ON EARTH OBSERVATIONS INITIATIVE-GLOBAL NETWORK FOR OBSERVATIONS AND INFORMATION IN MOUNTAIN ENVIRONMENTS (GEO-GNOME)

Anne Nolin, anne.nolin@gmail.com

University of Nevada-Reno, Reno, Nevada, United States Carolina Adler, carolina.adler@giub.unibe.ch

University of Bern, Bern, Switzerland Elisa Palazzi, e.palazzi@isac.cnr.it CNR-ISAC, Bologna, Italy

Earth's mountains are cover more than 20% of the global land surface and occur on all continents, in all latitude zones. Compared with other regions, mountain contribute a disproptionate amount of ecosystem services such as clean and abundant water, timber, hydropower; they also are the source of severe hazards such as floods, debris flows, and volcanic eruptions. Mountains are considered "sentinels of climate change" because of elevation dependent warming and disappearing ice but data from mountain observations are sparse and not necessarily spatially representative. The Group on Earth Observations Initiative - Global Network for Observations and Information in Mountain Environments (GEO-GNOME) is an international effort that aims to address the paucity of observations and information on mountains. GEOGNOME partners include the countries of Austria, Belgium, Brazil, Canada, China, Colombia, Denmark, EC, Ethiopia, France, Italy, Japan, Kazakhstan, Mexico, New Zealand, Pakistan, Russian Federation, Slovakia, South Africa, Switzerland, Uganda, UK, and USA. The goal of GEO-GNOME is to compile and provide data, both related to historical conditions and to future projections that support examination of the drivers, conditions and trends at a variety of different scales, from that of a single mountain range to that of the planet as a whole. Remote sensing plays a key role in GEO-GNOME mountain observations. Importantly, remote sensing experts are mapping and characterizing changes in snow and glaciers, vegetation, and land surface temperature in mountain regions. However, there remains a critical need to calibrate and validate these satellite observations with airborne and ground-based data. Such validated data need to be transformed into readily accessible information for developing informed policies and decision-making affecting mountain regions.

A0.2-0004-18 GEO-C: THE GEO CARBON AND GREENHOUSE GAS INITIATIVE

Antonio Bombelli, antonio.bombelli@cmcc.it

CMCC Foundation – Euro-Mediterranean Center on Climate Change, Viterbo, Italy GEO-C Team

Canadell J., Crisp D., DeCola P., Dolman A.J., Heiskanen J., Noda A., Obregón A., Saigusa N., Venkataraman S., and the entire GEO-C Team

Despite the recent progress, the budgets of carbon and greenhouse gases (GHGs) are still not closed and their spatial resolution and uncertainties undermine their use for decision making. Significant improvements are required in long-term for both in situ and space-based observing systems within and across the atmospheric, oceanic, terrestrial and human domains, as well as for the analytical and modelling tools, to reliably quantify GHG sources and sinks, to support the development of climate policies, and project future climate change. A coordinated global carbon and GHG observing system can provide valuable data and services in support to the Paris Agreement and other emission reduction policies, by assessing the needed emission reduction targets, contributing to the global stocktake and monitoring the effectiveness of the adopted climate change mitigation measures. The importance of satellite-borne sensors for GHG gas concentration measurements and their use for estimating carbon stocks and fluxes has been increasingly recognized. Satellites provide a synoptic view of the global carbon cycle and help to fill gaps between sparse in situ observations. Satellites, together with a robust in situ observing system and model analyses capabilities, can play an important role under the transparency framework and global stocktake of the Paris Agreement, for example by providing support to nations interested in tracking and managing their progress toward their Nationally Determined Contributions (NDCs). Currently, four GHG monitoring satellites are in operation (GOSAT, OCO-2, TanSat, Feng Yun 3D and Sentinel-5P) and other relevant missions are under development or in planning stages (GOSAT-2, OCO-3, MERLIN, MicroCarb, Sentinel-5, GeoCarb, Gaofen-5, and others). It is expected that this set of space-borne sensors will provide observations at significantly improved temporal and spatial resolutions all over the globe, particularly useful in estimating emissions from “hot spots”, advancing the scientific understanding of carbon and GHG cycles and their impacts to climate change, and supporting policy decisions. GEO-C acts as a common and open forum that promotes the inclusion of existing monitoring efforts, such as the WMO/UNEP Integrated Global Greenhouse Gas Information System (IG3IS) and others, into a coherent framework to plan and implement joint strategies and activities at the global level from science to policy. Special attention is dedicated to the domain interfaces, the complementarity and integration between ground and space-based observations, and the development of the analytical and modelling capacities. The intention is to obtain a comprehensive, coherent, globally coordinated, carbon and GHG observation and analysis system.

A0.2-0005-18 SUMMARY OF THE A0.2 SCIENTIFIC EVENT

Jean-Louis Fellous, jean-louis.fellous@cosparhq.cnes.fr COSPAR Secretariat, Paris, France

The A0.2 scientific event will gather GEO science leaders who will describe current developments and future activities and promote opportunities for COSPAR Associates to participate in GEO projects. This summary talk will review and highlight the main findings of the session. It will draw some concluding remarks from the expected enlightening discussion that will have taken place after the presentations on GEOGLAM, GEO Carbon and GEO-GNOME.

SPACE STUDIES OF THE EARTH'S SURFACE, METEOROLOGY AND CLIMATE (A)

IMPROVING THE UNDERSTANDING OF THE CARBON CYCLE WITH SATELLITE OBSERVATIONS AND MODELING (A0.3)

A0.3-0001-18 MEASURING GREENHOUSE GASES FROM SPACE: PROGRESS TOWARD AN OPERATIONAL CONSTELLATION

David Crisp, david.crisp@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Space based observations are providing new tools for measuring the sources emitting carbon dioxide (CO2), methane (CH4) and other greenhouse gases into the atmosphere, and the natural sinks that absorb these gases. These measurements are particularly challenging because both high precision and accuracy are essential to capture the small (< 0.25%) concentration changes associated with their surface sources and natural sinks. High resolution spectroscopic measurements of reflected sunlight at shortwave infrared wavelengths are well suited for this application because they can be analyzed to yield surface-weighted estimates of the columnaveraged dry air mole fractions of CO2 and CH4 (XCO2 and XCH4). Recent efforts to analyze the data collected by the pioneering EnviSat SCIAMACHY, GOSAT TANSO-FTS, and OCO-2 instruments have begun to demonstrate the precision needed to resolve anthropogenic as well as natural fluxes of CO2 and on scales ranging from individual power plants, to cities, to regional scales. Comparisons of space-based XCO2 and XCH4 estimates with ground-based standards such as the Total Carbon Column Observing Network (TCCON) are showing continuing improvements, with accuracies approaching 0.25% over most of the globe. In spite of this progress, space-based GHG sensors do not yet provide the spatial or temporal resolution and coverage needed to provide timely, quantified guidance on progress towards emission reduction targets at national scales. Three factors are limiting their performance: (i) Existing spatial sampling strategies acquire measurements at low spatial resolution (SCIAMACHY), at discrete points separated by large distances (GOSAT) or along narrow ground tracks, separated by large distances (OCO-2). (ii) Optically thick clouds and aerosols preclude full-column measurements of XCO2 and XCH4 for more than 90% of soundings collected by these systems. (iii) Passive remote sensing systems that retrieve XCO2 and XCH4 from reflected sunlight can only return data over this sunlit hemisphere, precluding observations of the variations in these species over the diurnal and seasonal cycle. To address the first of these shortcomings, future sensors in low Earth orbit could acquire measurements over a broad (> 200 k) swath, producing twodimensional (2-d) "images" of XCO2 and XCH4. The spatial sampling and revisit times will be reduced further in the early 2020's when the NASA GeoCarb mission begins returning 2-d images of XCO2, XCH4 and XCO over North and South America from Geostationary orbit. To improve the coverage of the night side and high latitudes in the winter hemisphere, active sensors (lidars), such as the CNES/DLR MERLIN mission are needed. The resolution, coverage and repeat frequency could be improved further if all available missions can be integrated into an ad-hoc constellation, and their data can be cross-calibrated and cross-validated to produce a harmonized data product. This presentation will summarize the lessons learned from the first

generation of greenhouse gas monitoring satellites, the methods needed to integrate their results into a common product, and the developments needed to support future, purpose-built greenhouse gas constellations.

A0.3-0002-18 USE OF THE 1.27 μM O2 ABSORPTION BAND FOR CO2 AND METHANE MIXING RATIO ESTIMATES IN NADIR VIEWING FROM SPACE: POTENTIAL AND APPLICATION TO MICROCARB

Jean-Loup Bertaux, jean-loup.bertaux@latmos.ipsl.fr LATMOS / UVSQ - IPSL - CNRS, Guyancourt, France Alain Hauchecorne, alain.hauchecorne@latmos.ipsl.fr LATMOS/IPSL/CNRS/UVSQ, Guyancourt, France François-Marie Bréon, breon@lsce.ipsl.fr

Franck Lefevre, franck.lefevre@latmos.ipsl.fr LATMOS / UVSQ - IPSL - CNRS, France

Laurent Blanot, laurent.blanot@acri-st.fr France

Pierre Lafrique, pierre.lafrique@cnes.fr CNES, Toulouse, France

Monitoring CO2 from space is essential to characterize the spatio/temporal distribution of this major greenhouse gas, and quantify its sources and sinks. The mixing ratio of CO2 to dry air can be derived from the CO2/O2 column ratio. The O2 column is usually derived form its absorption signature on the solar reflected spectra over the O2 A-band (OCO-2, Tanso/Gosat). As a result of atmospheric scattering, the atmospheric path length varies with the aerosols load, their vertical distribution, and their optical properties. The spectral distance between the O2 A-band (0.76 μm) and the CO2 absorption band (1.6 μm) results in significant uncertainties due to the varying spectral properties of the aerosols over the globe. There is another O2 absorption band at 1.27 μm with weaker lines than in the A-band. As the wavelength is much nearer to the CO2 and CH4 bands, there is less uncertainty when using it as a proxy of the atmospheric path length to the CO2 and CH4 bands. This O2 band is used by the TCCON network implemented for the validation of space-based GHG observations. However, this absorption band is contaminated by the spontaneous emission of the excited molecule O2*, which is produced by the photo-dissociation of O3 molecules in the stratosphere and mesosphere. From a satellite looking nadir, this emission has a similar magnitude as the absorption signal that is used. In the frame of the CNES Microcarb project, scientific studies have been performed in 2016-2017 to explore the problems associated to this airglow emission and methods to correct it. The intensities observed by SCIAMACHY/ENVISAT in limb viewing have been compared to a model of the emission based on the chemical-transport model Reprobus. The airglow intensities depend mostly on the Solar Zenith Angle and the agreement data/model is quite good. It was shown that, provided the spectra is acquired with a sufficient spectral resolution and SNR, the contribution of the O2* emission at 1.27 μm to the observed spectral radiance may be disentangled from the lower atmosphere/ground absorption signature. The

CO_2 mixing ratio may be retrieved with the accuracy required for quantifying the CO_2 sources (pressure level error < 1 hPa, mixing ratio error < 0.4 ppmv). As a result of these studies, it was decided to include such a band in the Microcarb design, although keeping the O_2 A band for reference. Some detailed results of these O_2^* studies and their 2018 update will be presented. We advocate for the inclusion of such a band in other GHG monitoring future space missions, such as GOSAT-2 and EU/ESA CO2M missions, for a better GHG retrieval.

A0.3-0003-18 OPTIMAL DESIGN OF OBSERVATIONAL NETWORK OVER INDIA FOR MAXIMUM INDIAN SUBCONTINENTAL CO2 FOOTPRINT

S Sijikumar, sijikumar@gmail.com

Space Physics Laboratory, Vikram Sarabhai Space Centre, Trivandrum, India Yogesh Tiwari, yktiwari@tropmet.res.in

Indian Institute of Tropical Meteorology, Pashan, Pune, Pune, India

An exhaustive set of ensemble simulations are carried out with a state of the art Lagrangian particle dispersion model (LPDM) FLEXPART to identify an 'optimal set' of ground based observation stations exclusive to Indian subcontinent to capture a maximum sub-continental footprints of CO_2 source and sinks. The Indian subcontinent is divided into a regular 20 x 20 grids assuming at least one station within each of these grids a priori. A suite of weekly ensemble backward trajectories from each of the a priori stations at every 7 day interval for 5 years (2010-2015, comprising of a total of 18,615 ensembles) were simulated. An optimal set of receptors wherein the boundary layer air from 'most' part of the Indian subcontinent during 'most' part of the year arriving have been identified by examining the ratio of area swept by the ensemble potential emission sensitivities (PES) to the area of the total Indian land mass. The same has been repeated by dividing the Indian subcontinent into 5 major zones to identify contribution from each zone. The positions of existing greenhouse gas observation stations relative to the 'optimal set' of stations are discussed further.

A0.3-0004-18 ESTIMATES OF CO2 CONCENTRATION FROM SATELLITE AND GROUNDBASED MEASUREMENTS OVER THE INDIAN REGION AND COMPARISON WITH FLEXPART SIMULATIONS

Radhika Ramachandran, radhikaspl@gmail.com

Space Physics Laboratory, VSSC, ISRO, Trivandrum, Trivandrum, India Nalini Krishna, naliniks91@gmail.com

Space Physics Laboratory, VSSC, ISRO, Trivandrum, Trivandrum, India

K.N. Uma, urmi_nmrf@yahoo.co.in

Space Physics Laboratory, Vikram Sarabhai Space Centre, Trivandrum, India S Sijikumar, sijikumar@gmail.com

Space Physics Laboratory, Vikram Sarabhai Space Centre, Trivandrum, Trivndrum, India Yogesh Tiwari, yktiwari@tropmet.res.in

Indian Institute of Tropical Meteorology, Pashan, Pune, Pune, India

The distribution of carbon dioxide (CO2) concentration over the Indian region and the surrounding oceanic regions during 2009-2012, was studied using measurements from satellites viz., Greenhouse gases Observation SATellite (GOSAT) and Atmospheric Infra-Red Sounder (AIRS), Carbon Tracker (CT) model simulations and flask measurements from two Indian stations Sinhagad (SNG) (73.75ºE 18.36ºN) and Cape Rama (CRI) (73.9ºE 15.1ºN). The concentration of CO2 was observed to be maximum during pre-monsoon. A decreasing phase was seen during the post-monsoon season. In a regional scale, it was found that the Indo-Gangetic plain and northern India have relatively higher concentrations compared to the other regions. The probability distribution of the concentration differences shows that for most of the time, the differences lie between ±3 ppm between GOSAT and CT. The comparison between the CO2 flask measurements over SNG and CRI with respect to that of GOSAT and CT clearly reveals that the differences in CO2 are as high as 10 ppm between the ground and satellite based measurements. FLEXPART model simulations were carried out to understand the source-receptor relationship over CRI, SNG, and over the equatorial Indian ocean. From the simulations, it is understood that the source contributions from the northern and eastern continental regions of the Indian region has more influence over SNG compared to CRI. Model simulations also revealed that the equatorial Indian ocean has less influence from the continental source and therefore has a reduced seasonal variability compared to the other regions considered in the present study, thereby lending support to the significant observations in the region.

A0.3-0005-18 THE GEOCARB MISSION

Berrien Moore, berrien@ou.edu

University of Oklahoma, Norman, Oklahoma, United States The GeoCarb Team

Berrien Moore, Dean Read, Sean Crowell, Gary Kushner, Norma Davilla, Benito Orozco, Bryan Benedict, Annmarie Eldering, Phillippe Ciais, Diego Santaren, Yilong Wang, Denis O'Brien, Hector Hernandez, Robert Chatfield, Cyril Crevoisier, Maria Guadalupe Galindo Mendoza, Steve Merrihew, Susan Kulawik, Christopher O'Dell, David Crisp, Xiangming Xiao, Peter Rayner, Gregoire Broquet, Enrique Pacheco Cabrera, Jon Jenkins, Stephan Kawa, John Kumer, James Lemen, David Schimel, Chris Hoffman, Frederic Chevallier

This paper presents a discussion of the GeoCarb Mission, which was selected in December of 2016 as NASA's Earth Venture Mission-2. GeoCarb will fly an instrument that will provide measurements of atmospheric carbon dioxide (CO2), methane (CH4), and carbon monoxide (CO) from geostationary orbit at roughly 85°W. The GeoCarb mission will deliver daily maps of column integrated mixing ratios of CO2, CH4, and CO over the observed landmasses at a spatial resolution of roughly 5 x 8 km.

The instrument exploits four spectral regions: The oxygen A-band for pressure and aerosols, the weak and strong bands of CO2 near 1.61 and 2.06 microns, and a region near 2.32 microns for CO and CH4. The O2 and CO2 components are very similar to the instrument aboard OCO-2, and so we envision OCO-2 in geostationary orbit with the addition of a fourth channel to measure CO and CH4, but without an oceanic capability. The chosen spectral channel for pressure and aerosols (0.765μm) permits measurement of Solar-Induced Fluorescence (SIF), which provides direct information about photosynthesis.

The 85°W slot allows observations of major urban and industrial regions in the Americas, large agricultural areas, and the expansive South American tropical forests and wetlands, which will help resolve flux variability for CO2 and CH4. As noted, the GeoCarb mission will produce daily maps at a spatial resolution of 5-8 km of the carbon gas concentrations and SIF. We believe that these persistent observations will provide the basis for a transformational improvement in our understanding of the carbon cycle, including climate-critical insights into the carbon-climate connection.

A0.3-0006-18 FORWARD MODELLING OF SOLAR INDUCED FLUORESCENCE FROM THE JULES LAND SURFACE MODEL

Tristan Quaife, t.l.quaife@reading.ac.uk University of Reading, Reading, United Kingdom

Solar induced fluorescence (SIF) is becoming widely used as a proxy for gross primary productivity (GPP), in particular with the advent of its measurement by Earth Observation satellites such as OCO and GOSAT. A major attraction of SIF is that it is independent of the assumptions embedded in light use efficiency based GPP products derived from satellite missions such as MODIS. The assumptions in such products are likely not compatible with any given land surface model and hence comparing the two is problematic. On the other hand to compare land surface model predictions of GPP to satellite based SIF data requires either (a) translation of SIF into estimates of GPP, or (b) direct predictions of SIF from the land surface model itself. The former typically relies on empirical relationships, whereas the latter can make direct use of our physiological understanding of the link between photosynthesis and fluorescence at the leaf scale and is therefore preferable.

Here I use a two stream model for fluorescence that is capable of translating between leaf scale models of SIF and the canopy leaving radiance taking into account all levels of photon scattering and use it to forward model SIF observations from JULES (the Joint UK Land Environment Simulator) which is the land surface model of the new UK Earth System Model (UKESM). The model is run at a number of sites where SIF measurements are available from both field and satellite observations. Results show that it is possible to reproduce the observed SIF signal, but that understanding the magnitude of non-photochemical quenching is key to making correct predictions.

A0.3-0007-18 UTILIZING POLSAR AND POLINSAR FOR FOREST ABOVE-GROUND BIOMASS MAPPING - CASE STUDY OVER INDIAN TROPICAL FORESTS

Unmesh Khati, khatyunmesh@gmail.com

Indian Institute of Technology Bombay, Mumbai, India

Presenting author: Debmita Bandyopadhyay, b.debmita@gmail.com Indian Institute of Technology Bombay, Mumbai, India

Gulab Singh, gulab.singh@iitb.ac.in

Indian Institute of Technology Bombay, Mumbai, India

Synthetic Aperture Radar (SAR) data has been extensively utilized for mapping and monitoring of forests. It has been shown that SAR data is sensitive to the structure, dielectric properties as well as the density of the forests among other factors. SAR remote sensing has been utilized for estimation of forest biophysical parameters such as forest stand height and forest above-ground biomass (AGB). Forest AGB is a critical factor, recognized by the UNFCC as an indicator of understanding climate change process. SAR data can be related to forest AGB using various empirical as well as physics-based models. However, for all the models, it is observed that the longer wavelength SAR signals (P-, L-band) are better suited for AGB estimation due to higher saturation values. Physics based models such as the water cloud model (WCM) as well as random volume over ground (RVoG) models can be utilized for AGB estimation, however the model parameters are empirically derived for each forest site, hampering global applicability. In forestry, the forest stand height can be related to the forest AGB using allometric equations unique to each species and geographic location. These equations provide an AGB estimate with much higher accuracy than model-based AGB estimates. With advanced SAR remote sensing techniques such as Polarimetric SAR Interferometry (PolInSAR), accurate estimation of forest stand height is possible. With the launch of TerraSAR-X/TanDEM-X platforms, PolInSAR data with zero temporal gap provides the opportunity to accurately estimate forest stand height without temporal decorrelation. Various studies have been carried out across boreal, temperate, tropical as well as peat-swamp forests to demonstrate the capability of TanDEM-X data for accurate forest height estimation. This study utilizes fully-polarimetric L-band ALOS2/PALSAR-2 SAR data to obtain backscatter as well as G4U child parameters over two Indian tropical forests. Further TanDEM-X forest stand height is measured and validated over these forest test sites. Then we combine the L-band PolSAR parameters and height estimated using the X-band data to estimate forest AGB using simple linear regression modeling. We show that the forest AGB is estimated with RMSE ranging between 25% and 30% of the mean forest AGB when modeled for a low-AGB (mean AGB 150 t/ha) and a high-AGB (mean AGB 350 t/ha) forest range. We also carried out cross-site validation where the model is trained on one site and applied on the other. This study shows a simple regression model based AGB

estimation combining the PolSAR and PolInSAR techniques. As the model shows more flexibility for cross-site applicability, it has potential for AGB estimation over larger regions.

A0.3-0008-18 ROLE OF CLIMATE VARIABILITY AND LAND USE ON FIRE EMISSIONS OF CARBON GASSES IN THE 21RST CENTURY

John Worden, john.r.worden@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Large scale reductions in biomass burning are observed across the globe from 2002 through the present through measurements of burnt area and carbon monoxide. These reductions are likely due to shifts in land-use changes as most declines are related to agricultural expansion. However, these reductions are in the context of environmental variability that can create dry conditions in Indonesia and the N. American Western states and possibly increased lightning in the Boreal forest that in turn can create large-scale fires. The changing character of fires has also altered the expected emissions. For example, emissions from fires in 2007 from South America were found to be larger than those in 2010 despite increased burnt area in 2010, likely because of changes in biomass density and combustion efficiency. Across the tropics, emissions in CO are decreasing faster than burnt area, also suggesting that the widespread shift in land-use is resulting in (not unexpectedly) changing fire combustion characteristics. Here we use data from the Terra MOPITT, Aura TES, OCO-2, and MODIS instruments as well as a state-of-the art land/atmosphere/ocean carbon cycle modeling data/model system to quantify emissions of carbon gasses using CO emissions and the range of emission factors up-scaled from vegetation type. We show that at least over the last two decades, until the 2015 El Nino, these changes in land-management practices has a substantial effect on the fire-component of global respiration that is larger in aggregate than environmental variability.

A0.3-0009-18 LEGACY EFFECT OF AMAZONIAN DROUGHT DELAYS THE SEASONAL TRANSITION FROM DRY TO WET

Mingjie Shi, mingjie.shi@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States

The long-term drought effect on forest coverage, so-called legacy effect, has been observed in ground and remote sensing measurements. Drought and forest loss may amplify each other through vegetation-atmosphere feedbacks. In this study, we investigated the impact of the reduced growth of southern Amazonian forest from the 2005 drought on dry-to-wet season transition and its variations in 2005 and 2006. We quantified the precipitation changes by using the Tropical Rainfall Measuring Mission (TRMM), which showed postponed wet season onset (WSO) for both 2005 and 2006 compared to the WSO in 2007. We further investigate the mechanism of vegetation-atmosphere feedbacks with data-constrained evapotranspiration (ET) and HDO/H2O observations from the Tropospheric Emission Spectrometer (TES). Our results show that postponed WSO is associated with the ET reduction over southern Amazonia, and the reduction of ET and its delaying effect on dry-wet season transition is further confirmed with TES HDO/H2O measurements. We also quantified the vegetation-atmosphere feedbacks with the Community Atmosphere Model version 5 (CAM5) with a control and a sensitivity experiments. The ensemble CAM5 simulations show that the WSO in southern Amazonian forest was delayed by 10 days in 2006 with drought induced leaf carbon pool reduction. Overall, this study demonstrates that the postponed WSO is triggered by the reduction of ET but amplified by change of large-scale circulation.

A0.3-0010-18 CONSTRAINING THE TERRESTRIAL CARBON CYCLE THROUGH ASSIMILATION OF EARTH OBSERVATION DATA INTO A MODEL OF THE TERRESTRIAL CARBON CYCLE

Marko Scholze, marko.scholze@nateko.lu.se Lund University, Lund, Sweden

CO2 is the most important anthropogenic greenhouse gas contributing to about half of the total anthropogenic change in the Earth's radiation budget. About half of the anthropogenic CO2 emissions stay in the atmosphere, the remainder is taken up by land and oceans. In the context of climate change it is of paramount importance to understand CO2 sources and sinks and their spatio-temporal distribution. This information is needed to improve the projections of future trends in carbon sinks and sources, and thus the potential magnitude of climate change. However, there are large uncertainties in the quantification of the terrestrial carbon sinks arising mainly from uncertainties in the underlying models used for the quantification of these sinks. A major source for these model uncertainties are uncertainties in their parameterisations and parameter values. Reducing these uncertainties is critical for reducing the spread in simulations of the global carbon cycle, and hence in climate change projections. The Carbon Cycle Data Assimilation System (CCDAS) is a system designed to optimise model process parameters based on the assimilation of multiple data streams. Besides deriving an optimal set of parameters for the underlying process-based terrestrial biosphere model, here the BETHY model, a main feature of CCDAS is its capability of determining posterior parameter uncertainties consistent with the observational uncertainties of the assimilated data. These parameter uncertainties are then propagated onto the target quantities such as the net atmosphere surface exchange flux (NEP). In this presentation, I will report on CCDAS studies that assimilate various Earth Observation data such as, e.g. XCO2, FAPAR, soil moisture, solar induced fluorescence. The assimilation of the various data streams allows to derive net and gross carbon fluxes (NEP and GPP) including uncertainty ranges consistent with the observational uncertainties.

A0.3-0011-18 HYPERSPECTRAL REMOTE SENSING OF FIRE: STATE-OF-THE-ART AND PERSPECTIVES

Fire is a widespread Earth system process with important carbon and climate feedbacks. Multispectral remote sensing has enabled mapping of global spatiotemporal patterns of fire and fire effects, which has significantly improved our understanding of interactions between ecosystems, climate, humans and fire. With several upcoming spaceborne hyperspectral missions like the Environmental Mapping And Analysis Program (EnMAP), the Hyperspectral Infrared Imager (HyspIRI) and the Precursore Iperspettrale Della Missione Applicativa (PRISMA), we provide a review of the state-of-the-art and perspectives of hyperspectral remote sensing of fire. Hyperspectral remote sensing leverages information in many (often more than 100) narrow (smaller than 20 nm) spectrally contiguous bands, in contrast to multispectral remote sensing of few (up to 15) non-contiguous wider (greater than 20 nm) bands. To date, hyperspectral fire applications have primarily used airborne data in the visible to short-wave infrared region (VSWIR, 0.4 to 2.5 μm). This has resulted in detailed and accurate discrimination and quantification of fuels, fire temperatures and emissions, fire severity and vegetation recovery. Many of these applications use processing techniques that take advantage of the high spectral dimensionality such as advanced spectral mixture analysis. So far, hyperspectral VSWIR fire applications are based on a limited number of airborne acquisitions, yet techniques will approach maturity for larger scale application when spaceborne imagery becomes available. Recent innovations in airborne hyperspectral thermal (8 to 12 μm) remote sensing show potential to improve retrievals of temperature and emissions from active fires, yet these applications need more investigation over more fires to verify consistency over space and time, and overcome sensor saturation issues. Furthermore, hyperspectral information and structural data from for example light detection and ranging sensors are highly complementary. Their combined use has demonstrated advantages for fuel mapping, yet its potential for post-fire severity and combustion retrievals remains largely unexplored.

We apply a statistical method of comparing anomalies in global atmospheric CO2 and CH4 (2009-2014) fields due to anthropogenic activities, using GOSAT observations of column-averaged dry air mole fractions (XCO2 and XCH4) with simulations by Lagrangian transport model FLEXPART. The CO2 and CH4 concentration enhancements due to anthropogenic activities, are estimated with the transport model for GOSAT observations using high-resolution emission inventories (ODIAC and EDGAR respectively). To account for strong vegetation signal we add biospheric CO2 fluxes simulated with VISIT model at 0.1° resolution. Based on these simulated values, anthropogenic greenhouse gas abundance is calculated using GOSAT observations as anomalies from clean background observations. These anomalies are binned and analysed for continental scale regions and countries. For CO2, we have found linear relationships between model and observed anomalies especially for the globe, Eurasia and North America. The analysis for East Asian region showed systematically higher observed enhancements (around 15%) that is comparable in magnitude to the reported uncertainties in emission inventories in that region. In the case of CH4, we found a good match between inventory-based estimates and GOSAT observations for continental regions. The inventory-based estimate over North American region is biased upward (around 35%) which is in qualitative agreement with recent reports. The results indicate the potential utility of GOSAT observations in monitoring reported anthropogenic emissions over different regions of varying spatial scales.

We use the same kind of high resolution transport modeling for the analysis of the CO2 emission signatures in the total column XCO2 data observed by OCO-2 satellite in 2014-2016. To reduce computational load, the OCO-2 observations are aggregated into 1 second averages prepared separately for two groups (left and right) made of simultaneously measured eight OCO-2 observations (footprints). Each group has surface footprint size of approximately 0.1°x0.1°. Same as for GOSAT, with OCO-2 data we have found linear relations between model and observed anomalies. Enhancements observed by OCO-2 match the simulated ones with a regression slope close to unity for global domain. Even after aggregation of OCO-2 data the number of enhanced XCO2 observations by OCO-2 is larger than that of GOSAT more than 15 times for same time period. The result confirms high potential of using OCO-2 observations for analyzing anthropogenic emission signatures. To fully exploit OCO-2 capability of observing narrow CO2 plumes emitted by individual power plants we prepare high resolution (1 arc min) global simulation of the CO2 transport with emissions based on ODIAC gridded emission inventory (30″ resolution) by applying a forward Lagrangian modeling approach. Preliminary results for 2015 demonstrate good correlation of the forward simulations with XCO2 enhancements observed by OCO-2 in dormant season, when correction for vegetation fluxes is not critical.

To extend the methane emission analysis made with GOSAT data we apply global highresolution methane flux inversion based on the Lagrangian-Eulerian coupled tracer transport model, aiming at estimating global methane emissions using atmospheric methane data collected at global in-situ network, which is archived at WDCGG, and GOSAT satellite observation. For better accounting for anthropogenic emissions, localized around in large cities, we use the Lagrangian particle dispersion model FLEXPART to model local tracer transport at 0.1° spatial resolution. FLEXPART is coupled to a global atmospheric tracer transport model

(NIES-TM). The adjoint of the coupled transport model is used in an iterative optimization procedure. High-resolution prior fluxes were prepared for anthropogenic emissions (EDGAR), biomass burning (GFAS), and wetlands (VISIT). High resolution wetland emission dataset was constructed using a 0.5° monthly emission data simulated by VISIT model and wetland area fraction map by Global Lake and Wetlands Database (GLWD). Inverse model optimizes corrections to two categories of fluxes: anthropogenic

and natural (wetlands). Biweekly methane emissions at high spatial resolution are estimated for the period of 2009 to 2012. The inverse model provides optimized fit to the ground-based observations around the globe. Notably, the coupled transport model manages to better reproduce the ground based continuous observations in midand high latitudes in winter, due to resolving both anthropogenic emission plumes and near-surface transport in the shallow boundary layer. Forward simulation with surface fluxes optimized by assimilating ground-based observations is used for reducing mismatch with GOSAT Level 2 XCH4 data. The monthly mean difference between GOSAT data and optimized forward simulation estimated for each 10x10° latitude-longitude box is subtracted from

GOSAT data before including the GOSAT data in inversion. The inverse modeling using combined ground-based and GOSAT data show the bias correction scheme is successful in retaining good fit to the ground-based observations. The suggested correction removes large scale biases in GOSAT data with respect to model simulation, while retaining local scale variability that contains most information on anthropogenic emissions, so it favors information on localized high emissions of anthropogenic origin over large scale atmospheric signals from natural fluxes.

A0.3-0013-18 RESPONSE OF ATMOSPHERIC CARBON-DI-OXIDE AT DIFFERENT GEOGRAPHICAL LOCATIONS OVER THE GLOBE DURING STRONG EL-NINO (2015-2016)

K.N. Uma, urmi_nmrf@yahoo.co.in

Space Physics Laboratory, VSSC, ISRO, Trivandrum, Trivandrum, India

Carbon-di-Oxide (CO2) is considered to be the most important green-house gas in the Earth's atmosphere. The increase in the concentration is mainly caused by the human activities (anthropogenic) which intensifies the global warming. It has a significant linkage with each of the biogeochemical processes involved in the earth's system. The tropical climate variability consists of two dominant modes El-Nino and La-Nina. In general, El-Nino Southern Oscillation (ENSO) affects the global climate by creating anomalous weather patterns even though it occurs over the Western Pacific. It also affects the global carbon cycle. It is indeed important to understand the relation between El-Nino and CO2. The present study focuses on the variability of CO2 concentration over different geographical locations over the Globe using Total Column Carbon Observatory Network (TCCON) that utilizes Fourier Transform Spectrometers and GLOBAL VIEW CO2 Network that uses flask measurements. In addition observations from OCO-2 and GOSAT are also utilized. The analysis shows that the response of El-Nino on the CO2 concentration is observed to be different over different geographical locations. The details will be presented in the upcoming workshop.

Drought events have significant impact on regional carbon balance and global atmospheric CO2 growth. In this study, we quantified the impact of the 2011 Texas drought and the 2012 Midwest drought on Net Biome Exchange (NBE), and its components including Gross Primary Productivity (GPP), fire, and total ecosystem respiration (TER) using multiple satellite observations. The NBE was constrained by column CO2 (XCO2) observations from the Greenhouse Gases Observing Satellite (GOSAT) using the NASA Carbon Monitoring System Flux (CMS-Flux) carbon cycle data assimilation system, while GPP was estimated with Solar Induced Chlorophyll Fluorescence (SIF) from GOSAT, and biomass burning was computed from CO emissions constrained by Measurements of Pollution in the Troposphere (MOPITT). Total ecosystem respiration (TER) was calculated as a residual term. We found that both drought events greatly increased NBE (i.e., reduced net uptake) due to reduced GPP and increased respiration during the peak, but had quite different sensitivity to temperature and soil moisture anomalies due to different geographic locations. The annual NBE was increased by 0.2 ± 0.10 GtC over the drought region in both 2011 and 2012 droughts, but the dominant drivers were different. The increase of NBE due to the 2011 and 2012 drought impact was 50% and 25% respectively of the regional annual fossil fuel emissions. The results show that natural carbon cycle interannual variability needs to be considered in order to accurately relate carbon mitigation strategies to regional and global CO2 growth rates.

A0.3-0015-18 AN INTRASEASONAL VARIABILITY IN CO2 OVER THE ARCTIC INDUCED BY THE MADDEN-JULIAN OSCILLATION

King-Fai Li, king-fai.li@ucr.edu

University of California, Riverside, Riverside, California, United States

Variability of atmospheric CO2 must be well understood for us to better characterize the anthropogenic CO2 release from the surface. A previous study revealed the influence of the Madden-Julian Oscillation (MJO) to tropical midtropospheric CO2 via convection. In this work, the observations by NASA's Atmospheric Infrared Sounder are used to further examine the MJO impact on the CO2 concentration over the Arctic. A composite analysis shows that the CO2 north of 60°N varies with a peak-to-peak amplitude of 1.2 0.2 ppm over the MJO cycle. An empirical correlation analysis is applied to examine possible effects of retrieval bias and dynamics on the MJO-related CO2 anomalies. It is shown that the spatial pattern of the MJO-related Arctic CO2 anomalies closely resembles that of the isentropic potential vorticity anomalies at 475 K.

A0.3-0016-18 IMPACT OF CALIFORNIA WILDFIRES ON ATMOSPHERIC CO2

Andy Li, andy122020@gmail.com

Clements High School, Sugar Land, Texas, United States Yuk Yung, yly@gps.caltech.edu

California Institute of Technology, Pasadena, California, United States

The 2017 California wildfires were the largest in the state's history. There were 9000 wildfires, burning 1.2 million acres, destroying more than 10 thousand structures, and killing 46 people. Using NCEP2 Reanalysis data, it is found that the averaged surface temperature in California has increased by 1.7 K during the past 39 years. An increased temperature and recent severe droughts contribute to stronger wildfires. Based on the CO2 retrievals from OCO-2, it is found that atmospheric CO2 increased by 2 ppm after the California wildfires for the first time. Results in this study can help us better understand wildfires and their impact on atmospheric CO2 in the California region.

A0.3-0017-18 INTERACTIONS BETWEEN CARBON DIOXIDE, SOLAR-INDUCED FLUORESCENCE, AND PRECIPITATION

California Institute of Technology, Pasadena, California, United States

To better understand the CO2 annual cycle and interaction between the biosphere and the atmosphere, we studied the column CO2 and solar-induced fluorescence (SIF) from Orbiting Carbon Observatory -2 (OCO-2). A negative correlation is found between atmospheric CO2 and SIF. SIF value is high during summer when there is more photosynthesis, which will lead to a low atmospheric CO2. Using precipitation data from TRMM and evaporation data from ECMWF, it is found that SIF can be influenced by the difference of precipitation and evaporation, suggesting there is more CO2 uptake by vegetation when more water is available. Results obtained from this study can help better understand the carbon cycle and the interaction between the biosphere and the atmosphere.

A0.3-0018-18 SPATIOTEMPORAL VARIABILITY OF ATMOSPHERIC CARBON MONOXIDE OVER THE ASIAN REGION AND RELATIONSHIP WITH QBO IN A CHEMISTRY-CLIMATE MODEL AND MACC REANALYSIS

Madhu Vazhathottathil, madhuv68@gmail.com

Graduate School of Environmental Studies, Nagoya University, Japan, NAGOYA,, Japan Kengo Sudo, kengo@nagoya-u.jp

Nagoya University, NAGOYA,, Japan

Carbon monoxide (CO) is one of the major air pollutants in the atmosphere produced due to the anthropogenic activities which cause incomplete fossil fuel (wood, coal and oils) burning emissions. CO plays a major role in the tropospheric oxidative chemistry and affects concentrations of tropospheric ozone and hydroxyl radical (OH) which is a primary sink for many species like CH4. The seasonal concentrations of CO are different across the globe depending on the sources and atmospheric transport through wind circulations. Forest fires, agricultural burning and industrial emissions are the most important sources of carbon monoxide pollution over the Asian region. The uncertainties in the location and drivers of these carbon uptakes, and their interactions with climate systems are the major constrains in the future climate projections. The trace gases such as carbon monoxide can directly affect the carbon cycle process and its interactions with climate systems. In the present analysis we made an attempt to understand the recent changes (spatial and temporal) in the atmospheric carbon monoxide over the Northeast Asian region (the major source region of CO) using chemistry-climate model CHASER (MIROC-ESM) simulations and MACC (Monitoring Atmospheric Composition and Climate) Reanalysis for the period 2003-2012. The CO concentration shows maximum (> 350 ppb) in winter and minimum (<100 ppb) during June to August months over this region. During summer (JJA) and Autumn (SON) seasons another peak region of CO is seen near to the equator over the Southeast Asian region (Singapore and Malaysia) due to the biomass burning. The short-term (10 year) pressure level trends of CO shows negative (-0.03 ppb/mon) at the surface and positive at the Upper Troposphere (UT) and reaches to the maximum near to tropopause level (0.08 ppb/mon) then becomes negative (-0.02 ppb/mon) at the Lower Stratospheric (LS) region. The CO distribution is modulated by stratospheric quasi-biennial oscillations (QBO) with positive and negative CO anomalies in phase coherences with westerly (+4 ppb) and easterly phases (- 4 ppb) of the equatorial lower stratospheric zonal wind. The lower tropospheric CO shows high positive correlation (0.8) with surface ozone implying that its role in the surface ozone (bad ozone) production through oxidative chemistry and negative correlation (-0.6) over the LS regions suggesting that CO is not largely contributing to the stratosphere ozone production processes.

A0.4-0001-18 OBSERVING THE CHANGING ANTHROPOCENE FROM SPACE: SOME RESULTS, CHALLENGES AND NEEDS

John Burrows, burrows@iup.physik.uni-bremen.de

Institute of Environmental Physics, University of Bremen, Bremen, Germany

The rapid growth of human population, since the industrial revolution, has been accompanied by a much increased standard of living, the bountiful production of food and a dramatic increase in mobility. The dominant energy source sustaining these developments has been fossil fuel combustion. However, the use of this energy source, coupled with the related growth of the transport and heavy, chemical and agrochemical industries, has resulted in unprecedented air and water pollution. The latter now spans all scales of the Earth System from the local to the global. As a result there have been significant impacts on air quality, water quality, human health, ecosystem services, stratospheric ozone and climate change. The impacts can be sudden and also slowly accumulate over time in the long term. The Earth has entered a new geological epoch, which is called the Anthropocene. Although already beginning at hte neolithic revolution, the impact of man has dramatically increased since the 1950s. This coincided with the birth of the space age, which subsequently led to pioneering efforts to establish an adequate technology to delivers an adequate and evolving Earth Observation measurement capability. Over the past four decades this system has been evolving. Specifically there is a clear need for a space segment, which can separate the impact of anthropogenic activity from that of natural phenomenon. This talk introduces this topic of the use of the space segment to deconvolve the changes from human activity and natural phenomena in the earth system.

A0.4-0002-18 THE MOPITT INSTRUMENT AS A PROTOTYPE FOR LONG-TERM SPACEBASED ATMOSPHERIC MEASUREMENTS IN THE ANTHROPOCENE

James Drummond, james.drummond@dal.ca Dalhousie University, Halifax, Canada MOPITT team

Merritt Deeter, David Edwards, John Gille, Florian Nichitiu, Helen Wordenn Jason Zou

One of the major characteristics of the Anthropocene will be changes in all the Earth systems on many timescales. Changes that occur within a generation will be very significant for policy decisions and these will require measurements on corresponding timescales from space-based instruments, but these times are long compared to traditional satellite lifetimes.

Whether by luck or by good design there are now a number of satellite missions that are recording data over long time periods. With a single instrument, decadal and longer time series of relevant atmospheric parameters have been achieved and the Measurements Of Pollution In The Troposphere (MOPITT) instrument is one such instrument. Launched on 18th December 1999 on the Terra spacecraft, MOPITT has now completed more than 18 years of operation measuring carbon monoxide (CO) over the planet and the mission continues. Given that the Terra spaceacraft is still in good condition, it is entirely possible that these measurements will span more than two decades before completion.

MOPITT therefore offers a case study of a very long single-instrument time series, albeit one with challenges because this longevity was not part of the original design criteria: The original design specified about a five year life and this has already been considerably exceeded. MOPITT does enable us to look at long term trends and intermittent phenomena over the planet for an extended period of time encompassing an entire solar cycle and many cycles of El Niño and other quasi-periodic phenomena. This presentation will consider, with examples, some of the advantages and some of the problems of these long-term space measurements with an eye to the future and the needs of future generations.

MOPITT was provided to NASA's Terra spacecraft by the Canadian Space Agency and was built by COMDEV of Cambridge, Ontario. Data processing is performed by the MOPITT team at the National Center for Atmospheric Research, Boulder, CO. Instrument control is by the MOPITT team at the University of Toronto.

A0.4-0003-18 SATELLITE AND IN SITU OBSERVATIONS OF TRENDS IN TROPOSPHERIC AIR POLLUTANTS: POLICY RELEVANT SCIENCE

Russell Dickerson, rrd@umd.edu

University of Maryland, College Park, College Park, Maryland, United States

Anthropogenic emissions of gaseous pollutants such as NO2, HCHO, SO2, NH3 and resultant O3 and particulate matter (PM) are associated with substantial adverse impacts on the environment and human health. A recent review (Landrigan et al. it Lancet, 2017) stated "Diseases caused by pollution were responsible for an estimated 9 million premature deaths in 2015 - 16% of all deaths worldwidethree times more deaths than from AIDS, tuberculosis, and malaria combined and 15 times more than from all wars and other forms of violence." Concentrations and emissions of air pollutants have changed substantially over recent decades, but not in uniform ways. North America and Europe have seen substantial improvement in NO2 and the near elimination of SO2 while East Asia has experienced mixed results and South Asia appears to show increases. One untended consequence of acid gas control has been increases in gaseous ammonia. Observations from in situ and satellite-borne sensors can guide numerical models to evaluate the efficacy of control measures and to provide policy relevant science.

A0.4-0004-18 AIR POLLUTION IN EAST ASIA: VIEWS FROM SPACE, GROUND AND MODELS

Hiroshi Tanimoto, tanimoto@nies.go.jp

National Institute for Environmental Studies, Ibaraki, Japan

Human emissions of pollutants and long-lived greenhouse gases into the atmosphere have caused dramatic transformations of the Earth, altering air quality, climate, the cryosphere, elemental cycles and nearly every ecosystem worldwide. Better understanding the global atmospheric chemistry requires an international network of the observations, and satellite observations from space provide global picture of trace gases and aerosols across geographical boundaries, thus being compliment to the observations from the ground and by other platforms such as aircraft or balloons. Air quality is now one of the most pressing global environmental issues, as the World Health Organization recently stated that air quality is the top environmental cause of premature deaths in the world, in particular, for people living in megacities of the developed countries as well as in developing countries. Here we present some highlights from the past research and its findings on air quality in east Asia, with particular emphasis on tropospheric ozone and its precursors including nitrogen oxides and volatile organic compounds, as revealed by the observations from space (e.g., GOME, SCIAMACHY and OMI satellites) and the groundbased network (e.g., EANET, GAW, and other research-based monitoring), with the aid of state-of-science global or regional chemistry-transport models.

A0.4-0005-18 THE CLIMATE OF THE 21ST CENTURY FROM AN INFRARED PERSPECTIVE: FIFTEEN YEARS OF THE ATMOSPHERIC INFRARED SOUNDER AIRS

While the early 21st century has seen dramatic changes in climate, it has also been the golden age of satellite observations of the Earth's climate. During this period, climate has been observed from space with revolutionary detail and, in particular, climate change has been monitored in unprecedented ways. Due to its high spectral resolution, hyperspectral infrared observations from space are capable of measuring a multitude of components of the climate system. Since its launch in 2002 (as part of the Aqua mission), the Atmospheric Infrared Sounder (AIRS) has played a key role in weather and climate science by, among other contributions, helping to dramatically improve the accuracy of numerical weather prediction, leading to the discovery of new source regions of atmospheric gravity waves, and monitoring key trends in our climate such as the increase of carbon dioxide. In this presentation, we will discuss some of the most significant aspects of the global climate in the 21st century. We will focus on the dramatic changes that we have been witnessing, from changes in atmospheric composition e.g. greenhouse gases and clouds - to the impact in terms of polar temperatures and extreme weather. At the end of the presentation, we will report on recent efforts to try to guarantee continuity of these essential measurements to monitor our planet's climate.

A0.4-0006-18 EFFECTIVE UTILIZATION OF SATELLITE-BASED AIR POLLUTION DATA AT KILOMETER-CLASS SPATIAL RESOLUTION: INTEGRATION WITH MAXDOAS OBSERVATIONS AND CHEMICAL TRANSPORT MODELS

Yugo Kanaya, yugo@jamstec.go.jp JAMSTEC, Yokohama, Japan

Hiroshi Tanimoto, tanimoto@nies.go.jp

National Institute for Environmental Studies, Ibaraki, Japan Yasuko Kasai, ykasai@nict.go.jp

National Institute of Information and Communications Technology, Tokyo, Japan

Our recent project activity is summarized, aiming to demonstrate effective utilization of satellitebased air pollution data (e.g., NO2) at kilometer (km)-class spatial resolution for robust science and policy on air quality and short-lived climate forcers (SLCF) management. Highlights are on (1) validation and integration of satellite observations with ground-based Multi-Axis Differential Optical Absorption Spectroscopy (MAX-DOAS) observations and (2) sophisticated methodology in emission estimation. More than 100,000 vertical profiles of NO2 were collected from MAX-DOAS network over Russia and Asia (MADRAS, Kanaya et al., ACP 2014) for more than 10 years since 2007 and were used for systematic validation of TropoNO2VCD from OMI (DOMINO v2). For simple cases with very small cloud fraction, presence of aerosol shielding effect was ascertained when tropospheric averaging kernels (AK) were taken into account. We attempted to derive near-ground NO2 concentration map over Tokyo-Yokohama metropolitan area from satellite observations, with recalculated air mass factors based on realistic vertical profiles of NO2 simulated with ADMER-PRO chemical transport model (CTM) at 2-km spatial resolution with correction terms to retain consistency with MAX-DOAS. Full suite of satellite observations of ozone and precursors were assimilated to a global CTM CHASER to derive tropospheric chemistry reanalysis data set (TCR-1 and 2) with optimized emission inventory. Estimation of NOx emission rates from single point sources based on recent satellite observations will also be discussed.

A0.4-0007-18 WHAT WE CAN SAY ABOUT THE ROLES OF NATURAL AND ANTHROPOGENIC AEROSOLS IN CLIMATE CHANGE

Ralph Kahn, ralph.kahn@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States

Although particles from natural sources dominate the globally averaged aerosol load, it is widely understood that human activity has added significantly to the atmospheric aerosol inventory in many regions. Anthropogenic contributions include pollution particles from industrial activity, transportation, cook-stoves, and other combustion sources, smoke from agricultural fires and those wildfires that result from land-management practices, soil and mineral dust mobilized in regions where overgrazing, severe tilling, or overuse of surface water resources have occurred, and biogenic particles from vegetation planted and maintained by the populance. The history of human influence is complex - in the 18th and 19th centuries agricultural burning tended to dominate the anthropogenic component in most places, whereas more recently, fossil fuel combustion leads the human contribution is many areas.

However, identifying and quantifying the anthropogenic aerosol component on global scales is a challenging endeavor at present. Most estimates of the anthropogenic component come from aerosol transport models that are initialized with aerosol and precursor-gas source locations, emission strengths, and injection heights. The aerosol is then advected based on meteorological modeling, possibly modified chemically or physically, and removed by parameterized wet or dry deposition processes. Aerosol effects on clouds are also represented in some climate models, but with even greater uncertainty than the direct aerosol effects on Earth's radiation balance. Even for present conditions, aerosol source inventories are deduced from whatever constraints can be found, along with much creativity and many assumptions.

Aerosol amount (i.e., aerosol optical depth) is routinely measured globally from space, but observational constraints on the anthropogenic component require some knowledge of the aerosol type as well, a much more difficult quantity to derive. As large-swath, multi-spectral, singleview instruments such as MODIS can provide some information about fine-mode vs. coarsemode dominated aerosol over dark water, early efforts to constrain aerosol type assumed that some or all the fine-mode fraction is anthropogenic. However, this information is not sufficient to make the key anthropogenic vs. natural distinction in most places where the likely answer is not already known. Instruments providing more detailed measurements, such as multi-spectral, multi-angle and polarimetric imagers and multi-channel lidars, can offer tighter aerosol-type constraints in some circumstances, though generally not enough to specifically identify anthro- pogenic aerosols. The best we seem to be able to do with current data is to combine satellite and suborbital observations with models. And for the "pre-industrial" period, the analogy is usually made to the "natural" component of present-day aerosol, although there are ambiguities in our ability to distinguish natural from anthropogenic particles on regional-to-global scales, and the natural component itself might have changed over time. This talk will review where we stand, and what might be possible to say in the future.

A0.4-0008-18 IASI SATELLITE OBSERVATION OF POLLUTANTS: BEST OF 2017-2018

Cathy Clerbaux, cathy.clerbaux@latmos.ipsl.fr CNRS UPMC, Guyancourt, France

IASI LATMOS & ULB

Anne Boynard, Maya George, Juliette Hadji-Lazaro, Maya George, Sarah Safieddine, Camille Viatte, Martin Van Damme, Lieven Clarisse, Pierre Coheur

The IASI family of instruments has been sounding the atmosphere since 2006 onboard the Metop satellite series. Using the radiance data recorded in the thermal infrared spectral range, concentrations for atmospheric pollutants such as carbon monoxide (CO), ozone (O3), sulfur dioxide (SO2) and ammonia (NH3) can be derived. IASI CO and O3 fields are currently assimilated in regional and global models in order to predict air quality over Europe; SO2 alerts are delivered when exceptional levels are encountered, and NH3 source hotspots are tracked throughout the globe.

Near-real time observation of these atmospheric pollutants allow to follow them at city, country and continent scales. This talk will present the findings for 2017-2018, with a focus on fire events, exceptional pollution episodes, and other unexpected features. Progresses to expect with the arrival of IASI on Metop-C and current limitations to derive long term trends will also be discussed.

A0.4-0009-18 LONG-TERM H2O TRENDS IN THE MIDDLE ATMOSPHERE OBSERVED BY SABER ON THE TIMED SATELLITE

James Russell, james.russell@hamptonu.edu

Hampton University, Hampton, Virginia, United States Jia Yue, jia.yue@hamptonu.edu

Hampton University, Hampton, Virginia, United States Pingping Rong, ping-ping.rong@hamptonu.edu Hampton University, Hampton, Virginia, United States

M. G. Mlynczak, martin.g.mlynczak@nasa.gov

NASA Langley Research Center, Hampton, Virginia, United States Thomas Marshall, thomas.marshall@gats-inc.com

GATS, Newport News, Virginia, United States

The primary science goal of the Sounding of the Atmosphere using Broadband Emission Radiometry (SABER) experiment on the TIMED satellite is to achieve major advances in understanding the structure, energetics, chemistry, and dynamics in the atmospheric region extending from 60 to 180 km altitude. The SABER instrument has been observing the atmosphere nearly continuously since data collection began in January of 2002 using the technique of spectral broadband limb emission radiometry applied in 10 infrared spectral bands ranging from 1.27 to 17 μm. Four CO2 bands - three in the 15 μm region and one in the 4.3 μm band - are used to retrieve temperature and CO2 concentrations and to correct retrievals for spacecraft motion effects. The remaining bands are used to retrieve O3, H2O, [O], [H], energetics parameters, and to observe atmospheric heating and cooling. The measured limb emission profiles are being processed on the ground to provide vertical profiles of these parameters with 2 km altitude resolution. Measurements are made both night and day over the latitude range from 52 degrees to 83 degrees with alternating hemisphere coverage every 60 days. Water vapor is measured over the range from near the tropopause to 80km altitude. This paper provides results of recent research to improve the H2O data product, describes data validation studies and presents long-term trends in H2O over the 16-year period from January 2002 to January 2018.

A0.4-0010-18 NICT PRIORITIES FOR OBSERVING THE ANTHROPOCENE FROM SPACE

Yasuko Kasai, ykasai@nict.go.jp

National Institute of Information and Communications Technology, Tokyo, Japan Takeshi Kuroda, tkuroda@nict.go.jp

National Institute of Information and Communications Technology, Tokyo, Japan Tomohiro Sato, tosato@nict.go.jp

National Institute of Information and Communications Technology, Tokyo, Japan Kota Kuribayashi, kuribayashi@nict.go.jp

National Institute of Information and Communications Technology, Tokyo, Japan Koji Zettsu, zettsu@nict.go.jp

National Institute of Information and Communications Technology, Tokyo, Japan

Air pollution causes important risk to health. The aim of NICT project is to provide a robust prediction system of air quality over Japan with km-class spatial resolution using satellitebased air pollution data, such as short-lived climate forcers (SLCF), NO2. The system is assumed to use for health care, health tourism by company and policy makers. Currently, we are developing 1. a forecasting modeling including PM2.5, oxidants (tropospheric ozone), NOx, SOx and so on with multi-modal area systems to realize both highspatial resolution in Japan and wide coverage of Asian/global scales, since significant pollutions are coming from cross-border transport from the continent. 2. Health impact estimation using hospital data and air-quality data. I will introduce overview, target, current status in detail in the presentation.

A0.4-0011-18 NASA LANGLEY RESEARCH CENTER CONTRIBUTIONS TO ADVANCING UNDERSTANDING OF EARTH'S ATMOSPHERIC COMPOSITION

Bruce Doddridge, bruce.doddridge@nasa.gov NASA/LaRC, Hampton, Virginia, United States

The Science Directorate at NASA Langley Research Center (LaRC) emphasizes an end-toend approach for small and medium flight and sub-orbital projects where technology development; mission formulation and implementation; calibration and validation activities; and data analyses are carried out with the goal of deriving scientific information from space-based and sub-orbital observations for decision support. This work includes scientific leadership in space-based missions; technology development; laboratory, surface, on-orbit (satellite and ISS) and sub-orbital (research aircraft) measurements; research and analyses projects; atmospheric science data stewardship; applied sciences research in developing decision support tools; and education and outreach activities, all in support of NASA's Science Mission Directorate (SMD). The LaRC Science Directorate strengths include Earth observation, interdisciplinary research, Earth system modeling, data processing systems, and advanced technology development, with an overall focus on atmospheric science, atmospheric composition and climate. The Directorate also provides significant support to the SMD Applied Sciences program, particularly in areas of air quality management, energy forecasting, aviation safety and earth science disaster response. In the context of Observing the Anthropocene from Space this presentation will reviewing the current and future portfolios of on-orbit and sub-orbital missions and research analysis projects in one of our key strength areas, measuring and characterizing atmospheric composition, including descriptions of space-based assets, airborne field campaigns, and small satellite concepts.

A0.4-0012-18 THE 2017-2027 NATIONAL ACADEMIES DECADAL SURVEY FOR EARTH SCIENCE AND APPLICATIONS FROM SPACE: AN OVERVIEW OF THE REPORT

Arthur Charo, acharo@nas.edu

National Academies of Sciences, Engineering and Medicine, Washington, District of Columbia, United States

A pre-publication version of the final report of the 2017-2027 National Academies' decadal survey for Earth Science and Applications from Space ("ESAS 2017") was delivered to its agency sponsors on December 31, 2017; publication of the edited version is expected in Spring 2018. Like the inaugural survey, which published its final report in 2007, ESAS 2017 was requested by NASA, NOAA, and the USGS. The survey's overarching objective was to develop consensus recommendations from the environmental monitoring and Earth science and applications communities for an integrated and sustainable approach to the conduct of the U.S. government's civilian space-based Earth observation programs. The survey co-chairs will review the report's findings and recommendations and discuss its implementation. A PDF of the report is posted at www.nas.edu/esas2017 where details about the survey may also be found.

A0.4-0013-18 SAGE III INSTRUMENT ON THE INTERNATIONAL SPACE STATION

Patrick McCormick, pat.mccormick@hamptonu.edu Hampton University, Hampton, Virginia, United States Michael Hill, michael.hill@hamptonu.edu

Hampton University, Hampton, Virginia, United States

A much-improved Stratospheric Aerosol and Gas Experiment (SAGE III) instrument was launched on February 19, 2017 from NASA's Kennedy Space Center aboard the SpaceX CRS-10 Dragon Spacecraft. It subsequently docked with the International Space Station (ISS), completed commissioning on July 1, 2017, and is now in its Mission Operations phase. SAGE III-ISS combines the experience and capabilities of its successful predecessor satellite instruments SAM II, SAGE, SAGE II, and SAGE III-Meteor-3M to measure aerosols, clouds, O3, H2O, and NO2 profiles from the upper troposphere through the stratosphere, and in the case of ozone, through the mesosphere. In addition to solar and lunar occultation with vertical resolutions of about 1.0 km, SAGE III-ISS is making limb scattering measurements on the solar side of each orbit greatly expanding the measurement coverage per spacecraft orbit, which ties the very high resolution and precise solar occultation measurements with the limb scattering measurements. The programmable readout array detector enhances its measurement capability and should allow for experimental data products like BrO, and IO, and along with a single photodiode detector, the measurement of larger aerosols. The wavelengths covered by SAGE III-ISS range from 280 to 1050 nm with 1 to 2 nm spectral resolution using a grating spectrometer. The single photodiode extends measurements to 1550 nm. This talk will describe the measurement capabilities of SAGE III, and include data and validation examples for its first year in orbit, its additional modes and increased geographical coverage, its calibration and characterization, and data archival and validation approach.

A0.4-0014-18 OUR CHALLENGE FOR ESTIMATING ANTHROPOGENIC GHG EMISSION FROM DIFFERENT SOURCES USING GOSAT

Akihiko Kuze, kuze.akihiko@jaxa.jp JAXA, Tsukuba, Japan

Hiroshi Suto, suto.hiroshi@jaxa.jp

Japan Aerospace Exploration Agency (JAXA), Japan Kei Shiomi, shiomi.kei@jaxa.jp

Japan Aerospace Exploration Agency, Tsukuba, Ibaraki, Japan Nobuhiro Kikuchi, kikuchi.nobuhiro@jaxa.jp

Japan Aerospace Exploration Agency (JAXA), 8505, Japan Fumie Kataoka, kataoka.fumie@restec.or.jp

RESTEC, 8505, Japan

Satellite observation is the only method to monitor greenhouse gases distribution globally and frequently. We launched the Greenhouse gases Observing SATellite (GOSAT) in 2009. Decade long data set of carbon dioxide (CO2) and methane (CH4)with the Thermal And Near infrared Sensor for carbon Observation Fourier-Transform Spectrometer (TANSO-FTS) are available. In addition to grid observation points, we are optimizing observation pattern by uploading pointing locations every day to estimate anthropogenic emission from various sources. We will demonstrate methane flux estimation from large point sources using GOSAT and wind speed data. We will also present how to reduce uncertainty and show test results with next generation instruments.

A0.4-0015-18 THE COPERNICUS PROGRAMME AND ITS CLIMATE CHANGE SERVICE (C3S): A EUROPEAN RESPONSE TO CLIMATE CHANGE

Jean-Noel Thepaut, jean-noel.thepaut@ecmwf.int ECMWF, Reading, United Kingdom

Bernard Pinty, bernard.pinty@ec.europa.eu DG Grow,

Dick Dee, dick.dee@ecmwf.int ECMWF, Reading, United Kingdom

This paper provides an overview of the European Union's flagship Earth Observation Programme, Copernicus, dedicated at monitoring the planet Earth and its environment for the benefit of all European citizens. The Programme offers information services based on satellite Earth observations, in situ (non-space), and modelling data. The paper focuses on one of the six Copernicus Services, the Copernicus Climate Change Service (C3S), which provides comprehensive climate information covering a wide range of components of the Earth-system (atmosphere, land, ocean, sea-ice and carbon), maximising the use of past, current and future earth observations (from in-situ and satellite observing systems) in conjunction with modelling, supercomputing and networking capabilities to produce a consistent, comprehensive and credible description of the past, current and future climate, via the generation of a large number of Essential Climate Variables (ECVs), as well as key generic (CO2 trend, reducing glaciers) or customisable (number of degree days, windstorm statistics, growing seasons, etc.) climate indicators for relevant economic sectors, such as energy, water management, agriculture, insurance, health, etc. The wealth of free and open data that C3S provides, supports users in making informed choices for their business decisions, thus delivering a more energy efficient and climate aware economy. These sound investment decisions now do not only stimulate growth in the short term, but reduce the impact of climate change on the economy and society in the future. Although the C3S portfolio is much broader than Earth Observation based climate information (multi-model seasonal forecasts, climate projections at global and regional level, sectoral impact indicators, etc. are also included in the Service) this paper focuses on monitoring aspect of the Service and in particular the Earth Observation based information. By monitoring a number of key ECVs, C3S ambitions to strongly contribute to the newly published implementation plan of GCOS (Global Climate Observing System). C3S is now becoming operational, the technical infrastructure is being developed and the first industrial activities have been kicked off. Climate monitoring information is routinely produced and available at climate.copernicus.eu, and the ECVs are being generated either via global reanalyses (this is the case for most of the atmospheric variables) or through the production of long term climate data records (CDRs). Although progressively, these CDRs will greatly benefit in the future from the family of Sentinel missions, they currently heavily rely on third party missions from NASA, NOAA, ESA, EUMETSAT and other Space Agencies. The importance of combining satellite, in situ and modelling information to ensure an Earth System approach

to monitoring the Anthropocene and guaranteeing consistency across the main Earth cycles (water, energy, carbon) will also be highlighted in this paper.

A0.4-0016-18 OBSERVING IMPACTS OF HUMANITY ON THE EARTH SYSTEM

Jack Kaye, jack.a.kaye@nasa.gov

NASA, Washington, District of Columbia, United States

The vantage point of space provides a unique way of studying the Earth in its entirety - both spatially and in terms of its interacting components (atmosphere, ocean, land surface, cryosphere, biosphere, etc.). This space-based perspective, accompanied by complementary measurements from surfaceand ground-based instruments, allows for characterization of both the direct forcings that human civilization imposes on the Earth system and the indirect responses from the Earth system, together with its inherent variability that then create our global environment. The combination of these observations with models that support quantitative hypothesis testing, prediction of future evolution, and preparation of comprehensive data sets for scientific study enhances the value of these observations for study of the present and future Earth. In this talk, recent results of NASA's Earth Science Division's programs (flight, research and analysis, applied sciences, and technology) will be summarized and their significance in helping to observe the Anthropocene will be discussed

A0.4-0017-18 COSPAR CONTRIBUTIONS TO SPACE-BASED OBSERVATIONS FOR GLOBAL INTEGRATED EARTH SYSTEM SCIENCE

Jean-Louis Fellous, jean-louis.fellous@cosparhq.cnes.fr COSPAR Secretariat, Paris, France

David Halpern, david.halpern@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

The Committee on Space Research (COSPAR) established in 1958 by the International Science Council (formerly ICSU) commissioned a study group to prepare a roadmap on satellite observations for integrated Earth system science for 2016-2025, as a contribution to the intergovernmental Group on Earth Observations (GEO), which was established in 2005. The roadmap focused on the use of integrated observations and modelling to address the functioning, predictability and projected evolution of the Earth system on timescales out to a century or so to enable enhanced sustainable development. The COSPAR roadmap was published in ASR, 57, n°10, 15 May 2016 and acknowledged with gratitude by the GEO Plenary. COSPAR is a Participating Organization in GEO since 2007 and has contributed notably to its Science and Technology Committee and its Data Sharing Working Group, through the COSPAR Task Group on GEO gathering of about 150 scientists from its Scientific Commission A. COSPAR is a founding member of the GEO Program Board and is actively pursuing the strengthening of the science, technology, and observing systems sustainability and enhancement. Within the GEO Program Board, COSPAR is leading efforts to evaluate the strengths and weaknesses of the global integrated in situ and satellite observing system over the past ten years. The present COSPAR Scientific Assembly program, as it relates to Earth sciences, shows the COSPAR support to the Paris Agreement on Climate Change. COSPAR, as an independent, academic organization, supports the Paris Declaration "Towards a Space Climate Observatory." The Declaration was adopted in December 2017 by senior leaders of over 25 space agencies worldwide (see the April issue of SRT). Without interfering in scientific debates, COSPAR recognizes the strength of the climate diagnostic posed by the Intergovernmental Panel on Climate Change and the high value of the results and recommendations of its sister organizations World Climate Research Program and Global Climate Observing System within the ISC. The space agencies involved in the Committee on Earth Observation Satellites and Coordination Group for Meteorological Satellites are progressing in their strategic analysis of observational needs for the weather-to-climate continuum and other aspects of the global integrated Earth system. COSPAR Scientific Commission A and sub-Commissions A1, A2 and A3 will continue to work through the COSPAR Scientific Assembly and other forums at promoting international collaboration to enhance and sustain space-based observations for improved understanding of global integrated Earth System science.

A0.4-0018-18 CURRENT STATE AND FUTURE NEEDS OF SPACE-BASED MONITORING OF THE EARTH

Hansjoerg Dittus, susanne.stiller@dlr.de

Deutsches Zentrum fuer Luft-und Raumfahrt (DLR), Cologne, Germany

Influence of mankind on Earth's climate is evident. The growing population using the resources available, especially by burning goal, oil and gas, changes the composition of the Earth's atmosphere with the result of a continuously increasing temperature. Effects are not limited to the regional scale but are evident on the whole planet, meanwhile named Anthropocene. According to this global influence, it's necessary to also extend monitoring to the entire planet. Space-based observation systems are not limited by any artificial borders and are in principle able, to cover the whole Earth. In principle, two different ways of observation can be selected: Either a dedicated spacecraft will be send into low earth orbit (LEO) or existing platforms are used. Advantages of satellites are the more or less freely selectable orbit (with orbits covering also the polar regions) and the possible adaption of spacecraft platform for the dedicated instrument. On the other hand platforms like the ISS space station enable continuous long term coverage with different instruments. The drawback of an only limited coverage based on the orbit inclination is made up by the possibility to service systems on the station. Furthermore different generations of sensors can be run in parallel and therefore cross calibrated if needed. This paper reviews the currently available sensors types and discusses potential future needs. Included in this discussion is the international space station as an already available platform for earth observation. Furthermore, discussion should also take into account, that an increasing number of constellations with dozens or even thousand satellites are planned. Are these constellations also an option for an increased temporal and spatial monitoring of the Earth?

A0.4-0019-19 ESA'S EARTH OBSERVATION PROGRAMMES IN THE CONTEXT OF SPACE

4.0 AND WITH A VIEW TO THE CHANGING ANTHROPOCENE

Josef Aschbacher, josef.aschbacher@esa.int European Space Agency, ESRIN, Frascati, Italy Michael Rast, michael.rast@esa.int

ESA, Frascati, Italy

The Earth system behaves as a single, highly coupled system comprising physical, chemical and biological components and processes, on which humanity is having significant effects. There are complex interactions and feedbacks between the Earth system components that cut across disciplinary boundaries of the Earth sciences and take place over a wide range of spatial and temporal scales. Even in the absence of external forcing, the Earth system exhibits considerable natural variability, which needs to be understood and distinguished from human-induced trends.

The societal challenges that humankind faces require a strategic and sustained response also in the view of new Earth Observation techniques such as data analytics and artificial intelligence, as well as the advent of Big Data. This presentation will give an overview of ESA's Earth Observation programmes with its major 'pillars', its relevance to studying the anthropocene and provide a look into the future in the context of Space 4.0.

ESA's Earth observation missions are mainly grouped into three major categories: The operational Sentinel satellites in the context of the European Copernicus Programme, the scientific Earth Explorers and the meteorological missions, which ESA is jointly developing with Eumetsat. Developments, applications and scientific results for the different mission types will be addressed, along with overall trends and strategies.

The Earth Explorers, who form the science and research element of ESA's Living Planet Programme, focus on the atmosphere, biosphere, hydrosphere, cryosphere and Earth's interior. The Earth Explorers also aim at learning more about the interactions between these components and the impact that human activity is having on natural Earth processes.

The Sentinel missions provide accurate, timely, long term and uninterrupted data to provide key information services, improving the way the environment is managed, and helping to mitigate the effects of climate change. The operational Sentinel satellites can also be exploited for scientific studies of the anthropocene. ESA's meteorological programmes include the geostationary (Meteosat) and low-Earth polar orbit Meteorological Operational (MetOp) satellites, both of which have been developed in cooperation with Eumetsat. In the anthropocene human activities affect the whole planet and space is a very efficient means to measure their impact, but for relevant endeavours to be successful they can only be carried out in international cooperation. ESA maintains long-standing partnerships with other space agencies and institutions worldwide. In running its Earth observation programmes, ESA responds to societal needs and challenges and to requirements resulting from political priorities set by decision makers. Activities related to Climate Change are a prime example. Within ESA's Climate Change Initiative, Essential Climate Variables are constantly monitored to create a long-term record of key geophysical parameters.

Chapman University, Orange, California, United States Akhilesh Gupta, akhilesh.g@nic.in

India

Glacier mass balance is treated as the proxy for understanding the impact of changing climate hence it is one of the essential variables required for climate system monitoring. The study represents the six years of annual mass balance using most accurate glaciological measurements on the Naradu glacier, western Himalaya. To support this result an energy balance model based on meteorological parameters like air temperature, wind speed, net radiation etc. have been used to compute mass balance. This study also finds the robustness of the energy balance model over the glaciological method. The glaciological mass balance for 2011-17 has shown a continuous negative specific balance of -1.09, -1.15, -0.86, -0.79, -0.72 and -0.41 meter water equivalent (m w.e.) during respective years of 2011-2017 showing decrease in the negativity of mass loss. The calculation of energy balance also shows the negative mass balance of -1.36, -0.92, -0.79 and -0.68 m w.e. for the year 2012-13, 2013-14, 2015-16 and 2016-17 respectively showing the reducing trend of mass loss. The mass balance deduced by energy balance model is very closely in agreement with the glaciological mass balance. The continuous negative mass balance in the region is reflecting the influence of the weather parameters especially the high net radiation along with the increasing temperature in the region are the major controlling factors for glacier mass balance.
Key words: Climate change, Mass balance, Energy Balance, Western Himalaya, increasing temperature and Naradu Glacier

A0.5-0002-18 CLIMATE CHANGE AND ITS IMPACT IN WESTERN HIMALAYA (NARADU VALLEY)

India

Present study uses MERRA data to analyse the trend of temperature and snowfall for the period of 1979/80 to 2012/13 in Naradu Valley, western Himalaya. An attempt has also been made to find the snowline by establishing a multiple regression equation by taking annual temperature and precipitation and corresponding snowline of few years into consideration. Long-term trend direction and magnitude of change over time (annual and seasonal) were detected and analyzed by Mann-Kendall test, Spearman Rank Correlation, Sen's slope estimator and Sequential MannKendall (SQMK) test. Temperature trend analysis shows the rise of 0.9 C whereas snowfall trend analysis shows decrease of 112.03 cm and the estimated annual snowline shows an increase of 75.65 m for study period. All statistical tests show significant increase in annual temperature and snowline data whereas significant decreasing trend was found in annual snowfall data. SQMK test shows that 1997/98 is the beginning of the change point for temperature and snowline whereas this test fails to deduct any beginning of the change point in case of snowfall.

Key Words: Climate Change, Temperature Trend, Precipitation Trend, Snowline Trend and Western Himalaya

A0.5-0003-18 RESPONSE OF HIMALAYAN GLACIERS TO CLIMATE CHANGE

Debmita Bandyopadhyay, b.debmita@gmail.com Indian Institute of Technology Bombay, Mumbai, India Gulab Singh, gulab.singh@iitb.ac.in

Indian Institute of Technology Bombay, Mumbai, India

Climate change is a natural phenomenon, but the rate at which it is happening is completely unprecedented. This accelerated rate has been attributed to anthropogenic sources like fossil fuel burning, industrial activities, wildfires as a part of land management etc. To monitor the effect of climate change on the natural resources, glaciers form one of the best models of study owing to their sensitivity towards changing climate. Although the glaciers constitute only 1% of the supply to the freshwater system, they are one of the major contributors to the sea-level rise today. Further, Indian Himalayas have been established to have a major contribution when this cryosphere component (Mountain glaciers) is taken into consideration. For understanding the effect of climate change, long-term glacier studies i.e. continuous monitoring is required. However, the rugged terrain and steep slopes render it impossible to carry out ground-based surveys at regular intervals especially in the Himalayan terrains. Remote sensing has the advantage of providing a synoptic coverage on a multi-temporal scale. Apart from long-term monitoring, there is a need for prediction of future scenarios as well. With the help of climate modeling, the dynamics of the glaciers can be simulated in real-time. But, for modeling the future scenarios of the glacier dynamics, certain specific parameters of the glacier are required. For example, terrain slope, thickness change, mass balance, and local temperature and precipitation conditions. With the advent of high spatial resolution dataset both in optical (ALOS AVNIR and Sentinel: 10m) and microwave (TerraSAR-X/TanDEM-X: 7m), most of these above-mentioned parameters can be well estimated, which can act as an input for the developed climate models. In this paper, we present a time-series analysis of glacier attributes such as elevation change and mass balance with a level of accuracy comparable to ground measurements. This shows the applicability of the remotely sensed data as a useful alternate even for the highly steep topography of the Himalayas. Hence, this study would facilitate studies for assessing the contribution of the Indian Himalayas towards the melt-water for the early twenty-first century and eventually help quantify the sea-level rise at a global scale.

A0.5-0004-18 ASSESSING WATERCOURSE REHABILITATION PROGRAMS IN SINDH USING GEOSPATIAL TECHNIQUES

Pakistan

Indus Basin Irrigation System (IBIS), the largest contiguous irrigation system of the world, loses around 41 percent of its total water derived from the river through seepage and leaks. About 40 percent of this loss is through the tertiary channels called watercourses. To encounter this problem, the irrigation system rehabilitation programs in Pakistan, including National Program for Improvement of Watercourses (NPIW) and Sindh On-Farm Water Management Project (SOFWMP), were initiated focusing on improvement of canal system at the watercourse level. Under these programs more than two third of the total watercourses have been improved in the province of Sindh. In this paper, a study is presented that evaluated the effectiveness of these programs in Sindh. Changes in the cultivable command areas before and after the improvement work and the availability of water at the tail end have been selected as the efficiency indicators of the improved watercourses in Larkana, Mirpurkhas, Khairpur and Thatta districts. Relevant data were acquired from National Program for Improvement of Watercourses (NPIW), Pakistan Space and Upper Atmospheric Research Commission (SUPARCO) and Sindh irrigation department. Google Earth archive images of 2004 and 3013 were utilized to identify the changes in the cultivable command areas of the watercourses. A recognizable expansion in the cultivable lands in the command areas of the improved watercourses was identified. Study results were validated from field survey in which farmers' point of view regarding the effectiveness of the improvement programs were recorded. Majority of the farmers and landowners were found satisfied with the improvement work and confirmed the availability of water at the tail end. They also endorsed the study results in terms of increased cultivable command areas.

A0.5-0005-18 APPLICATION OF SATELLITE REMOTE SENSING TO OBSERVE AND ANALYSE TEMPORAL CHANGES OF COCOA PLANTATION IN ONDO STATE, NIGERIA.

Emmanuel Dada, vissitemma@gmail.com

Adekunle Ajasin University, Akungba-Akoko, Ondo State, Akungba Akoko, Nigeria

This study examined the changes in the area of land occupied by cocoa plantation in Ondo state in order to provide useful and adequate information for effective agricultural policy to increase cocoa yield as the leading export agricultural commodity in Nigeria. Satellite remote sensing technique was employed using satellite imagery of year 2000, 2002, 2014 and 2015 respectively acquired from Landsat-7 ETM+ and Landsat-8 TIRS. The land cover of the study area was classified into six classes of cocoa plantation, forest, light forest and grassland, water body, bare surface and rock outcrop as well as settlement area. The result revealed that cocoa plantation occupied 31.3% in 2000, 32.7% in 2002, 41.4% in 2014 and 41.6% in 2015 respectively which depicts gradual increased in the area of land covered by cocoa plantation and its yield at the expense of other land cover classes which prove the potency of this tree crop of generating huge amount of foreign earning for supplementing revenue derived from crude oil in Nigeria. Key words: cocoa plantation, satellite imagery, land cover classes, change in area of land.

A0.5-0006-18 IMPACT OF LOWER TROPOSPHERIC STABILITY ON THE REGIONAL VARIABILITY OF INDIAN SUMMER MONSOON RAINFALL

Hrudya P.H, hrudya.ph@gmail.com

Sree Krishna College, Guruvayur (University of Calicut), Kerala, India, Thrissur, India Hamza Varikoden, hamzavarikoden@gmail.com

Vishnu R, vishnuplr@gmail.com

Sree Krishna College, Guruvayur, Thrissur, Kerala State, India

Asian summer monsoon that mainly affects India and its surrounding regions during June to September and that contribute more than 75% of the annual total rainfall. It exhibits large variability on temporal scale ranging from diurnal to multidecadal. In addition to the temporal fluctuations, rainfall exhibits spatial fluctuations manifesting the higher amount of rainfall in the west coastal belts and northeast regions of India and less amount of rainfall in the northwest and southeast regions. These variabilities are influenced by many factors from topography to oceanic and atmospheric factors including teleconnections. So studying the variability of summer monsoon rainfall especially in regional scale is very important and useful to the Indian society and thus to the economy. This paper mainly aims to explore the regional variability of Indian summer monsoon rainfall especially over west coast, north east, north west and central India for the period 1948-2016, by identifying its relationship with the lower tropospheric stability (LTS) and moisture flux over the monsoon domain. LTS and moisture flux are calculated using wind, potential temperature, humidity at different atmospheric levels form NCEP/NCAR reanalysis data set during the period 1948 to 2016. The variations in LTS have a major impact on cloud fraction and thus the summer monsoon rainfall. The moisture flux is a measure of amount of water in the atmosphere to precipitate and hence that can be correlated for different regions to explore the ideal relationship with rainfall. We used CRU rainfall data for the same period to evaluate the variability during the summer monsoon season. We found that the linkage between the LTS and rainfall is nonlinear in space and time. The LTS is negatively correlated with rainfall over Western Ghats, however, positive correlation is observed with rainfall in other Indian regions. Therefore, it can be concluded that relation between lower atmospheric stability with monsoon rainfall and moisture flux during the monsoon period is different over different regions with different influencing mechanisms.

A0.5-0007-18 POLLUTION PLUMES TRANSPORTED FROM EASTERN GHAT AND INDOGANGETIC PLAIN AFFECTING MARINE AIR QUALITY OVER SUNDARBAN AT THE NORTH-EAST COAST OF BAY OF BENGAL

Abhinandan Ghosh, abhinandan1011@gmail.com Bose Institute, KOLKATA, India

Abhijit Chatterjee, abhijit.boseinst@gmail.com Bose Institute, Kolkata, India

Arindam Roy, arindamroy115@gmail.com Bose Institute, Kolkata, India

Sanjay Ghosh, sanjay@jcbose.ac.in Bose Institute, India

Sibaji Raha, sibaji.raha@jcbose.ac.in Bose Institute, India

A study was conducted on the interaction between the marine and the anthropogenic aerosols over remote and pristine Sundarban mangrove forest at the north-east coast of Bay of Bengal. Size segregated aerosols were collected using a nine stage cascade impactor over Sundarban mangrove forest during winter, 2014 and premonsoon, 2015 and 2016. Collected samples were chemically analyzed for major water soluble ionic spices using Ion Chromatograph. The degree of interaction was quantified through the chloride depletion from sea-salt particles originated from the Bay of Bengal It was observed that the chloride depletion occurred mostly in ultra fine (UFP, Dp < 0.4 μm), accumulation (AP, 0.4<Dp<1.1 μm) and super fine (SFP, aerodynamic diameter, Dp, 1.1<Dp<2.1 μm) mode compared to the coarse mode (CMP, 2.1<Da<10 μm) particles. Satellite observation revealed the presence of elevated smoke, polluted dust and marine aerosol over the region during pre-monsoon. Air mass back trajectories have shown the influence of biomass burning plumes transported from Eastern Ghat regions on the size distribution of aerosols during premonsoon. High loading of non-sea-SO42- and NO3- was observed over this marine ecosystem with their significant contributions to the depletion of chloride from sea-salt particles. In addition to the transported biomass burning plumes from Eastern Ghat, anthropogenic aerosols were also found to be highly loaded over the region transported from the highly polluted Indo-Gangetic Plain (IGP) during winter. Overall we observed that pollution plumes from Eastern Ghat regions and the Indo Gangetic Plain regions significantly affected the pristine marine ecosystem.

A0.5-0008-18 METHODOLOGY OF PROCESSING SATELLITE IMAGERY TO IDENTIFY OIL-DERIVED WATER POLLUTANTS

Piotr Walczykowski, piotr.walczykowski@wat.edu.pl Military University of Technology, Warsaw, Poland Anna Fryskowska, anna.fryskowska@wat.edu.pl Military University of Technology, Warszawa, Poland Michal Kedzierski, michal.kedzierski@wat.edu.pl Military University of Technology, Warsaw, Poland

Emilia Wasilewska, emilia.wasilewska@student.wat.edu.pl Military University of Technology, Warsaw, Poland

Publication presents determination of optimal methods for processing satellite imagery to provide information on marine oil derivative pollutants. As a part of the research, a series of operations were conducted to extract thematic information about the oil spill. Starting from techniques that improve the visual properties of the interpretation and ending with semi-automatic techniques or automatic extraction of thematic information.

The comparative analysis of the methods used was directed both at the effectiveness and speed of their execution. Multispectral data recorded by the ETM + sensor was used for the purposes of the research. Processes were conducted to enhance the content of individual images as well as the full set of channels. Information about the oil spill was extracted on the basis of acquired imagery. The result of the research is the selection of optimal Landsat 7 satellite spectral channels for detecting crude oil in the marine environment and the selection of the best digital image processing methods to extract leak information from the image. The information obtained, allowed to determine the location of oil spots, and also confirmed the usefulness of Landsat images recorded in SLC-off mode for performing such analyzes.

A0.5-0009-18 NOVEL METHOD OF SATELLITE IMAGE CORRECTION FOR MULTI-TEMPORAL ANALYSIS OF ENVIRONMENTAL CHANGES PURPOSES

Michal Kedzierski, michal.kedzierski@wat.edu.pl Military University of Technology, Warsaw, Poland Aleksandra Grochala, aleksandra.grochala@wat.edu.pl Military University of Technology, Warsaw, Poland Anna Fryskowska, anna.fryskowska@wat.edu.pl Military University of Technology, Warszawa, Poland Piotr Walczykowski, piotr.walczykowski@wat.edu.pl Military University of Technology, Warsaw, Poland

Multi-temporal, long-term environmental analyzes require imagery that are diverse in terms of spatial, radiometric and spectral resolution. Satellite imagery acquired with various sensors over more than 30 years are usually used for such analysis. To carry out analyzes it is necessary to perform the correction of archival images. The classical radiometric correction (including solar, topographic and atmospheric correction) is not sufficient for correct analysis of such data set. The classic radiometric correlation is only the initial stage of the total correction of the set. In order for the results of multi-temporal analyzes to be reliable and more precise, it is necessary to bring the data to the same spatial, spectral and radiometric resolutions.

Resampling the spatial resolution in the context of multi-temporal analyzes of the environment is not the only process. Except that also the extraction of characteristic details to further analysis mandatory. The publication presents a new method of image resampling based on wavelet analysis. Resampling will standardize the resolution of the spatial set. In addition, spectral image resolution also plays an important role in the detection of environmental changes. It is crucial that the subsequent images have a similar spectral resolution. A new spectral resolution correction algorithm based on sequential fusion of images acquired in subsequent dates was proposed, where the resulting images are a weighted average of the data to be integrated. The weights depend on the content of spatial and spectral information in the processed images. As part of the research experiment, new corrected spectral channels of images were determined, the same for all images in a given integration sequence. The similarity of corrected images to original images is over 60%, which guarantees that important spectral information recorded in each subsequent image is preserved.

A0.5-0010-18 MONITORING OF CHANGES OF THE SHORELINE OF GLACIERS AND CONTINENTAL ICE SHEETS BASED ON ARCHIVAL AND MODERN OPEN SOURCE SATELLITE IMAGERY

Anna Fryskowska, anna.fryskowska@wat.edu.pl Military University of Technology, Warszawa, Poland Michal Kedzierski, michal.kedzierski@wat.edu.pl Military University of Technology, Warsaw, Poland Piotr Walczykowski, piotr.walczykowski@wat.edu.pl Military University of Technology, Warsaw, Poland Damian Wierzbicki, damian.wierzbicki@wat.edu.pl Military University of Technology, Warsaw, Poland Aleksandra Grochala, aleksandra.grochala@wat.edu.pl Military University of Technology, Warsaw, Poland

In the study of environmental changes, the continuous monitoring of land changes in the glacier is now a very important aspect. The use of correct archival data from the first remote sensing satellites is a key issue in the study of global environmental changes. Archival satellite data, in a sense, stand out from the modern images. The necessity to do the temporal analyzes based on these images and, consequently, the development of the shoreline of glaciers and ice sheets is only a seemingly simple task. When we want to achieve high accuracy, we need to apply the appropriate methods of image processing. Due to the low resolution of the open source satellite scene, an algorithm based on wavelet analysis for extracting shoreline details was proposed in the publication. This approach will enable accurate determination of changes in the coastline, which occurred over 30 years.

Because the shelf of ice shelf is getting smaller, the glacier that supports inland can slip off into the ocean faster and thus lose mass faster than it gains. This situation is referred to as the “negative mass balance” and it leads directly to the sea level rise. It is estimated that shelf glaciers are the most important factor affecting the stability of the Antarctic ice sheet. Therefore, thanks to the developed method, it will be possible to conducts detailed analysis and documentation of the changing coastline of glaciers, and this will enable research into the change of glaciers and oceans, which is of great importance to the modern world.

A0.5-0011-18 ANALYSIS OF THE POSSIBILITY OF USING POINT CLOUDS GENERATED ON THE BASIS OF ARCHIVAL SATELLITE IMAGERY IN ENVIRONMENTAL ANALYZES

Anna Fryskowska, anna.fryskowska@wat.edu.pl Military University of Technology, Warsaw, Poland Damian Wierzbicki, damian.wierzbicki@wat.edu.pl Military University of Technology, Warsaw, Poland Michal Kedzierski, michal.kedzierski@wat.edu.pl Military University of Technology, Warsaw, Poland Piotr Walczykowski, piotr.walczykowski@wat.edu.pl Military University of Technology, Warsaw, Poland

The paper presents an innovative method of a dense image matching of archival satellite imagery for the purposes of generating accurate point clouds representing Digital Surface Models (DSMs) of the Earth surface. On the basis of these point clouds advanced analyzes of environmental changes (eg. icebergs, glaciers, etc.) will be conducted. This approach will allow the development of accurate models of icebergs resulting from the division of the glacier and a comparison of this changes over time. For the ocean areas, no stereo images were ever acquired, but only this support 3D models production. We propose a novel algorithm that will allow to get a dense point cloud of a glaciers based on the Structure from Motion (SfM) algorithms. By using selected image matching descriptors, it will be possible to create the 3D surface geometry from archival satellite imagery. The proposed method will be effective also when satellite scenes will be acquired at different time. The article presents a new approach in obtaining 3D information based on dense image matching (DIM) in application to archival satellite imagery. Our method will be based on SIFT and SURF descriptors and the RANSAC algorithm. In the proposed solution, in each iteration RANSAC randomly selects several matched pairs of points to obtain the best matched transformation matrix. In the case when selected pairs of points are compatible with the matrix, they are treated as correctly matched. After many iterations, the transformation has the largest number of valid matches, which are treated as the final result of the algorithm. The proposed algorithm will allow to increase the accuracy of the accuracy of whole point clouds and 3D models developed on their basis. As a result of the experiment, based on the proposed algorithm, several DSMs were developed based on archival satellite imagery of Landsat. The comparative analyzes were carried out. The results of the experiment showed that the predicted accuracy of the models was 1-2 pixels of source images. Thanks to this approach, 30 years glaciers and icebergs can be analyzed now. It will also be possible to determine exactly how much glaciers have been melted with accuracy of a few meters (depending on the original spatial resolution of archival satellite imagery).

A0.5-0012-18 ESA'S SCIENCE DATA EXPLOITATION PROGRAMME

Jérôme Benveniste, jerome.benveniste@esa.int European Space Agency, Frascati, Italy

Diego Fernández Prieto, diego.fernandez@esa.int European Space Agency, Frascati, Italy

Yves-Louis Desnos, yves-louis.desnos@esa.int European Space Agency, Frascati, Italy

This paper will present the main opportunities and plans offered by ESA to the scientific community in the timeframe 2017-2021, where the scientific exploitation of the Sentinels represents a priority.

The Scientific Data Exploitation element represents the main instrument for scientific innovation of ESA exploitation activities, addressing the RD needs and requirements of the EO and Earth system science communities in terms of novel observations, advanced scientific tools, innovative retrieval methods and products and new Earth system science results.

The programme will be articulated through five main action lines:

Engaging International Science Communities ESA's structured dialogue with international EO science communities will be strengthened through regular series of dedicated conferences, thematic workshops and user consultations. EO scientists, Earth system scientists, and modellers will be brought to together in a continuous exchange of ideas. As a result various multidisciplinary expert communities will periodically assess the state-of-art in their fields and prepare research roadmaps jointly with relevant international scientific programmes, recommending priority topics for future ESA projects and work plans.

Developing Open Science Practices and Tools Open source science practices will be developed to enlarge the user base for European Earth Observation and broaden participation. EO data, information and tools will be made readily accessible to scientists from other fields. Open source scientific toolboxes will be developed to animate science communities, capitalising on various ESA multi-mission toolboxes experiences and assets. Citizen science and crowd-sourcing projects will be launched, as appropriate. On-line courses, science blogs and social media will address the general public. The EO applications platforms will be developed for these purposes.

Advancing EO Methods and Techniques Targeted research projects will develop cutting-edge methods, novel algorithms, new EO products, and extend the use of Earth Explorers into domains beyond their primary mission objectives. The overall aim is to stimulate widespread scientific use of open data from research and operational missions by pioneering the development of new EO methods to harvest the full scientific potential of these missions. When validated, such new techniques will be made available to other research communities and programmes, and new prototype products will be transferred to operational frameworks and systems.

Advancing Earth System Science The specific goal is to maximize the scientific impact of ESA and European missions in terms of new discoveries in Earth system science and thereby ensure a major ESA contribution to global Earth Science endeavours. Dedicated projects will research priority questions posed by international Earth System Science communities and will explore new research avenues opened up by the ESA EO science strategy. These activities will strengthen and extend ESA's cooperation with the major international global research programmes.

Translating Exploitation into Novel Mission Concepts The role of exploitation results as a catalyst for novel mission concepts and future observational principles will be reinforced. Projects will explore, develop, and consolidate the scientific aspects of novel mission concepts, and thereby stimulate ideas for future generation EO missions.

A0.5-0013-18 CLOUD CHARACTERISTICS OVER TIBETAN PLATEAU REVEALED BY CLOUDSAT AND GROUND-BASED W/KA CLOUD RADAR

Chinese Academy of Sciences, Beijing, China

Tibetan Plateau plays important role to local, eastern Asia and even global climate. To understand its function of dynamics, radiation and heat flux, water cycle, and surface emissions transpart via long range horizontal and terrian induced/convective transport from earth surface to the stratosphere, its is needed to investigate the cloud structure and their temporal and spatial distribution over the Tibet and surrounding area. Satellite observation, in particular Cloudsat, TRMM, and GPM have supplied systimatic products of cloud parameter for the Tibeten plateau and surrounding areas, including cloud vertical structure, macro and micro physical characteristics. Since 2018, a ground-based W/Ka cloud radar system with Doppler ability and dual-polarization has been deployed and started continuous observation at Yangbajing field observatory, a site near Lhasa with 4300 m ASL. In this paper we will analyze the satellite products combined with our surface-based radar observation and thus reveal the cloud characteristics over Tibet plateau, including regional, seasonal and diurnal variation. The function of clouds over Tibet will be analyzed.

SPACE STUDIES OF THE EARTH'S SURFACE, METEOROLOGY AND CLIMATE (A)

SPACE-BASED AND SUB-ORBITAL OBSERVATIONS OF ATMOSPHERIC PHYSICS AND CHEMISTRY (A1.1)

A1.1-0001-18 LONG TERM SURFACE TEMPERATURE CHANGES OVER INDIAN REGION AND SOLAR VARIABILITY

Nagaraja Kamsali, kamsalinagaraj@bub.ernet.in Bangalore University, Bengaluru, India

S.C. Chakravarty, chakravarty08@gmail.com Bangalore University, Bangalore, India

B.V. Appa Rao, bvarmv@gmail.com Bangalore University, Bengaluru, India

Variations of solar energetic electromagnetic and charged particle radiations are known to be correlated with the 11-year solar cycle of sunspot numbers. However, except for a specific period between 1645 and 1715 when the solar activity was very low (Maunder Minimum) associated with severely cold winter seasons also known as 'little ice age', the overall climate system of the earth does not show any statistically significant response to variations in solar activity. This paper deals mainly with a detailed investigation of possible correlation with long term surface-air temperatures. The grid point temperature data for 1970-2009 over the Indian region has been analysed along with solar activity parameters such as sunspot numbers, galactic cosmic ray fluxes (GCR) and El Nino Southern Oscillation (ENSO) indices. A better correlation of 0.21 has been seen between long term temperature change and GCR fluxes. The change in annual temperatures for the 40 year period is found to be about 0.5 °C over the whole Indian region with considerable latitudinal variation of ±0.2 °C with latitudes higher than 20° N showing greater warming signals. The mean annual temperature curve for the whole period shows higher frequency temperature excursions of ± 0.5 °C that are quite regular and present in all latitude regions with good coherence. These relatively short-period temperature variations need to be studied further for a better assessment of the warming due to climate change.

A1.1-0002-18 DETECTION OF SOLAR CYCLE SIGNAL IN THE TROPOSPHERIC TEMPERATURE USING COSMIC DATA

Vinay Kumar, dabas.vinay@gmail.com University of Delhi, Delhi, India Surendra Dhaka, skdhaka@gmail.com Delhi University, Delhi, India

Influence of the solar cycle on temperature structure is being investigated using radio occultation measurements by COSMIC/FORMASAT-3. Observations from January 2007 to December 2015 comprising of 37,64,728 numbers of occultations, which are uniformly spread over land and sea, have been used to study temperature changes mainly in the troposphere along with the solar cycle over 60°N - 60°S geographic latitudes. It was challenging to identify the height level at which the solar cycle signal can be seen in temperature perturbation as different atmospheric processes contributes towards temperature variability. Using high spatial resolution data set from COSMIC satellite we are able to detect signal of solar cycle in the mean temperature profiles near surface at 2 km and upward. A consistent rise in the inter-annual variation of temperature is observed along with solar cycle. The change in the temperature structure showed a latitudinal variation from southern to northern hemisphere over a period of 2007-2015 with a significant positive influence of sun spot numbers in the solar cycle. It is concluded that solar cycle induces the changes in temperature by as much as 1.5°C. However, signal of solar cycle in the stratospheric region could not be identified as the region is dominated by large scale dynamical motions like QBO which suppress the influence of solar signal in temperature perturbations due to its quasi-periodic nature.

A1.1-0003-18 MODELLING AND VALIDATION OF THE WEIGHTED MEAN TEMPERATURE IN THE TROPICAL REGION OF TAHITI: IMPLICATIONS FOR PRECIPITABLE WATER MONITORING

Fangzhao Zhang, zhaosunshine@163.com

Geodesy Observatory of Tahiti, Faa'a, French Polynesia Jean-Pierre Barriot, jean-pierre.barriot@upf.pf University of French Polynesia, Faaa, French Polynesia Guochang Xu, gcxu@sdu.edu.cn

Shandong University at Weihai, Weihai, China

Water vapor is the primary greenhouse gas in Earth's atmosphere, and is a key ingredient in climate modelling. Delays of propagation of GPS signals in the atmosphere are now routinely used as a tool to monitor the water vapor contents of the atmosphere, in the form of precipitable water (PW), as a complement to radiosounding (RS) measurements. One of the main parameter to obtain PW estimates from GPS Zenith Wet delays (ZWD) is the so-called weighted mean temperature (Tm), a weighted average of the troposphere temperature with respect to the water vapor contents over a given atmospheric column. Currently, the most used model is the linear model of Bevis et al. (1992) based on the surface temperature, but developed for mid-latitude regions. In this study, a new site-specific Tm model is proposed, specially tailored to tropical regions, based on the comparison of RS and ZWD data collected between January 2014 and

December 2016 in the Tahiti Island (149°25'W, 17°40'S) located in the South Pacific. Our

ZWD data was estimated by using the Bernese 5.2 package with VMF1/ECMWF dry model and VMF1 dry and wet mapping functions. We recomputed high precision PW RS from raw balloon data from Météo-France, up to altitudes of 25,000 m for the balloons. We show that, in our case, this new Tm model leads to a better estimation of the PW from GPS measurements than the standard Bevis et al. model. Finally, the correlation between the fluctuations of ENSO Index and the time series of PW are presented based on the local El Niño events.

A1.1-0004-18 DIURNAL VARIATION OF IWV VALUES OBTAINED FROM GNSS AND MERRA OVER CENTRAL AND SOUTH AMERICA

Amalia Meza, amalia.meza@gmail.com

Water vapor has an important role in radiative balance, hydrological cycle, in transport of large amounts of latent heat energy and instability and convective activity. Therefore, the quantity of the integrated of water vapor (IWV), along a vertical column, must be well known in order to understand, associate and forecast environmental processes. The IWV values obtained from Global Navigation Satellite System (GNSS) observations with a 30 minutes sampling allow us to have a better knowledge of water vapor variability at high frequency. The diurnal variations of IWV are studied in Central and South America region during the period 2007-2013. The analysis was performed in 69 GNSS tracking sites (GPS + GLONASS), which have more than 5 years of data. The selected area involves different climate types, from polar to tropical, with different diurnal variations of the integrated total humidity content. This study describes the main characteristics of the diurnal cycle obtained at every station by using Principal Component Analysis (PCA). Our results highlight the global main behaviors for all stations in its first and second PCA mode. They are are associated to the most relevant causes that induce diurnal variations in atmospheric water vapor: the surface evapotranspiration, atmospheric large-scale vertical motion and atmospheric low-level moisture convergence. Then, the diurnal cycle is analyzed for each stations separately. As a consequence seasonal and local variations that spotlight the breeze regime are detected among other characteristics. Afterwards, IWV values obtained from the reanalysis model MERRA (Modern Era Retrospective-Analysis for Research and Applications) produced by NASA are also analyzed using the same numerical procedure described before. We perform the first analysis of IWV diurnal anomaly realized in Central and South America, consequently our contribution is important to improve the knowledge of water vapor global variability in the Earth atmosphere. Besides, the numerical tool employed to isolate the before mentioned variabilities is also an original application in this topics.

Seven years (2007-2013) of Integrated Water Vapor (IWV) data derived from the geodetic processing of GNSS data (GPS + GLONASS) in Central and South America were regionally analyzed comparing it with respect to IWV values from two different reanalysis: the European Centre for Medium-Range Weather Forecast (ECMWF) reanalysis data (ERA Interim) and the Modern-Era Retrospective analysis for Research and Applications (MERRA2) from the National Aeronautics and Space Administration (NASA). Although the statistical analysis of the differences was performed in 110 GNSS sites, the most interesting results came from the 73 sites which have more than 5 years of data. The study was performed spatially discriminating not only areas that involve different climate types from polar to tropical, but also different topography characteristics by classifying the rank of geopotential height differences between the different data sets. Besides the comparison was also performed on several time scales: from hours to years. Finally a correction is suggested for the lack of consistency of IWV values from reanalysis in mountain areas. This work provides information about the regional performance of reanalysis models based on complex processes of assimilation of a large number of data from different techniques, in a region where the scarce coverage of operational radiosonde stations is noticeable. In addition, considering that atmospheric water vapor has a complex and variable distribution, and that its knowledge is essential for local meteorological studies and predictions, this study also provides information about IWV from GNSS as a source of data to improve simulations and forecasts in regional models.

A1.1-0006-18 VARIABILITY OF RELATIVE HUMIDITY IN THE TROPOSPHERE USING SAPHIR ON-BOARD MEGHA-TROPIQUES

K.N. Uma, urmi_nmrf@yahoo.co.in

Space Physics Laboratory, Vikram Sarabhai Space Centre, Trivandrum, India

The variability of global relative humidity (RH) and its distribution is studied during different seasons using a new global satellite, SAPHIR (Sounder for Atmospheric Profiling of Humidity in the Inter-tropical Regions) using data from 2012 to 2017. SAPHIR has six channels viz., S1(183.31±0.2), S2(183.31±1.1), S3(183.31±2.8), S4(183.31±4.2), S5(183.31±6.8) and

S6(183.31±11.0), that has peak contribution respectively in the six altitudinal layers viz., 1000- 850, hPa (layer-1), 850-700 hPa (layer-2), 700-550 hPa (layer-3), 550-400 hPa (layer-4), 400-250 hPa (layer-5), and 250-100 hPa (layer-6). The monthly mean of all the years during January and July shows the migration of Inter-tropical convergence zone (ITCZ). The tropical northern (southern) latitudes are found to have humidity higher than 90%, during July (January). The equatorial central pacific show dry compared to the other tropical regions. The upper tropospheric humidity (UTH) is high over the Indian and the surrounding oceanic regions compared to the other tropical regions. Further analysis is carried out by calculating Probability Density Function (PDF) by dividing the globe into different latitudinal sections extending from equator to the tropics in both the hemispheres. The distribution shows unimodal in the deep tropics and bimodal in the tropics. Further the analysis is also extended to delineate the difference in the distribution of RH during El-Nino and normal years. The details will be presented in the workshop.

A1.1-0007-18 ESTABLISHMENT OF A NEW RELATIONSHIP BETWEEN THE DYNAMICS OF THE INTEGRAL MOISTURE CONTENT OF THE ATMOSPHERE AND THE SEASONAL COURSE OF SECONDARY COSMIC RAYS (MUONIC COMPONENT)

Gavriil Pavlov, ganya1981@mail.ru

Institute of Cosmophisical Research and Aeronomy SB RAS, Yakutsk, Republic Of Sakha (Yakutia), Russia

This paper presents the first analysis to be carried out of the dynamics of the integral moisture content of the atmosphere (W) with the seasonal course of the muonic component of cosmic rays, as observed on the ground. The data of ERA-Interim reanalysis is used, which is based on regular meteorological observations, aerological and satellite information, as well as data from cosmic ray detectors of Yakutsk and Nagoya stations. A sufficient correlation value of the mean monthly moisture values for the year between the muonic component of cosmic rays has been found.

A1.1-0008-18 ASSESSMENT OF AMBIENT AIR POLLUTANTS LEVEL DURING ANTHROPOGENIC EPISODE I.E., DIWALI FESTIVAL ACTIVITIES OVER WESTERN SEMI-ARID TROPICAL SITE, UDAIPUR, INDIA

Brij Mohan Vyas, bmvyas@yahoo.com

Mohanlal Sukhadia University, Udaipur, Rajasthan, 313 001, India
Abhishek Saxena, saxenaabhishek85@gmail.com

Department of Physics, M.L.Sukhadia University, Udaipur-313 001, RAJASTHAN, India

The influence of fireworks display emissions of anthropogenic activity during the Indian Diwali festival on the ambient atmospheric gaseous as well as material pollutants levels, such as Surface ozone (O3), Nitrogen Oxides (NOX), Carbon monoxide (CO) and Suspended fine size particulate matters of size less than 2.5 µm (PM 2.5) have been assessed for main episode as well as before to after Diwali days as control daus over Udaipur i.e., a western Indian tropical typical urban and semi-arid site. The comparative study of derived air pollutant source identification parameters namely, angstrom absorption coefficient of Black Carbon (BC) (abs) and ratio of CO by NOx values have been investigated for direct influence of extra firework crackers, lightening due to various kind of burning of chemical materials in such specific human made activities. In overall, unusual degradation of ambient air quality level and altering the share of different air pollutant emission source types of burning materials such as biomass and fossil fuel ignition materials are more visible, especially at night time Diwali festival event in relative to their in sunlight hours. A significant enhancement by three to four time folds in the average daily PM2.5 levels (about 165 µg m-3) is unusually recorded especially in the Diwali day relative to their respective normal days values, which is exceeding more than four time value above from the healthy NAAQSL of PM2.5 concentration, (ii) during main Diwali celebration activity period, of sunset to pre midnight hours, the magnitude of NOx, CO and O3 along with abs and ratio of CO to NOx showed remarkable enhancement by 1.5 to 3 times higher as compared to those of their normal day level in the same interval. It obviously gives an clear manifestation about the modulation in origin as well as changes in the anthropogenic source strength. But, their prevailed maximum amount of air pollutants gas species in Diwali episode do not reach to go beyond above from their already reported peak values of O3, CO and NOx at major polluted, populated and urban industralised regions. Moreover, during sunlight hours, the elevated level of averaged O3 value only is also recorded as high as the high their extreme value of 67.5ppbv in Diwali eve period, which is greater than double value relative to their observed values on the similar interval on non-festival days, (vi) a wide temporal variations in air pollutant source discrimination parameter values, such as abs and CO/NOx segregated based on the magnitude of above 1.1 and 150, respectively, have given an evidence and clear insight in changing the potential origin of air pollutant source emission materials characteristics in the night and day-time festival celebration. The majority observed abs

values above 1.1 and CO /NOx exceeding of 150 gave an obvious indication and support of the view of predominant nature of production of atmospheric pollutants due to bio-mass and bio-fuel activity emission processes in Diwali episode, while in non festival period, their calculated values are found to be lower than above the prescribed limit magnitude and, hence, gave the confirmation of the predominance abundance of the inefficient combustion of fossil fuel ignition materials.

A1.1-0009-18 MESOSCALE MODELING OF SEA BREEZE INDUCED CONVECTION OVER SOUTH EAST COAST OF INDIA

Jyoti Bhate, jnbhate@gmail.com

National Atmopsheric Research Laboratory, Chittoor, India Amit Kesarkar, amit@narl.gov.in

National Atmopsheric Research Laboratory, Chittoor District, India

Sea breeze is a mesoscale phenomenon occurs over coastal region. The dynamic interactions of sea breeze with the prevailing synoptic flow can give rise to meteorological conditions conducive for the occurrence to the convection over coastal and adjoining regions. We have studied sea breeze cases over the south-east India using the satellite data and its mesoscale modeling with the objective of understanding the underlying physical mechanism of initiation of such convection. A set of meteorological observations obtained from microwave radiometer profiler, eddy covariance flux tower system, satellite sounder and imager observations and Doppler weather radar, are used for investigating the convection genesis characteristics. In conjunction with observations, to bridge the gap of lack of high-resolution spatial observations, the high-resolution (2km) model analysis is developed using Weather Research and Forecasting (WRF) model and four-dimensional variational data assimilation technique. The analysis of thermodynamical and dynamical indices carried out from the model analysis as well as insitu and satellite observations. The results obtained from these studies indicated the presence of a wind discontinuity line, and a warm air advection from the north Indian region towards south-east coast, causes the boundary layer hot dry and convectively active. We found that the inland penetration of sea-breeze front caused advection of moist and cold air over warm and dry region. It leads to convection and thunderstorms over the coastal region. Different physical mechanisms will be discussed in this presentation. The study has potential implications in identifying and early prediction of thunderstorms.

A1.1-0010-18 UPPER TROPOSPHERIC OZONE TRANSPORT FROM THE SUB-TROPICS TO TROPICS OVER THE INDIAN REGION DURING ASIAN SUMMER MONSOON USING SPACE BORNE AND IN SITU OBSERVATIONS

Siddarth Shankar Das, dassiddhu@yahoo.com

Space Physics Laboratory, Vikram Sarabhai Space Centre, Trivandrum, India Suneeth K V, suneeth07kv@gmail.com

Systems Engineering & Assessment Ltd., Trivandrum, India Madineni Venkat Ratnam, vratnam@narl.gov.in

National Atmospheric Research Laboratory, Tirupati, India

In this study, we investigate the role of Asian summer monsoon (ASM) anticyclone in the ozone distribution over the tropical Indian region using Microwave Limb Sounder (MLS) onboard the Aura satellite and in situ ozonesonde observations. We present the horizontal and vertical structure of ozone in the upper troposphere and lower stratosphere (UTLS) region. In addition, the role of tropical tropopause derived from the vertical profiles of temperature obtained from the "Constellation Observing System for Meteorology Ionosphere and Climate" (COSMIC) satellite in the distribution of ozone in the UTLS region is also investigated. Results show that the ASM anticyclone region has low ozone, more water vapour, high cold-point tropopause (CPT) altitude, and low CPT pressure, compared to the other ASM regions during boreal summer. Southern side of ASM anticyclone, i.e. the tropical Indian region shows a remarkable high ozone concentration in the UTLS region during summer. Ozone concentration in the upper troposphere increases with strength of the tropical easterly jet, which is an outcome of the ASM phenomena. The mechanism responsible for the enhancement of ozone concentration in the UTLS region over the tropical Indian region has been discussed in this paper. The in situ ozonesonde observations from six Indian stations also support the space-based AuraMLS observations, concluding that ASM anticyclone effectively transport ozone from the midlatitude stratosphere to the tropical upper troposphere over the tropical Indian region. The detailed results will be presented in the upcoming symposium.

A1.1-0011-18 BENCHMARKING CHEMISTRY-CLIMATE MODELS' TOP-OF-ATMOSPHERE FLUX IN THE 9.6-MICROMETER OZONE BAND USING AURA TES INSTANTANEOUS RADIATIVE KERNEL

Le Kuai, kl@gps.caltech.edu

University of California, Los Angeles, Los Angeles, Wyoming, United States

Increases in tropospheric ozone from pre-industrial to present day add radiative forcing (RF) to the climate with a widely range of estimates from +0.2 to +0.6 Wm-2 by IPPCC chemistryclimate models. About 80% of O3 RF is due to O3 longwave absorption and 97% of this longwave absorption is in the 9.6-m O3 band [Rothman et al., 1987]. The global outgoing fluxes at the top-of-atmosphere (TOA) over 9.6-m ozone band have strong geographic and seasonal variations. The variations of TOA fluxes highly depend on the distributions of ozone, water vapor, air temperature, and surface temperature. The biases in these quantities are sources of biases in both the O3 band TOA flux and O3 RF. Benchmarking present day O3 band flux is the first step for understanding climate feedbacks from O3 forcing.

An instantaneous radiative kernel (IRK) represents the sensitivity of TOA fluxes to the vertical distributions of the geophysical variables, such as ozone, water vapor, temperature, and so on. The products of 9.6-m ozone band IRK for ozone, water vapor, air temperature, surface temperature, and etc., have been developed with observations by AURA TES and could be extend the record by MetOP-IASI and SNPP-CrIS Fourier Transform spectrometer (FTS) measurements. In this study, we demonstrate the method of using the observations of tropospheric compositions, atmospheric state, and IRK from TES to attribute the biases of the fluxes in a suite of CCMI models to these key parameters. In this way, we show the TOA flux biases differs significantly between models and for different reasons. We found the principle contributors governing the variation for each model are under different processes or over different regions, and also provided quantitatively estimates of the influence from ozone, water vapor, and temperature bias in models.

A1.1-0012-18 MONITORING OF UNUSUAL OUTGOING LONGWAVE RADIATION (OLR) DURING THE MAY, 2015 NEPAL EARTHQUAKE USING SATELLITE OBSERVATIONS

Suman Chakraborty, suman.chakrabarty37@gmail.com Indian Centre for Space Physics, Kolkata, India Sudipta Sasmal, meet2ss25@gmail.com

Indian Centre for Space Physics, Kolkata, India Sandip Kumar Chakrabarti, chakraba@bose.res.in

S.N. Bose National Centre for Basic Sciences, Kolkata, India Arnab Bhattacharya, arnabseacom@yahoo.com

Indian Centre for Space Physics, Kolkata, India

Earthquake preparation processes start within the earthquake preparation zone much prior to the occurrence of the main event. The preparation processes begin from the ground surface and can be detected from different layers of the atmosphere with a time delay from the ground surface to upper heights. There are several channels through which this coupling process, generally termed as the Lithosphere-Atmosphere-Ionosphere Coupling (LAIC) mechanism can happen, such as the thermal channel, the electromagnetic channel, the acoustic channel and the chemical channel. Outgoing Longwave Radiation (OLR) is an important parameter for understanding this LAIC mechanism. In the present study, we monitored the OLR data as archived by NOAA satellites, prior, during and after the major earthquake that took place in Kodari, Nepal on May 12, 2015 with Richter scale magnitude M = 7.3. The data was downloaded from NOAA website on a two degree grid basis with a temporal extent of 45 days from April 16, 2015 to May 30, 2015. This exercise was done because the May earthquake was preceded by another major earthquake on April 22, 2015 with Richter scale magnitude M = 7.9. As the April earthquake was followed by several aftershocks that might get superimposed with the May earthquake, the data was downloaded for that period also and the spatial extent was chosen to include both the epicenters. 'Eddy field calculation mean' was performed on the data and singularities in the daily Eddy field around the earthquake epicenters was found two/three days before both the earthquakes that exhibited a general trend of fading away after the events. The OLR data for the whole month of January, 2015 was also analyzed to check its distribution over the same operational area during a seismically quiet scenario and the values were found to be pretty low. Thus, the sudden intensification of the Eddy field just few days prior to the earthquake days and their fading away after the events can be attributed to the release of a huge amount of energy during the earthquakes.

A1.1-0013-18 3D TOMOGRAPHY OF UTLS WITH GLORIA IR LIMB SOUNDER: TECHNIQUES AND SOME RECENT RESULTS

Lukas Krasauskas, l.krasauskas@fz-juelich.de

Forschungszentrum Jülich, Institute of Energy and Climate Research (IEK-7), Jülich, Germany Joern Ungermann, j.ungermann@fz-juelich.de

Forschungszentrum Juelich, Juelich, Germany Michael Höpfner, michael.hoepfner@kit.edu

Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany Felix Friedl-Vallon, felix.friedl-vallon@kit.edu

Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany Peter Preusse, p.preusse@fz-juelich.de

Forschungszentrum Juelich, Juelich, Germany Martin Riese, m.riese@fz-juelich.de Forschungszentrum Jülich, Jülich, Germany

The Gimballed Limb Observer for Radiance Imaging of the Atmosphere (GLORIA) is an aircraft-based Fourier transform spectrometer with a 2D detector array jointly developed by Forschungszentrum Jülich and Karlsruhe Institute of Technology. The measured IR spectra can be used to retrieve air temperature and volume mixing ratios of various trace gases. GLORIA can be panned between 45° and 135° w. r. t. the flight direction. Using this capability and/or flight paths that encircle the observed atmospheric region, multiple measurements of the same air mass are performed, allowing for 3D tomography of the atmosphere with a vertical resolution down to 250 m and horizontal resolution of around 25 km.

3D tomography is a large ill-posed inverse modeling problem, which requires the introduction of some general prior knowledge about the atmosphere by means of a regularisation algorithm. We present a physically motivated (without unphysical ad-hoc parameters) variant of Tikhonov regularisation based on first-order and second-order spatial derivatives. It is implemented efficiently using irregular grids and Delaunay triangulation. Compared to simpler, ad-hoc Tikhonov regularisation schemes, this approach requires less parameter tuning for each use case and has some advantages in retrieval quality.

GLORIA instrument flew aboard the German HALO research aircraft during the Wave Driven Isentropic Exchange (WISE) measurement campaign held in Ireland in September/October 2017. Among other phenomena, Rossby-wave breaking events were observed on multiple flights, some of them showing a lot of stirring, filamentation, strong tropopause inversion layers and wet air masses lifted to high altitudes by warm conveyor belts. We present some of the data products, including HNO3, O3, and water vapour volume mixing ratios both as 2D curtains and 3D tomographic retrievals. These results can be used to quantify the

length scales of filamentation and mixing. Several cross-sections of some filaments were recorded over the course of the two flights, allowing for analysis of their development timescales as well as possible identification of transport pathways.

A1.1-0014-18 LATITUDINAL IMPRESSIONS OF QBO VARIABILITY AND ITS ASSOCIATION WITH TEMPERATURE IN THE UPPER TROPOSPHERE OVER A PERIOD OF 2007-2017 USING COSMIC SATELLITE DATA

Surendra Dhaka, skdhaka@gmail.com Delhi University, Delhi, India

The effect of Quasi-Biennial Oscillation (QBO) on the temperature of cold point tropopause (T-CPT) and its height (H-CPT) is being investigated using radio occultation measurements by

Constellation Observing System for Meteorology, Ionosphere and Climate (COSMIC/FORMOSAT3)during 2007-2017. The disruption of QBO in temperature data during 2016, which is unprecedented, is shown. In general, T-CPT is found to be the coldest in February and warmest in August. The H-CPT also shows a maximum between December and February and minimum during July -August in both the hemispheres. Interestingly, however, the H-CPT shows off-equatorial maxima (beyond 20°N or 20°S) as we move from equator to middle latitude in both the hemispheres during all the seasons. The increase in H-CPT at off-equatorial region is higher (1.0 km) during Northern Hemisphere (NH) winter as compared to monsoon season (0.5 km). Inter-seasonal variation in T-CPT and H-CPT is found to be clearly influenced by QBO wherein the westerly (easterly) phase favors warm (cool) T-CPT with a decrease (increase) in H-CPT. It is concluded that QBO induces the changes in T-CPT by as much as 2°C and in H-CPT by 0.5 km. Unique feature of QBO over the different longitude sector are observed. The feature of QBO over the different longitude sectors shows the great potential of COSMIC mission.

A1.1-0015-18 ENHANCED DAYTIME OCCURENCE OF CLOUDS IN THE TROPICAL UPPER TROPOSPHERE AND OBSERVATIONAL EVIDENCE FOR RADIATIVELY DRIVEN CONVECTION

Space Physics Laboratory, Vikram Sarabhai Space Centre, Thiruvananthapuram, India

The space-borne active sensors (e.g., CloudSat and CALIPSO) enable direct observation of the global 3-dimensional distribution of clouds. While the CloudSat observation can provide the 3-dimensional structure and evolution of thick clouds, the CALIPSO can provide information on the vertical profile of thin clouds. A combined product of CloudSat-CALIPSO has the potential to provide a more comprehensive picture of the clouds. These satellites data are used to address the day-night changes in the occurrence of clouds in the tropical upper troposphere. This study investigates:(i) contrasting day-night variations in the altitude distribution of optically thick tropical convective clouds in the upper troposphere and the convective region, and (ii) cloud radiative heating rates and their potential impact on the enhanced daytime vertical growth of clouds in the upper troposphere. It has been observed that the combined occurrence of all cloud types maximizes in the nighttime throughout the middle and upper troposphere. However, the CloudSat observations reveal contrasting day-night variations in the frequency of occurrence of clouds in the upper troposphere (above sim12 km) and below. While the altitude region below sim12 km exhibit a pronounced nighttime peak in cloud occurrence, the upper tropospheric cloud occurrence above sim12 km shows a distinct enhancement during the daytime over both land and oceanic regions. Enhancement during the daytime arises from the more frequent occurrence of thick cirrus and deeper penetration of daytime convective clouds to the upper troposphere, as evidenced from larger probability of occurrence of deep convective clouds having thickness of sim9-16 km during the daytime. Further to this, the magnitudes of the net cloud radiative heating rate and its vertical gradient in the upper troposphere are largest and the altitude of peak cloud radiative heating is highest during the daytime in all seasons. These are conducive for the occurrence of thicker cirrus as well as deeper penetration of convection in the upper troposphere. The above inferences are further supported by the mean vertical wind profiles derived from reanalysis data. These observations illustrate the role of radiationinduced convection in the vertical growth of convective clouds to the upper troposphere during the daytime.

A1.1-0016-18 RELATIVE ROLE OF CONVECTION AND DYNAMICS IN MAINTAINING UTLS AEROSOLS AND TRACE GASES OVER INDIAN REGION OBSERVED BY GROUND BASED AND SPACE BORNE MEASUREMENTS

Madineni Venkat Ratnam, vratnam@narl.gov.in

National Atmospheric Research Laboratory, Tirupati, India ARTG

M. Venkat Ratnam, Ghouse Basha, B.L. Madhavan, V. Ravikiran, Chaithanya D Jain, M. Roja Raman, P. Prasad, S. Ravindra Babu, N. Narendra Reddy, A. Jayaraman and B.V. Krishna Murthy

Knowledge on the vertical distribution of aerosol and trace gases is essential to estimate its radiative effects on the atmosphere. Several studies have been carried out on the vertical and spatial distribution of these pollutants using both ground based and space borne observations. However, large uncertainity is still existing in considering the effect of aerosols on radiation budget, clouds, climate prediction due to limited observation data. We have investigated the long-term variabilities of the upper troposphere and lower stratosphere (UTLS) aerosols and trace gases (Ozone, Water Vapor, Carbon monoxide) over the Indian monsoon region (IMR) using the long term data constructed from multi satellite observations. We also make use of long-term data obtained from ground based lidars located at Gadanki (13.5oN, 79.2oE) to support the satellite observations. Special emphasis is given to see the variability of these aerosols and trace gases in the anticyclone region which will persist during ISM over the Indian region. A distinct maximum in the aerosols and all the trace gases has been noticed during monsoon season. Dominance of annual oscillation, quasi-biennial oscillation and ENSO is found in these UTLS pollutants suggesting that dynamics play major role on the vertical distribution of these pollutants. Transport of tropospheric aerosols and trace gases from boundary layer through tropical deep convection during ISM is thought to be the main mechanism for the observed enhancements in the UTLS region. However, detailed analysis suggests that the tropospheric aerosols undergo several removal mechanisms like rainout and wash out in the troposphere itself. If yet all any traces of these are remained, strong vertical shear in the horizontal wind arising due to monsoon level jet (at 850hPa) and tropical easterly jet (at 100 hPa) does not allow anything to penetrate above 500 hPa. Back trajectory analysis further revealed that the observed UTLS enchantments in these aerosol and trace gases are through the long-range transport. Difference in the aerosol types observed in troposphere and UTLS also confirms that they are not from below. This mechanism is true for complete south Indian region. However, deep convection persisting over head Bay of Bengal and north east part of India during monsoon season can be source for transporting boundary layer pollutants to the UTLS region which need to investigate separately.

A1.1-0017-18 PREFERRED SOLAR SIGNAL AND ITS TRANSFER IN THE ASIAN-PACIFIC SUBTROPICAL JET REGION

Delin Li, ldl@lasg.iap.ac.cn

Institute of Atmospheric Physics, Chinese Academy of Sciences, Beijing, China Ziniu Xiao, xiaozn@lasg.iap.ac.cn

Institute of Atmospheric Physics, Chinese Academy of Sciences, Beijing, China Liang Zhao, zhaol@lasg.iap.ac.cn

Institute of Atmospheric Physics, Chinese Academy of Sciences, Beijing, China

Solar impact on the tropospheric subtropical jet (SJ) has been identified previously from a zonally averaged perspective. The zonal mean SJ was observed to be weaker in the high solar activity winters. However, some regional features of solar-induced SJ variations might remain unrecognized. Here it is found that the regional solar signal in the wintertime Asian-Pacific zonal wind at 200 hPa, which exhibits a banded structure (i.e., easterly anomalies within the subtropics and westerly anomalies on the poleward and equatorward sides), greatly resembles the second internal mode of zonal wind within the same sector. Significant response of the Asian-Pacific SJ (APSJ) to solar activity in boreal winter exclusively marks its center region, showing a deceleration in westerlies. Further exploration suggests two possible top-down routes to interpret this particular manifestation of solar signal in APSJ center, a tropical route and a middle-high latitude route. Regarding the tropical route, during the cold season, driven by the solar-associated reduction in Brewer-Dobson circulation, ozone concentration in the tropical lower stratosphere increases evidently within the zonal range of APSJ center. This heats the air here and the tropical tropospheric regional upwelling is thereby suppressed. Consequently, a significant weakened APSJ center is produced via local Hadley cell. Regarding the middlehigh latitude route, in early winter, pronounced strengthened westerlies in the mid-latitude stratosphere created by solar forcing are confined to the longitudinal range of the APSJ center. As winter progresses, through wave mean flow interactions, a resultant weakened APSJ center markedly presents in the middle of winter.

A1.1-0018-18 A FAST VECTOR RADIATIVE TRANSFER MODEL FOR POLARIMETRIC REMOTE SENSING

Jiachen Ding, njudjc@tamu.edu

Texas A&M University, College Station, Texas, United States Ping Yang, pyang@tamu.edu

Texas A&M University, College Station, Texas, United States Michael King, michael.king@lasp.colorado.edu

University of Colorado, Boulder, Boulder, Colorado, United States Steven Platnick, steven.platnick@nasa.gov

NASA/GSFC, Greenbelt, Maryland, United States Kerry Meyer, kerry.meyer@nasa.gov

NASA/GSFC, Greenbelt, Maryland, United States

Spaceborne remote sensing instruments provide decades of continuous observations of the earth system. Due to limited capabilities of remote sensing instruments and techniques, there are still substantial uncertainties in inferring atmosphere and ocean properties. Spaceborne and airborne polarimetric remote sensing techniques reduce the uncertainties for cloud, aerosol, and phytoplankton concentration retrievals. Because of the large volume of remote sensing observational data, an efficient retrieval algorithm is needed while achieving the accuracy comparable to in-situ measurements. The accuracy and efficiency of the retrieval algorithm depends on the radiative transfer model (RTM) used in the forward calculations. On-line RTM can incorporate atmospheric profiles and surface properties directly into the retrieval system to improve the accuracy, but it is challenging to satisfy the efficiency requirements in remote sensing applications. To fully exploit the capability of the polarimetric instruments, it is imperative to develop an accurate and fast on-line vector RTM. In this study, a fast vector RTM is developed in support of atmospheric and oceanic polarimetric remote sensing. This model is capable of simulating the Stokes vector observed at the top of the atmosphere (TOA) and at the terrestrial surface by considering absorption, scattering, and emission. The gas absorption is parameterized in terms of gas concentration, temperature, and pressure. The parameterization scheme uses a regression method and can be incorporated into multiple scattering computations. With errors less than 0.2 K in terms of TOA brightness temperature, the approach is more than four orders of magnitude faster than a line-by-line RTM. A two-component approach is utilized to solve the vector radiative transfer equation (VRTE). The VRTE solver separates the phase matrices of aerosol and cloud into forward and diffuse parts, and thus the solution is also separated. The forward solution can be expressed by a semi-analytical equation based on the small-angle approximation, and serves as the source of the diffuse part. The diffuse part is solved by the adding-doubling method. The adding-doubling implementation is computationally efficient because the diffuse component needs much fewer generalized spherical function expansion terms. The simulated Stokes vectors at the TOA and surface are as accurate as the counterparts based on numerically rigorous methods. In this presentation, we compare the radiance calculations at the TOA to satellite observations.

The most recent Earth Science Decadal Survey from the U.S. National Research Council identified several key science questions and observables related to atmospheric composition. These include questions related to vertical profiling of aerosols; emission, transformation and longrange transport of tropospheric pollutants and greenhouse gases that drive radiative forcing. The next generation of instruments and platforms must address the specific requirements that flow from the measurement requirements articulated in the Decadal Survey. The Panchromatic Fourier Transform Spectrometer (PanFTS) is a NASA Earth Science Technology Programfunded development to demonstrate a geostationary instrument capable of meeting or exceeding measurement requirements posed by the Decadal Survey. The PanFTS flight instrument design combines measurement capabilities for the 0.26-15 micron spectral range in a single package. The wide spectral coverage is important for retrieving the entire suite of target molecules, including several in widely different wavebands. Measurement of the same species in different spectral regions significantly enhances the information content of the vertical profile retrievals. PanFTS combines an imaging Michelson interferometer design with several unique features. The PanFTS instrument is a hybrid based on spectrometers like TES (Tropospheric Emission Spectrometer) that measures thermal emission, and those like OCO (Orbiting Carbon Observatory) and OMI (Ozone Monitoring Instrument) that measure scattered solar radiation. As such the PanFTS design has two parallel optical trains, one for infrared wavelengths and one for UV-Vis. These channels incorporate imaging focal planes to meet requirements for high spatial resolution (few km) and large instantaneous field of regard from geostationary orbit. This presentation will discuss the development status and future evolution of the PanFTS instrument. We will present results obtained from versions of the PanFTS instrument located at JPL's California Laboratory for Atmospheric Remote Sensing (CLARS) on Mt. Wilson, California, overlooking the Los Angeles Basin. These will include long-term measurements of greenhouse gas emissions and solar-induced fluorescence from vegetation.

A1.1-0020-18 NASA'S ICECUBE TECHNOLOGY DEMONSTRATION: A PATHWAY FOR FUTURE COST-EFFECTIVE SUBMM-WAVE REMOTE SENSING FROM SPACE

Dong Wu, dong.l.wu@nasa.gov

Goddard Space Flight Center, Greenbelt, Maryland, United States IceCube Team

NASA continues to develop and mature cost-effective submm-wave technologies for various science applications with Earth and planetary remote sensing from space. IceCube is the latest spaceflight demonstration of submm-wave technology on a 3U cubesat using a commercial 883- GHz radiometer for Earth's cloud ice remote sensing. Cloud ice plays important roles in Earth's radiation budget and cloud-precipitation processes. Knowledge of global cloud ice distribution and its variations with the changing climate is a critical part of understanding about the Earth's system as a whole.

The IceCube project took advantage of emerging cubesat opportunities and established effective government-commercial partnerships, to achieve a fast-track development for the 883-GHz cloud radiometer and raise the technology readiness level (TRL) from 5 to 7. The IceCube system was successfully delivered to ISS in April 2017, deployed from the International Space Station (ISS) in May 2017, and acquired the first global 883-GHz cloud map by July 2017. It continues collecting cloud data at present as well as exploring capabilities of cubesat submmwave observations. The maturation of commercial submm-wave radiometer technologies up to 883 GHz opens up a host of cost-effective remote sensing applications for future Earth and planetary sciences. The new results of IceCube 883-GHz measurements and cubesat operation experiments will be discussed in this presentation.

A1.1-0021-18 VALIDATING THE ICE CLOUD PARTICLE MODELS FOR THE TERRESTRIAL ATMOSPHERE BY SPACEBORNE MULTI-ANGLE IMAGES

Souichiro Hioki, s.hioki@tamu.edu

Texas A&M University, College Station, Texas, United States Ping Yang, pyang@tamu.edu

Texas A&M University, College Station, Texas, United States

Ice clouds in the terrestrial atmosphere occur mostly in the upper troposphere and lower stratosphere. These clouds substantially modulate the energy budget of the planet. Airborne in-situ measurements indicate that the size and shape of ice cloud particles are diverse, and light scattering calculations demonstrate that the single-scattering properties of these particles depend significantly on the particle shape and surface roughness. To accurately estimate the climatic impact of ice clouds, it is necessary to improve the current level of the knowledge about ice particle shapes at the global scale.

To obtain the shape and surface roughness distribution at the global scale, the radiometric measurements from satellite sensors at visible and near-infrared wavelengths are viable. Because of minimal absorption by the atmospheric trace gases and large particle size compared to the wavelength, multi-angle cloud reflectance measurements characterizes the cloud particle properties. The separation of contribution from cloud optical thickness and phase function requires at least two viewing directions for every pixel of measurement, and this is more easily achieved by polar-orbiting satellites.

Two polar orbiting satellite sensors collected multi-angle images at visible/near-infrared wavelength from more than 8 viewing directions: The Multi-angle Imaging Spectroradiometer (MISR) sensor aboard NASA's Terra platform and the Polarization and Directionality of the Earth's Reflectance (POLDER) sensor aboard the Polarization and Anisotropy of Reflectances for Atmospheric Sciences coupled with Observations from Lidar (PARASOL) satellite. These two sensors have different optical systems to measure the reflectivity, thus the different viewing geometries and spectral resolution.

In this presentation, we validate ice cloud particle models using the MISR and POLDER sensors. We first estimate the spherical albedo from multi-angle measurements pixel-by-pixel, and then compute the anisotropic component of the reflectance for every viewing direction. The degree of agreement between the observed and simulated anisotropies is compared. The preliminary results from two satellite sensors are different, particularly in the tropics. The present results are stratified by cloud scene inhomogeneity and pixel selection criteria.

A1.1-0022-18 DETERMINATION OF GLOBAL EARTH OUTGOING LONGWAVE RADIATION AT HIGH TEMPORAL RESOLUTION USING MOON-BASED PLATFORM

Hanlin Ye, yehl@radi.ac.cn

Institute of Remote Sensing and Digital Earth, Chinese Academy of Sciences, Beijing, China Huadong Guo, hdguo@radi.ac.cn

Institute of Remote Sensing and Digital Earth, Chinese Academy of Sciences, Beijing, China Guang Liu, liuguang@radi.ac.cn

Institute of Remote Sensing and Digital Earth, Chinese Academy of Sciences, Beijing, China

An Earth observation strategy that equipping sensors on the lunar surface have attracted great attention across many scientific communities. Yet the potential and the characteristics of the global Earth outgoing radiation monitoring using such a new platform has not been explored sufficiently. To explore the potential of the Moon-based platform and to reveal the observation parameters requirement for measuring global Earth outgoing radiation, we have developed a new method and conducted a series of simulation experiments. Using idealized active radiometers as an example, we find that the Moon-based platform can monitor global Earth outgoing longwave radiation reliably at hourly time scale, showing the features of planetary spatial scale and high temporal resolution observation.

The Earth system receives energy from the Sun and releases energy via thermal radiation out to space. The detection of variation in the Earth radiation budget at the top of atmosphere (TOA) is essential to our understanding of global change. Measurement of the Earth radiation budget have been made from dedicated missions since 1975, the early Earth Radiation Budget experiments. Now, the Clouds and the Earth's Radiant Energy System (CERES) experiments have provided valuable data for global climate change study. Another platform is Geostationary Earth Radiation Budget (GERB) experiment, which provides outgoing radiation products at a 15-min temporal resolution. Deep Space Climate Observatory (DSCOVR) took the first step in an effort to deep space observatories of the Earth radiation. It offers the data of the sunlit hemisphere of the Earth. Based on the previous research, we will perform extensive simulation experiments to evaluate the possibility and the capability of the Moon-based platform concept for observing Earth outgoing longwave radiation. Similarly to other platforms case, we use the angular distribution model, but necessarily, different angular constraints are applied to make the model. In this paper, the observation angles are defined and the data is binned and averaged in angular bins as functions of cloud fraction and surface type of the observational scope. Then, the angular distribution model is detailed and the results are shown. Finally, our key findings and highlights are summarized.

A1.1-0023-18 BAND SELECTION STUDY FOR SMILES-2

Makoto Suzuki, suzuki.makoto@jaxa.jp

Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, Sagamihara, Japan

Naohiro Manago, manago@gfd-dennou.org

Japan Aerospace Exploration Agency, Sagamihara, Japan Philippe Baron, baron@nict.go.jp

NiCT, Koganei, Japan

Satoshi Ochiai, ochiai@nict.go.jp

National Institute of Information and Communications Technology, Tokyo, Japan

SMILES-2 is one of the satellite proposal submitted to JAXA/ISAS small satellite program in January 2018, and it is waiting for the first selection scheduled in June 2018 (3 proposals can go to pre-phase-A1B among 8 proposals. If it is selected, 2024/25 launch is expected). SMILES-2 satellite proposal is 600 km, 66 degree, 550 kg satellite carrying SMILES-2 (core instrument, Ochiai et al, 2017), in-situ instruments for ionosphere (Langmuir Probe and Ion Drift Analyzer) and GPS occultation (stratospheric temperature and ionosphere electron density). SMILES-2 will be similar to ISS/JEM/SMILES, with adding 2-3 sub-mm bands using SIS mixer and THz band (1.8 THz for OH, HO2, and O3, and 2.0 THz for O atom) using HEB (Hot Electron Bolometer). SMILES-2 program has four science objectives: (MO.1) To investigate the 4-D space-time structure of the diurnal variations (atmospheric tides) in view of dynamics, chemistry, and electromagnetic processes. (MO.2) To unveil the vertical propagation of planetary scale disturbances from the middle atmosphere (non-migrating tides and stratospheric sudden warming events) to the upper atmosphere. (MO.3) To understand atmospheric variations due to electromagnetic energy input from the magnetosphere (particle precipitation and magnetic storm). (MO.4) To provide benchmarks for whole atmosphere models and climate models with detailed description of the background thermal structure and distribution of minor species. Previously, SMILES-2 was to have 3 sub-mm bands (LO=507 GHz, 566.5 GHz, and 638.075 GHz). After preliminary satellite design study, we should reduce sub-mm antenna size (80-100 cm down to 75 cm) and minimize the size of 4K cooled part. By choosing higher frequency band (LO=763.5 GHz), we concluded almost same (or better) sensitivity other than CO and BrO with (LO=638.075 GHz, and 763.5 GHz). Expected SMILES-2 data are: Horizontal wind (30-150 km), Temperature (15-150 km), O3, all O3 isotopes, O atom (80-150 km), H2O (20-100 km), HO2, OH, HCl, ClO, HOCl, BrO, N2O, NO, NO2, HNO3, CH3CN, HCN, and volcanic enhanced SO2.

A1.1-0024-18 AN OVERVIEW OF THE STRATOSPHERIC AEROSOL AND GAS EXPERIMENT III ON THE INTERNATIONAL SPACE STATION (SAGE III ISS)

Charles Hill, charles.a.hill@nasa.gov NASA/LaRC, Hampton, Virginia, United States David Flittner, david.e.flittner@nasa.gov NASA/LaRC, Hampton, Virginia, United States Larry Thomason, l.w.thomason@nasa.gov NASA/LaRC, Hampton, Virginia, United States Marilee Roell, marilee.m.roell@nasa.gov NASA/LaRC, Hampton, Virginia, United States Michael Pitts, michael.c.pitts@nasa.gov NASA/LaRC, Hampton, Virginia, United States Robert Damadeo, robert.damadeo@nasa.gov NASA/LaRC, Hampton, Virginia, United States Brooke Thornton, brooke.thornton@nasa.gov NASA/LaRC, Hampton, Virginia, United States Amy Rowell, amy.rowell@nasa.gov NASA/LaRC, Hampton, Virginia, United States Randy Moore, james.r.moore@nasa.gov

SSAI, Hampton, Virginia, United States Kevin Leavor, kevin.r.leavor@nasa.gov SSAI, Hampton, Virginia, United States Ryan Stanley, ryan.p.stanley@nasa.gov SSAI, Hampton, Virginia, United States

The Stratospheric Aerosol and Gas Experiment III (SAGE III) on the International Space Station (ISS) extends NASA's long legacy of satellite atmospheric occultation measurements with the primary objective to monitor the vertical distribution of aerosol, ozone, and other trace gases to enhance understanding of ozone recovery and climate change processes in the upper atmosphere. The SAGE III payload was delivered to the ISS by the Falcon 9 Commercial Resupply Services 10 mission launched on 19 February 2017 from Kennedy Space Center. The SpaceX Dragon spacecraft berthed and docked with the ISS on 23 February, and the external SAGE III payload was installed on 7 March with first light following on 17 March. The ISS is an attractive platform because power and data service are readily available and because the 52° inclined orbit is ideal for the desired low and mid latitude coverage, similar to the SAGE II mission. Occultation instruments measure the unattenuated balance of light along the lineof-sight to the target to infer the molecular species and aerosol extinction present within the atmospheric path. Although in the visible portion of the spectrum the brightness of the Sun is a million times that of the full Moon, SAGE III can perform both solar and lunar occultations as well as limb scatter events that measure the scattering of solar radiation by Earth's blue sky. The nominal solar science products include vertical profiles of ozone, nitrogen dioxide, and water vapor, along with multi-wavelength aerosol extinction. The standard lunar products include ozone, nitrogen dioxide, and nitrogen trioxide. An overview of the first year of routine operations of the SAGE III ISS mission will be discussed along with the status of validation efforts and science results. The SAGE IV Pathfinder development project will be introduced with thoughts towards the future of SAGE.

A1.1-0025-18 SCIENTIFIC RESULTS FROM THE OMPS LIMB PROFILER SENSOR ON SUOMI NPP SATELLITE

Pawan Bhartia, pawan.bhartia@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States SNPP OMPS Limb Profiler Science Team

Pawan K Bhartia, Glen Jaross, Natalya Kramarova, Omar Torres, Ghassan Taha, Matt DeLand, Zhong Chen, Robert Loughman, Gerald Ziemke, Richard McPeters, Stacey Frith, Gordon Labow

The Ozone Mapper and Profiler Suite (OMPS) consists of two nadir and a limb-viewing sensor that was launched on the Suomi NPP satellite in October 2011. In this talk we will focus primarily on the OMPS LP sensor that measures limb-scattered solar radiation in the 290- 1000 nm wavelength range at 1.8 km vertical resolution over the entire sunlit globe. These measurements are inverted to produce vertical profiles of ozone and aerosols. There are also plans to derive temperature profiles in the 35-55 km altitude range, and to estimate spectrally resolved short-wave outgoing radiation. We will discuss how well this sensor has captured the evolution of the ozone layer in the past 6 years by comparing with other limb and occultation sensors, and the challenges in monitoring the expected ozone recovery due to phase out of the ozone destroying substances and cooling of the stratosphere due to greenhouse gases. We will show the morphology and evolution of stratospheric aerosols produced by recent volcanoes and intense fires, such as the Pyro-Cb event that occurred in Western Canada in August 2017. Finally, we will highlight merging of data from multiple sensors, including nadir, limb-viewing, occultation, and LIDAR sensors. We will discuss our recent studies to derive long-term dataset of tropospheric ozone column from nadir UV sensors by using EOFs of ozone profiles derived from limb data combined with time series of tropopause height and QBO to constrain the stratosphere. For aerosols studies we will discuss our approach of combining occultation and limb scattered data, with balloon and Lidar data, to constrain the aerosol size distribution parameters.

A1.1-0026-18 RADIATIVE TRANSFER CORRECTIONS FOR OMI BRO

Global observations of BrO are crucial for monitoring the health of the stratospheric ozone layer, as bromine mediated catalytic destruction cycles have an important impact on the ozone budget. Bromine also plays an important role in the tropospheric chemistry of ozone and mercury. A changing climate is expected to affect the production of ozone, sources of bromine in the atmosphere, and injection of bromine into the stratosphere. It is therefore necessary to monitor BrO, ozone, and related molecules with a high degree of accuracy on a global scale to ensure the recovery of the stratosphere as well as changes in tropospheric composition using satellite instruments such as OMI.

We present results of an intercomparison between the operational OMI BrO data product, OMBRO, and ground-based Differential Optical Absorption Spectroscopy BrO vertical column densitiy, VCD, retrievals from Summit Station, Greenland. Results of this comparison motivated reconsideration of the radiative transfer calculations and a priori approximations used to retrieve OMBRO. We find that the OMI BrO VCD retrievals can be improved by more accurately accounting for the latitudinal variation in the stratospheric BrO profile shape and the presence of tropospheric BrO. We present a simple global correction function for OMBRO based on radiative transfer calculations of several scenarios utilizing a stratospheric BrO climatology. This correction reduces OMBRO measurement errors and better accounts for latitudinal and small-scale variability in the OMI BrO retrievals. The correction improves BrO VCD accuracy and benefits any work that relies on this dataset.

A1.1-0027-18 STRATOSPHERIC AEROSOL CHARACTERISTICS RETRIEVED FROM SPACEBORNE OBSERVATIONS IN LIMB VIEWING GEOMETRY

Stratospheric aerosols play an important role in the processes relevant to climate change, affecting them both directly and indirectly. The direct effect arises from the scattering of solar radiation back to space and by heating the stratosphere after strong volcanic eruptions through the absorption of thermal infrared radiation upwelling from the troposphere. Besides, stratospheric aerosols influence the Earth's climate indirectly by providing the surface for heterogeneous reactions, which lead to the ozone depletion. Measurements of the scattered solar light in the limb viewing geometry from the spaceborne instruments is a valuable source of global information on stratospheric aerosols. In this study limb observations from two limb-scatter instruments are used: SCIAMACHY on Envisat operated from 2002 till 2012, and OMPSLP on Suomi-NPP, which was launched in 2011 and is operating till now. Here we present stratospheric aerosol data sets developed in the Institute of Environmental Physics, University of Bremen. As aerosol extinction coefficient is widely used to describe aerosol loading in the stratosphere, we provide data sets of this parameter, retrieved from SCIAMACHY and OMPSLP measurements. Furthermore, aerosol particle size distribution (PSD) parameters (mode radius and distribution width) are retrieved using SCIAMACHY observations. Assuming a fixed aerosol particle number density profile, mode radius and distribution width are retrieved with the accuracy of better than 20% and 10% respectively. For a purpose of comparability with the other instruments, we also provide Angström exponents.

These are calculated using PSD data with about 5-10% accuracy depending on the wavelength ratio. The quality of the presented aerosol products is assessed through extensive comparisons with results from other spaceborne instruments (SAGE II and OSIRIS). The data sets are used to analyze the stratospheric aerosol behaviour over the last 15 years.

Carbon dioxide (CO2) emissions from fossil fuel combustion (Fossil fuel CO2, FFCO2) is the main input to the global carbon cycle over the decadal time scales. The emissions need to be accurately quantified and monitored in order to deduce the carbon uptakes by natural sinks using atmospheric measurements as well as support emissions reduction and management. The Open-source Data Inventory for Anthropogenic CO2 (ODIAC) is a global, high-spatial resolution, gridded emission data product for FFCO2. We first introduced the combined use of the point source information and satellite-observed nighttime lights data for emission downscaling in order to achieve global 1×1km spatial resolution emission fields. The use of nightlight data allows us to detect dynamic changes in emissions spatial distributions in a timely manner and incorporate these into the high-resolution

emission field. Since its establishment in 2009, the ODIAC emission data product has been extensively used in global and regional flux inversions especially with CO2 data collected by carbon observing satellites such as the Japanese Greenhouse gas Observing SATellite (GOSAT) and NASA's Orbiting Carbon Observatory 2 (OCO-2) and also successfully applied to studies for localized emissions point sources such power plants and cities. The good model reproducibility of the atmospheric CO2 observations in transport model simulations even at a high spatial resolution supports the validity of the ODIAC spacebased emission downscaling. To further improve the accuracy of the emission downscaling, we have explored the use of other space-based data such as NASA's new Visible Infrared Imaging Spectrometer Suite (VIIRS) Nighttime Environmental Product (nightlight) and LandSat data. We confirmed the excellent performance of the VIIRS nightlight data in spatial emission allocations at regional scales as well as spatial pattern depictions of emissions at urban scales from an extensive comparison to a fine-grained country emission inventory as well as high-resolution WRF transport model simulations. A new feature to be incorporated in modeling the distribution and partition of CO2 is a breakthrough by the patented Dense Sampling Method for satellite radar observations of global urbanization in three dimensions, including lateral sprawl and vertical build-up. The ability to create global high-resolution spatial emissions patterns from emissions reported on a country basis is one of the key elements of future Monitoring and Verification Support (MVS) scientific systems that consist of carbon data assimilation. Our advanced satellite-based emission downscaling model holds the promise of playing a critical role in such future systems.

A1.1-0029-18 MEASURING METHANE FROM ORBIT WITH A LIDAR: CHALLENGES AND PROGRESS

Haris Riris, haris.riris@nasa.gov

NASA Goddard Space Flight Center, GREENBELT, Maryland, United States

The global and regional quantification of methane fluxes and identification of its sources and sinks has been highlighted as one of the goals of the 2017 Earth Science Decadal Survey. Detecting methane from space with an active (laser) remote sensing instrument presents several unique technology and measurement challenges. The instrument must have a single frequency, narrow-linewidth light source, and photon-sensitive detector at the right spectral region to make continuous measurements from orbit, day and night, all seasons and at all latitudes. It must have a high signal to noise ratio and must be relatively immune to biases from aerosol/cloud scattering, spectroscopic and meteorological data uncertainties, and instrument systematic errors. The technology needed for a spaceborne mission is currently being developed by NASA and industry. At Goddard Space Flight Center (GSFC), we have developed an airborne instrument to measure methane. Our instrument is a nadir-viewing lidar that uses Integrated Path Differential Absorption (IPDA), to measure a methane vibration-rotational line near 1.65 m that is relatively free of interferences from other trace gases. We sample the absorption line using multiple wavelengths from a narrow linewidth laser source and a sensitive photo detector. This measurement approach provides maximum information content about the vertical distribution of CH4, minimum bias, and sensitivity to atmospheric temperature uncertainty in XCH4 retrieval. However, technical and measurement challenges remain. In this paper, we will review our progress to date and discuss the technology challenges, options and trade offs to measure methane from space.

A1.1-0030-18 RETRIEVAL OF ELEVATED ATMOSPHERIC CARBON DIOXIDE CONCENTRATION FROM AVIRIS-NG DATA USING RADIATIVE TRANSFER MODEL: A CASE STUDY OVER A POWER PLANT AT KOTA, INDIA

Mehul Pandya, mrpandya@sac.isro.gov.in

Carbon dioxide (CO2) is one of the major greenhouse gases that has increased significantly in pre and post-industrial times and this rise has caused positive radiative forcing resulting in increased global temperature. Observing atmospheric CO2 concentration through spaceborne platform is very important and many Earth observing satellite missions have been designed to detect atmospheric CO2 since mid-1990s. The satellite missions with variety of sensors have the capability to map CO2 concentration on global scale with relatively coarse spatial resolution. However, spaceborne sensors can't provide very fine spatial resolution required to detect CO2 plumes from the point sources. In such cases, airborne hyperspectral instruments with high spatial resolution at each pixel can detect CO2 plumes from the point sources. Imaging spectroscopy through the Airborne Visible/Infrared Imaging Spectrometer Next Generation (AVIRIS-NG) instrument has the capability of retrieving CO2 concentration by measuring the reflected radiance in 380-2510 nm spectral range with a spectral sampling of 5 nm, fine spatial resolution and high signal to noise ratio. Potential of AVIRIS-NG has been used in the present study to retrieve the atmospheric CO2 concentration using radiative transfer modelling from a power plant site located in Kota, India during ISRO-NASA joint airborne hyperspectral science campaign. The method used in the present study involves theoretical simulations of at-sensor radiance in AVIRIS-NG spectral bands by an atmospheric radiative transfer (RT) model. MODTRAN 5.3 was used to simulate the systematic variations occurring in at-sensor radiance due to increased carbon dioxide concentration varying from 25 ppmv to 1600 ppmv. The basis of the retrieval technique is that CO2 absorption lines in the spectrum are related to the CO2 concentration in the atmospheric column, the higher the gas concentration, the deeper are the gas absorption lines. Simulation exercise was performed for the specific scene-sensoratmospheric conditions corresponding to AVIRIS-NG pass over Kota site on 4th February, 2016. In order to incorporate the effect of interfering atmospheric water vapour, a variation in the water vapour values ranging from 0.25 to 4.5 g/cm^2 was also used in the simulations. Using the distinct absorption bands of CO2 in shortwave infrared spectral range of AVIRIS-NG radiance data, a theoretical model was developed between continuum interpolated band ratio (CIBR) and CO2 concentration. Once the set CIBR-CO2 model coefficients for each of the water vapour sub-ranges was developed, it was applied to AVIRIS-NG L1 radiance data over Kota. A CO2 concentration map was generated for the site, which also contains the Kota Super Thermal Power Station (KSTPS). The CO2 concentration (XCO2) ranging from 360 ppmv to 525 ppmv was observed within the scene. Elevated CO2 plumes having XCO2 value more than 500 ppmv were clearly detected near the KSTPS stacks. The study has provided encouraging results for the retrieval of atmospheric CO2 concentration from the AVIRIS-NG data, however detailed analysis is in progress to incorporate the effect of varying surface reflectance in the retrieval. Attempts are also underway to apply the Cluster-Tuned Matched Filter technique for detection of CO2 plumes in AVIRIS-NG data.

A1.1-0031-18 INFLUENCE DUE TO CIRRUS AND THICK AEROSOL ON ESTIMATION OF COLUMN CO2 AND CH4 WITH GOSAT/FTS DATA

Kohei Arai, arai@is.saga-u.ac.jp Saga University, Saga, Japan

Influence due to cirrus and thick aerosol on estimation of column CO2 and CH4 with GOSAT/FTS data Kohei Arai1, Takashi Higuchi1, Hiroshi Okumura1, Hirofumi Ohyama2, Shuji Kawakami3, Kei Shiomi3 1: Saga University, 2: National Institute of Environmental Science, 3: JAXA Influence due to cirrus and thick aerosol on estimation of column CO2 and CH4 with GOSAT/FTS data is clarified. Relatively large estimation errors are observed in column CO2 and CH4 retrievals with FTS data in some atmospheric conditions. In order to find such cases, retrieval results and quality/cloud flags in the GOSAT/FTS data products are checked. Through the investigation, it is found that relatively large error is caused by convergence problem due to cirrus clouds and thick aerosols. In the proposed paper, some of the cases of which relatively large estimation error is occurred at the Saga TCCON site are investigated. Also, a comparative study is conducted between standard products provided by NASA/JPL and the Levenberg-Marquardt based least square method of column CO2 and CH4 retrieval. It is suggested that some improvements of estimation accuracy of column CO2 and CH4 retrieval with GOSAT/FTS data can be expected.

A1.1-0032-18 SEASONAL AND ANNUAL VARIATION OF AIRS RETRIEVED CO2 OVER INDIAN REGION DURING 2003-2016

Surendra Dhaka, skdhaka@gmail.com Delhi University, Delhi, India

The present study shows spatio-temporal variability in carbon dioxide (CO2) in the midtropospheric region over India (0-32N, 60-100E) during 2003-2016. CO2 data used in the study is retrieved from Atmospheric Infra-Red Sounder (AIRS). Analysis of 14 years of data shows that the CO2 exhibits a linear increasing trend of 2.01 ppm/year. Besides displaying the linear increasing trend, data show strong seasonal and annual variability. Concentration of CO2 is observed to be highest around April-May (summer months), which decreases by 4-5 ppm during the monsoon months. Seasonal decrease in CO2 concentration appeared to be influenced by the monsoonal activity. Low OLR (proxy of convection) associated with high rainfall during summer monsoon via increasing vegetation index (NDVI) appears to be the primary cause for the seasonal decrease in CO2 through photosynthesis. Correlation coefficient between Co2 and NDVI is of the order of -0.90 suggesting vegetation as a seasonal sink of Co2. Decrease in Co2 concentration takes place at a delay of 2-3 months of rainfall. However, convection seems to be another component, which causes uplifting of Co2 during dry summer (April-May) making high concentration in the mid troposphere as shown by increase in the planetary boundary layer (PBL) height in this period. Eastward propagating intra-seasonal oscillations with period 30-40 days in OLR anomalies are found to modulate (with a fluctuation of 1-2 ppm) mid-tropospheric CO2. Analysis of seasonal anomalies in CO2 over four different regions (Northern, Southern, Western and Eastern) of India is also being investigated. The regional variability of CO2 in northern region show marginal larger values suggesting more anthropogenic activities especially during late winter.

The European Union's Copernicus Earth Observation programme provides operationally advanced information services on our environment and security based both on satellite and nonspace data. Launched on October 13, 2017, European Space Agency (ESA)'s Sentinel-5 Precursor (Sentinel-5p) is the first atmospheric composition satellite of this programme. On board, developed jointly by ESA and the Netherlands Space Office (NSO), the UV/VIS/NIR/SWIR spectrometers of TROPOspheric Monitoring Instrument (TROPOMI) measure on the global scale, on a daily basis, and at unprecedented horizontal resolution the atmospheric abundance of species related to air quality, climate forcing, ozone, UV radiation and volcanic hazards: O3, NO2, HCHO, SO2, CO, CH4, clouds, aerosols. The Sentinel-5p ground segment development has been funded by ESA and with national contributions from The Netherlands, Germany, and Belgium. Part of this ground segment, the Validation Data Analysis Facility (VDAF) of the Sentinel-5p Mission Performance Centre (MPC) aims at providing a routine TROPOMI validation service to ESA, Level-2 data developers, Copernicus services and other data users. Building upon the heritage of two decades of geophysical validation applications for precursor instruments (GOME, SCIAMACHY, OMI, GOME-2) and on recent advances in Cal/Val practices and operational validation systems, VDAF has been tailored to the TROPOMI and Copernicus needs. It ingests Fiducial Reference Measurements (FRM) archived at ESA's Validation Data Centre (EVDC) and collected from high-quality ground-based monitoring networks (GAW GO3OS, EARLINET, NDACC, TCCON.), and it compares them to TROPOMI data following community-endorsed protocols.

In this paper we present plans for the operational geophysical validation of TROPOMI data, with highlights on the heritage and the advances implemented in the VDAF system, and with illustrative initial results. Nine months only after the launch of the satellite, those initial results are based on preliminary (not fully calibrated/validated) Sentinel-5p data that will still change in the near future.

A1.1-0034-18 LONG-TERM VALIDATION FOR THE ATMOSPHERIC CHEMISTRY EXPERIMENT (ACE) SATELLITE MISSION

Kaley Walker, kwalker@atmosp.physics.utoronto.ca University of Toronto, Toronto, Canada

Patrick Sheese, psheese@atmosp.physics.utoronto.ca University of Toronto, Toronto, Canada

Jiansheng Zou, jzou@atmosp.physics.utoronto.ca University of Toronto, Toronto, Canada

Chris Boone, cboone@uwaterloo.ca University of Waterloo, Waterloo, Canada

C. Thomas McElroy, tmcelroy@yorku.ca York University, Toronto, Canada

The Canadian-led Atmospheric Chemistry Experiment (ACE) satellite mission has completed fourteen years of measurements from orbit. It uses infrared and UV-visible spectroscopy to investigate the chemistry and dynamics of the Earth's atmosphere. The two instruments on-board are the ACE Fourier Transform Spectrometer (ACE-FTS), a high-resolution (0.02 cm−1) FTS operating between 750 and 4400 cm−1, and a dual UV-visible-NIR spectrophotometer called ACE-MAESTRO (Measurements of Aerosol Extinction in the Stratosphere and Troposphere Retrieved by Occultation), which extends the ACE wavelength coverage to the 280-1030 nm spectral region. The ACE instruments make solar occultation measurements from which altitude profiles of atmospheric trace gas species, temperature and pressure are retrieved. The 650 km altitude, 74 degree circular orbit provides global measurement coverage with a focus on the Arctic and Antarctic regions. This paper will describe recent validation results for the ACE-FTS and ACE-MAESTRO data sets and describe the analyses that are being undertaken to characterize the ACE-FTS data to enable the generation of climate data records.

Our understanding of the stability of ground-based and space-based ozone profile data records remains an important issue in monitoring the state of the atmospheric ozone layer. Recent assessments by WMO and by LOTUS (Long-term Ozone Trends and Uncertainties in the Stratosphere), a research activity supported by SPARC (http://www.sparc-climate.org/activities/ozonetrends), have concluded that there is now substantial observational evidence of increasing upper stratospheric ozone concentrations since the late 1990s, although magnitude and significance of the positive trend vary depending on the data record considered (WMO, 2014; SPARC, 2018). This observational variance in upper stratospheric data limits our ability to test and refine chemistry-climate model predictions for policy making. Also, a recent analysis of satellite measurements indicated, quite unexpectedly, that lower stratospheric ozone has declined continuously since the mid 1980s at mid and low latitudes (Ball et al., 2018). If the latter finding is correct, it may uncover an unexpected gap in our understanding of the physical and chemical processes that govern ozone. Obtaining independent confirmation by analyses

of other data records, e.g. from ground-based instruments, and by using different analysis techniques will be key in establishing observational evidence for this decline. Both issues illustrate the need for continued investigations of the agreement between available ozone profile data records, in order to identify potential issues in the data records and determine their strengths and limita- tions. This should ultimately pave the way to improved data records and lead to more informed interpretation of analysis results.

We present results of a coherent, comprehensive comparative analysis of present ozone profile data records acquired from space (limb and occultation sounders) and from the ground (GAW/NDACC/SHADOZ-affiliated sonde, stratospheric lidar and microwave radiometer sites). We show updated estimates of drift of individual satellite data records relative to ground-based network data (Hubert et al., 2016). This analysis was recently extended -in the framework of ESA's Climate Change Initiative and the EC Copernicus programme - to gridded, monthly averaged profile data. We present first results of the stability of ten gridded single-sensor and of the merged SAGE-CCI-OMPS stratospheric ozone datasets (Sofieva et al., 2017). In return, the satellite data are used to identify inhomogeneities in time and space in the ground-based time series. Some of these coincide with known instrument or measurement changes in the network, other features have -so farno clearly identified cause. Such changes add to the challenge to derive unbiased ozone trends from ground-based observations and they impede our ability to constrain satellite drift to the level required for current and future ozone trend assessments. This clearly shows the need to continue ongoing efforts to homogenise the ground-based data records.

The geographical and vertical distribution of atmospheric species is monitored on the pseudoglobal scale by complementary satellite remote sounding instruments and by airand groundbased networks. Due to its particular spectral range, viewing geometry and other properties, every measurement technique samples and smoothes differently the vertical and horizontal distribution of an atmospheric species. Those sampling and smoothing properties can affect the interpretation of the data, as well as the comparison of two different data sets for validation purposes, in data merging, and in chemical data assimilation schemes. While vertical sampling and smoothing properties of atmospheric remote sensing have been studied for decades and are usually taken into account in scientific applications, horizontal smoothing has become a subject of interest more recently with the advent of high resolution satellite instruments like Sentinel-5p TROPOMI launched in October 2017 and the future constellation of geostationary air quality satellites (GEMS, TEMPO and Sentinel-4). On top of the sampling and smoothing properties of a single measurement, every global measurement system also samples differently the structures, cycles, trends and other features of the global atmosphere. Therefore, Observing System Simulation Experiments (OSSE) have been developed to better account for the different sampling properties of global observing systems and to better understand their value added in applications like chemical data assimilation.

Coupling the OSSE approach with recent advances in the multi-dimensional metrology of atmospheric remote sensing, "Observing System of Systems Simulator for Multi-missiOn SynErgies" (OSSSMOSE) is a versatile software environment designed to provide realistic simulations of the output of both real and hypothetical global observing systems for atmospheric composition. It is based on a suite of: (i) state-of-the-art description of multi-dimensional sampling and smoothing properties of key measurement techniques; (ii) recent developments in metadata catalogues of global measurement systems; and (iii) the OSSE approach based on global reanalysis data sets (ERA, MERRA.) OSSSMOSE will be described and its application illustrated in a few domains of current interest: the quantification of sampling and smoothing errors in global data records of atmospheric ECVs, the error budget closure of atmospheric data comparisons, and the design of satellite validation strategies including optimization of co-location criteria.

University of Maryland Baltimore County, Baltimore, Maryland, United States Mobile in situ gas concentration and meteorology data were collected for the Chino Dairy Complex in the Los Angeles Basin by AMOG (AutoMObile trace Gas) Surveyor on 25

June 2015 to characterize husbandry emissions in the near and far field in convoy mode with MISTIR (Mobile Infrared Sensor for Tactical Incident Response), a mobile upwards-looking, column remote sensing spectrometer. MISTIR provided reference fluxes to validate AMOG plume inversions, which considered different levels of information including multiple gases, Google Earth, and airborne trace gas remote sensing data. Long-term (9-yr.) satellite measurements by the Infrared Atmospheric Sounding Interferometer provided spatial and temporal context.

For the Chino Dairy Complex (one to two hundred thousand cattle), MISTIR-AMOG ammonia (NH_3) agreement was within 5% (15.7 versus 14.9 Gg yr^{-1}, respectively) using all information sources. The remaining discrepancy could be accounted for by increasing the turbulence class by 5%, likely due to higher turbulence from structures. CH_4 emissions were 30 Gg yr^{-1}.

Single dairy inversions were less successful, with 57% AMOG-MISTIR agreement due to wind heterogeneity (convergence and divergence) from downwind structures in these near-field measurements, along with emissions unsteadiness. AMOG CH_4, NH_3, and CO_2 emissions were 91,

209, and 8200 Mg yr^{-1}, implying 2480, 1870, and 1720 head of cattle. Plumes were fingerprinted and attributed to likely source locations that included manure storage, cowsheds, and a structure with probable natural gas combustion.

NH_3 downwind of Chino showed seasonal variation by a factor of ten, three times larger than literature suggests. Higher emissions were proposed to result from legacy soil emissions resulting from a century of husbandry. This conclusion was supported by airborne remote sensing data showing widespread emissions from neighborhoods that were dairies 15 years prior, and also combined AMOG and MISTIR observations. Seasonal variations provide insights into the implications of global climate change and must be considered when comparing surveys from different seasons.

A1.1-0038-18 TEMPERATURE AND WIND MEASUREMENTS IN THE STRATOAND MESOSPHERE BY LIDAR: GRAVITY WAVES AT THE POLAR NIGHT JET.

Gerd Baumgarten, baumgarten@iap-kborn.de

Leibniz-Institute of Atmospheric Physics (IAP), Kühlungsborn, Germany Franz-Josef Luebken, luebken@iap-kborn.de

Leibniz-Institute of Atmospheric Physics (IAP), Kuehlungsborn, Germany Irina Strelnikova, strelnikova@iap-kborn.de

Leibniz-Institute of Atmospheric Physics (IAP), Kühlungsborn, Germany

Measurements of wind and temperature in the stratosphere and mesosphere are crucial for understanding the dynamics in the middle atmosphere. However wind measurements covering the range of 20 to 70 km are challenging and only very few methods are capable to derive winds and temperatures with sufficient vertical and temporal resolutions for gravity-wave studies.

It was recently found that the polar vortex in the stratosphere (polar night jet) is linked to the global surface temperatures and that the vortex is affected by energy and momentum transported by planetary and gravity waves. Waves in the atmosphere are usually seen as perturbations of wind and temperature. For gravity waves the relation between the quantities is simple in an atmosphere at rest. For example the time evolution of a vertical profile of temperatures gives enough information to deduce upward and downward energy transport. In a situation with atmosphere motions, eventually changing with altitude and time, the relation between wind and temperature perturbations is more complicated. Such situations are typical in the vicinity of the polar night jet. Combined temperature and wind observations enable characterization of inertia-gravity waves (IGW) even in changing background wind situations.

In this work we use the phase relation between both zonal and meridional wind components, and temperature. The method is based on localized linear theory of gravity waves and has been used to determine the intrinsic frequency, propagation direction, and phase velocity of IGW. The main challenge for this method is the identification of nearly monochromatic waves. We developed an approach that isolates one dominating wave in a limited altitude range. This allows analyzing IGW individually and subsequently applying different averaging to selected IGWproperties. We show measurements performed at the ALOMAR research station in northern Norway (69°N, 16°E) in winters 2012 to 2016. In January 2016 the observations were performed while the polar night jet introduced a large shear above the lidar station leading to a complicated but striking situation for up and downward propagating gravity waves.

A1.1-0039-18 VARIATION OF HO2 AND HCL IN MLT (MESOSPHERE AND LOWER THERMOSPHERE) REGION

Kota Kuribayashi, kuribayashi@nict.go.jp

National Institute of Information and Communications Technology, Tokyo, Japan Tomohiro Sato, tosato@nict.go.jp

National Institute of Information and Communications Technology, Tokyo, Japan Yasuko Kasai, ykasai@nict.go.jp

National Institute of Information and Communications Technology, Tokyo, Japan

Chemical and Dynamical behavior of HO2 radical, a key atmospheric oxidant, and HCl, oxidant depleting species, has an important role for the chemistry in the mesosphere and lower thermosphere (MLT) region. There has been no observation evidence for the vertical behavior of HO2 and HCl simultaneously near the mesopause region. We retrieve vertical profile of HO2 and HCl up to about 100km with new algorithm from spectra measured using the Superconducting Submillimeter-Wave Limb-Emission Sounder (SMILES) on the Japanese Experiment Module (JEM) of the International Space Station (ISS) between 12 October 2009 and 21 April 2010. We improved the internal consistency between vertical profile of atmospheric species, temperature/ pressure, and altitude to use of "one" atmosphere for from ground to upper thermosphere from the model named GAIA (Ground-to-topside model of Atmosphere and Ionosphere for Aeronomy) for the retrieval calculation. New products are named SMILES NICT level 2 product version 3.0.0 (L2 ver. 3.0.0). The quality of the L2 ver.3.0.0 were assessed t by comparing with several model calculations. We for the first time revealed a diurnal variation of HO2 in the mesosphere and mesopause. The interesting chemical mechanism of HO2 in mesopause is explained by comparing with simple 1D model calculations by us, qualitatively. We also found the cause of latitudinal and seasonal variation of HCl in the lower thermosphere is due to various dynamical process in the MLT region, including semi-annual oscillation and intraseasonal oscillation.

A1.1-0040-18 SEASONAL, INTERANNUAL AND LONG-TERM VARIABILITIES AND TENDENCIES OF WATER VAPOUR IN THE UPPER STRATOSPHERE AND MESOSPHERIC REGION OVER TROPICS (30°N-30°S)

Oindrila Nath, oindrila.nath27@gmail.com

National Atmospheric Research Laboratory, TIRUPATI, India Sridharan Sundararajan, susridharan@narl.gov.in

National Atmospheric Research Laboratory, Pakala, India

Tropical water vapour volume mixing ratio (WVMR) data for October 2004-September 2015 obtained from the Microwave Limb Sounder are used to study its long-term variabilities and tendencies in the height region 12.1-0.002 hPa. Above 0.01 hPa, the WVMR shows minimum March-May and September-November (0.7-0.8 ppmv) and maximum during June-August. It shows a large interannual variability at 31-64 km. The results from multivariate regression analysis show an increasing trend with maximum value of 0.045 ppmv/yr at 1.21-0.41 hPa. It shows a significant negative solar cycle response at mesospheric heights.

A1.1-0041-18 N2O PRODUCED IN THE MESOSPHERE - LOWER THERMOSPHERE AND ITS EFFECT ON O3 AND NOX IN THE MIDDLE ATMOSPHERE

Martyn Chipperfield, m.chipperfield@leeds.ac.uk University of Leeds, Leeds, United Kingdom

The satellite limb sounder ACE-FTS (Atmospheric Chemistry Experiment - Fourier Transform Spectrometer) is a solar occultation instrument that has been measuring trace gases and temperatures in the atmosphere since February 2004 and is still in operation. Throughout the mission, ACE-FTS has been measuring N2O concentrations in the mesosphere - lower thermosphere (MLT), which increase with altitude in the mesosphere. N2O has been hypothesised to be produced at high latitudes through energetic particle precipitation, and this study will compare the ACE-FTS N2O time series to simulations with the Whole Atmosphere Community Climate Model (WACCM) in different configurations to test possible N2O production mechanisms. WACCM-D (version with detailed ion chemistry in the lower D region of the ionosphere) will be used in a specified dynamics mode where temperature and wind values below 60 km are nudged towards reanalysis fields. The SD-WACCM-D runs will be modified to include the ion chemistry that can lead to N2O production in the MLT. In separate experiments, an updated version of WACCM but with simplified ion chemistry will be used to look at the potential additional role of photoelectrons in producing the MLT N2O, particularly at extra-polar latitudes. For both model versions, runs spanning the ACE-FTS time series with and without the relevant N2O production chemistry will be compared to ACE-FTS profile measurements in order to better understand how N2O is created in the MLT and its effects on O3 and NOx budgets throughout the middle atmosphere.

A1.1-0042-18 CUAD: CONSTELLATION FOR UPPER ATMOSPHERE DYNAMICS

Larry Gordley, l.l.gordley@gats-inc.com GATS, Newport News, Virginia, United States David Fritts, dave@gats-inc.com

GATS, Boulder, Colorado, United States John Fisher, jfisher@bphotonics.com

Brandywine Photonics, Exton, Pennsylvania, United States Benjamin Marshall, tom@gats-inc.com

GATS, Newport News, Virginia, United States

The dynamical coupling of lower to upper atmosphere has become an intense research topic. It is now quite clear that the lower atmosphere continuously imprints its dynamical state onto the upper atmosphere in the form of winds and waves. This signature from the dense lower atmosphere dynamically expands into the thin upper atmosphere like tsunamis coming ashore. The resulting waves and winds, if adequately observed, could be used not only to reveal their effects on the upper atmosphere, but to help monitor and forecast the evolution of lower atmosphere weather. This would require global observation from orbit, quite a challenge due to the required space and time resolution. Until now, such observations have been limited to Earth limb sensors (ex: GPS-RO and thermal imagers), which have an intrinsic horizontal resolution of 100 to 200 km. As a result, wave field measurements are smeared in time and space to the point of limited value for forecasting. But, if these upper atmosphere signatures could be resolved, it has been shown by a variety of groups that those wave and wind fields would act as powerful boundary conditions on forecast models. We show that new and enabling technologies, and a novel observation technique (gas filtered Doppler scanning, see Gordley and Marshall 2011), now make it possible to observe these parameters at resolutions required to fill this measurement deficiency. The proposed Constellation for Upper Atmosphere Dynamics (CUAD) could observe the upper atmosphere on a global scale at a resolution sufficient to resolve the dynamical connection of lower to upper atmosphere. This can now be accomplished with four types of simple static broadband emission imagers, two of which are gas filtered. The first sensor is a gas filtered broadband nadir emission imager, HATS™ (High Altitude Thermal Sounder). The second is a simple broadband limb emission radiometer LCER™ (Limb CO2 Emission Radiometer). The third is a gas filtered limb emission radiometer, DWTS™ (Doppler Wind and Temperature Sounder). The fourth is a star field limb imager, TStar™ (Temperature sounder using Star field images). These 4 imagers have a unique synergistic connection that eliminates the need for on-board calibration systems. Plus, each sensor technique, though new in its implementation, has space heritage. Finally, we show results of rigorous performance estimates, and describe how modern detector FPAs, satellite bus ADCS, processor power and downlink bandwidth have come together to enable a complete system calibration anchored to the refractive index of

air. This dramatically simplifies the hardware, and insures reliable observation of long-term trends. The talk will conclude with a list of major CUAD challenges and research needed for their solutions.

Gordley, L. L., Benjamin T. Marshall, "Doppler Wind and Temperature Sounder: A new approach using gas filter correlation radiometry", JARS, Vol 5, 2011.

A1.1-0043-18 MIGHTI (MICHELSON INTERFEROMETER FOR GLOBAL HIGH-RESOLUTION THERMOSPHERIC IMAGING): THE WIND AND TEMPERATURE INSTRUMENT ONBOARD THE NASA IONOSPHERIC CONNECTION (ICON) MISSION

The Michelson Interferometer for Global High-resolution Thermospheric Imaging (MIGHTI) is one of four instruments on the NASA Ionospheric Connection (ICON) Explorer mission currently scheduled for launch in 2018. ICON will investigate the extreme variability of the Earth's ionosphere with a unique combination of sensors on-board a single low Earth orbit satellite. The MIGHTI instrument will measure the global distribution of neutral winds and temperatures over an altitude range not accessible to in-situ probes using the Doppler Asymmetric Heterodyne Spectroscopy (DASH) technique for the wind measurements and a multi-color photometer technique to measure temperature. In this presentation, we discuss the instrument concept, design challenges and achievements, as-built specifications, and the anticipated data from orbit.

A highly miniaturized limb sounder for the observation of faint emissions in the atmosphere is presented. The selected technology is a Spatial Heterodyne Spectrometer (SHS). The throughput of a SHS is orders of magnitude larger than of a conventional grating spectrometer of the same size. Its monolithic design makes it extremely robust against vibrations and shocks. It can be designed to deliver spectra at very high spectral resolution to resolve individual emission or absorption lines, or even Doppler shifts to derive winds. The small mass and low energy consumption makes SHS instruments particularly suitable for the deployment on nano-satellites or as secondary payloads on larger satellites. In this presentation we introduce an instrument design for the measurement of temperature in the mesosphere and lower thermosphere by observing the rovibrational structure of the O2 atmospheric band at 762 nm in limb viewing geometry. This instrument is suited to fly on a 3-6 unit Cubesat or as a secondary payload on a larger satellite. To increase the horizontal resolution of the measurements, new observation strategies to operate such an instrument from an agile satellite platform are discussed.

A1.1-0045-18 THE MATS SATELLITE MISSION - TOMOGRAPHIC STUDIES OF CONSTITUENTS AND GRAVITY WAVE CHARACTERISTIC IN THE UPPER MESOSPHERE AND LOWER THERMOSPHERE

Linda Megner, linda@misu.su.se Stockholm University, Stockholm, Sweden Jorg Gumbel, gumbel@misu.su.se Stockholm University, Stockholm, Sweden

Chalmers University of Technology, Gothenburg, Sweden Nickolay Ivchenko, nickolay.ivchenko@ee.kth.se

Royal Institute of Technology, Stockholm, Sweden

MATS is an upcoming Swedish satellite mission designed to investigate structures and gravity waves in the mesosphere lower thermosphere. It will do so by observing O2 atmospheric band airglow in the near infrared (759-767 nm) and sunlight scattered from noctilucent clouds in the ultraviolet (270-300 nm). The main instrument is a limb imager with 6 spectral channels. Via tomographic retrieval the observed images will yield 3-dimensional data of airglow, temperature and cloud properties, allowing studies of gravity wave structures, wave parameters and variability. Scheduled for launch next year we are now in the phase where the flight models of the instruments are being assembled, and the data retrieval algorithms are being developed. While focusing on the scientific mission and analysis ideas this presentation therefore also reports on the current status and progress of the project.

A1.1-0046-18 GLOBAL 3D IONOSPHERE OBSERVATION SYSTEM BASED ON THE LEO NANOSATELLITE CONSTELLATION

Kateryna Aheieva, aheieva.kateryna486@mail.kyutech.jp Kyushu Institute of Technology, Kitakyushu, Japan Mengu Cho, cho@ele.kyutech.ac.jp

Kyushu Institute of Technology, Kitakyushu-shi, Japan

Ionospheric variability is strongly affected by the perturbations in the neutral atmosphere, electrodynamics, solar activity, geomagnetic activity and constantly fluctuates in a global scale. To improve and validate ionosphere numerical models, measurements taken by the individual satellite are used. To have higher spatial/temporal resolution, higher accuracy and lower cost than a system utilizing Global Navigation Satellite Systems (GNSS), we propose a constellation of nanosatellites to the LEO to do inter-satellite ranging to measure the total electron content (TEC) along the path. The electron density distribution will be known by the solving the inverse problem from many observations. This system aims at measuring ionosphere density with a spatial resolution of 15 km, a temporal resolution of 30 minutes with 1,000 CubeSats in different orbital planes in LEO. These target values have, much higher accuracy than GNSS and can be achieved with much lower cost than using GNSS system. Inter satellite ranging is the next generation technology that also can improve the accuracy of GNSS positioning. Currently, the first path-finder satellite, SPATIUM-I, is under development. SPATIUM-I will validate the key technologies, such as Chip-Scale Atomic Clock and the spread-spectrum modulated RF signal transmission as well as derivation of TEC.

A1.1-0047-18 A ROAD TOWARDS EARTHCARE: REMOTE SENSING OF ICE CLOUD PROPERTIES USING COMBINED LIDAR-RADAR MEASUREMENTS

Florian Ewald, florian.ewald@dlr.de

German Aerospace Center (DLR), Oberpfaffenhofen, Germany Silke Gross, silke.gross@dlr.de

German Aerospace Center (DLR), Oberpfaffenhofen, Germany Martin Wirth, martin.wirth@dlr.de

German Aerospace Center (DLR), Oberpfaffenhofen, Germany Julien Delanoë, julien.delanoe@latmos.ipsl.fr LATMOS/UVSQ/IPSL/CNRS, Guyancourt, France

Ice clouds play an essential role in the climate system since they have a large direct effect on the Earth's radiation budget. Their reaction to changes in water vapor concentrations and their interaction with aerosols still constitutes one of the largest uncertainties in climate change predictions. These uncertainties arise from uncertainties associated with the optical and microphysical properties of ice clouds as well as from insufficient knowledge about their spatial and temporal distribution.

Substantial improvement of our understanding of the interconnection of aerosols, clouds and radiation is expected from the combination of multiple instruments exploiting sensitivities at different wavelengths. To this end, the upcoming ESA/JAXA satellite mission EarthCARE will combine a new generation spaceborne lidar system, a cloud radar, and a multi-spectral imager on one single platform. In our work, we investigate the potential to combine lidar and radar measurements to retrieve ice cloud microphysics. For the first time, this study combines the high spectral resolution (HSRL) and differential absorption (DIAL) lidar system WALES and the 35 GHz cloud radar onboard the German High Altitude and LOng range research aircraft to retrieve ice cloud properties. During flight experiments over Europe and over the extra-tropical North-Atlantic (NARVAL1-2/NAWDEX), collocated measurements with the spaceborne CALIPSO/CALIOP lidar and CloudSat radar are used to investigate the influence of different wavelengths and spatial resolutions on retrieved ice cloud properties.

In our presentation, we will give first results of the synergistic approach using the differential sensitivity of the WALES lidar and the cloud radar to retrieve ice particle size and their concentration. Here, the central focus will be on the coordinated airborne and satellite measurements and on the comparison of retrieved ice cloud microphysics in preparation for the EarthCARE mission. In a

closure study with simultaneous solar radiance measurements and by comparison to in-situ the results of the synergistic approach will be furthermore evaluated.

A1.1-0048-18 MEGHA-TROPIQUES SCARAB OBSERVATIONS OF THE SEASONAL MEAN DIURNAL VARIATION OF CLOUD RADIATIVE FORCING OVER THE TROPICS

Space Physics Laboratory, VSSC, Thiruvanathapuram, India

Clouds are the largest modulators of earth energy balance. They play a major role in regulating energy and moisture transport, hydrological cycle and climate of the earth-atmosphere system. Cloud radiative forcing (CRF), defined as the change in radiative fluxes (shortwave, longwave or net) caused by the presence of clouds compared to when they are absent, varies with cloud properties and local time. Model estimation of cloud radiative forcing (CRF) is quite complex. Satellite observations of the upwelling shortwave and longwave radiative fluxes, on the contrary, provide the most reliable observations on CRF at TOA and their spatio-temporal variations. Diurnal variation of CRF cannot be estimated using observations made from polar sun-synchronous satellites. Observations carried out using the ScaRaB payload flown onboard the low-inclination (20°) Indo-French Megha-Tropiques (MT) satellite enable multiple observations of a given geographical location during the day, which can be used to address this objective. The results are in agreement with the CERES observations at 01:30 and 13:30LT (when the latter is available). The LWCRF shows intensification and deepening of organized convection during night, especially over the deep convective oceanic regions. Large meridional gradient of LWCRF occurs across the ITCZ, magnitude of which often exceeds 10 Wm−2 per degree latitude. In contrast, the convection intensity reduces significantly during the morning and noon period. This results in a diurnal variation of LWCRF with amplitude of about 10 to 20 Wm−2, which is over 20% of the magnitude of mean LWCRF over deep convective regions.

Over the deep convective areas (mainly in the ITCZ), though the peak noontime SWCRF exceeds 200 Wm−2, the diurnal mean SWCRF are comparable to the corresponding LWCRF.

The relationship between the instantaneous values of SWCRF and LWCRF for deep convective clouds is distinctly different from the other cloud types. Regions of major cooling are associated

with the occurrence of widespread and thick low level clouds. In addition to this, estimation of CRF during the normal and ElNino years is also investigated.

A1.1-0049-18 A COMPREHENSIVE VIEW ON THE CLOUD TYPE DISTRIBUTIONS IN SYNOPTIC AND MESOSCALE SYSTEMS OVER THE INDIAN SUMMER MONSOON REGION USING CLOUDSAT OBSERVATIONS

Subrahmanyam Kandula, kvsm2k@gmail.com

Indian Space Research Organization, Trivandrum, India Kishore Kumar Karanam, kishore_nmrf@yahoo.com Indian Space Research Organization, Trivandrum, India

Clouds have an enormous influence on the Earth's energy balance, climate and weather and play a key role in controlling the planet's temperature. The observations of clouds are more important for improving and validating the numerical models of Earth's weather and climate predictions. There has been plethora of studies on the spatial and vertical distribution of clouds using various satellites observations, which have enhanced the understanding of cloud dynamics and their representation in general circulation models. However, one of the outstanding research problems in realms of cloud dynamics is the vertical distribution of various types of cloud and multi-layered cloud distribution and their associated dynamics, which are yet to be understood thoroughly. In this regard, the present study quantifies the frequency of occurrence of the vertical distribution of various types of cloud and their associated dynamics over the Indian Summer Monsoon (ISM) region using CloudSat observations from 2006 to 2010. It provides the preferential regions of occurrence of each cloud type over the ISM region for the first time. The mean distribution of cirrus clouds emphatically showed the role of Tropical Easterly Jet in spreading the anvils of Deep Convective clouds forming over the head Bay of Bengal (BoB). It is observed that the stratocumulus clouds form most frequently over the north Arabian Sea and are confined to a narrow region. The distribution of DC clouds showed a pronounced peak in their occurrence frequency overhead BoB and secondary peaks over western coast, south BoB and central India. The prevailing dynamical features during the ISM period are studied in details to investigate their role in preferential formation of these clouds in a given region.

Further, using CloudSat observations, the distribution of vertically resolved multi-layered clouds and the role of large scale dynamics in controlling the formation of multi-layered cloud are studied. It is observed that over the Indian region one-, two-, three-, fourand five-layer clouds occur about 46, 26, 10, 4 and 2% of the time respectively. High fraction of single layer clouds is observed over the descending limbs of Hadley cell where relatively large lower tropospheric stability is found. It is found that the maximum occurrence of multilayer clouds migrates along with the movement of Inter tropical convergence zone (ITCZ). Apart from the equatorial region, multilayer clouds are observed more frequently over Indian summer monsoon region and mid-latitude storm tracks. The significance of the present study lies in establishing the vertical distribution of various types of cloud and distribution of vertically resolved multi-layer clouds and the role of dynamics

in modulating their distribution for the first time. It is envisaged that the present results may help in better understanding of cloud feedback mechanisms.

A1.1-0050-18 STUDY OF MICROPHYSICAL AND OPTICAL PROPERTIES OF LOW-HEIGHT WARM-CLOUD FROM MODIS LEVEL-2 DATA OVER INDIAN LANDMASS

Subhasis Banerjee, subhasis@jcbose.ac.in Bose Institute, Kolkata, India

Satellite retrievals of cloud properties play very important role in understanding impact of cloud system on earth's radiation budget and on climate systems. Cloud effective radius and cloud optical thickness, estimated from non-absorbing and absorbing wavelengths, are the two most important independent variables retrieved from sensors on-board many satellites including Earth Observing System (EOS) satellites Terra and Aqua. From cloud effective radius and cloud optical thickness other properties can be derived like cloud liquid water path, droplet number concentration etc. In my present study, MODIS level-2 cloud product from Terra have been used to asses micro-physical and optical properties of low-height, single-layer warm-clouds over entire landmass of India. Certain conditions were imposed in selecting cloud scenes to make sure that we choose liquid-only warm-cloud scenes. Cloud top height was set less than 2 km, cloud top temperature was set greater than 0°C and cloud effective radius was chosen to be within 3 to 30 mum. Such cloud scenes of an entire year have been utilized to study cloud effective radius, cloud droplet number concentration, cloud liquid water path and cloud geometrical thickness. MODIS level-2 cloud property data have been assessed for a whole year (2013 Nov 2014 Oct) over entire landmass of India. Data pixels averaged over 0.2 x 0.2 degree grid for latitude 10 to 30 and longitude 70 to 90. Comparative analysis of these properties also carried out for different climatic regions of India. Three different regions from west to east in the Indo-Gangetic plane have been chosen for this study. Three regions were designated as zone-1 to zone-3 respectively and they approximately fall in Arid, Humid subtropical and Tropical wet and dry regions. In our study, it is revealed that annual average cloud effective radius is lowest (7.5 mum) for zone-1 which falls approximately in arid region and highest for zone-3 (9.5 mum) i.e, increases form west to east. Droplet number concentration varies form 320/cc (zone-1) to 200/cc (zone-3). But in case of cloud liquid water path zone-1 shows lowest value (63 g m−2) and other zones more or less same value (sim 75 g m−2). Annual average of cloud optical thickness and cloud geometrical thickness is highest for zone-2. To best of my knowledge, such quantitative estimation and comparative analysis of cloud microphysical and optical parameters for low-lying warm-clouds over this region, is first of its kind.

A1.1-0051-18 SEASONAL VARIATION IN RAINDROP VELOCITY DISTRIBUTION AND ITS VERTICAL PROFILE IN THE WESTERN GHATS MOUNTAIN RANGE

Sreekanth T S, chlsreekanth@gmail.com

National Centre for Earth Science Studies(NCESS), ESSO-MoES, Govt. of India, Thiruvananthapuram, India

Dharmadas Jash, dharmadas.jash@gov.in

Nita Sukumar, nitasukumar@gmail.com

National Centre for Earth Science Studies(NCESS), ESSO-MoES, Govt. of India, Thiruvananthapuram, India

To study the seasonal variations in raindrop velocity distribution (DVD) and its vertical profile, a Parsivel disdrometer and a micro rain radar (MRR) are operated at a tropical mid altitude site, Braemore (8.5o N 77.6o E, 40 m amsl) in the Western Ghats mountain range for past one year. The site is already reported to be instrumental in Cumulonimbus (Cb) cloud formation (Vishnu et al 2013). Raindrop velocity distribution and its vertical profiles are recorded during pre monsoon (March, April May), monsoon (June, July, August September) and post monsoon (October, November December). Rain intensity RI (mm h–1), Mean diameter Dm (mm), Total number concentration NT (m–3) and Mean velocity VT (m s–1) are calculated in each one minute sampling interval. VT is arranged in 8 velocity bins (1-8 m s–1) of bin width 1m s–1.

Frequency of occurrence and water contribution in percentage are computed for each bin in all seasons. In all seasons maximum water contribution is from V7 (6-7 ms–1) and occurrence maximum in V5 (4-5 ms–1). In pre monsoon, percentage of occurrence in V6 (5-6 ms–1) is high (more than 40%). The relation between mean drop size (Dm) and VT are also analyzed in four seasons and found some preliminary observations. Violations are observed in GunnKinzer relations during pre monsoon, monsoon and post monsoons. Number of small/slow moving drops are more in summer monsoon and number of large/fast moving drops are more in pre monsoon seasons. DVD and its vertical profile are studied using MRR and disdrometer observation for different precipitation type such as convective, stratiform, transition and mixed phases. The effect of orography in precipitation and its seasonal variations are also investigated. Temporal variation of size velocity distribution along with RI, Total number concentration NT, Dm and VT for different rain events in three seasons are also studied. A sample event on June 5th, 2017. It is observed that in initial phase of the rain event the NT (m–3) is high and Dm is less but after this the NT shoot up again with less Dm and thereby less RI. The same is repeated again in the rain event after 25 minutes. Additional events will be investigated for a detailed picture of this kind variations.

A1.1-0052-18 TRANSPORTED AND AGED ANTHROPOGENIC AEROSOLS ACT AS BETTER CLOUD CONDENSATION NUCLEI COMPARED TO SEA-SALT AND FRESHLY EMITTED ANTHROPOGENIC AEROSOLS OVER EASTERN HIMALAYA, INDIA

Abhijit Chatterjee, abhijit.boseinst@gmail.com Bose Institute, Kolkata, India

Arindam Roy, arindamroy115@gmail.com Bose Institute, Kolkata, India

Abhinandan Ghosh, abhinandan1011@gmail.com Bose Institute, KOLKATA, India

Sanat Kumar Das, sanatkrdas@gmail.com Bose Institute, Kolkta, India

Sanjay Ghosh, sanjay@jcbose.ac.in Bose Institute, India

Sibaji Raha, sibaji.raha@jcbose.ac.in Bose Institute, India

The aerosol particles having the ability to form and foster the growth of cloud droplets at atmospheric SS are called cloud condensation nuclei (CCN). CCN has a great ability to perturb the cloud albedo, cloud lifetime, cloud height and other microphysical properties of cloud. Model and field based observations over marine and continental environments have shown the increase in cloud droplet numbers with the increase in CCN concentrations and that in turn increases the cloud reflectivity and cools the climate and suppresses the precipitation as well. A study was conducted on the relative role of freshly emitted and aged anthropogenic aerosols as well as transported sea-salt aerosols on the formation of cloud condensation nuclei over a high altitude (2200 m amsl) station, Darjeeling (27.01 °N, 88.15 °E) at eastern Himalaya in India. Condensation nuclei (CN) and cloud condensation nuclei (CCN) were measured using optical particle counter and CCN counter respectively during premonsoon (March-May) and monsoon (June-September) in 2016 and 2017. Size segregated aerosols were also collected and chemically analyzed in order to investigate the chemical composition of ultrafine aerosols activated to CCN. Sampling events were categorized based on the air mass trajectories. During premonsoon, most of the air masses were found to be arrived from western and central IndoGangetic Plain (IGP) driven by westerly winds. These air masses carried high amount of aged soot particles along with other anthropogenic sulphur and nitrogen species with higher hygroscopicity compared to freshly emitted soot and anthopogenic aerosols from local sources. The transported and aged soot and anthropogenic aerosols activated to CCN to a larger extent (CCN 2000 cm-3 with 45 % activation ratio) compared to the locally generated aerosols (CCN 1200 cm-3 with 25 % activation ratio). It was also observed that the activation of the transported soot and anthropogenic aerosols to CCN was higher than the transported sea-salt aerosols from the Bay of Bengal during monsoon. This could be due to

the fact that the sea-salt aerosols originated from the Bay of Bengal depletes chloride interacting with the anthropogenic SO42- and NO3- before arriving at eastern Himalaya and thus the activation potential decreases significantly. The study enables us to understand the fact that the soot and anthropogenic aerosols serve as better CCN due to atmospheric aging compared to transported sea-salt aerosols and locally generated anthropogenic aerosols over eastern Himalaya. Thus transport of anthropogenic aerosols from IGP is of paramount importance for modifying the cloud microphysical properties and in turn affecting the regional hydrological cycle over eastern Himalaya in India.

A1.1-0053-18 FIRST OBSERVATIONS OF TOTAL COLUMN OZONE, AEROSOL OPTICAL DEPTH AND PRECIPITABLE WATER CONTENT AT VILLAGE ATIGRE

Dada Nade, dada.nade@gmail.com

National Remote Sensing Center (NRSC) - Hyderabad, Hyderabad, India

This paper reports the results related to measurements of total column ozone (TCO), aerosol optical depth (AOD) and precipitable water vapor (PWC) at different wavelength using compact, handheld, multichannel sunphotometer (Microtop-II ozonometer) at Village Atigre. The Village is situated in a tropical region (16.74° N latitude, 74.37° E longitude, 604 meters altitude above sea level) and surrounded by vast agriculture and industry area, thus it is a unique place to study variations in TCO, AOD and PWC by anthropogenic activities. We have been collecting data from 1st September, 2017 and in this paper, we have selected only 45 days for presentation as first observations from 1st September,2017 to 15th October,2017. Overall mean values of TCO, AOT and PWC are 263(±5) DU, 0.25(±0.1) and 3(±0.27) cm respectively are observed in this period. Hourly mean daily variation in TCO, AOD and PWC show different characteristics. The observation of TCO taken on the autumnal equinox day (23rd Sept. 2017) is also presented. We found the negative correlation in daily mean of AOD and PWC. This may happen due to washout of the atmospheric aerosols by water molecules because the period was rainy season. We have compared our results with satellite data, total ozone mapping spectrometer (TOMS) data, from nearby stations, Pune and the results very much agree with TOMS values. We have planned to take observations for long period to study the diurnal, seasonal and annual variations TCO, AOT and PWC as well as natural and anthropogenic activity impacts on them. Keywords: Total column ozone (TCO), Aerosol optical depth (AOD), precipitable water vapor (PWC), Microtop-II ozonometer and TOMS

A1.1-0054-18 CHARACTERIZATION OF AEROSOL LOADING IN URBAN AND SUB-URBAN LOCATIONS: IMPACT ON ATMOSPHERIC EXTINCTION AND RELATIVE HUMIDITY

The study of atmospheric aerosols remains a very strong factor in the understanding of the earth's climate and its impact on the environment. Therefore, multiple satellite data was used to study the various aerosol species in Nigeria over a period of 10years. Furthermore, the effects of aerosols on relative humidity (RH) and atmospheric extinction was investigated. The result showed that aerosol loading peaks in the south and middle belt regions during the dry season (NovemberMarch), while the reverse was the case in the north during the rainy season (AprilOctober). It was found out that coarse aerosols prevail all year round within this region, with the rate of occurrence varying with season. The Carbon Monoxide (CO) data from Atmospheric Infrared Sounder (AIRS) satellite was converted to fine aerosols using the fine mode aerosol optical depth (AODf) data from AERONET as the conversion factor. Furthermore, the range of the ratio of coarse to fine aerosol was found to be as high as 19:1 during the rainy season in the north, while it reduced to 3:1 during the dry season. In Abuja and Ilorin, it ranged from 13:1 to 2:1 in both seasons with a similar situation for Port Harcourt and Ikeja at a relative ratio of 13:1 to 2:1 for the coarse to fine aerosol ratio for both the dry and the rainy seasons respectively. The atmospheric extinction values plotted against RH, showed that extinction grows at very low RH of about 45

A1.1-0055-18 MULTI-SATELLITE OBSERVATIONS OF THE TRANSPORT OF AEROSOLS AND MINERAL DUST OVER THE BAY OF BENGAL AND ITS IMPLICATIONS TO THE REGIONAL CLIMATE

S. Suresh Babu, sureshsplvssc@gmail.com

Vikram Sarabhai Space Centre, Thiruvananthapuram, India Lakshmi N B, nb.lakshmi26@gmail.com

ISRO, Thiruvananthapuram, India

Vijayakumar S Nair, vijayakumarsnair@gmail.com

Space Physics Laboratory, VSSC, Thiruvananthapuram, India

Bay of Bengal is playing an important role in the onset and progress of Indian monsoon through ocean - atmosphere coupling. The atmosphere over Bay of Bengal is more turbid compared to Arabian Sea and Indian Ocean due to the transport of aerosols from the nearby continents. In this context, the vertical distribution of aerosol and dust extinction coefficient over the Bay of Bengal is examined using multi-satellite observations (Cloud Aerosol Lidar with Orthogonal Polarization (CALIOP) and Moderate Resolution Imaging Spectroradiometer (MODIS)) for the period from 2006 to 2017. Distinct seasonal pattern is observed in the vertical structure of both aerosol and dust over the Bay of Bengal with an enhancement of 24 % in the aerosol extinction above 1 km from winter (December, January and February) to pre-monsoon (March, April, and May). Significant contribution of mineral dust is observed over the northern Bay of Bengal during pre-monsoon season where 22 % of the total aerosol extinction is contributed by dust aerosols transported from the nearby continental regions. During winter, dust transport is found to be less significant with fractional contribution of around 10% to 13% to the total aerosol optical depth over the Bay of Bengal. MODIS derived dust fraction (fine-mode based) shows an overestimation up to 2 fold compared to CALIOP dust fraction (depolarization based) whereas the GOCART (chemical transport model) simulated dust fraction underestimates the satellite derived dust fractions over the Bay of Bengal. The long term variation in dust aerosol showed a decreasing trend over the Bay of Bengal. However, significant dust induced heating is observed above the atmospheric boundary layer during pre-monsoon season. This dust induced elevated heating during the pre-monsoon can affect the convection over the Bay of Bengal which will have implication on the monsoon dynamics over the Indian region.

A1.1-0056-18 SPATIO - TEMPORAL VARIATION OF AEROSOL AND ITS INTERRELATIONSHIP WITH LAND USE LAND COVER (LULC) OVER NEW DELHI

MODerate resolution Imaging Spectro-radiometer (MODIS) on board NASA's Terra and Aqua satellite Level 2 Aerosol Optical Depth (AOD) data is used for aerosol study and LISS III sensor on board Indian Remote Sensing (IRS) Satellite procured from the National Remote Sensing Centre (NRSC), Hyderabad, India was used for vegetation cover estimation over New Delhi and its surrounding regions. Lowest AOD was found in the spring season where highest AOD in summer months. Different dates representing different seasons LISS III imageries were used for generation of land use land-cover (LULC) maps. A seasonal variation in the LULC has been observed. The land cover maps reveal that most of the surrounding areas of Delhi are covered with vegetation in March. By the month of May-June herbs are cut or dry from most of the region surrounding Delhi and the land cover in the surrounding areas changes to bare soil. During the rainy season (July to September) the vegetation cover over Delhi and the surrounding areas increases considerably. In November - December there is dispersed vegetation cover over New Delhi and its surrounding regions depending upon the age of the newly sown crop and ornamental plants. We found that, there is statistically significant negative correlation between AOD and Vegetation in every season. Further, a relatively higher AOD has been observed over the urban settlements and barren area over New Delhi.

A1.1-0057-18 SEASONAL VARIATION OF SOLAR IRRADIANCES AND AEROSOL RADIATIVE FORCING OVER DELHI-NCR

Purnima Bhardwaj, puru1939@gmail.com Jawaharlal Nehru University, New Delhi, India Amit Kumar Mishra, amit.mishra.jnu@gmail.com Jawaharlal Nehru University, New Delhi, India Alok Pandey, akpandeyjnu@gmail.com Jawaharlal Nehru University, New Delhi, India Krishan Kumar, kklab301@gmail.com

Jawaharlal Nehru University, New Delhi, India

V. K. Jain, vkj0400@hotmail.com

Jawaharlal Nehru University, New Delhi, India

Present study investigates the variation of the solar irradiances and radiative forcing (RF) during the summer and winter season over an urban and rural location in Delhi and National Capital Region (NCR), India. The solar irradiance (global and direct) measurements were carried out using a handheld FieldSpec Spectro-radiometer (325-1075nm wavelength range). NASA's Clouds and the Earth's Radiant Energy System (CERES) gridded Single Scanner Footprint (SSF) datasets of fluxes at the surface and top of the atmosphere (TOA) as well as Aerosol optical depth (AOD) products from collocated MODerate resolution Imaging Spectroradiometer (MODIS)-AQUA sensor were used to estimate the radiative forcing efficiency due to aerosol load at the Surface and TOA. The solar irradiances, both global and direct, were observed to be higher at the rural site as compared to the urban location in both summer and winter season. However, during the winter season only, the variation in the irradiances, especially direct, was found to be highly significant. TOA radiative forcing was estimated to be higher in summer than winter whereas at surface and in the atmosphere (ATM), RF was estimated to be higher in the winter season compared to summer at both the urban and rural locations. During the summer season, the ATM forcing was estimated to be higher at the rural site than that at the urban location. Whereas, not much significant difference in the ATM forcing during the winter season could be observed at both the sites.

A1.1-0058-18 VARIABILITY OF AEROSOL OPTICAL DEPTH AND ITS EFFECT ON CLIMATIC PARAMETER OVER VARANASI DURING 2011-2016

Aerosol is highly spatially and temporally variable. Nowadays it is playing an important role to understand the thermodynamics of climate. To study the variability of aerosol and its effect on climate satellite data are used. In our present study we have tried to know the direct or indirect effect of aerosol. Varanasi is highly populated city in the heart of Indo-Gangetic basin (IGB). Variability of aerosol in term of aerosol optical depth (AOD) over Varanasi (25.26° N, 82.99°

E) during 2011-2016 is analyzed and a slight increment has been found in the aerosol optical depth. AOD and surface air temperature are compared and observed that the temperature either found to be decreased with respect to high AOD or vice versa. It may be seasonal effect but over all, there is decrease in temperature on increasing AOD. Further AOD and relative humidity are compared and it is found that relative humidity is increasing on increasing AOD. It is also found that when temperature increases relative humidity decreases and vice versa which assure that AOD and temperature have negative correlation. Long term analysis, for the parameters aerosol optical depth, relative humidity and temperature, has been done. Small increment in these parameters is found during the year 2011-2016 which is contradicted to the results of their mutual comparison. It is to be concluded that no direct impact has been observed on the temperature influenced by AOD. There may be some other parameters which could affect the temperature.

A1.1-0059-18 AEROSOL CHEMICAL CHARACTERISTICS AT ALAKNANDA VALLEY (SRINAGAR) IN THE CENTRAL HIMALAYA REGION, INDIA

Indian Institute of Tropical Meteorology (Delhi Branch), New Delhi, India

The atmospheric aerosol is linked to poor air quality, adverse health effects and heat balance of the Earth directly through absorbing/scattering the solar radiation, indirectly by influencing cloud microphysics and possibly by changing the heterogeneous chemistry of reactive greenhouse gases. The direct and indirect effects of aerosols depend on size distribution and chemical composition of atmospheric aerosols. Apart from the size of aerosols, assessment of their chemical composition as a function of time is of crucial importance to understand atmospheric processes such as radiative transfer, cloud droplet nucleating ability, acidification, precipitation chemistry and dry deposition. A year-long (2016) ground-based measurements of PMs (PM2.5 and PM10) and its chemical constituents were made over Srinagar, Garhwal, Uttarakhand. Collected samples of PMs were analyzed for major water soluble chemical species such as anions (F-, Cl-, SO42-, NO2-, NO3-) and cations (Na+, K+, NH4+, Ca2+, Mg2+). The concentrations of PM2.5 and PM10 were 78.7 ±25.1 and 111.8 ±23.4 g m-3, respectively during the study period. The measured chemical species were found a large variability in different seasons due to the impact of emissions and meteorological parameters. The measured water-soluble chemical species of PM2.5 and PM10 were 43% (33.7 g m-3) and 57% (64.2 g m-3) during the study period. Higher concentrations of water soluble species were during the winter season followed by summer, monsoon and post-monsoon seasons. A significant correlation among NH4+ and Cl-, SO42-, NO3- in PM2.5 and PM10, respectively indicates its presence in the atmosphere in salt form. Neutralisation of acidic species due to cations was estimated and found that NH4+ play a crucial role in neutralisation in the winter season; however, the contrary feature was observed in the summer season where Ca2+ was responsible for the neutralisation of acidic components in

the PMs samples which were transported from the inland region during the summer. Principal Component Analysis shows that secondary aerosol, biomass burning, and soil-driven dust were the possible sources of the measured species over the station, which was further confirmed with the air mass back-trajectory analysis.

A1.1-0060-18 LONG RANGE TRANSPORT OF AIR MASS FROM THE CROP RESIDUE BURNING (WESTERN PARTS OF INDIA) DURING WINTER SEASON AND ITS IMPACTS ON HUMAN HEALTH AND WEATHER CONDITIONS OVER THE INDO-GANGETIC PLAINS (IGP)

Akshansha Chauhan, akshansha1886@gmail.com Sharda University, Greater Noida, India

Chapman University, Orange, California, United States

In this study, we have analysed Aerosols Optical properties over the Indo-Gangetic Plains (IGP) using Ground, Satellite and Aeronet data for the periods 2003-20017 from Lahore, Jaipur, Kanpur and Gandhi College during rice crop residue burning mainly in October-November. The plumes from the crop burning source region, depending upon the meteorological conditions (wind speed, relative humidity and air temperatures) are transported up to the eastern parts of the IGP and over the Bay of Bengal. Pronounced changes in atmospheric and meteorological parameters have been observed when farmers burn their crop residues, as a result dense haze, fog and smog are formed impacting weather conditions (dense haze, smog and fog) and human health. The air quality parameters degrade so fast and enhancement in greenhouse emissions are observed. Weekly analysis of all the parameters during the study period will be discussed. We have found the extent of smoke on the meteorological conditions. While the smoke is transported from the source region, the local dust emissions show strong mixing that is observed from the two AERONET stations (Kanpur and Gandhi College) in the eastern parts of the IGP. During October-November, we have observed changes in the weather conditions that may be related to increasing aerosol loading with the industrial developments and emissions from the coal based power plants.

A1.1-0061-18 TRENDS AND SEASONAL VARIABILITY OF PM10, PM2.5 AND BLACK CARBON IN MEGACITY DELHI: IMPACTS ON RADIATIVE FORCING

Arti Choudhary, artimavis@gmail.com

CSIR-Central Road Research Institute, New Delhi, New Delhi, India
Pradeep Kumar, pradeepph84@gmail.com

Banaras Hindu University, Varanasi, India Manisha Gaur, manisha.gaur@gmail.com

Central Road Research Institute, New Delhi, India Anuradha Shukla, anuradha.crri@gmail.com Central Road Research Institute, New Delhi, India

Atmospheric aerosols has gained great attention due to its radiative property, which impacts on climate change at local, regional and global scale. Specially, black carbon is a major contributor of climate change, second to CO2. Continuous and real-time measurements of the mass concentration of particulate matter (PM10, PM2.5) and black carbon (BC) were carried out in CSIR-CRRI, New Delhi. Daily data of aerosol optical depth (AOD), angstrom exponent (AE) and single scattering albedo (SSA) were taken from the space-borne satellite MODISterra at level 2 for the years 2015, 2016 and 2017. The annual mean concentrations of PM10 were observed 193±87, 227±72 and 257±159 gm3; PM2.5 were 172±92, 187±69 and 217±137 gm3; and BC were 4.3±1.8, 4.8±2.1 and 5.8±2.3 gm3 for the years 2015, 2016 and 2017 respectively. The average annual increment of PM10, PM2.5 and BC concentrations were found about 15, 14.3 and 13.8% from year 2015, 2016 and 2017, respectively,. The higher concentration were found during winter (1076, 789 and 10 gm3 of PM10, PM2.5 and BC, respectively) and a minimum were found in monsoon season (36, 17 and 2.7 gm3 of PM10, PM2.5 and BC, respectively) whereas, post and pre-monsoon seasons average concentration of PM10, PM2.5 and BC were 184±62, 87±43 and 4.7±1.7 gm3; and 69±28, 28±16 and 4.4±1.2 gm3, respectively. The BC concentration was found significantly high, nearly doubled during cloudy-sky conditions as compared to during clear-sky conditions. Seasonal trend decomposition were analysed based on locally weighted regression smoothing technique, and identified marginally decreasing trend (Delhi0.0079; Varanasi, 0.0087 DU year-1) due to reduction in monsoon time minima and summer time maxima. The aerosol optical properties like, AOD and SSA were found higher in winter but does not show a significant variation for other seasons, whereas AE exhibits significant seasonal variation, higher during winter and post-monsoon, indicative of high concentration of fine aerosols (BC and PM2.5) and found lower in pre-monsoon and monsoon, when coarser aerosols (PM10) were in abundant. The percentage contribution of BC to the net atmospheric forcing is varied between 54 to 68% during the years 2015-2017, which is supporting to strong radiative forcing of BC, that causing solar dimming to earth surface and global warming at local and regional scale. Key worlds: Black carbon; PM10; PM2.5; MODIS; AOD; Angstrom exponent; Single scattering albedo

A1.1-0062-18 VARIABILITY OF PARTICULATE MATTER AND ITS RELATIONSHIP WITH THE OPTICAL PROPERTIES OF AEROSOLS IN VARANASI, INDIA

Pradeep Kumar, pradeepph84@gmail.com Banaras Hindu University, Varanasi, India Arti Choudhary, choudharyarti12@gmail.com

Central Road Research Institute, New Delhi, India Vineet Pratap, vineet.prtp@gmail.com

Banaras Hindu University, Varanasi, India Abhay Kumar Singh, abhay_s@rediffmail.com Banaras Hindu University, Varanasi, India Rajendra Prasad, rprasad.app@itbhu.ac.in Institute of Technology-BHU, Varanasi, India

Associations of particulates have often been reported with bad health impacts, visibility reduction, variation in monsoon and change in climate and reduction of agricultural production. Further, information regarding variation of accumulation mode particles is rare over Varanasi, India. Driven by such knowledge gap, variation of particulates was analyzed at Varanasi over middle Indo Gangetic Plain. The particulate matters (PM: PM2.5 and PM10) were observed using two high volume samplers installed at Varanasi, India during November 1, 2016 to June 7, 2017. Space-borne passive (MODIS-Terra) daily observations were simultaneously used with ground based aerosol mass measurement for the winter (November-February) and summer (March-June) months. Exceptionally high aerosol mass loading was recorded for both PM10 and PM2.5, typically exceeding national standard. Wintertime PM2.5 and PM10 were found to be the major air pollutant causing significant deterioration of air quality with mean concentrations of PM2.5 (134.18 ± 47.16 g m3, range 42.83 - 257.76 g m3), PM10 (211.89 ± 79.02 g m3, range 123.23 - 464.52 g m3) and PM10-2.5 (77.71 ± 54.15 g m3, range 3.66 - 206.76 g m3). Wintertime is characterised with frequent events of biomass burning and poor dispersion of PM. During summer season low concentration of PM2.5 (39.05 ± 26.98 g m3, range 4.33 - 105.41 g m3), PM10 (135.95 ± 49.57 g m3, range 2.55 - 212.04 g m3) and PM10-2.5 (96.90 ±

55.55 g m3, range -102.86 ± 175.93 g m3) were found. The correlation coefficient (R = 0.74) was found between PM2.5 and PM10 in the winter season however R = 0.04 was found in the summer season. Very poor correlation between PM2.5 and PM10-2.5 were found in both winter and summer seasons. During summer months dust storms and transboundary emissions are prevalent resulting into persistence of mixed type of aerosols. The mean PM2.5/PM10 ratio was 63% in the winter season, is the indicative of a higher loading of the fine aerosol particles compared to the coarser aerosols in Varanasi. The Angstrom exponent values (> 1.0) over winter season indicating that in winter small aerosols particle are dominant. However, in summer season < 1.0 indicates the existence of bigger size of aerosol particles. A significant correlation between PM2.5 and MODIS-aerosol optical depth (AOD) ie.0.70 and between PM10 and MODIS-AOD i.e. 0.48 was found in the winter season. However a poor correlation was found in the summer season. Concentration Weighted Trajectory analysis show that PM2.5 and PM10 levels at the land stations were influenced by weak to moderate contributions from Arabian Sea, Tropical Indian Ocean and the arid South-west Asia and North-west India, peninsular India and from the polluted Indo Gangetic Plain region. Major source reasons were determined for the winter and summer seasons using back trajectory cluster analysis. Outcomes of the present study may be helpful to improve regional air quality and also for the other particulate source apportionment studies.

A1.1-0063-18 THE ENHANCEMENT OF SOOT PARTICLE, PARTICULATE AND GASEOUS POLLUTANTS ALONG WITH CHEMICAL SPECIES OF FINE PARTICLES DURING THE FOG EVOLUTION IN THE URBAN ATMOSPHERE

Suresh Tiwari, smbtiwari@yahoo.co.uk

Indian Institute of Tropical Meteorology, Pune, New Delhi, India Peter Tunved, peter.tunved@aces.su.se

Stockholm University, Stockholm, Sweden Atul Kumar Srivastava, atulkms@gmail.com

Indian Institute of Tropical Meteorology, Delhi, India Deewan Singh Bisht, dsbisht@tropmet.res.in

Indian Institute of tropical meteorology, Delhi, New Delhi, India Philip K Hopke, phopke@clarkson.edu

New York, United States

Multiple institution and sophisticated instruments were involved in making observations of atmospheric particulate matter at Indira Gandhi International Airport Delhi during the foggy period of 2016-2017 to understand the physical/chemical mechanism of fog formation that is useful to develop a suitable fog forecasting system and fog dispersal strategy. The observations of atmospheric black carbon (BC), online particulate matter (PM2.5 and PM10), gaseous pollutants (GP: NOx, CO, CO2 and O3) and various chemicals species (CS: F-, Cl-, SO42, NO22-, NO3-, Na+, K+, NH4+, Ca2+, and Mg2+) using a particle-in-liquid sampler for PM2.5 along with meteorological parameters were made during the winter foggy period. During this period, the mean concentrations of equivalent black carbon (eBC) was 11973 ± 5541.7 ng m-3 (12 µg m-3), much higher than most of the other parts of the world. The high values are due to increased emissions combined with poor dispersion conditions. The contributions of BCbb (biomass burning) and BCff (fossil fuel) were estimated to be 14% and 86% of the eBC, respectively, clearly indicating that the fossil fuel combustion BC dominated in Delhi in winter relative to biomass burning. The mean PM2.5 and PM10 concentrations were 139.5 (12 times higher than USEPA standard) ± 132.5 and 279.3 (8 times) ± 195.1 µg m-3, respectively. However, the mean gaseous concentrations were 22.2 ppb (NOx), 1.2 ppm (CO), 332 ppm (CO2), and 32.3 ppb (O3). The contributions of anions (F-, Cl-, SO42-, NO22- and NO3-) and cations (Na+, K+, NH4+, Ca2+ and Mg2+) were 47% and 53%. The highest contributions were Ca2+ (23%) followed by SO42- (18%). Additionally, the source regions and contributions to CS were studied with concentration weighted trajectory analysis. Six major source regions were identified. The concentrations of secondary acidic aerosol species (sulfate and nitrate) were significantly higher when the air masses pass within the Indian subcontinent mostly from Haryana state and the industrial zones of Faridabad and Okhla in Delhi. However, the calcium component was highest when air masses arrive from a long distance including desert areas. The chloride concentrations were highest when air masses arrive from northern Afghanistan, Pakistan during western disturbances in winter season. In overall, the study clearly indicated that the north-west part of India is highly polluted region and suggesting that the stagnant strategy is be required for its mitigation. The detailed findings of the present study will be presented.

A1.1-0064-18 EARTH OBSERVATION WITH THE ORBITAL-HUB FREE FLYER

In order to perpetuate the achievements of the International Space Station (ISS), DLR has conducted an extensive Post-ISS concept study by means of a series of Concurrent Engineering studies. The outcome design, referred to as Orbital-Hub, is based on a small crewed LEO platform including a human-tended Free Flyer and is centred on financial feasibility and user needs in the frame of human spaceflight. Beside diverse use cases for the Orbital-Hub, such as scientific and commercial µg application, exploration and technology demonstration, one application area comes from the Earth observation and climate measurement community. Within this paper it is elaborated, how the Orbital-Hub's Free Flyer could serve as an observation platform for passive and active atmospheric physics and for optical Earth observation in order to monitor trace gases, aerosols, greenhouse gases, hot spots and analysing the dynamic of our Earth's atmosphere.

A1.1-0065-18 INVESTIGATION OF ATMOSPHERIC ATTENUATION AND INFLUENCES FOR INTERPRETING MSI IMAGERY USING SENTINEL-2

Laura Santos, laura.b.santos07@gmail.com

Pennsylvania State University, Old Main, Pennsylvania, United States Guido Cervone, cervone@psu.edu

Penn State University, Old Main, Pennsylvania, United States

Each day hundreds of images are taken of the Earth's surface. These images are then used to gain information on topics including spatial planning, disaster management, natural resource sustainability, crop health/agriculture, urban planning, security, and others. Atmospheric effects can drastically affect the generation of physical products from reflected electromagnetic radiation. However, most satellites lack various bands that are required for a full characterization of the atmosphere, and instead model data are used during product generation.

The goal of this research is to investigate how the atmosphere (water vapor and aerosols) change the remotely-sensed image over different land covers and different seasons. The methodology uses two Sentinel-2 MSI products: the S2MSI1C, which is top-of-atmosphere reflectance and the S2MSI2Ap which is bottom-of-atmosphere reflectance. Comparison of the two products allows for quantization of the atmosphere as seen by the Sentinel-2 spectral bands. For this research, the within image atmosphere over three types of land cover is assessed: water, urban area, and forest. Finally, the quantization of the atmospheric attenuation is studied via time-series analysis over multiple images to understand how dynamic atmospheric effects change data and to identify seasonal patterns.

A1.1-0066-18 AMBIENT NEUTRON AND GAMMA MONITORING IN BRAZILIAN TROPICS

Anatoly Gusev, pesadelo@yandex.ru

Instituto Tecnologico de Aeronautica, Sao Jose Dos Campos, Brazil

Natural background of gammas (0.2-10.0 MeV) and neutrons were continuously monitored during a period from January 2016 to February 2017 in the region of south Atlantic Magnetic Anomaly (Sao Jose dos Campos, SP, Brazil). During this period abnormal rainfalls at twice of the historical average severity occurred in this location. After that, in February 2017, the region suffered extremely low precipitation and high temperature. Analysis of the data obtained revealed a distinct diurnal variation in the both natural radiation component and the correspondent temperature variation. It was also found that during rainfalls, the gamma radiation intensity increased and the neutron fluxes decreased. The first effect appears to be caused by atmospheric radiation fallout of radon gas accompanying liquid precipitation, the latter one - by cosmic ray neutron thermalization caused by the hydrogen contained in the atmospheric water vapor. A few events of short duration (1 minute); moreover, sporadic enhancements in neutron count rates were also observed. It is possible that these events are related with and modulated by thunderstorm and/or mild sporadic seismic activity in the region.

A1.1-0067-18 DYNAMICS OF NEAR-GROUND THERMAL NEUTRONS OF NATURAL ORIGIN

Anatoly Gusev, pesadelo@yandex.ru

Space Research Institute (IKI),Russian Acad. Sciences, Moscow, Russia Inacio Martin, martin@ita.br

Instituto Tecnologico de Aeronautica, Sao Jose Dos Campos, Brazil Walther Spjeldvik, wspjeldvik@weber.edu

Weber State University, Ogden, Utah, United States Mauro Alves, mauro.a.alves@gmail.com

Instituto Tecnologico de Aeronautica, Sao Jose Dos Campos, Brazil

Dynamics of near ground concentration of ambient thermal neutrons (TN) was studied using data of neutron detectors of the COsmic-ray Soil Moisture Observing System (COSMOS) network and those of the Laboratory of environmental radiation of the Instituto Tecnológico de Aeronáutica (Brazil). A significant excess of TN count rate over that of rapid neutrons was found in two COSMOS probes located in Brazil and in other sites in North America and Europe. The effect can be explained in terms of neutron production in nuclear (, n) reactions initiated by decay of radon gas comprised in the ground rather than in the lower atmosphere. The monitoring revealed strongly marked diurnal variation of the TN concentration which proved to be in anti-phase with air temperature; a feature that is characteristic for particles in thermal equilibrium with air. A previously unknown effect of saturation of nighttime TN concentration was observed. That effect appears to be explained in terms of a dynamic equilibrium state, which sets in because of the absence of vertical convection between the neutrons escaping from the ground and their losses in nuclear reaction in the air. The results hereby described can potentially be used for the determination of ground concentration of ambient radon and its related dynamics in boundary layer of atmosphere as well as in other geophysical studies.

A1.1-0070-18 STUDY OF LIGHTNING ACTIVITY USING WORLD WIDE LIGHTNING LOCATION NETWORK (WWLLN) OVER BENGALURU, INDIA

Nagaraja Kamsali, kamsalinagaraj@bub.ernet.in Bangalore University, Bengaluru, India

Robert Holzworth, bobholz@ess.washington.edu

University of Washington, Seattle, Washington, United States

The lightning, thunderstorm and electrical conductivity are the manifestation of electrical nature of the earth's atmosphere. The observations were made by the WWLLN network of USA, which includes a station at Bangalore University, Bengaluru, India. The continuous measurements shows the pronounced lightning activity and exhibits distinct diurnal and seasonal variability. Lightning is most frequent during afternoon hours and will continue till night-time. From recent years, the loss of lives due to lightning activity have crossed 1000 per year over India and the statistical variability of lightning stroke density over Bengaluru confirms the enhancement of activity from recent past. Preliminary study show that in addition to the observations of WWLLN over Bengaluru requires similar ground based and satellite data from/over other low latitude stations and also integrates it with visual and other observations reported in the media. An effort is also made to compare the data with TRMM/LIS to have the distribution of lighting stroke density. The details are discussed in the paper.

A1.1-0071-18 AN AI APPROACH FOR UNCERTAINTY MODELING AND PREDICTION OF AIR QUALITY, BASED ON LANDSAT8 AND MODIS-MISR ASYNCHRONOUS TIME SERIES BIG DATA

Ananjay Kumar Singh, ananjaysingh@gmail.com Indian Institute of Technology Roorkee, Roorkee, India Durga Toshniwal, durgafec@iitr.ac.in

Indian Institute of Technology Roorkee, Roorkee, India

The continuously deteriorating air quality specifically in major developing nations is a challenge for sustainability of healthy human race. One of the worst recent toxic smog formations was in the National Capital Territory of Delhi (NCT) in India during November-December 2017. Finding the multidimensional causality aspects of this dangerously hazardous situation is an important direction of research before devising any practical recommendations; henceforth any resilient solution. Landsat and MODIS satellite data are two of the most valuable data sets available in public domain for vegetation and other land cover changes on the earth's surface, particularly, the study of human influences involving agricultural farming(Cohen et al., 1998; Coiner, 1980; Coppin Bauer, 1994; Seto et al., 2002). The addition of thematic mapping(TM) sensors in 1982 provided additional higher resolution spectral bands. However, the main utility hindrances in these Landsat images are the occlusion by cloud, aerosol and other atmospheric artifacts (Asner, 2001). Estimated by The International Satellite Cloud Climatology ProjectFlux Data (ISCCP-FD), the annual mean cloud cover is approximately 66% at the global scale (Zhang et al., 2004). Therefore correction in cloud, aerosol and cloud shadow occluded band values are essential for any accurate analysis based on these data. This research presents a porotype model for utilization of heterogeneous Satellite and ground-based sensor data sets comprising Air Quality Index (AQI), Satellite retrievals of aerosol optical depth (AOD) and surface reflectance in various bands, to identify the causality patterns(particularly the effect of kharif crop shoot burning in neighboring states of Delhi (NCT) viz. Punjab, Haryana and Uttar Pradesh). The approach comprises Artificial Intelligence (AI) techniques for logical representation of heterogeneous satellite Big Data and data from in-situ ground-based sensors, causality relation weights learning to quantify uncertainty in band values(with/without occlusions), supplemented with inference and prediction capabilities. We have utilized Satellite retrievals of aerosol optical depth (AOD) from Landsat8 and MODIS-MISR (Multi-angle Imaging Spectroradiometer) along with New Delhi Historical data of Air Quality Index (AQI) from AirNow(Environment Protection Agency, USA) and data from Central Pollution Control Board, Government of India. This prototype approach of AI derived process pipeline can be easily replicated for other locations with capabilities such as timely forecast/warning issue and other long-term recommendations.

A1.1-0072-18 COINCIDENT OBSERVATIONS OF SURFACE OZONE AND NMVOCS OVER ABU DHABI

University of Miami, Miami, United States

The vertical profiles of ozone are measured coincidently with non-methane volatile organic compounds (NMVOCs) at the meteorological site located at the Abu Dhabi international airport (latitude 24.45N; longitude 54.22E) during the years 2012 - 2014. Some of the profiles show elevated surface ozone >95 ppbv during the winter months (December, January and February). The ground-level NMVOCs obtained from the gas chromatography-flame ionization detection/mass spectrometry system also show elevated values of acetylene, ethane, propane, butane, pentane, benzene, and toluene. NMVOCs and ozone abundances in other seasons are much lower than the values in winter season. NMVOCs are emitted from an extensive number of sources in urban environments including fuel production, distribution, and consumption, and serve as precursor of ozone. Transport sources contribute a substantial portion of the NMVOC burden to the urban atmosphere in developed regions. Abu Dhabi is located at the edge of the Arabian Gulf and is highly affected by emissions from petrochemical industries in the neighboring Gulf region. The preliminary results indicate that wintertime enhancement in ozone is associated with large values of NMVOCs at Abu Dhabi. The domestic production of surface ozone is estimated from the combination of oxygen recombination and NMVOCs and compared with the data. It is estimated that about 40-50This work is supported by National Research Foundation, UAE.

A1.1-0073-18 SIZE RESOLVED POLYCYCLIC HYDROCARBONS INTRINSIC TO PARTICULATE MATTER IN AMBIENT AIR OF A MEGACITY IN THE LOWER INDO-GANGETIC PLAIN: SEASONAL VARIATION, SOURCE APPORTIONMENT AND HEALTH EFFECT

Debajyoti Ray, debajray@gmail.com Bose Institute, Kolkata, India

Abhinandan Ghosh, abhinandan1011@gmail.com Bose Institute, KOLKATA, India

Abhijit Chatterjee, abhijit.boseinst@gmail.com Bose Institute, Kolkata, India

Sanjay Ghosh, sanjay@jcbose.ac.in Bose Institute, India

Sibaji Raha, sibaji.raha@jcbose.ac.in Bose Institute, India

An investigation was carried out to better understand the size distribution of particulate matter bound polycyclic aromatic hydrocarbons (PAHs) and their source contribution to the public health in the ambient air of Kolkata (22.33 °N and 88.20 °E), a densely populated megacity in the lower Indo-Gangetic Plain during October 2016 to May 2017. The PM bound PAHs were sampled by a 9-stage Anderson cascade impactor and 18 PAHs were quantified by highperformance liquid chromatography. The results showed that PAHs had bimodal distribution during both post monsoon (October November) and premonsoon (March to May) with mode peaks in the accumulation (0.4 µm < Dp<1.1 µm) and coarse (2.1 µm < Dp<10 µm) size ranges, whereas a sharp unimodal distribution during winter (December to February) in the accumulation size range. Additionally, the slope value of larger than -1 in the plot of log(PAH/PM) vs logDp suggested that the seasonal size distribution of the PAHs was influenced by multiple mechanisms, such as adsorption and absorption. Moreover, the total respiratory deposition flux was calculated to be (5.7 ± 1.2) ngh-1 and upper limit of the incremental lifetime cancer risk (ILCR) was observed to be mostly influenced by the ultrafine (Dp < 0.4 µm) and accumulation mode and the value was estimated to be 4.27 x 10-6. Furthermore, results from positive matrix factorization model indicated contributions of unburned petroleum, incineration, fossil fuel and coal burning at varying percentages as the major sources. The current study added useful information for better mechanistic understanding of size segregated seasonal distribution of PAHs intrinsic to ambient PM of a megacity, as well as the study provided information on its hazardous impacts on public health.

A1.1-0074-18 LONG TERM SATELLITE BASED STUDY ON AEROSOL AND TRACE GASES OVER THE CAPITAL CITY OF ASSAM, GUWAHATI

Jhuma Biswas, jhumabiswasdu@gmail.com Birjhora Mahavidyalaya, Bongaigaon, India Papori Dahutia, dahutia.papori@gmail.com Dibrugarh University, 786004, India

The variability and trend in aerosol optical depth (AOD) by using the Moderate Resolution Imaging Spectroradiometer (MODIS) level 3 Collection 6 data at 550 nm for the period January, 2004 to December, 2016 and tropospheric columns of nitrogen dioxide (NO2) and sulfur dioxide (SO2) data by using Ozone Monitoring Instrument (OMI) has been studied for the period October, 2004 to December, 2016 over capital city of Assam, Guwahati. The monthly average AOD value varies from its highest value (0.63±0.09) in March to its lowest value (0.23±0.05) in October for the study period over Guwahati. The seasonally averaged AOD reached its maximum in pre-monsoon (0.61 ± 0.06), followed by winter (0.47 ± 0.07) and monsoon (0.41

± 0.04), with the minimum occurring in post-monsoon (0.25 ± 0.06) season. The observed Ångström exponent value varies from its minimum value (1.18 ± 0.05) in monsoon season to its maximum value (1.35 ± 0.09) in post-monsoon season. Considerable long-term annual increasing trends in AOD, Ångström exponent and tropospheric NO2 column has been observed over the study location. An increasing trend of total number of vehicles along with their emissions degrades the air quality and thereby contributing to the increasing trend of AOD over Guwahati. A significant correlation between long term averaged MODIS AOD and OMI NO2 tropospheric columns with same seasonality indicating their same source of origination. Long term increasing trend in Ångström exponents (0.008 per year) signify the contribution of smaller size aerosols attributed to urbanization and human activity over Guwahati. The monthly average visibility in Guwahati is highest (27.5 km) in October with a moderate reduction observed during the monsoon, reaching a minimum of 7.2 km in March. With increasing AOD values, horizontal visibility decreases over Guwahati.

A1.1-0075-18 FEASIBILITY STUDY OF THE PREDICTIONS ABOUT THE CROSS-BORDER TRANSPORT OF AEROSOLS/PM2.5 USING THE DATA ASSIMILATION WITH HIMAWARI 8 DATA AND NICAM-CHEM MODEL

National Institute of Information and Communications Technology, Tokyo, Japan

We are making a forecasting system of air quality for human health from the distributions of aerosols including PM2.5, oxidants (tropospheric ozone), NOx, SOx and so on. A report by WHO estimated that the air pollution due to those species caused the health damage such as lung trouble and cerebrovascular disease corresponding to kill 3.7 million people in the world during the year of 2012. In the case of Japan, about a half of the observed PM2.5 and tropospheric ozone originate outside of the country, and, especially in the western Japan, the cross-border transport of PM2.5 from the continent is significant. Therefore, in the prediction of air pollution there, the enough consideration of the global-scale transports of aerosols and oxidants is indispensable.

Himawari 8 observes the column distributions of aerosols covering the East Asia with very high resolutions for both time (10 minutes) and space (5 km), and provide the open observational data sets within a day. We have derived the column density of PM2.5 from the data sets assuming the bimodal size distribution of aerosols based on the algorithm by Higurashi and Nakajima (1999), and assimilated the density data into the NICAM-Chem general circulation model (Goto et al. 2015). The method of assimilation is based on the optimal interpolation to be adaptable for the fast predictions with small computational resources. In the presentation we show the preliminary results of the assimilated PM2.5 distributions on Japan, and discuss the connection with the km-scale regional simulations to predict the urban air quality.

A1.1-0077-18 LONG TERM TRENDS IN VARIABILITY OF AIR POLLUTANTS AND PARTICULATE MATTERS OVER VARANASI, INDIA

Abhay Kumar Singh, abhay_s@rediffmail.com Banaras Hindu University, Varanasi, India Vineet Pratap, vineet.prtp@gmail.com Banaras Hindu University, Varanasi, India Akhilesh Kumar, akhi3006@gmail.com Banaras Hindu University, Varanasi, India Upal Saha, upalsaha22@gmail.com

National Centre for Medium-Range Weather Forecasting (NCMRWF), Noida, India

Varanasi (25.31 N, 82.91 W), a densely populated city which lies in the mid of Indo-Gangetic Basin (IGB) has been chosen as site for monitoring the present study. This study is carried out in order to examine long term (2005-2016) trends of different Air pollutants viz. (AOD, BC, SO2, NO2, CO) and particulates over Varanasi.In this study data has been collected from MODIS of various meteorological parameters for a long period (2005-2016) and seasonal variability is analysed for these years. Further Seasonal variation is classified in four seasons viz. winter, pre monsoon, monsoon and post monsoon. January,February are considered as Winter season and similarly March, April, May as Pre-monsoon June, July, August, September as Monsoon and October, November, December as Post-Monsoon period consecutively. AOD was observed lowest for monsoon season for all the years and comparatively higher values for winter and post monsoon seasons. Pre monsoon also witnesses higher value compared to monsoon period due to increased wind speed which carries soil with it which gets suspended in the atmosphere. Black Carbon (BC) isa result of incomplete combustion of fossil fuels such as coal, diesel, petrol and biofuel and biomass burning. BC is observed highest during post monsoon season and winter and comparatively lower in pre monsoon and monsoon. Since monsoon season experiences regular rainfall these shoots get washed away with rain and hence lower BC concentrations is observed in this season. Higher BC during winters may be the result of burning of woods and shrubs which people do practice during this season in order to keep themselves warm.NO2 column was observed highest during pre-monsoon period and subsequently lower for winter and post monsoon period for all the years and lowest for monsoon period, attributing the fact that in monsoon period NO2 present in the atmosphere get wet with rain and comes down to the earth with the rain. SO2 is observed highest for most of the years during post monsoon season and is recorded higher in winter as well as a result of burning of fossil fuels in this seasonand it attains lower values for both the seasons viz. monsoon and pre monsoon. CO also shows increase in winter season due to burning of fossil fuels in this season and lowest value in monsoon period is observed due to its wet removal in this season.

A1.1-0078-18 FINE MODE AEROSOL CHEMISTRY OVER A RURAL ATMOSPHERE NEAR THE NORTH-EAST COAST OF BAY OF BENGAL IN INDIA

Anandamay Adak, adak_bi@yahoo.com Bose Institute, KOLKATA, India

Abhijit Chatterjee, abhijit.boseinst@gmail.com Bose Institute, Kolkata, India

Arindam Roy, arindamroy115@gmail.com Bose Institute, Kolkata, India

Sanjay Ghosh, sanjay@jcbose.ac.in Bose Institute, India

Sibaji Raha, sibaji.raha@jcbose.ac.in Bose Institute, India

A study was conducted on the chemical characterization of fine mode aerosol or PM2.5 over a rural atmosphere near the coast of Bay of Bengal in eastern India. Samples were collected and analyzed during March 2013 - February 2014. The concentration of PM2.5 was found to span over a wide range from as low as 3 g m-3 to as high as 180 g m-3. Maximum accumulation of fine mode aerosol was observed during winter whereas minimum was observed during monsoon. Water soluble ionic species of fine mode aerosol were characterized over this rural atmosphere. In spite of being situated near the coast of Bay of Bengal, we observed significantly higher concentrations for anthropogenic species like ammonium and sulphate. The concentrations of these two species were much higher than the sea-salt aerosols. Ammonium and sulphate contributed around 30 % to the total fine mode aerosols. Chloride to sodium ratio was found to be much less than that in standard sea-water indicating strong interaction between sea-salt and anthropogenic aerosols. Non-sea-sulphate and nitrate showed significant contributions in fine mode aerosols having both local and transported sources. Source apportionment shows prominent emission sources of anthropogenic aerosols from local anthropogenic activities and transported from nearby Kolkata metropolis as well.

A1.1-0079-18 AEROSOLS AND SMOKE PLUMES CHARACTERISTICS DURING HIMALAYAN FOREST FIRE EVENT, 2016

Sarvan Kumar, shravanbhu09@gmail.com ARIES, Nainital, Nainital, India

Umesh Chandra Dumka, dumka@aries.res.in ARIES, Nainital, Nainital, India

The forest fires are common events seen over the Central Himalayan region during the premonsoon season (March - June). Some fire occurs naturally while some are reported as manmade. Forest fire plays a crucial role in governing the vegetation structure, ecosystem, climate change as well as in atmospheric chemistry. In regional and global scales, the combustion of forest and grassland vegetation releases large volumes of smoke, aerosols, and other chemically active species that significantly influence Earth's radiative budget and atmospheric chemistry, impacting air quality and risks to human health. Massive forest fires had recorded over the Central Himalayan region of Uttarakhand, Himachal, and Nepal during the year 2016, which continues for several weeks. To study this event we used the multi-satellite and ground-based observations of aerosols and pollutants during pre-fire, fire and post-fire period over the central Himalayan region. The data used in this study are active fire count and aerosol optical depth (AOD) from MODIS and ground-based AERONET, aerosol index and gases pollutants from OMI, along with vertical profiles of aerosols and smoke plume height information from Cloud-Aerosol Lidar and Infrared Pathfinder Satellite Observations (CALIPSO). The result shows that the mean fire counts were maximum in April. The daily average AOD value shows an increasing trend during the fire events. The mean value of AOD before the massive fire (25 April), during the fire (30 April) and postfire (5 May) periods are 0.3, 1.2 and 0.6 respectively. We find an increasing trend of total columnar NO2 over the region during the massive fire event. Space-born Lidar (CALIPSO) retrievals show the extent of smoke plume heights beyond the planetary boundary layer (free troposphere) up to 6 km during the peak burning day. The HYSPLIT air mass forward trajectory shows the long-range transportation of smoke plumes. The results of the present study provide valuable information for addressing smoke plume and aerosol transport in the Himalayan region.

Keywords: Forest-fire; Fire counts; AOD, Smoke plumes; CALIPSO

A1.1-0080-18 BIOMASS BURNING IMPACT ON AIR QUALITY IN NORTHERN SUB-SAHARAN AFRICA (NSSA)

Richard Damoah, richard.damoah@nasa.gov

NASA/GSFC, MSU/GESTAR, Greenbelt, Maryland, United States

Emissions from biomass burning such as nitrogen oxides (NOx), carbon monoxides (CO), and primary aerosols do not only affect air quality locally, but also on continental to hemispheric scales through long-range transport. It is estimated that about 350 Million hectares of land burn globally every year of which 54 % are in Africa. The northern sub-Saharan African (NSSA) region (0 - 20N, 20W - 55E) is known to show one of the highest biomass burning rates (in terms of per unit land area) among all regions of the world. This is due to the high concentration and frequency of fires in this region. In 2016 a newly installed AERONET (Aerosol Robotic Network) sun photometer at All Nations University College (6.2N, 0.3W) within the NSSA region recorded enhanced aerosol optical depth presume to be triggered by smoke from fires. We will discuss sources of this enhancement as well results obtained from NASA's Global Modeling Initiative Chemistry and Transport Model (GMI-CTM), to quantify the impact on air quality by biomass burning.

A1.1-0081-18 A DECADAL (2007-2017) STUDY ON MERIDIONAL COUPLING BETWEEN POLAR AND TROPICAL REGIONS DUE TO SUDDEN STRATOSPHERIC WARMING (SSW) EVENTS

Vinay Kumar, dabas.vinay@gmail.com University of Delhi, Delhi, India Surendra Dhaka, skdhaka@gmail.com Delhi University, Delhi, India

The meridional coupling between polar and tropical stratospheric regions due to sudden stratospheric events is being investigated during all events occurred in the last decade (from 2007 to 2017). Using COSMIC RO data during two strong SSW events (2009, and 2013), It is observed that polar and tropical regions get coupled possibly through the rapid setup of strong meridional circulation within a period of one day, as a result significant temperature changes are observed in stratosphere and tropopause region from polar to tropical region. SSW event can strongly modify the polar and tropical stratospheric circulation pattern, which results a new pattern after termination of SSW. The newly emerged pattern usually dominates for 2-3 months. Stratospheric and tropospheric region have shown certain unique changes after the event such as a clear downward propagating cold phase at polar region, which located at similar heights as that of SSW phase. The magnitude of this cold phase was -80°C whereas the temperature prevailed of with 40°C in upper stratosphere (>30 km altitude) during SSW event. On the other hand, during cold phase at polar region that followed after the SSW event, a new warm motion emerged over tropical region. Strong implications of these unusually warm and cold phases are shown. Specifically it altered the cold point tropopause temperature and its height significantly for a period of 2-3 months from polar to tropical region. Cross equatorial response from northern to southern hemisphere of both cold and warm anomalies are also seen, such features are reported using COSMIC data which unprecedented.

A1.1-0082-18 SUDDEN STRATOSPHERIC WARMING (SSW) EVENTS AND RAPID SETUP OF DYNAMICAL CONNECTION FROM POLAR TO TROPICAL REGION: RESULTS FROM COSMIC OBSERVATIONS

Surendra Dhaka, skdhaka@gmail.com Delhi University, Delhi, India

Vinay Kumar, dabas.vinay@gmail.com University of Delhi, Delhi, India

We have analyzed temperature changes in troposphere and stratosphere from polar to tropical region during major sudden stratospheric warming (SSW) using data derived from COSMIC over a period of 2007-2016. During peak period of SSW, a large variability noted in temperature structure, rise in temperature occurred down to the tropopause height (8 km height) in polar region. At around 40 km altitudes (as COSMIC data is available to this height), temperature increased by several tens of degrees within few days of SSW. After SSW termination, temperature decreased up to 80°C in strong SSW cases. After about a week of SSW event, descending cold anomalies emerged at polar region. These features are emerging normally known as polar night jet oscillations (PJO). The cooling phase was much longer along with large spatial coverage than the warm phase. Due to SSW, polar T-CPT and H-CPT alter significantly. As a consequence of SSW, bottom of stratospheric region expands and hence the tropospheric region shrunk by the same height. A rapid atmospheric response is identified between polar and tropical region possibly through set up of strong meridional circulation. During occurrence of SSW, at 40 km altitude in polar region, large increase in temperature noted, while in the tropics temperature dropped at similar heights. After termination of SSW, descending warm anomalies observed over the tropical region for a longer duration, while the long cold phase persisted at the polar region. These warm anomalies at tropical region are much longer and deeper in comparison to those of the cold anomalies. It is concluded that SSW event at polar region connects to the entire tropical tropopause region across the equator in SH up to 40°

S. Hence these processes need to be understood thoroughly to contribute to the temperature change.

A1.1-0083-18 RESIDUAL MEAN CIRCULATION DURING THE EVOLUTION OF SUDDEN STRATOSPHERIC WARMING

Sourabh Bal, sourabhbal@gmail.com

Swami Vivekananda Institute of Science and Technology, Kolkata, India Semjon Schimanke, semjon.schimanke@met.fu-berlin.de

Freie Universität Berlin, Berlin, Germany Thomas Spangehl, spangehl@met.fu-berlin.de Freie Universität Berlin, Berlin, Germany Ulrich Cubasch, cubasch@zedat.fu-berlin.de Germany

Zonal mean flow changes during the evolution of sudden stratospheric warming are investigated by composite analyses of 76 warming events identified in the present day simulation from 299 winters. Their dynamical signatures are compared with the 17 SSW events using EraInterim data from 34 years (1979-2013). The main difference is that monthly distribution of the model SSW events are relatively less than reanalysis. The SSW events are classified as displacement or split events based on the geopotential field values at 10 hPa. The streographic projection of geopotential field values identifies 10 and 3 split events in model and observation respectively. The model quite accurately simulates some dynamical features associated with the major SSW. Residual mean circulation induced by EP-flux divergence, sum of advection and residual forcing are stronger in split events than displacement type SSW has been confirmed by both simulation and observation. Composite analysis of warming events from Era-Interim (1979-2013) record a cooling of the tropical lower stratosphere with corresponding changes in the mean meridional stratospheric circulation. A cooling of the upper troposphere induces enhanced convective activity near the equatorial region of the Southern Hemisphere and suppressed convective activity in the off-equatorial Northern Hemisphere. After selecting vortex splits, the sea-saw pattern of convective activity in the troposphere grows prominent and robust but the signal evolves somewhat earlier in model.

A1.1-0084-18 CHANGES IN MIDDLE ATMOSPHERIC CHEMICAL COMPOSITION OVER EQUATOR DURING SUDDEN STRATOSPHERIC WARMING EVENTS

Oindrila Nath, oindrila.nath27@gmail.com

National Atmospheric Research Laboratory, TIRUPATI, India Sridharan Sundararajan, susridharan@narl.gov.in

National Atmospheric Research Laboratory, Pakala, India

Microwave Limb Sounder (MLS) and Michelson Interferometer for Passive Atmospheric Sounding (MIPAS) data are used to investigate the variation of ozone (O3), water vapour (H2O) and methane (CH4) volume mixing ratios (VMRs) in the equatorial stratosphere during 2009 and 2012 sudden stratospheric warmings, whose occurrence are identified using the ERA (European Center for Medium Range Weather Forecasting Reanalysis) Interim temperature and zonal wind. The Whole Atmosphere Community Climate Model (WACCM) reproduces the observed increase (decrease) of CH4 (H2O). It is suggested that short-term CH4 and H2O variations are due to tropical upwelling of air rich in CH4-rich and H2O-poor air.

A1.1-0085-18 MERGING DATASET OF STRATOSPHERIC OZONE PROFILES FROM OMPS, SCIAMACHY AND MLS LIMB OBSERVATIONS

Carlo Arosio, carloarosio@iup.physik.uni-bremen.de University of Bremen, Bremen, Germany

Elizaveta Malinina, malininaep@iup.physik.uni-bremen.de

Institute of Environmental Physics, University of Bremen, Bremen, Germany Alexei Rozanov, alex@iup.physik.uni-bremen.de

University of Bremen, Bremen, Germany

John Burrows, burrows@iup.physik.uni-bremen.de

Institute of Environmental Physics, University of Bremen, Bremen, Germany

A constant monitoring over a global scale of the stratospheric ozone layer is carried on by means of several techniques. The limb geometry of observations from satellite platforms enables to obtain ozone profiles with a good vertical resolution, spatial and temporal coverage. SCIAMACHY and OMPS-LP are two satellite instruments able to collect shortwave scattered radiance in limb geometry. Ozone profiles from OMPS-LP and SCIAMACHY have been retrieved at the University of Bremen using the same radiative transfer model, a similar algorithm and spectral ranges. This study illustrates the merging of these two data sets, to obtain a consistent time series of ozone global distributions in the stratosphere. Since OMPS' scientific operations started at the beginning of 2012, the overlapping period of these 2 missions consists of only 3 months and a transfer function is needed to overcome issues related to the instrument calibration. To this aim, we used measurements performed by the MLS suite as a reference: this sensor has been operating from 2004 till present, collecting atmospheric emission in the microwave spectral region in limb geometry. Latitudeand longitude-resolved time series of ozone profiles retrieved from the three instruments have been calculated, thanks to the high spatial resolution of the merged data sets. After an inter-comparison of the three time series and their respective seasonal cycles, the merging has been performed minimizing the bias of both OMPS-LP and SCIAMACHY ozone number density profiles to MLS values, for each latitude, longitude and altitude independently. The seasonal cycle was not subtracted, because it was found to be consistent enough among the three instruments. Linear trends over the 2003-2017 merged time series were calculated considering QBO, ENSO and a solar forcing. Results are shown in this poster.

A1.1-0086-18 LONG-TERM VARIABILITIES AND TENDENCIES IN ZONAL MEAN TIMEDSABER OZONE AND TEMPERATURE IN THE MIDDLE ATMOSPHERE AT 10-15°N

Oindrila Nath, oindrila.nath27@gmail.com

National Atmospheric Research Laboratory, TIRUPATI, India Sridharan Sundararajan, susridharan@narl.gov.in

National Atmospheric Research Laboratory, Pakala, India

Long-term variabilities and trends of middle atmospheric (20–100 km) ozone volume mixing ratio (OVMR) and temperature and their responses towards quasi-biennial oscillation (QBO), solar cycle (SC) and El Niño-southern oscillation (ENSO) have been investigated using monthly averaged zonal mean Sounding of Atmosphere by Broadband Emission Radiometry (SABER) observations at 10–15°N for the years 2002–2012. Composite monthly mean of OVMR shows semi-annual oscillation (SAO) predominantly in the lower stratosphere (20–30 km) and in the upper mesosphere (above 90 km), whereas that of temperature shows SAO in the upper stratosphere (45–55 km) and lower mesosphere (60–75 km). Amplitudes of SAO and annual oscillation (AO) in OVMR show enhancement above 80 km and 90 km respectively in the mesosphere and both show maximum around 30 km in the stratosphere. The amplitudes of SAO and AO in temperature show maxima just below and above 80 km in the mesosphere, whereas in the stratosphere, they show maxima around 40 km and 20 km respectively. The phase profiles of SAO and AO in temperature show downward progressions below 80 km, whereas the phase profile of SAO in OVMR shows downward progression only below 40 km and the phase remains constant above 80 km. Regression analysis of OVMR shows increasing trend at 23 km, and small decreasing trend at 30 km, 34 km and above 80 km. Above 92 km, the trend sharply decreases. OVMR response to QBO winds at 30 hPa shows negative maxima at 30 km and 91 km, positive maximum at 26 km and is insignificant at other heights. The OVMR response to SC is positive in the middle stratosphere peaking at 31 km and in the upper mesosphere peaking at 95 km. The OVMR response to ENSO shows mixed behavior in stratosphere and positive in the upper mesosphere. It is positive in the lower height region 20–27 km with maximum at 25 km. The response to ENSO is insignificant up to 70 km and it is positive above 80 km with two maxima at 87 km and 97 km. Regression analysis of temperature shows cooling trends in most of the stratosphere and the mesosphere (40–90 km). The temperature response to SC is increasingly positive above 40 km. The temperature response to ENSO is negative in the middle stratosphere and positive in the lower and upper stratosphere. In mesosphere, it is largely negative in the height range 60–80 km and positive above 80 km.

A1.1-0087-18 PREDICTIONS OF THE ONSET OF MINI ICE AGE IN THE 25TH SOLAR CYCLE

Rajiv Kumar, captainrajiv@live.com

Department Of Physics Govt. College Parasia, Chhindwara, India

Predictions of the ir-regularity in the 11 year heartbeat of the Sun due to asynchronous of the two layered dynamo effect would result in mini ice-age as in the Maunder minimum. The onset of this event is expected in the beginning of 25th Solar cycle and would go to its maximum in the 26th Solar cycle. The minimum temperature is expected in 2028 due to the fall of solar activity by 60% termed as Solar Hybernation. The predictions are based on the observations obtained by the Royal Greenwich Observatory since 1874.

Keywords: Dynamo effect, Munder Minimum, Solar hybernation

A1.1-0088-18 THE ANGULAR CHARACTERISTICS AND POTENTIAL APPLICATION OF MOON-BASED EARTH OBSERVATION IN THE ELECTRO-OPTICAL REGION

Yuanzhen Ren, ryz1123@163.com

Institute of Remote Sensing and Digital Earth, Chinese Academy of Sciences, Beijing, China Huadong Guo, hdguo@radi.ac.cn

Institute of Remote Sensing and Digital Earth, Chinese Academy of Sciences, Beijing, China Guang Liu, liuguang@radi.ac.cn

Institute of Remote Sensing and Digital Earth, Chinese Academy of Sciences, Beijing, China Hanlin Ye, yehl@radi.ac.cn

Institute of Remote Sensing and Digital Earth, Chinese Academy of Sciences, Beijing, China

So far, space-borne, airborne, and ground-based remote sensing have provided us with a lot of valuable observation data. However, it is difficult or impossible for the existing remote sensing platforms to achieve the long-term consistent measurements. Thus, Moon, the only natural satellite of Earth seems to be a good platform for earth observation to solve the problem. However, the orbit and motion of Moon is completely different from other earth observation platforms, resulting in entirely different geometric characteristics.

Meanwhile, the angular information is an important and typical geometric characteristic of remote sensing with extensive applications, especially in the fields of atmosphere, radiation, oceanography and vegetation. Therefore, we focus on the angular characteristic of Moon-based earth observation in this paper. Considering equipment cost, energy demand and processing complexity, the optical remote sensing is mainly discussed in this research as the first step. As there is no long-term and stable Moon-based Earth observation data, a combination of simulation, numerical calculation and theoretical derivation were used.

Based on the Jet Propulsion Laboratory DE430 and Earth orientation parameters, together with related coordinate systems transformation, the position and attitudes of Sun, Earth and Moon were derived. At the same time, the direct illuminated region on the Earth is decided. Then, an angular geometrical model of Moon-based Earth observation was constructed and the angular algorithm was designed. The angular results were analyzed and it turned out that the solar and viewing zenith and azimuth angles of Moon-based Earth observation showed a good performance with the potential for global energy budget monitoring. Compared with space-borne remote sensing, the lunar observatory is able to observe the whole disk of Earth with various angular range, showing the potential for monitoring the large-scale geoscientific phenomena, especially energy budget.

A1.1-0089-18 A STUDY OF TROPICAL CYCLONES OVER INDIA (BAY OF BENGAL AND ARABIAN SEA) AND SOLAR INFLUENCE ON IT

Dhruba Banerjee, dhrubabanerjee81@gmail.com

Swami Vivekananda Institute of Science and Technology, KOLKATA, India

A prominent example of extreme weather event in India is Cyclonic Storm. In this paper annual variation of tropical Cyclonic Storm (CS), Severe Cyclonic Storm (SCS), Very Severe Cyclonic Storm (VSCS) and Super Cyclonic Storm (SuCS) over Bay Of Bengal (BOB) and Arabian Sea (ARS) during last 20 years (1990-2009) have been analyzed .The analysis revels that the total number of cyclone (TNC) has increased with high rate(gradient being +1.67 per year) and although C.S. is more over BOB than that over ARS.The rate of increase of

C.S. over Arabian Sea is more than that over Bay of Bengal. Furthermore, two interesting features have been noted: (i) Monsoon tends to prohibit the formation of C.S (ii) Cyclonic Storm(C.S.) increases with the increase of Global Sea Surface Temperature (GSST) during said period. Attempt has also been made to find out the influence of solar activity on these extreme weather events. Keeping in mind that the Sun Spot Number (SSN) is an indicator of the strength of solar effects, it has been found that in most of the times the high value of SSN is associated with small number of total cyclone (C.S.). Specifically, when only the years of high Sun's Spot Number (approximately greater than 90) are taken into consideration then Correlation Coefficient (C.C.) between SSN and number of cyclones comes out to be quite high (-0.78) significance at 99.99. The wavelet analysis also has been done to get a significant periodicity of the tropical cyclone.

A1.1-0090-18 THE TROPICAL CYCLONES OVER INDIA (BAY OF BENGAL AND ARABIAN SEA) AND THE IMPACT OF THIS HAZARD IN TO THE SOCIOECONOMIC STRUCTURE OF THE MEGA CITIES AND THE COASTAL AREA OF INDIA

Dhruba Banerjee, dhrubabanerjee81@gmail.com

Swami Vivekananda Institute of Science and Technology, KOLKATA, India

A prominent example of extreme weather event in coastal area of India is Cyclonic Storm. In this paper annual variation of different types of tropical Cyclonic Storm (CS) over Bay Of Bengal (BOB) and Arabian Sea (ARS) during last 40 years (1970-2010) have been analyzed .The analysis revels that the total number of cyclone (TNC) has increased with high rate (gradient being +1.67 per year) but the rate of increase of C.S. over Arabian Sea is more than that over Bay Of Bengal. Furthermore, two interesting features have been noted: (i) Monsoon tend to prohibit the formation of CS (ii) Global Sea Surface Temperature (GSST) increases with the increase of CS (if not facilitate) the Cyclonic Storm to form during said period. Attempt has also been made to find out the impact of such hazard into the vast coastal area of 7516.6 km long and the population of 14.2% with respect to whole nation. From last 4 decades the no. of cyclone become increases but the life causalities has been decreases. On the other hand the damage on the aspect of property and economy it increased. The increase of population and construction in coastal area also enhance the property damage and economic losses. Here in this study we have found some significant result to understand this impact of cyclonic storm in the coastal area and some megacities of there of India over Bay of Bengal and Arabian Sea.

A2.1-0001-18 THE PROGRESS OF SATELLITE ALTIMETRY IN OCEAN CIRCULATION LEADING TO THE SWOT MISSION

Lee-Lueng Fu, llf@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Rosemary Morrow, rosemary.morrow@legos.obs-mip.fr LEGOS/GRGS, Toulouse, France

The Surface Water and Ocean Topography (SWOT) is a satellite mission to map the elevation of water on Earth over both the ocean and land surface water for applications to oceanography and hydrology (https://swot.jpl.nasa.gov/). This presentation will address the progress from conventional altimetry leading to the oceanographic objectives and plans of the mission. Over the ocean, this new measurement will extend the two-dimensional resolution of ocean surface topography estimated from conventional radar altimetry from 150 km wavelength to possibly 15 km, offering opportunities to study the oceanic dynamic processes at these scales over the global oceans.

The dynamic processes at the scales of 15-150 km have typical temporal scales of days to weeks and act as one of the main gateways that connect the interior of the ocean to the upper layer. These processes provide both sink and source for the kinetic energy at larger scales, involving both low-frequency geostrophically balanced motions and high-frequency internal tides and gravity waves. The active vertical exchanges linked to these scales are a key aspect of the role of the ocean in the climate system. These vertical exchanges have impacts on the local and global budgets of heat, carbon and nutrients for biogeochemical cycles.

It is currently a major observational challenge to measure the ocean fine scales over domains large enough to quantify their global effects. For this reason our knowledge on the fine scales is largely based on simulations performed by high-resolution circulation models. SWOT will address this observational gap, and provide an unprecedented opportunity to study these motions and their interactions, which is key to understanding the energy budget of the global ocean dynamics. Model simulations have been conducted to illustrate the impact of the mission on the study of the oceanic mesoscales and submesoscales.

In terms of applications, the high-resolution SWOT data will allow a more accurate observation of fine-scale ocean currents, sea level and tides, in the coastal regions. These joint geostrophic and tidal currents feeding into operational models will help improve maritime operations, ship- ping routes, pollution and debris monitoring.

A2.1-0002-18 SENTINEL-3 SAR ALTIMETRY OVER COASTAL AND OPEN OCEAN: PERFORMANCE ASSESSMENT AND IMPROVED RETRIEVAL METHODS IN THE ESA SCOOP PROJECT.

The European Sentinel-3 satellite, launched by ESA in February 2016 as a part of the Copernicus programme, is the second satellite to operate a SAR mode altimeter. The Sentinel 3 Synthetic Aperture Radar Altimeter (SRAL) is based on the heritage from CryoSat-2, but this time complemented by a Microwave Radiometer (MWR) to provide a wet troposphere correction, and operating at Ku and C-Bands to provide an accurate along-track ionospheric correction.

SRAL is operated in SAR mode over the whole ocean and promises increased performance w.r.t. conventional altimetry. SCOOP (SAR Altimetry Coastal Open Ocean Performance) is a project funded under the ESA SEOM (Scientific Exploitation of Operational Missions) Programme Element, started in September 2015, to characterise the expected performance of Sentinel-3 SRAL SAR mode altimeter products, in the coastal zone and open ocean, and then to develop and evaluate enhancements to the baseline processing scheme in terms of improvements to ocean measurements. Another objective is to develop and evaluate an improved Wet Troposphere correction for Sentinel-3, based on the measurements from the on-board MWR, further enhanced mostly in the coastal and polar regions using third party data, and provide recommendations for use.

In this presentation we present results from the SCOOP project that demonstrate the excellent performance of SRAL in terms of measurement precision, and we illustrate the development and testing of new processing approaches designed specifically to improve performance close to the coast.

The SCOOP test data sets and relevant documentation are available to external researchers on application to the project team. At the end of the project recommendations for further developments and implementations will be provided through a scientific roadmap.

Haruhisa Shimoda, smd@keyaki.cc.u-tokai.ac.jp Tokai University, Tokyo, Japan

The Global Change Observation Mission-Water (GCOM-W) satellite was launched by the Japan Aerospace Exploration Agency (JAXA) on 17 May 2012, as a member of the A-Train satellite constellation. The GCOM-W satellite carries the Advanced Microwave Scanning Radiometer 2 (AMSR2), which is a 6-band multi-frequency (6.9/7.3, 10.6, 18.7, 23.8, 36.5, and 89.0 GHz), dual-polarization (V and H) microwave radiometer and is a successor of the AMSR on the Advanced Earth Observing Satellite-II (ADEOS-II) satellite launched in December 2002 and the AMSR for NASA's Earth Observing System (AMSR-E) onboard the Aqua satellite launched in May 2002. The AMSR2 measures microwave brightness temperature over a 1600-km-wide swath with spatial resolutions of 5-50 km depending on the frequency. The conical scan mechanism of the AMSR2 covers more than 99% of the Earth's surface every 2 days. From the multi-frequency and dual-polarized measurements, several parameters of the ocean, atmosphere, land, and cryosphere were retrieved through theoretical and empirical algorithms. The JAXA's standard AMSR2 data product contains the sea surface wind speed, vertically-integrated water vapor, cloud liquid water, precipitation, sea surface temperature (SST), sea ice concentration, snow depths, and soil moisture. AMSR2 has completed its 5-year designed mission life in May 2017, and has transferred to extended-mission. Besides the 10-month gaps between AMSR-E and AMSR2, the AMSR series provide long-term global observation data for studies of air-sea interactions and polar oceans. Currently, JAXA is studying possible payload capability of the AMSR-2 follow-on instrument onto the Greenhouse Gases Observation Satellite-3 (GOSAT-3).

A2.1-0004-18 THE IMPORTANCE TO CONTINUE AND ENHANCE SPACEBORNE SALINITY OBSERVING CAPABILITY TO STUDY OCEAN-WATER CYCLE-CLIMATE LINKAGES

In-situ observing system has provided the capability to monitor multi-decadal changes of salinity in the open ocean and on large scales. However, in-situ platforms are inadequate to monitor salinity changes in marginal seas and coastal oceans as well as salinity variations on mesoscales. Monitoring longer-term changes of salinity in these regions and scales are important to the studies of terrestrial-ocean water cycle linkage, cross-shelf exchanges, coastal-open ocean connection, energy transfer, and biogeochemistry. Satellite measurements of sea surface salinity (SSS) have demonstrated their values to enhance salinity observing capability in these regions and scales. This presentation highlights the accomplishments of satellite SSS, especially in studying salinity variations for regions and scales not well resolved by in-situ platforms. Examples will be provided to emphasize the synergy of satellite and in-situ salinity observing systems to investigate the linkage of open-ocean and marginal sea salinity in relation to longer-term changes in the climate and water cycle. Recognizing this need, the Global Climate Observing System (GCOS) Implementation Needs (Belward et al.2016) suggested Action 032: Ensure the continuity of space-based SSS measurements. Sustaining satellite SSS observing capability, enhancing spatial resolution, and improving accuracy (especially in high-latitude oceans) are important to studying the linkages of the ocean with the water cycle and climate variability.

A2.1-0005-18 MEASURING OCEAN SURFACE WINDS AND CURRENTS FROM SPACE

Ernesto Rodriguez, ernesto.rodriguez@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Mark Bourassa, mbourassa@coaps.fsu.edu Florida, United States

Ocean surface vector winds and currents are tightly coupled Essential Climate Variables (ECVs) that play a critical role in ocean-atmosphere interactions. Although ocean surface vector winds have been observed for close to two decades, only the long-wavelength geostrophic component of ocean currents derived from sea surface height (SSH) have been available from nadir altimetry. The recent US National Academy Decadal Review, Thriving on Our Changing Planet A Decadal Strategy for Earth Observation from Space, (2018), has identified “coincident highaccuracy currents and vector winds” as a high priority Targeted Observable for the next decade exploration. Collecting these measurements would be the goal of a potential candidate for the new class of NASA competed Earth System Explorer missions.

In our presentation, we review the scientific, operational, and applications benefits of such a potential Winds and Currents Mission (WaCM). Simultaneous measurements of winds and currents will allow a direct assessment of momentum transfer between the ocean and the atmosphere. They will also improve our understanding of the fluxes of heat, gas, and momentum across the air-sea interface. We expect these measurements to be useful inputs for weather, ocean circulation and climate models, and to impact the science, applications and operational communities. We also expect that they will have societal benefits by informing coastal circulation and weather warnings, routing of shipping, and disaster management from current current-borne pollutants as well as marine debris. A system capable of making these measurements is also expected to be of benefit for arctic applications, such as determining sea ice motion.

In the second part of the presentation, we show how a Ka-band Doppler scatterometer instrument using existing technology could make these measurements from space in the next decade. The WaCM scatterometer would provide daily global coverage, similar to NASA’s QuikSCAT, by using rotating pencil-beam scanning covering a 1,400 km swath. The azimuth spatial resolution is expected to be on the order of 5 km, or a factor of 5-times better than QuikSCAT, enabling better coastal coverage and better resolution of fronts. To show the viability of the measurement concept and measurement physics, NASA has funded the DopplerScatt instrument (PI, D. Perkovic-Martin), which has collected substantial amounts of data in 2016 and 2017. We use these data to demonstrate the measurement capabilities of the potential WaCM mission concept, including the predicted error budgets for the space-borne scatterometer instrument.

A2.1-0006-18 DEVELOPMENT, VALIDATION, AND APPLICATIONS OF A NEW OCEAN OSE-OSSE SYSTEM FOR QUANTITATIVE ASSESSMENTS OF SATELLITE AND IN-SITU OBSERVING SYSTEMS

Robert Atlas, robert.atlas@noaa.gov NOAA, Miami, Florida, United States George Halliwell, george.halliwell@noaa.gov NOAA, USA, Miami, Florida, United States Villy Kourafalou, vkourafalou@miami.edu

University of Miami, Miami, Florida, United States

A new ocean OSE-OSSE system has been developed by the Joint AOML/CIMAS/RSMAS Ocean Modeling and OSSE Center (OMOC). It is the first ocean system that follows best practices for design and rigorous validation that were established for atmospheric OSSE systems to ensure credible observing system impact assessments. It is a fraternal twin system that uses two substantially different configurations of the HYbrid Coordinate Ocean Model (HYCOM) as the unconstrained Nature Run (NR) and the data-assimilative Forecast Model (FM). The system was initially developed in the Gulf of Mexico, and it has since been extended to a North Atlantic domain. Validation of the North Atlantic system was conducted in three steps: First, the NR was evaluated based on the realism with which it reproduced climatological mean conditions and mesoscale variability. It was judged to be sufficiently realistic to represent the truth with respect to these ocean properties. Second, errors (differences) between unconstrained simulations of the FM and NR were analyzed to establish that the two models were neither too similar nor too different. Finally, OSE and OSSE pairs were conducted where data denial experiments assimilated the same sets of real (OSE) and simulated (OSSE) observations. These experiments demonstrated that OSSEs produced consistently similar impact assessments.

System capabilities are illustrated by performing OSSEs to quantitatively assess the impact of assimilating satellite altimetry. Given that the NR provides a high-resolution, three-dimensional representation of the truth, the ability of satellite altimetry to improve analyses of ocean mesoscale features is quantitatively assessed using horizontal wavenumber power spectrum analysis, an approach that is not possible in the OSE framework. Correction of mesoscale structure extends to smaller wavelengths in the meridional (predominantly along-track) direction compared to the zonal (predominantly across-track) direction. By assimilating zero through four altimeters in addition to all other ocean observations, assimilation of two altimeters provides over 90% of the correction provided by four altimeters. In particular, the fourth altimeter only provides redundancy with respect improving mesoscale ocean analyses. Future plans include extending the OSE-OSSE system to global and to develop the capability of performing OSSEs in the coastal ocean.

A2.1-0007-18 ACCURATE ESTIMATION OF REGIONAL SEA LEVEL CHANGES WITH THE ESA CCI SEA LEVEL ESSENTIAL CLIMATE VARIABLE

Accurate monitoring of the sea level is required to better understand its variability and changes. In particular, this is of crucial importance in coastal zones regarding the societal impact of climate change in these regions. Sea level is one of the Essential Climate Variables (ECV) selected in the frame of the ESA Climate Change Initiative (CCI) program. It aims at providing a longterm homogeneous and accurate sea level record at global and regional scales. The needs and feedback of the climate research community have been collected so that the development of the products is adapted to the users. The range of applications of the dataset covers the analysis of the global and regional sea level changes, from the periodic and inter-annual signals to the longterm evolution. A fully reprocessed time series of monthly sea level maps has been produced in 2016 and is now available for the users (see http://www.esa-sealevel-cci.org/products). About 70 cumulated years of satellite altimetry data from 9 different missions (TOPEX/Poseidon, Jason-1/2, ERS-1/2, Envisat, Geosat-FO, CryoSat-2 and SARAL/AltiKa) have been reprocessed and the dataset covers the period 1993-2015. Within the project, the 15-partner consortium has focused on the development, validation and selection of the best algorithms that contribute to increase the ECV homogeneity and reduce the errors. Among the selected algorithms, some have led to improved sea level estimation in coastal regions. These are the GPD+ wet troposphere correction (based on radiometer and GNSS measurements including inter calibration with respect to external sensors) and the new ocean tide model FES14. Other global algorithms also contribute to the improved quality of the time series such as the orbit solutions (POE-E and GFZ15), the ERA-Interim based atmospheric corrections and the Mean Sea Surface (MSS DTU15). In addition, a dedicated study has led to improved retracking of the altimeter radar echoes in coastal areas

(2D waveform retracker) and specific validation activities have been carried out in these regions with in-situ and geodetic data, partly focusing on the estimation of the total relative sea level. The presentation will focus on the description of the new Sea Level record and the impacts of the different altimeter standards. The associated uncertainties have been characterized at different spatial scales (global, regional, mesoscale) and temporal scales (long-term, inter-annual, periodic signals). The perspectives on improvement of the sea level estimation in coastal zones will be also highlighted.

A2.1-0008-18 USING SATELLITE ALTIMETRY TO ENHANCE MONITORING AND SIMULATION OF STORM SURGES

Guoqi Han, guoqi.han@dfo-mpo.gc.ca

Fisheries and Oceans Canada, St. John's, Canada

Storm surges are the major factor causing coastal flooding, resulting in catastrophic damage to properties and loss of life in coastal communities. In this presentation, I will show how satellite altimetry can be used to enhance observation and simulation of storm surges, by overcoming challenges associated with individual events. These events include storm surges during Hurricane Sandy off New York, Hurricane Isaac off Florida York, Typhoon Seth off East China, and an extratropical storm off Newfoundland. Satellite results are evaluated against tide-gauge data and dynamic mechanisms for storm surges are explained. Finally, I discuss the potential of a wide-swath altimetry mission, the Surface Water and Ocean Topography (SWOT), for observing storm surges.

A2.1-0009-18 INTERANNUAL FORCING OF MESOSCALE EDDY KINETIC ENERGY IN THE SUBTROPICAL SOUTHERN INDIAN OCEAN

Andrew Delman, andrew.s.delman@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Tong Lee, tlee@jpl.nasa.gov

JPL, Pasadena, California, United States Bo Qiu, bo@soest.hawaii.edu

University of Hawaii, Honolulu, Hawaii, United States

A region of elevated mesoscale eddy activity spans the subtropical southern Indian Ocean (SSIO) between Madagascar and Australia. Interannual and decadal changes in eddy activity in the SSIO eddy band have implications for the shallow overturning circulation, meridional heat transport, and biological productivity in the Indian Ocean basin. The sea level anomalies (SLA) from merged satellite altimeter data are decomposed into large-scale and mesoscale components. Near Australia, where eddies are generated in the Leeuwin Current hugging the coast, the spatial distribution and temporal variability of eddy kinetic energy (EKE) derived from the mesoscale SLA field is positively correlated with the total SLA. This correlation is attributed to remote forcing from the Pacific: a higher sea level in the western tropical Pacific (e.g., during La Niña or negative PDO conditions) drives downwelling coastal Kelvin waves and a stronger Leeuwin Current, increasing the generation of mesoscale eddies that radiate towards the west.

In the central SSIO, interannual and decadal variability of mesoscale eddy activity is not well explained by large-scale climate mode forcing. However, EKE variations propagating northwestward from the mid-latitudes southwest of Australia are associated with central SSIO mesoscale EKE variability, with a lag of 2-3 years. The zonal and meridional propagation of eddy energy is consistent with the advection of the mean flow towards the northwest at depths below 150 meters. When elevated mesoscale activity south of Australia propagates into the usually quiescent region just south of the SSIO eddy band, instability promotes further eddy development in the central SSIO. The identification of these boundary and interior mechanisms for EKE variability facilitates predictions of SSIO eddy activity levels with lead times of several months to several years, and provides a basis for assessment of model simulations of eddy activity in the region.

A2.1-0010-18 THE POTENTIAL USE OF SARAL ALTIKA TOWARDS COASTAL REGIONS

- A CASE STUDY ON EAST COAST OF INDIA.

Psn Acharyulu, acharyulu.psn@gmail.com Andhra University, Visakhapatnam, India Kvsr Prasad, prasadkvsr@yahoo.co.in Andhra University, Visakhapatnam, India

The Indian coastline has been subjected to several geomorphological changes due to natural processes and manmade activities. There are areas of severe erosion and accretion, which lead to loss of several acres of coastal land and accretion of river mouths/inlet preventing the waste water entering into the sea. The most important factor which governs the coastal erosion is wind waves. Attempts were made to predict the waves in deep and intermediate waters but no attempts are made to obtain waves nearer to the coast as the conventional altimeters provide wave measurements as close as maximum up to 6-10 km only but SARAL being new in its kind having such a high frequency and smaller foot print enables measurements of wave data as close as three km from the coast. Also Higher pulse repetition frequency enables more sampling rate. The Bay of Bengal is influenced by three different conditions during a year. They are Southwest monsoon SW (June to September), Northeast monsoon NE (December to February) and a transition period between these two seasons. The wave data obtained from the conventional altimeters during the calm season are are not reliable because of wave heights are so small that will fall within the accuracy of the instrument and provides better correlation of higher wavelengths. The eight-millimetre wavelength of SARAL enables more accurate measurement of the backscatter coefficient over calm or moderate seas. Hence, SARAL data provides better measurements of wind and wave data as close as 3km away from the coast and thus helps us to measure shallow water wave characteristics.

A2.1-0011-18 DIRECT RETRIEVAL OF STRESS AND EVAPORATION FROM SPACE OBSERVATIONS

W. Timothy Liu, w.t.liu@jpl.nasa.gov

Caltech JPL, Pasadena, California, United States Xiaosu Xie, xiaosu.xie@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Momentum flux (stress) and latent heat flux (evaporation) at ocean surface are transported by turbulence, which is small scale random process generated/subdued by wind shear and buoyancy (vertical wind and density gradients). Turbulence is difficult to measure and, traditionally, transfer coefficients (bulk parameterization formula) are used to related them the mean parameter measured on ships, such as, wind and humidity in air, and temperature and current at ocean surface. Satellite sensors measure radiance and backscatter at the ocean surface and there is no critical reason to reproduce measurements of meteorological and oceanic sensors on ships. We show that direct retrieval of latent heat flux from the radiance measured by microwave radiometers mitigate errors caused by the multiplication of retrieval uncertainties of wind to those of temperature or humidity while facing the uncertainty of the transfer coefficient. We will address the uncertainty of retrieving strong wind caused by backscatter saturation and the change behavior of the transfer coefficient under tropical cyclone by direct stress retrieval. We will show that scatterometers measurements represent the vector difference between wind and current, the characteristic of stress rather than wind. As different from the prevailing winds, stress spins down the mesoscale eddies and reduce the kinetic energy into the ocean.

A2.1-0012-18 DATA VISUALIZATION FOR CITIZEN ENGAGEMENT IN OCEAN ENVIRONMENTAL CHALLENGES

Jeremy Stroming, stroming@mit.edu

Massachusetts Institute of Technology, Boston, Massachusetts, United States Dava Newman, dnewman@mit.edu

Massachusetts Institute of Technology, Cambridge, Massachusetts, United States Max Vilgalys, vilgalys@mit.edu

Massachusetts Institute of Technology, Cambridge, Massachusetts, United States

One of the most critically overlooked aspects of climate change is the declining health of Earth's oceans. The oceans have absorbed 25-30% of all human produced carbon emissions since the Industrial Revolution and 93% of the excess heat generated by anthropogenic global warming. As a result, oceans have shielded us from more severe surface warming effects, but at a high cost. This paper will take steps to connect individuals to tools including data visualizations and satellite imagery to learn about and understand challenges to Earth's oceans including warming, acidification, sea level rise, hypoxia, pollution, and overfishing. Exabytes of data exist on all of the Earth's subsystems, but such information is often disparate and expertoriented. People are too overwhelmed to take action to change our harmful relationships with the Earth. Starting with the North Atlantic region, this paper connects ocean challenges to local climate, ecosystem, and human development issues, making these topics more personal to stakeholders. Next, these problems are mapped to specific, adoptable actions and behavior changes ranging from consumer choices and diet, to more sustainable daily habits, to local policy activism. With this framing, people can be motivated rather than defeated and start making a positive difference. A catalogue of available data visualization resources-including from NASA, ESA, and nonprofit organizations-was assembled and curated for interactivity and user-friendly design. As a part of the larger MIT Earth Speaks initiative to develop a digital interface for engagement with earth conservation and sustainability, this paper will lay out a roadmap for more widespread understanding of ocean challenges and practical individual actions to take to heal endangered marine ecosystems and prepare for inevitable changes in ocean climate systems. User interface and user experience (UI/UX) concepts for the oceans section of Earth Speaks platform will also be presented.

A2.1-0013-18 INSIGHTS ON TSUNAMI GENESIS FROM SATELLITE GRAVITY CHANGES OF LARGE EARTHQUAKES

Y. Tony Song, tony.song@jpl.nasa.gov

NASA Jet Propulsion laboratory, Pasadena, California, United States

Large earthquakes at subduction zones usually generate tsunamis and coseismic gravity changes. These two independent oceanic and geodetic signatures of earthquakes can be observed individually by modern geophysical observational networks. The Gravity Recovery and Climate Experiment (GRACE) twin-satellites can detect gravity changes induced by large earthquakes, while altimetry satellites and Deep-Ocean Assessment and Reporting of Tsunamis (DART) buoys can observe resultant tsunamis. In this study, we introduce a method to connect the oceanic tsunami measurements with the geodetic gravity observations, and apply it to the 2004 Sumatra Mw 9.2 earthquake, the 2010 Maule Mw 8.8 earthquake and the 2011 Tohoku Mw 9.0 Earthquake. Our results indicate consistent agreement between these two independent measurements. Since seafloor displacement is still the largest puzzle in assessing tsunami hazards and its formation mechanism, our study demonstrates a new approach to utilizing these two kinds of measurements for better understanding of large earthquakes and tsunamis.

A2.1-0014-18 SEA SURFACE SALINITY VARIATIONS IN THE MARITIME CONTINENT REGION AND THE RELATIONSHIPS WITH CLIMATE VARIABILITY AND OCEAN CURRENTS

Tong Lee, tlee@jpl.nasa.gov

JPL, Pasadena, California, United States Severine Fournier, severine.fournier@jpl.nasa.gov

NASA Jet Propulsion Lab / California Institute of Technology, Pasadena, California, United States

Variations of sea surface salinity (SSS) in the Maritime Continent (MC) region have important implications to ocean circulation and climate variability. Systematic monitoring of salinity changes in the MC region has been extremely challenging due to the complicated geometry and other factors. This has hindered our understanding of freshwater changes in the MC region, the relationships with climate variability (e.g., monsoon, El Nino-Southern Oscillation, and Indian Ocean Dipole), and the potential implications to climate predictions. NASA's Soil Moisture Active Passive (SMAP) satellite has been providing sea surface salinity (SSS) measurements at 40-km spatial resolution and 8-day repeat cycle since April 2015. Here we examine seasonal-tointerannual variations of SSS in the MC region using SMAP SSS in relation to other satellite observations, including precipitation, sea surface height, ocean surface currents, ocean color, and soil moisture. The analysis results illustrated the relationships of SSS variations with monsoonal forcing in the northern and southern parts of the MC region, the effects of the 2015 positive Indian Ocean Dipole, the 2015-16 El Nino, and the exchange between the MC and the Pacific Ocean. In particular, we identified the source of freshwater in the MC region that modifies the structure and transports of the Indonesian throughflow, a climatically important element of the global ocean circulation that connects the Pacific and Indian Oceans.

A2.1-0015-18 USE OF REMOTELY SENSED SEA SURFACE TEMPERATURE (SST) VALUES TO ASSESS THE BLEACHING EVENTS IN THE NORTHERN PERSIAN GULF

Keivan Kabiri, kabiri@inio.ac.ir

Iranian National Institute for Oceanography and Atmospheric Science, INIOAS, Tehran, Iran

The bleaching events have become more repeated worldwide and may affect the health of coral communities permanently and irreversible. The most important reason of this phenomenon is high amounts of sea temperature, where it is more efficient if it remains high for a long period of time. Continuous measuring of sea temperature may help us to assess the effects of fluctuation of this value on health coral reefs. Remotely sensed data have provided us a proper source of sea surface temperature (SST) data from early 70s. This research employed historical remotely sensed SST values from the northern Persian Gulf (spatial resolution= 1°×1°) to assess the relationship between variations of this value and coral bleaching events happened in this area. In this regard, degree heating weeks (DHWs) was selected as main indicator, because it considers the persistence of positive water temperature anomalies which is most effective parameter on coral bleaching. Normal values of SST for each cell were extracted from a remotely sensed data source between 1971 and 2000 and the mean weekly SST values were compared with it form 1981 to 2017. Pierce skill score (PSS) was selected to quantify the capability of selected threshold for DHW. The final results demonstrated that the DHW value more than 5.3 may cause bleaching in coral reefs, where it happens on 1998, 2007, 2015, and 2017 in the studied area.

A2.1-0016-18 HIGH FREQUENCY BISTATIC RADAR OBSERVATIONS OF THE OCEAN SURFACE WITH GROUND-IONOSPHERE-OCEAN-SPACE (GIOS) SCATTER

Paul Bernhardt, paul.bernhardt@nrl.navy.mil

Naval Research Laboratory, Washington, District of Columbia, United States Stan Briczinski, stan.briczinski@nrl.navy.mil

United States

Carl L Siefring, carl.siefring@nrl.navy.mil

Naval Research Laboratory, Washington, United States Andrew Howarth, howarth@phys.ucalgary.ca University of Calgary, Calgary, Canada

Gordon James, james@phys.ucalgary.ca Natural Resources Canada, Ottawa, Canada Andrew W. Yau, yau@phys.ucalgary.ca University of Calgary, Calgary, AB, Canada

Knowledge of the sea is of primary importance for both ship transportation and HF radar clutter prediction. A new concept has been developed called HF Ground-Ionosphere-OceanSpace (GIOS) which can view vast regions of the Earth's surface. Ground HF transmissions are reflected by the ionosphere to illuminate the ocean over a few thousand kilometers. HF receivers on low-earth-orbit satellites detect the radio waves scattered by the sea and land surface. Using the theory of radio wave scatter from ocean surfaces, the GIOS data is then processed to yield the directional wave-height spectrum of the ocean. The GIOS technique has several advantages over existing remote sensing methods. First, a large area of the ocean can be sampled to yield the wave-height characteristics with high, km-scale resolution. This measurement scale matches the grid size used in physics-based oceanographic models. The wave height spectrum can be directly compared with temporal frequency spectrum obtained with buoys at specific points in the ocean volume. Furthermore, the GIOS technique uses HF waves which penetrate the dense rain found in hurricanes. Microwave attenuation inside strong sea storms blocks mapping of the sea surface.

The GIOS program at NRL is being developed using both experimental and theoretical methods. To test the GIOS concept, ground HF transmissions from over-the-horizon radars were employed to scatter sky wave signals from the ocean to radio receivers in low-earth-orbit. The HF receiver (RRI) on the Canadian ePOP/CASSIOPE satellite has collected radio signals scat- tered from the ocean illuminated by ground transmitters in the US, Australia and Northern Europe. This satellite has two dipole antennas in a crossed configuration to measure HF waves below 18 MHz. Right and left hand circular polarization is synthesized from the data from the in phase (I) and quadrature (Q) data provided by the RRI digital instrument. For the ground HF transmission source, the Relocatable Over the Horizon Radar (ROTHR) system in

Chesapeake Virginia was used to illuminate the ocean extending from coast of Florida to south of Jamaica. Range and Doppler processing of the radar waveforms yields an ocean scatter map at each time in the ePOP orbit.

Tests of the GIOS technique were conducted with the NRL Surface Wave Radar located at Cape May, New Jersey scatter up from the ocean to the ePOP satellite and the NRL Airborne HF Sensors. The Twin Otter will be flown east and south of Wallops Island Virginia while the ePOP is passing overhead. The airplane component provides a calibration point over the ocean to aid in the range-Doppler analysis of the HF data from the satellite receiver. All of these experiments are analyzed using both ocean scatter data and ray trace simulations.

A2.1-0017-18 ON THE SPATIAL SCALE OF THE SWOT KARIN MEASUREMENT OVER THE OCEAN

Jinbo Wang, jinbo.wang@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Lee-Lueng Fu, llf@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Bo Qiu, bo@soest.hawaii.edu

University of Hawaii, Honolulu, Hawaii, United States Shuiming Chen, schen@soest.hawaii.edu

University of Hawaii, Honolulu, California, United States Hector Torres Gutierrez, hector.torres.gutierrez@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Dimitris Menemenlis, dimitris.menemenlis@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

The Surface Water and Ocean Topography (SWOT) mission aims to measure the sea surface height (SSH) at a high spatial resolution using Ka-band Radar Interferometer (KaRIN). The primary oceanographic objective is to characterize the ocean eddies at a spatial resolution of 15 km for 68% of the ocean. This resolution is derived from the ratio between the wavenumber spectrum of the conventional altimeter (projected to submesoscale) and the SWOT SSH errors. While the 15km threshold is useful as a global approximation of the spatial scales resolved by SWOT (SWOT-scale), it can be misleading for regional studies. Here we revisit the problem using a high-resolution (2km) tide-resolving global ocean simulation and map the SWOTscale as a function of latitude-longitude and season. The results show that the SWOT-scale has a strong geographic and seasonal dependence. In general, it is smaller (<15km) in low latitudes, increases to 30km in mid-latitudes and 40km in high latitudes especially over the Southern Ocean. It also shows a seasonality with a maximum during the local winter and minimum during the local summer. Both balanced motions and internal gravity waves/tides have a significant contribution to the scale variation. These characteristics provide a guideline for interpreting the satellite fidelity with ocean physics in consideration and shed light on the development of the future SWOT data assimilation system.

A2.1-0018-18 OBSERVATION OF SATELLITE DERIVED MONTHLY SCALE VARIABILITY OF SURFACE WATER CHLOROPHYLL, TEMPERATURE, SALINITY AND NITRATE IN THE BASINS BAY OF BENGAL AND ARABIAN SEA

Rk Sarangi, rksarangi.2011@gmail.com ISRO, Ahmedabad, India

The analysis has been carried out to study the monthly scale variability of sea surface chlorophyll, temperature (SST) and nitrate using Modis-Aqua and ocean salinity using SMAP satellite datasets during 2016 and 2017. The chlorophyll, SST and derived nitrate products are of 4 kilometre resolution data and the SMAP salinity data is of 25 kilometre resolution. The nitrate images have been generated using the in situ data based model using chlorophyll and SST datasets. The model has been developed for the southwest Bay of Bengal and has been applied for the Bay of Bengal (BoB) and Arabian Sea (AS). There has been observation of high salinity trend (34-36 psu) in AS during most of the months, but the BoB salinity range is broader, 22-36psu. The variability of salinity is well observed in the BoB, depicting the river water flux and dilution of the BoB water. The chlorophyll observed to be higher (0.4-5.0 mg/m3) in northern Arabian Sea as compared to other regions. The BoB productivity has shown lesser chlorophyll biomass as compared to AS, except few months during northeast monsoon (November-December) and southwest monsoon (June-August). During southwest monsoon months (July-September), the low saline water (22-26 psu) has been observed to be linked to high chlorophyll water with chlorophyll concentration 0.3-4.5 mg/m3 in the coastal BoB water. This is due to the riverine fluxes with high nutrients inducing to have more productivity in the coastal water. The winter cooling like in AS and has been observed in the BoB and well depicted with the decrease in SST (range 24-26°C) during December to February in the northern BoB coastal water. The BoB region SST has shown linkage to salinity but in Arabian Sea the relationship is different as the salinity is higher and uniform almost round the year. The nitrate image has shown more resemblance to chlorophyll images. Only few coastal region has shown match trend to SST. The nitrate on monthly scale ranged 0.01-6.0 µM. The observed high productivity zones with effect of southwest and northeast monsoons in the coastal BoB and AS has been suitable for fishing resources exploration. The phytoplankton distribution and the habitat suitability and biogeography of zooplankton and fishes can be understood referring different physicochemical parameters variability in synoptic scale using different satellite datasets irrespective resolutions and different platforms.

A2.1-0019-18 CHLOROPHYLL VARIABILITY IN THE BAY OF BENGAL AND ITS RELATION WITH ENSO AND IOD

Muni Krishna Kailasam, munikrishnna@yahoo.co.in Andhra University, Visakhapatnam, India

J Annapurna, purna.jagarapu96@gmail.com Andhra University, Visakhapatnam, India

The present study focuses on the variability of the biological parameter (chlorophyll) and physical, dynamical parameters like sea surface temperature, sea surface wind and sea surface height over the Bay of Bengal during 1998 - 2017. Satellite observations chlorophyll and sea surface temperature clearly shows the seasonal and inter-annual variability along the central east coast of India which is associated with upwelling process. The upwelling index varies from 9 to 135 m3/s/100m of coastline and the corresponding chlorophyll concentration is 2 to 8 mg/m3. The lack of upwelling favorable conditions results in the majority of the southern side of the central east coast of India waters being insufficient, which is reflected in low or moderate productivity. Drastic decrease in chlorophyll concentration is observed during ENSO and as well as in IOD periods.

A2.1-0020-18 INVESTIGATION OF THE INTRA-ANNUAL VARIABILITY OF THE NORTH EQUATORIAL COUNTERCURRENT/NORTH BRAZIL CURRENT EDDIES AND OF THE INSTABILITY WAVES OF THE NORTH TROPICAL ATLANTIC OCEAN USING SATELLITE ALTIMETRY AND EMPIRICAL MODE DECOMPOSITION

Jean-Luc Mélice, jlmelice@locean-ipsl.upmc.fr

Institut de Recherche et de Développement, Paris, France Sabine Arnault, sa@locean-ipsl.upmc.fr

LOCEAN Laboratory, Paris, France

The intra-annual variability of the tropical Atlantic Ocean north of the equator is investigated with satellite altimetry mean sea level anomaly data and with an algorithm based on empirical mode decomposition (EMD) methods. Two regions of high variability are identified. The first region, between 3° and 12°N, is characterized by the presence of westward-propagating eddies linked to the North Brazil Current retroflection in the vicinity of the Brazilian coast. They show a strong annual cycle. In this paper the EMD algorithm points out that this signal is frequency modulated shifting from large length-scale structures in October to smaller ones in March. Consequently, the number of "eddies" per year can be aliased, according to the time and location of sampling, and can impact the percentage they explain of the interhemispheric exchange of mass and heat associated with the meridional overturning circulation's upper limb. A scenario concerning this dynamics is proposed. The second region reveals the presence of westward-propagating instability waves centered north of the equator (3°-7°N) between 50° and 10°W. These instability waves are also frequency modulated and show a strong seasonal cycle with maximum amplitude around August.

A2.1-0021-18 GLOBAL SEA LEVEL BUDGET AND OCEAN MASS BUDGET ASSESSMENT: PRELIMINARY RESULTS FROM ESA'S CCI SEA LEVEL BUDGET PROJECT

Martin Horwath, martin.horwath@tu-dresden.de Technische Universität Dresden, Dresden, Germany ESA CCI Sea Level Budget Closure team

Studies of the sea level budget are a means of assessing and understanding how sea level is changing and what are the causes. Closure of the total sea level budget implies that the observed changes of global mean sea level equal the sum of observed (or otherwise assessed) contributions, namely changes in ocean mass and ocean thermal expansion. Closure of the ocean mass budget implies that the observed ocean mass change equals assessed changes in mass from glaciers, ice sheets, land water storage, snow pack and atmospheric water content. Misclosure of these balances indicates errors in some of the components or contributions from missing or unassessed elements in the budget.

ESA's Climate Change Initiative (CCI) has conducted a number of projects related to sea level, namely the Sea Level CCI project, the Greenland and Antarctic Ice Sheet CCI projects, the Glaciers CCI project and the Sea Surface Temperature CCI project.

The aim of the ongoing CCI Sea Level Budget Closure project is to use the CCI data products, together with further data products provided by the project partners to re-assess the sea level budget and ocean mass budget. Specifically, the project further develops and analyzes products based on the CCI projects mentioned above in conjunction with data products from ocean profilers (e.g., Argo), GRACE-based ocean mass change assessments, and model-based data for glaciers and land hydrology. The work benefits from directly involving the expertise on the product generation for all the involved sea level contributions. The presentation will report on preliminary assessments of global sea level budget and global ocean mass budget closure. We focus on two periods: 1993-

2015 (the altimetry period) and 2003-2015 (the GRACE / ARGO period). We consider the budget of the long-term trends as well as the budget of the overlaid interannual variations. A special focus is on the account for uncertainties of the individual contributions, building on the expertise of all project partners.

A2.1-0022-18 IMPROVEMENT OF THE ARCTIC OCEAN BATHYMETRY AND REGIONAL TIDAL ATLAS (CP4O-CRYOSAT PLUS 4 OCEANS)

Ole Andersen, oa@space.dtu.dk

Danish National Space Institute, Kgs Lyngby, Denmark Mathilde Cancet, mathilde.cancet@noveltis.fr NOVELTIS, Ramonville Saint-Agne, France

David Cotton, d.cotton@satoc.eu SATOC, Stockport, United Kingdom

Jérôme Benveniste, jerome.benveniste@esa.int European Space Agency, Frascati, Italy

Cryosat Plus for Oceans (CP4O) is a project under the European Space Agency's "Support to Science Element" programme which aims to develop and evaluate new ocean products from the Cryosat cryosphere earth observation mission. The main focus of CP4O has been on the additional measurement capabilities that are offered by the Synthetic Aperture Radar mode offered by the innovative SIRAL altimeter, with further work in developing improved geophysical corrections

The Arctic Ocean is a challenging region, because of its complex and not well-documented bathymetry, together combined with the intermittent presence of sea ice and the fact that the in situ tidal observations are scarce at such high latitudes. This initiative initially addresses the bathymetry in the Arctic in attempting to improve altimetric bathymetry using the near 7 years of Cryosat-2 high quality and high resolution "geodetic" SAR altimetry all the way up to 88°N. Subsequently the project progresses to use Cryosat-2 in TWO ways for improved ocean tide modelling in the Arctic Ocean. One is to use Cryosat-2 improved bathymetry the second is to use Cryosat-2 derived harmonic tidal constituents for assimilation into a regional tide model.

The project runs during 2017 and includes the following activities: • Evaluate existing bathymetries available for the Arctic (R-TOPO2, IBCAO etc). • Generate an improved Arctic bathymetry by inverting the high resolution DTU15 gravity field derived from Cryosat-2 data, and combining with the bathymetry selected in the previous task. • Evaluate this new bathymetry through comparisons against available reference data, and assessments with the TUGO hydrodynamic model. • Using tidal constituents (with associated error estimates) derived from Cryosat-2 data, together with the TUGO hydrodynamic model, develop and evaluate a new regional Arctic Tidal model for the Arctic Ocean.

A2.1-0023-18 A STUDY ON THE COMPATIBILITY OF THE SEA SURFACE TEMPERATURES BETWEEN HIMAWARI-8/AHI AND LANDSAT-8/TIRS

Yoshinari Oguro, y.oguro.yx@it-hiroshima.ac.jp Hiroshima Institute of Technology, Hiroshima, Japan Tomohisa Konishi, t.konishi.vd@cc.it-hiroshima.ac.jp Hiroshima Institute of Technology, Hiroshima, Japan Seiji Ito, seiji@cc.it-hiroshima.ac.jp

Hiroshima Institute of Technology, Hiroshima, Japan Chiemi Miura, c.miura.6u@it-hiroshima.ac.jp Hiroshima Institute of Technology, Hiroshima, Japan

Japanese geostationary meteorological satellite Himawari-8 was launched on October 7, 2014. The Himawari-8 is equipped with an Advanced Himawari Imager (AHI). The AHI has total of 16 observation bands (3 for visible, 3 for near-infrared and 10 for infrared). The Himawari-8 observes the whole of Japan with 2.5 minutes intervals. The spatial resolutions of the Himawari8 are 0.5 - 1 km for visible bands and 1 - 2 km for near-infrared and infrared bands. On the other hand, American earth observation satellite Landsat-8 was launched on February 11, 2013. The Landsat-8 is equipped with the Operational Land Imager (OLI) and the Thermal Infrared Sensor (TIRS). The OLI has total of 8 observation bands (4 for visible, 3 for near-infrared and 1 for infrared) and the TIRS has 2 observation bands (2 for infrared). The Landsat-8 observes the same area with 16 days intervals. The spatial resolutions of the OLI are 30 m and those of the TIRS are 100 m. Utilizing the data of bands 13 and 14 of the Himawari-8/AHI which observed the whole of Japan, and the data of bands 10 and 11 of the Landsat-8/TIRS which observed over the Uwa Sea of Japan, we compared the Brightness temperatures (BTs) and the Sea Surface Temperatures (SSTs) obtained from the synchronous observation by both satellites. From the analysis of correlation of the BTs of the Himawari-8/AHI and those of the Landsat8/TIRS in the thermal infrared bands of similar wavelength, we found that the correlation coefficient was the highest between the band 13 (10.194-10.612 μm) of the Himawari-8/AHI and the band 10 (10.780-11.280 μm) of the Landsat-8/TIRS. Finally an atmospheric correction and an emissivity correction were applied to the BTs, we compared the measurement SSTs of in situ survey and the computed SSTs obtained from satellites over the Uwa Sea of Japan. From the analysis, we confirmed that the error between the measured SSTs and the computed SSTs of both satellites were within approximately 1 Kelvins.

The universal altimetry toolbox BRAT (Broadview Radar Altimetry Toolbox) is a collection of tools and tutorial documents designed to facilitate the processing of radar altimetry data. It can read all previous and current altimetry missions' data. It incorporates the capability to read the upcoming Sentinel-3 L1 and L2 products. ESA endeavoured to develop and supply this new capability to support the users of the Sentinel-3 mission.

The toolbox is freely available at http://earth.esa.int/brat. The BRAT suite is mostly made of command line tools, of which the BratGUI is the front-end. BRAT can be used in conjunction with MATLAB/IDL (via reading routines) or C/C++/Python/Fortran via a programming API, allowing users to obtain the desired data, bypassing the data-formatting hassle. BRAT can also be used to simply visualise data quickly or to translate the data into other formats such as NetCDF, ASCII text files, KML (Google Earth) and raster images from the data (JPEG, PNG, etc.).

Several kinds of computations can be done within BRAT, involving both user-defined combinations of data fields that can be saved for posterior use and the BRAT's predefined formulas from oceanographic altimetry. BRAT also includes the Radar Altimeter Tutorial, which contains an extensive introduction to altimetry,

showing its applications in different fields. Use cases are also available, with step-by-step examples, covering the toolbox usage in the different contexts.

A2.1-0025-18 SATELLITE DERIVED SEA SURFACE TEMPERATURE FRONTS IN RELATION WITH TUNA CATCH IN THE EEZ OF PAKISTAN

Muhammad Abdullah, mabdullahsiddiqui88@gmail.com

Institute of Space Technology, Islamabad Pakistan, Karachi, Pakistan

Sea surface temperature (SST) is an important parameter in marine ecosystem studies as its relations of Fishery and other marine resources. In this study SST fronts have also been studied with relate to tuna fish catch data of April and August 2014 was acquired. Satellite derived MODIS daily products have been used to derive thermal fronts in the exclusive economic zone (EEZ) of Pakistan. Research results indicated that the Sea surface temperature gradually changed from 22C to 24C where Tuna catch is high and By Catch is low in frontal region. The further Relationship between these two data are discussed in this study and also made recommendations for in what way these two datasets should be handled. Remote sensing data and GIS tools are efficient and less time consuming for mapping and classifying sea surface temperature in a broader way. Survey of fishing resources is really time consumed and costly, Satellite Remote sensing data shows a promising tool to monitor fishery resources in a cost effective manner. Satellite data play an important role to identify fish aggregation zones and these techniques could also be used to forecast potential fishing zones by measuring oceanic parameters which influence on fish distribution on a broader scale and these techniques can help to local fisherman and fishery organizations to observe fishery resources.

A2.1-0026-18 SALINIFICATION IN THE SOUTH CHINA SEA SINCE LATE 2012: A REVERSAL OF THE FRESHENING SINCE 1990S

Lili Zeng, zenglilicn@qq.com

South China Sea Institute of Oceanology, Guangzhou, China Eric Chassignet, echassignet@fsu.edu

Center for Ocean–Atmospheric Prediction Studies, Florida State University,, Tallahassee, Florida, United States

Dongxiao Wang, dxwang@scsio.ac.cn

South China Sea Institute of Oceanology, Chinese Academy of Sciences, Guangzhou, China

Salinification has occurred in the South China Sea (SCS) from late 2012 to the present, as shown by satellite Aquarius/SMAP data and Argo float data. This salinification follows a 20-year freshening trend that started in 1993. The salinification signal is strongest near the surface and extends downward under the seasonal thermocline to a depth of 150 m. The salinification occurs when the phase of the Pacific Decadal Oscillation switches from negative to positive. Diagnosis of the salinity budget suggests that an increasing net surface freshwater loss and the horizontal salt advection through the Luzon Strait driven by the South China Sea throughflow contributed to this ongoing salinification. In particular, a decrease in precipitation and enhanced Luzon Strait transport dominated the current intense salinification. Of particular interest is whether this salinification will continue until it reaches the previous maximum recorded in 1992.

A2.1-0027-18 SAR ALTIMETRY PROCESSING ON DEMAND SERVICE FOR CRYOSAT-2 AND SENTINEL-3 AT ESA G-POD

Jérôme Benveniste, jerome.benveniste@esa.int European Space Agency, Frascati, Italy Jérôme Benveniste, jerome.benveniste@esa.int European Space Agency, Frascati, Italy

Salvatore Dinardo, salvatore.dinardo@eumetsat.int EUMETSAT, Darmstadt, Germany

Giovanni Sabatino, giovanni.sabatino@esa.int Progressive Systems/ESRIN, Frascati, Italy Marco Restano, marco.restano@esa.int SERCO/ESRIN, Frascati, Italy

Américo Ambrózio, americo.ambrozio@esa.int DEIMOS/ESRIN, Frascati, Italy

The scope of this presentation is to feature the G-POD SARvatore service to users for the exploitation of CryoSat-2 and Sentinel-3 data, which was designed and developed by the Altimetry Team at ESA-ESRIN EOP-SER. The G-POD service coined SARvatore (SAR Versatile Altimetric Toolkit for Ocean Research Exploitation) is a web platform that allows any scientist to process on-line, on-demand and with user-selectable configuration CryoSat-2 SAR/SARIN and Sentinel-3 SAR data, from L1a (FBR) data products up to SAR/SARin Level-2 geophysical data products.

The G-POD graphical interface allows users to select a geographical area of interest within the time-frame related to the Cryosat-2 SAR/SARin FBR and Sentinel-3 L1A data products availability in the service catalogue. The processor prototype is versatile, allowing users to customize and to adapt the processing according to their specific requirements by setting a list of configurable options. Pre-defined processing configurations (Ocean, Inland Water, Ice and Sea-Ice) are available for the Sentinel-3 service. After the task submission, users can follow, in real time, the status of the processing. The output data products are generated in standard NetCDF format (using CF Convention), therefore being compatible with the Multi-Mission Radar Altimetry Toolbox (BRAT, http://www.altimetry.info/toolbox/) and typical tools. The following upgrades have been recently introduced: 1) Inclusion of SAR echo and SAR RIP (Range Integrated Power) waveforms in the NetCDF files; 2) Inclusion of STACK Data in the NetCDF files.

Initially, the processing was designed and uniquely optimized for open ocean studies. It was based on the SAMOSA model developed for the Sentinel-3 Ground Segment using CryoSat data (Cotton et al., 2008; Ray et al., 2014). However, since June 2015, a new retracker (SAMOSA+) is offered as a dedicated retracker for coastal zone, inland water and sea-ice/ice-sheet. Following the launch of Sentinel-3, a new flavour of the service has been initiated, exclusively dedicated to the processing of Sentinel-3 mission data products. The scope of this new service is to maximize the exploitation of the Sentinel-3 Surface Topography Mission's data over all surfaces providing user with specific processing options

not available in the default processing chain. The service is open, free of charge (supported by the ESA SEOM Programme Element) for worldwide scientific applications and available at https://gpod.eo.esa.int/services/CRYOSATSAR/.

A2.1-0028-18 SPICE: SENTINEL-3 PERFORMANCE IMPROVEMENT FOR ICE SHEETS

Malcolm McMillan, m.mcmillan@leeds.ac.uk University of Leeds, Leeds, United Kingdom Roger Escolà, roger.escola@isardsat.co.uk isardSAT Ltd., Guildford, United Kingdom Mònica Roca, monica.roca@isardsat.co.uk isardSAT Ltd., Guildford, United Kingdom Pierre Thibaut, pthibaut@cls.fr

Jérôme Benveniste, jerome.benveniste@esa.int European Space Agency, Frascati, Italy

For the past 25 years, polar-orbiting satellite radar altimeters have provided a valuable record of ice sheet elevation change and mass balance. One of the principle challenges associated with radar altimetry comes from the relatively large ground footprint of conventional pulse-limited radars, which reduces their capacity to make measurements in areas of complex topographic terrain. In recent years, progress has been made towards improving ground resolution, through the implementation of Synthetic Aperture Radar (SAR), or Delay-Doppler, techniques. In 2010, the launch of CryoSat-2 heralded the start of a new era of SAR Interferometric (SARIn) altimetry. However, because the satellite operated in SARIn and LRM mode over the ice sheets, many of the non-interferometric SAR altimeter processing techniques have been optimized for water and sea ice surfaces only. The launch of Sentinel-3, which provides full non-interferometric SAR coverage of the ice sheets, therefore presents the opportunity to further develop these SAR processing methodologies over ice sheets. Here we present results from SPICE (Sentinel-3 Performance Improvement for Ice Sheets), a 2 year study that focuses on (1) developing and evaluating Sentinel-3 SAR altimetry processing methodologies over the Polar ice sheets, and (2) investigating radar wave penetration through comparisons of Kuand Ka-band satellite measurements. The project, which is funded by ESA's SEOM (Scientific Exploitation of Operational Missions) programme, has worked in advance of the operational phase of Sentinel-3, to emulate Sentinel-3 SAR and pseudo-LRM data from dedicated CryoSat-2 SAR acquisitions made at the Lake Vostok, Dome C and Spirit sites in East Antarctica, and from reprocessed SARIn data in Greenland. In Phase 1 of the project we have evaluated existing processing methodologies, and in Phase 2 we are investigating new

evolutions to the Delay-Doppler Processing (DDP) and retracking chains. In this presentation we (1) evaluate the existing Sentinel-3 processing chain by comparing our emulated Sentinel3 elevations to reference airborne datasets, (2) describe new developments to the DDP and retracking algorithms that are aimed at improving the certainty of retrievals over ice sheets, and (3) investigate radar wave penetration by comparing our SAR data to waveforms and elevations acquired by AltiKa at Ka-band.

A2.1-0029-18 GOCE USER TOOLBOX AND TUTORIAL

Per Knudsen, pk@space.dtu.dk

Technical University of Denmark, Kgs. Lyngby, Denmark Jérôme Benveniste, jerome.benveniste@esa.int

European Space Agency, Frascati, Italy

The GOCE User Toolbox GUT is a compilation of tools for the utilisation and analysis of GOCE Level 2 products.GUT support applications in Geodesy, Oceanography and Solid Earth Physics. The GUT Tutorial provides informationand guidance in how to use the toolbox for a variety of applications. GUT consists of a series of advancedcomputer routines that carry out the required computations. It may be used on Windows PCs, UNIX/Linux Workstations,and Mac. The toolbox is supported by The GUT Algorithm Description and User Guide and The GUTInstall Guide. A set of a-priori data and models are made available as well. Without any doubt the developmentof the GOCE user toolbox have played a major role in paving the way to successful use of the GOCE data foroceanography. The GUT version 2.2 was released in April 2014 and beside some bug-fixes it adds the capability for the computation of Simple Bouguer Anomaly (Solid-Earth). During this fall a new GUT version 3 has been released. GUTv3 was further developed through a collaborative effort where the scientific communities participate aimingon an implementation of remaining functionalities facilitating a wider span of research in the fields of Geodesy,Oceanography and Solid earth studies. Accordingly, the GUT version 3 has: - An attractive and easy to use Graphic User Interface (GUI) for the toolbox, - Enhance the toolbox with some further software functionalities such as to facilitate the use of gradients,anisotropic diffusive filtering and computation of Bouguer and isostatic gravity anomalies. - An associated GUT VCM tool for analysing the GOCE variance covariance matrices.

A2.1-0030-18 THE FORMATION AND "MULTI-HAZARD" EFFECT OF TROPICAL CYCLONES

Liudmila Vanina-Dart, vandart@seeingear.org

(1) The Seeingear LTD, Battle, United Kingdom (vandart@seeingear.org), (2) Space Research Institute RAN, Moscow, Russia, St Leonards On Sea, United Kingdom

A tropical cyclone (TC) is one of the strongest atmospheric hazards. The tropical cyclone creates a "multi-hazard" effect. It is accompanied with very strong winds, heavy rain, high ocean waves and damaging storm surge which can produce extensive coastal flooding. The appearance of a tropical cyclone is also accompanied by multi-hazard conditions. Several centuries ago it was noticed that the appearance of a tropical cyclone is associated with such primary hazard as earthquakes and volcanoes. So, we can say that the tropical cyclone is not only the cause of other hazards (secondary hazards), but can itself be created "at list in part" by those very same hazards (primary hazards). This is the "multi-hazard" effect. The formation of tropical cyclones is the topic of extensive ongoing research and is still not fully understood. While some factors (for example, the water temperature, a rapid cooling with height, etc.) appear to be generally necessary, TCs may occasionally form without meeting all of the following conditions. In this paper, the author analyzes the reasons for the TC's appearance which based on the available international common results. For example, it is a well-known fact that in the Southern hemisphere around South America TCs are absent. Why? The author makes an attempt to find the answer. How the salinity of the ocean can affect it? How it can be connected to the geomagnetic field. This analysis based on many years ongoing research of the author.

A2.1-0031-18 SMALL PARAMETRIC MODEL FOR NONLINEAR DYNAMICS OF TROPICAL CYCLONES WITH OCEAN TEMPERATURE VARIATIONS

Nikolay Erokhin, nerokhin@iki.rssi.ru

Space Research Institute, Russian Academy of Sciences, Moscow, Russia Sergey Artekha, sergey.arteha@gmail.com

Space Research Institute, Russian Academy of Sciences, Moscow, Russia Nadezhda Zolnikova, nzolnik@iki.rssi.ru

Space Research Institute, Russian Academy of Sciences, Moscow, Russia Ludmila Mikhailovskaya, ludamikh@iki.rssi.ru

Space Research Institute, Russian Academy of Sciences, Moscow, Russia Rumen Shkevov, shkevov@space.bas.bg

Space Research and Technology Institute - Bulgarian Academy of Sciences, Sofia, Bulgaria

A numerical investigation of a self consistent small parametric model (SPM) of tropical cyclones is performed by usage of connected nonlinear equations for mean wind speed in the atmosphere and the ocean surface temperature, taking into account small variations of ocean temperature in the cyclone background. Previously it was shown that these equations describe a different scenario of temporal dynamics of a powerful atmospheric vortex (tropical cyclone - TC) during its full life cycle. Our numerical calculations have shown that the choice of the SPM's initial parameters allows us to obtain the seasonal behavior of a regional large scale cyclogenesis dynamics for a given number of TC during the active season in a particular region, which allows a plausible explanation of the observation data. The SPM allows us to obtain the essential variable wind speed variations (created by nonstationary background) inside the TC and their influence on the TC temporal dynamics. It is shown, on the basis of numerical calculations, that such an influence may create an essential variation in the TCs dynamics. Such a conclusion is important for the correct interpretation of observations data on TC. Thus by usage of the nonlinear SPM, with motivated choice of background characteristics, it is possible to study the features of TC temporal behavior during the active season in a specific area. The correlation between regional cyclogenesis parameters and different external factors as the space weather, including solar activity level and cosmic rays variations is also possible to analyze. It is important to note, as it is known, that the cosmic rays variations may provoke essential changes in the Earth atmosphere dynamics. The cosmic rays may have an essential influence on sediments through the atmosphere ionization. A particle of cosmic rays, due to its very large energy, may produce million and more ionization events in the atmosphere. The numerical analysis results are graphically presented in figures and conclusions about SPM range applicability are made.

A3.1-0001-18 AN ALGORITHM OF GROSS PRIMARY PRODUCTION CAPACITY ESTIMATION FROM GLOBAL OBSERVING SATELLITE AND THE DIFFERENCE BETWEEN GPP CAPACITY AND GPP.

Kanako Muramatsu, muramatu@ics.nara-wu.ac.jp Nara Women's Univ., Nara, Japan

An algorithm to estimate gross primary production (GPP) capacity from global satellite data was developed. The characteristic of this method corresponds to photosynthesis process. The photosynthesis velocity depends on it's capacity and its' depression because of weather conditions. The capacity part depends on one of plant physiological parameters of chlorophyll contents of a leaf. In the previous study (J. Thanyapraneedkul et al., 2013), the framework of estimation method using light-response curve was developed. The two parameters of lightresponse curve of the maximum of GPP capacity in the light saturation and relating on the initial slope were determined. The parameter relating on an initial slope was used as fixed values for each plant functional types. The maximum of GPP capacity at the light saturation was determined from the linear relationship between GPP capacity at 2000 (μmolm−2s−1) and

Chlorophyll index (CIgreen) using green band developed by Gitelson et al. (1996). The relationship determined for plant functional types of needleleaf deciduous trees, broadleaf deciduous trees, needleleaf evergreen trees, broadleaf evergreen trees, C3 grass, open and closed shrubs, and crops were determined. In this study, the difference between GPP capacity and GPP was studied using several years Flux data. From this study, GPP was more than 90 % of GPP capacity of paddy field and other vegetation types when vegetation was under less stress for the dry condition. This result means that GPP capacity was the first approximation of GPP when vegetation was under less stress. And the differences were discussed when vegetation was under high stress.

A3.1-0002-18 VALIDATION OF OGVI (OLCI GLOBAL VEGETATION INDEX) AND OTCI (OLCI TERRESTRIAL CHLOROPHYLL INDEX) PROVIDED BY THE OLCI (OCEAN AND LAND COLOR INSTRUMENT) SENSOR AT THE VALENCIA ANCHOR STATION

Erika Albero Peralta, erika.albero@uv.es University of Valencia, Burjassot, Spain Antonio Lidon Cerezuela, alidon@qim.upv.es

Polytechnic University of Valencia, Valencia, Spain Inmaculada Bautista Carrascosa, ibautista@qim.upv.es Polytechnic University of Valencia, Valencia, Spain Cristina Lull Noguera, clull@upvnet.upv.es Polytechnic University of Valencia, Valencia, Spain Ernesto Lopez-Baeza, ernesto.lopez@uv.es

University of Valencia, Burjassot, Valencia, Spain

Vegetation plays a key role in the global energy balance, carbon cycle, and water budget of the Earth by controlling the exchanges between the lower atmosphere and the continental biosphere. The Fraction of Absorbed Photosynthetically Active Radiation (FAPAR) is a primary variable controlling the photosynthetic activity of plants, and therefore it constitutes an indicator of the presence and productivity of live vegetation, as well as of the intensity of the terrestrial carbon sink. It is the fraction of incoming solar radiation in the spectral range from 400 - 700 nm that is absorbed by plants and one of the 50 Essential Climate Variables (ECVs) recognized by the WMO Global Climate Observing System.

The Sentinel-3A (Copernicus Programme) satellite launched in February 2016, has onboard the Ocean and Land Colour Instrument (OLCI) with the primary objective of screening the ocean and land surface to harvest information related to biology, the atmosphere and climate. OLCI's spectral definition permits a fine characterisation of the vegetation with three parameters: FAPAR, LAI and Chlorophyll.

For the validation of FAPAR and chlorophyll, 3 full-balance PAR (Photosynthetically Active Radiation) stations were installed over an OLCI pixel (300 m x 300 m) in a vineyard field at the Valencia Anchor Station, Earth Observation validation site in Spain. Continuous comparisons have been made with the processed field data and the data obtained from the satellite. Each station has four sensors for calculating the energy balance, collecting the incident PAR, the reflectance of the vegetation cover, the transmittance of the foliar mass and the reflectance of the soil, taking into account the lambertian character of the reflectivity. Manual measurements of chlorophyll content were also performed.

In order to obtain a better representativity of the satellite estimations, a transect was defined manually measuring the PAR fluxes and chlorophyll content over the 8 pixels surrounding the main one above mentioned.

A3.1-0003-18 COMPARISON OF SUPERVISED CLASSIFICATION METHODS ACCURACIES USING SENTINEL-2 DATA

Dogus Guler, gulerdo@itu.edu.tr

Istanbul Technical University, Istanbul, Turkey Tahsin Yomralioglu, tahsin@itu.edu.tr

Istanbul Technical University, Istanbul, Turkey

The understanding and sustainability of the earth we live in is one of the important research topics, and the quality of the data held in such research is of importance. Land use and land cover (LULC) analyzes are frequently used in research. Today there are remote sensing satellites that are shared with all the world's users and enable the environmental analysis to be done temporally. As a result of analysis using remote sensing, meaningful outputs can be produced and interpretations can be made for study areas. One of the most important of the used satellites is Landsat. In order to carry out analyzes with Landsat satellites, the data for Sentinel-2 satellite, which are among the aims, are shared with researchers free of charge. The most important steps taken in the analysis of LULC are the classification of one of the steps. The comparison of the accuracy of supervised classification methods with Sentinel-2 satellite data, which is used today and intensively in the future, has been carried out. The image at the 1C level of the Sentinel-2 was upgraded to 2A level by the transformations performed. The study area is located in the province of Istanbul in Turkey. Analyzes of Binary Encoding, Mahalanobis Distance, Maximum Likelihood, Minimum Distance, Neural Net, Parallelepiped and Support Vector Machine supervised classification methods were obtained separately from the commonly used methods in the literature and the accuracy percentages of each method were obtained.

A3.1-0004-18 MONITORING LAND USE/LAND COVER CHANGE USING REMOTE SENSING AND GIS TECHNIQUE: A CASE STUDY OF BARANI AREAS PUNJAB, PAKISTAN

Vengus Panhwar, venguspanhwar23@gmail.com

Mehran University of Engineering and Technology, Jamshoro Sindh, Pakistan, Jamshoro, Pakistan

Small dams have traditionally been the permanent source of water in the arid province of punjab in Pakistan. A check dam is used to delay the floodwater runoff to make it available for domestic and agriculture purposes or to recharge aquifers. The aim of this study is to present and illustrate different techniques for evaluating the performance of small dams. The data were collected based on studies of published research papers and reports of international organizations containing key characteristics of performance evaluation techniques. This review will help to evaluate techniques, policy, and governance interventions in Punjab by comparing them with the best practices being employed in other regions of the world. In this paper, performance evaluation of check dams for specific cases is presented. The knowledge acquired will be utilized to highlight state-of-the-art practices and to identify the need for further research in this field.

A3.1-0005-18 GEOSPATIAL APPROACH FOR LAND USE/LAND COVER CHANGE PREDICTION: A CASE STUDY OF BHAGIRATHI BASIN, UTTARAKHAND, INDIA

Nisha Singh, nishajnu07@gmail.com Jawaharlal Nehru University, New Delhi, India Milap Punia, milap.punia@gmail.com Jawaharlal Nehru University, 110067, India

Changes in land use and land cover (LULC) in mountainous areas have been less studied with remote sensing due to obvious difficulties in observations and interpretation. These regions are often hard to access and are also poorly instrumented and documented by conventional methods. As a result, there is a gap in our knowledge concerning the extent and impacts of land use change in high elevations. These regions are also where we are likely to see the early impacts of climate change. The main objective of this paper is to evaluate the land use change in Bhagirathi basin based on the need and purpose to predict future scenario of the region. Bhagirathi Basin being a hilly terrain has been challenged by numerous difficulties like deforestation, dam construction, expanding urbanization, tourism activities, land degradation etc. Land use classification and analysis is performed using Geographic Information System (GIS) and Remote sensing technique, and GIS aided 'Markov Cellular Automata' technique is used to model the land use change. Based on the past trend (1979 to 2010) of land use changes, the future land use map of Bhagirathi Basin for the year of 2020 has been generated. Landsat TM image of 1979 and 2010 were employed in this study to produce land use classification based on Anderson modified version method. Land change Modeler (LCM) was used to analyze the land use / cover changes between various classes and prediction of 2020 scenario of the region. The result of LULC analysis in the reference period depict that major changes includes increase in built-up area beside the increment in agriculture land in lower basin region. In upper basin region snow cover area has shown positive growth. Area under dense forest cover has increased marginally, whereas area under open forest cover has decline over all. There has been a remarkable increase in area of water bodies showing fivefold increment which can be attributed to Tehri Dam Project and area surrounded by it. According to LCM Modeling, Land use change projection in 2020 highest growth would be seen in agriculture land. Further, this study may contribute in land use planning and development of mountainous region. Keywords: LULC, Remote Sensing, GIS, Climate Change, Land Change Modeler.

A3.1-0006-18 THE CLASSIFICATION OF THE RICE FIELDS BY THE SEASONAL VARIATION TENDENCY OF THE NDVI IN THE LANDSAT-8/OLI

Seiji Ito, seiji@cc.it-hiroshima.ac.jp

Hiroshima Institute of Technology, Hiroshima, Japan Tomohisa Konishi, t.konishi.vd@cc.it-hiroshima.ac.jp Hiroshima Institute of Technology, Hiroshima, Japan Yoshinari Oguro, y.oguro.yx@it-hiroshima.ac.jp Hiroshima Institute of Technology, Hiroshima, Japan Jukkrit Mahujchariyawong, mjukkrit@hotmail.com Kasetsart University, Bangkok, Thailand

In order to estimate the quantity of yield from a rice crop or to manage water resources, it is necessary to classify land surface into the rice fields from satellite images. However, it is difficult to classify agricultural fields into the rice and another fields. The aim of this study is to classify the agricultural fields from the difference in the tendencies of the seasonal change by using Normalized Difference Vegetation Index (NDVI). The NDVI seasonal variation tendency in the grassland, the rice field and another field in Chiba prefecture of Japan had been analyzed by using Landsat-8/OLI data observed several years. As the results, the NDVI of the three kind of area had been different tendencies. The NDVI of rice fields from growing to harvest seasons had been increased, and drastically decreased in the season after harvest. The NDVI of another fields had been similar to rice field, but the peak of it had been different season depending on the growth period of farm products. In the grassland, the peak of it had spread out for several months.

A3.1-0007-18 APPLICATION OF HYTES DATA FOR HYSPIRI OPTIMAL BAND POSITIONING TO MAP VEGETATION AND URBAN ENVIRONMENT

Noora Khalid, noora.khalid92@yahoo.com

Institute of Space Technology, Islamabad, Islamabad, Pakistan Saleem Ullah, ullah19488@itc.nl

ITC, Enschede, Netherlands

Saleem Ullah, sirifsaleem@gmail.com

Institute of Space Technology (IST), Islamabad, Islamabad, Pakistan

A new space-borne sensor HyspIRI (Hyperspectral and Infrared Imager) is soon to be launched by NASA Jet Propulsion Laboratory (JPL). Out of the two instruments on board HyspIRI is the Thermal Infrared (TIR) multispectral scanner, while the other being hyperspectral imaging spectrometer sensing from the Visible to Short Wave Infrared (VSWIR: 0.38 - 2.5 µm). The TIR scanner will comprise of eight spectral bands operating between 3 and 12 m, one of these is present in the MIR (3-5 µm) while the remaining are located in TIR (7-12 m) region of EMR spectrum. However, the exact spectral location of these bands is not yet assigned and will be defined in a way to assist in various applications such as mapping GHG emissions (i.e., SO2, CH4 and NH3), minerals, vegetation health and urban materials. This study explored the possibility of using Genetic Algorithms coupled with Spectral Angle Mapper (SAM) for the selection of optimal bands from the TIR emissivity spectra to map four vegetation species and five land use land cover (LULC) classes. In this research the precursor dataset over the region of Santa Barbara was provided by Hyperspectral Thermal Emission Spectrometer (HyTES). HyTES is an airborne hyperspectral sensor, having a high spectral resolution (256 spectral channels in TIR). The GA-SAM was trained for nine classes and the algorithms were made to run repeatedly for 40 iterations. Genetic Algorithm (GA) even coped with spectral similarity at the species level and efficiently selected a meaningful subset of bands with high training (> 85 %) and testing (> 70 %) accuracies. Information on significant spectral band locations in TIR will help scientists of HyspIRI group in positioning spectral bands at best suited locations.

A3.1-0008-18 URBAN LANDUSE SPATIAL ANALYSIS: A CASE STUDY OF NORTH-NAZIMABAD BLOCK-D, E, F, G, H

Muhammad Rovaid Uddin, rovaiduddin90@gmail.com Institute of Space and Technology, Karachi, Pakistan Saad Ul Haque, saad_haq@hotmail.com

Institute of Space Technology, Karachi, Pakistan

Process of urbanization is on peak in Karachi for last fifty years. It's considered as a mega polis in Pakistan with population of approx. 20 million. Therefore planners and administrative unit's need spatial and socio economic data for analysis at multiple places specially in urban planning for unplanned physical environment. The most planed housing sector after independence is North Nazimabad located at northern suburbs of Nazimabad region. It was developed to manage the residential needs of federal employee because Karachi at that time served as the capital of Pakistan. For that purpose town is alphabetically located blocks with well-planned structure. It's considered as the modern planed town of Karachi. For this GIS technology having effective use to study and analysis the comprehensive planning, site suitability, zoning, temporal variation and specially for all mapping purpose. To study and analysis purpose data is acquire in the form of satellite imageries and ground surveys. Absolute position of land cover mark through GPS. GPS points converted into ground control points in GIS. GCP's are plot on satellite imageries for absolute position of places. Satellite imageries are acquired from Google Earth for high spatial resolution. Also Landsat images are acquired due to their high spectral resolution. This helps to determine change through different indices. North Nazimabad is a well-planned and modernized town of Karachi city based on the concept of Clarence Perry. It started out as a planned town with residential development as the main focus with well-defined areas assigned for commercial and residential uses. However from our survey it has become apparent that most of the residential areas along the roads have been converted for commercial use, also the growing need for residency has led to vertical growth resulting in the construction of apartment buildings.

A3.1-0009-18 URBANISATION AND ITS IMPACT ON ECOSYSTEM SERVICES IN THE NATIONAL CAPITAL REGION, INDIA

Nisha Singh, nishajnu07@gmail.com Jawaharlal Nehru University, New Delhi, India Milap Punia, milap.punia@gmail.com Jawaharlal Nehru University, 110067, India

Urbanisation and land change are interrelated however it's difficult to interpret different processes on ground regarding immediate consequences. Change in land use and land cover are emerging as central to a range to development-linked sustainability challenges, leading to loss of ecosystem services in urban and peri-urban regions. It has impacted the productivity capacity (via intensification and land degradation) of ecosystem and polluted the environment, impacting socio-ecological sustainability and livelihood security and thus exacerbating existing social and economic vulnerability. This study is an attempt to assess the impacts of urbanisation on ecosystem services in the National Capital Region (NCR).To assess spatial and temporal trends of land use land cover change (1991, 2001 and 2011) for National Capital Region, satellite images have been taken from the Landsat 5 (TM) and Landsat 7 (ETM). Further, the coefficients published by Costanza et al. (Global Environmental Change, 26:152-158, 2014) were used to quantify changes in ecosystem services for each land use land cover category. Results showing the rate of decline in ecosystem services value from 1991 to 2011 is $ 0.03 million per year. The influence of land use change on individual ecosystem functions indicated the decline in the contribution of food production services, genetic resources, soil formation, water supply, waste treatment, raw materials, habitat/refugia, erosion control, biological control, and gas regulation while contribution of recreation, climate regulation, disturbance regulation, water regulation and nutrient cycling functions has increased substantially over the 20 years' time period. For the sustainable development of ecosystems in NCR, it is significantly important to understand the factors that facilitate urban sprawl and associated loss in ecosystem service and further policy intervention is required in urban and peri-urban regions for protecting and enhancing ecosystems at local as well as regional level. Keywords: Ecosystem Services; Peri-urban; Urban Sprawl; Sustainable Development; Land use land cover change.

A3.1-0010-18 THERMAL INERTIA AND URBAN HEAT ISLAND IMPACT ON CLIMATOLOGY OF DELHI

Shivesh Berwal, shiveshberwal@gmail.com Jawaharlal Nehru University, Delhi, India

This study attempts to examine the role of thermal inertia in the variable behaviour of day-time Urban Heat Island over Delhi. LISS-III data of Resourcesat-I, MODIS (Moderate Resolution Imaging Spectroradiometer) combined Aqua and Terra, 16-day, Level 3 Albedo Product (Black Sky Albedo and White Sky Albedo) and 8-day Land Surface Temperature Product have been used to investigate the spatial variations in land cover, albedo, land surface temperature and thermal inertia for the month of March, 2015. The LISS-III image shows the predominance of built-up area over Delhi, which is surrounded by agricultural land covered by crop vegetation at this time of the year. The albedo map shows that albedo over Delhi is significantly less (0.08 to 0.13) over major part of Delhi, while albedo in its surrounding regions ranges from 0.15 to 0.2. This suggests that a significantly greater fraction of the incoming solar radiation is utilized for heating up of land surface over Delhi as compared to its surrounding regions. The Enhanced Vegetation Index (EVI) Map of Delhi for March 2015 reveals that EVI over Delhi varies from 0.06 to 0.29 whereas EVI over the surrounding regions reaches up to 0.66, which confirms the prevalence of crop vegetation in the surrounding regions. The day and night-time land surface temperature maps reveal that temperatures over Delhi are significantly higher (8°C

-10°C) than those over the surrounding regions. The day and night time temperature maps are then used to obtain the diurnal temperature range and together with albedo maps of the study region, are used to estimate the thermal inertia over the region. The study reveals that the dense built-up urban area of Delhi has higher thermal inertia than that of the surrounding rural areas during the March.

A3.1-0011-18 ESTIMATION OF HEAVY METALS CONCENTRATION IN CROPS USING SENTINEL-2 DATA

Shahzad Zafar, shzd326@gmail.com

Institute of Space Technology Islamabad, Islamabad, Pakistan Saleem Ullah, sirifsaleem@gmail.com

Institute of Space Technology (IST), Islamabad, Islamabad, Pakistan Asad Ali, asad06@gmail.com

Institute of Space Technology, Islamabad Pakistan, Islamabad, Pakistan

Excess of heavy metals concentration in crops exert negative impact on crops, animals and human health. Information about the level of contamination in crops is of critical importance for understanding the problem and formulating its possible solutions. Remote sensing provides fast, efficient, cost effective alternative to quantify and map the distribution of heavy metal contamination in crops. Sentinel 2 is relatively new addition to the constellation of optical remote sensing satellites and the bands are positioned for studying vegetation health and status. In this research, the potential of Sentinel-2 data was investigated for the retrieval of heavy metals contents in crops in Kusur district, Pakistan. The study area is part of Upper Indus basin and is densely vegetated due to the availability of water for irrigation from Sutlej and Ravi rivers. A total of sixty six samples were collected in the field and heavy metal concentration of Zinc (Zn), Copper (Cu), Nickel (Ni), Lead (Pb) and Chromium (Cr) was measured using Atomic Absorption spectroscopy. The values of the field data were regressed against Sentinel

-2 derived vegetation indices (NDVI, SAVI, TSAVI, MTCI, REP and band depth parameters). Using NDVI, the highest R2 was obtained for Zn (R2 = 0.60) followed by Cu in NDVI (R2 = 0.26) and Cr in (R2 = 0.18). The relationship of Lead (Pb) and Nickel (Ni) with vegetation indices was found very low (0.05). The multiband index (band depth parameters: CR, BD, NDBI, BDR, BNA) yielded R2 of (0.53, Zn vs. BDR), (0.20, Cu vs. BDR) and (0.18, Cr vs. CR). This study concludes that Sentinel 2 data is quite effective for quantifying heavy metal concentration in crops and for monitoring spatial distribution of heavy metals and its effects on crops health.

A3.1-0012-18 EARTH OBSERVATION IN SUPPORT OF SUSTAINABLE WATER RESOURCES MANAGEMENT IN THE FRAMEWORK OF EIT CLIMATE KIC COPERNICUS CLIMATHON 2017

Climathon attracts innovators, entrepreneurs, students and professionals to create innovative solutions to cities climate challenges. The Climathon Challenge for each city consists of setting its own local climate challenge that reflects what affects their urban life the most. Challenges can vary from air quality, water and waste management, and extreme weather events, use of city satellite data, etc. Participants then tackle the set challenge for a full 24-hours, before pitching their ideas in front of relevant local stakeholders. These ideas can develop into tangible sustainable solutions and businesses that address city climate challenges across the globe. Now its third year of operation, the Climathon movement has grown tremendously over the past two years, encouraging more innovators across the globe to drive climate action <https://climathon.climate-kic.org>.

The it University of Valencia Climatology from Satellites Group developed the it Copernicus Climathon 2017 Burjassot City Challenge basically consisting of the ideation of adaptation to climate change projects using Copernicus Earth Observation data and products in support of water management solutions. The goal was to encourage participants to study water-related negative climate change impacts and low-efficiency usage to tackle them and generate incomes.

This paper explains the development of the it Copernicus Climathon 2017 Burjassot activity and the ideas developed on it Smart Water for Cities (SAT WATERS), it Make Available Water Visible (MAWV) and it Irrigation optimization software (CROPSENSING)

A3.1-0013-18 CLIMATE RESILIENT WATER SECURITY PLANNING USING SPACE

Jagannatha Venkataramaiah, jagsiobbindia@gmail.com Indian Space Research Organization, Mysuru, India

In the Backdrop of Paris agreement on climate Change and the adoption of the Sustainable development goals(SDGs), when the environments degrade either locally or globally, it is the poorest countries, communities and the people that bear the brunt of the damage(Rebecca Grynspan, IIED). It is also a fact that the occurrence of natural disasters about 50 in 1900 have reached 200 per year by 2000(UN reports). Shockingly, during 1875 and 1975 the population has increased three fold while the primary energy consumption has been a shocking 32 times. Global warming and related climate changes are likely to significantly increase the weatherrelated risks facing human settlements, including floods, water and power supply failures and associated economic collapse into failed cities.(David S, 2018). IMSD-1995,Integrated Mission on Sustainable Development under ISRO is a pioneering watershed management in 195 districts of India focusing on the decentralised community governance using the space technology. In continuation World Bank Supported SUJALA Watershed is one of the space best practices. In the recent past, river restoration projects and water resources aiming community empowerment with Corporate Social Responsibility are a reality (Art of Living, 2017). Water Resources Information System WRIS under NRSC ISRO is pioneering platform hub for application of Space Technology for Water Resources Management in India. In this presentation with the backdrop of a unique self-reliant space technology heritage for water resources management in India, water security issues for Irrigation in the state of Karnataka and Bangalore Urban settlement are reported. Case Studies of a new trend of community cantered water security governance by monitoring using simple techniques and remote sensing data are reported.

A3.1-0014-18 FUTURE SPACEBORNE MEASUREMENTS NEEDED TO CHARACTERIZE THE WATER CYCLE IN SNOW-DOMINATED WATERSHEDS

Jeff Dozier, dozier@ucsb.edu

University of California, Santa Barbara, Santa Barbara, California, United States Thomas Painter, thomas.painter@jpl.nasa.gov

Institute of Remote Sensing and Digital Earth, Chinese Academy of Sciences, Beijing, China

Measurements of snow-covered area have been a staple of remotely sensed operations for more than fifty years, and passive microwave estimates of snow water equivalent provide information in areas with shallow, spatially homogeneous snow cover. In the mountains especially, where the snow is often deep and always heterogeneous at the scale of the topography, improved knowledge of the snow water equivalent (SWE) and snow albedo () will help us manage water resources, understand anthropogenic effects on snow and glaciers, and validate models of precipitation and snowmelt.

Snow water equivalent: SWE = depth × density, but most of the spatiotemporal variability owes to depth, with variation in density a secondary contributor. Shortcomings of directly retrieving SWE from passive microwave sensors include its low saturation threshold of about 200 mm, its large pixel size causing substantial subpixel heterogeneity, and its lack of any ability to estimate SWE when snow is wet. Snowpack resources computed from numerical weather models, such as SNODAS, show discouraging results with significant underand over-estimates. Directly measuring SWE from synthetic aperture radar (SAR) has been investigated, but wet snow and snowpack stratigraphy complicate the results. An alternative approach, which we describe in detail, is to measure depth instead with a high-frequency (Wor Ka-band) altimeter or interferometer, and to either model density or measure it less frequently with SAR or a scatterometer. The advantage of measuring snow depth and inferring SWE through density is a feasible, economical implementation, and the measurement of snow depth is insensitive to liquid water in the snowpack.

Snow albedo: As with any process driven partly by absorbed solar radiation, variability in snow albedo causes variability in the rate of melt. For surfaces with high albedo, an error in the measurement of albedo leads to a greater proportional error in absorption of the solar radiation (absorption = 1-α, so for values of α closer to 1.0, a small error in causes a greater proportional error in 1-). Changes in snow albedo are tied to changes in snow microstructure and contamination by absorbing particulates like dust and soot. Over homogeneous snow covered areas like Antarctica or Greenland, measurement of albedo with multispectral sensors is feasible, but in pixels that also contain vegetation and soils along with snow, the science of imaging spectroscopy must be brought to bear.

The river basins having significant contribution of snow and glacier melt water are highly susceptible by falling future flows owing to climate change. The high altitude cryospheric

/ hydrological observations are still remains scarce particularly in the Karakoram-Himalayan region of Pakistan due to remoteness and limited accessibility. Notwithstanding, the future behavior of their water resources is still unclear, although for the sustainable management of water resources, better assessment and quantification of snow and glacier melt contributions in the river runoff is crucial. In order to quantify the daily contributions of melt-water yield from snow and glaciers in the basin, the degree day melt runoff model was calibrated for Astore stream-flow by employing daily snow cover products of MODIS satellites to estimate spatiotemporal snow cover extents. Similarly, the

high resolution SPOT and Landsat imagery to map the areas of exposed ice separately from the snow covered area towards the end of the snowmelt season were also employed in combination with in-situ hydro-meteorological observational data. Most of the parameters used in the calibration process were measured directly from the field or either measured from satellite data. The simulated stream-flow shows good agreement with the measured stream-flow during the calibration as well as validation period, since the NashSutcliffe model efficiency coefficient was never become <0.8. The simulation results suggested that although the glacier ablation started in May in the basin, but the volumetric contribution in the stream-flow was very little, however, in the month of June the glacier melt contribution is stared to increase and after July almost all the flows were dependent on glacier melt produced water. Although there is also some contribution from the summer rain but its volumetric contribution is almost negligible as compare to glacier melt. The overall contribution from snow and glacier melt was calculated as 76% of the basin runoff. The results revealed that the simulated glacier melt runoff during 1960-2013 displayed a marked decreasing trend from the early 1960s to the late 1980s, afterwards it began to increase from the early 1990s. However, there has been a general decrease of glacier melt contribution in the basin runoff, since the early 1990s this trend has become more pronounced. The decreasing trend of glacier melt runoff was in contrast of the increasing trend of Astore River runoff during this period. This implies that the increase in the river runoff of the Astore river basin was very likely to be because of the influence of increase in winter precipitation but not due to the increase in the glacier melt runoff. The calibrated model was used to simulate future melt-flows of Astore basin under different climatic warming scenarios. The future runoff simulations under projected climatic warming trends suggested that it would significantly influence the contribution of glacier melt yield in the Astore basin stream-flow. Due to persistent warming initially the glacier melt runoff would be increased significantly (+14%) by 2050, however afterwards it would start to decline abruptly due to the continuous mass shedding of glaciers and by the end of this century the contribution from the glacier melt would be declined by more than 30% of current glacier melt runoff contribution in the main stem of Astore river, which would significantly influence the summer and autumn stream-flows of Astore river basin which may adversely affect the ecological environment and water resources in the region.

A3.1-0016-18 GLACIER DYNAMICS STUDY USING C-AND L-BAND SAR DATASETS IN HIMALAYAN REGION

Praveen K Thakur, praveen@iirs.gov.in

Indian Institute of Remote Sensing, Dehradun, India WRD IIRS

Dr. Vaibhav Garg, Arpit Chouksey, Dr Bhaskar R Nikam, Pankaj Dhote, Dr. S.P. Aggarwal and Dr. A. Senthil Kumar

The Himalayan region contains third largest amount of fresh water in form of seasonal snow and permanent glacier ice, outside the Polar Regions. This regions is home to world's largest rivers and glaciers, and water from these rivers feeds the billions of people in its downstream locations. Remote sensing plays an important role in mapping and monitoring of snow and glacier of this region, which otherwise is very difficult using traditional survey methods. The present work have utilized freely available C-band Synthetic Aperture Radar (SAR) data from Sentinel-1 and 1A satellites and ALOS-PALSAR-2 PolInSAR data for glacier dynamics study of major Himalayan glaciers such as Siachen, Bara Shigri, Samudra Tapu, Gangotri, Milam, Zemu etc. PALSAR-2 data was provided by JAXA under announcement of opportunity science project and Sentinel data was taken from Alaska SAR facility. Earlier studies using Interferometric SAR (InSAR) data has suffered from loss of coherence due to high temporal resolution of SAR images and high glacier velocity. Glacier velocity was derived using InSAR based method using 6 day temporal interval (During winter of 2016-2017) images from SENTINEL-1A and 1B satellites and at 14 day interval for PALSAR-2 data. High coherence was obtained for all main glaciers in both the data sets, which resulted accurate line of site (LOS) glacier velocity estimates for glacier. In both cases, SRTM-x band 30 m DEM was used to remove topographic phase due to its better vertical accuracy. ALOS-PALSAR-2 during shows the mean velocity of 3.2 to 5.2 cm day-1 during 14 day time interval for full glacier and main trunk glacier respectively. This is after gap of 19 to 21 years that InSAR data has given suitable data for glacier velocity estimation. In addition, TANDEM-x data of year 2012 and 2013 was also used to derive temporal elevation changes due to dynamic snow/ice in condition of Gangotri glacier. The time series of SAR data from SENTINEL-1A and 1B and Indian RISAT-1 MRS satellites was also used for glacier in Chenab and Gangotri basins, for creating SAR image time series composites, and to identify and map radar glacier zones such as debris ice, bare ice zone, percolation-refreeze zone at different elevations, wet snow and dry snow zones. All these maps were verified by extensive ground done at these sites during 2014-2017 time. In September 2017, Gepang glacier differential GPS and hyperspectral survey was conducted to quantify the glacier and glacier lake dynamics. The lake growth, moraine survey and GLOF modelling was also done to quantify vulnerability of Gepang glacier lake. This study highlights use and applicability of InSAR data sets for glacier dynamics study, supported by ground truth. This study will help in refining algorithms to be used for such studies using upcoming NASA-ISRO SAR (NISAR) InSAR data sets.

A3.1-0017-18 THE PRODUCTION OF HR WATER MASKS WITH SENTINEL-1, THEIR VERIFICATION WITH SENTINEL-2 IMAGES AND THEIR USE IN SENTINEL3 ALTI-HYDROLOGY

Pierre Fabry, pfabry@along-track.com Along-Track, PLOUGONVELIN, France Moein Zohary, mzohary@along-track.com Along-Track, Plougonvelin, France

Nicolas Bercher, nbercher@along-track.com CNRS, PLOUGONVELIN, France

Jérôme Benveniste, jerome.benveniste@esa.int European Space Agency, Frascati, Italy

This work tests and refines some pixel-based water mapping algorithms for Sentinel-1 SAR images. Updated High Resolution water masks are needed to produce a water fraction field as an auxiliary data to Sentinel-3 SRAL products. The objective is to 1. help better characterise Sentinel-3 SAR waveforms, 2. help analyse SAR retrackers performances, 3. help alti-hydrology processing chain in many aspects among which the rejection of spurious signals during the production of water levels over rivers and lakes (low water fraction associated to an outlier measurement).

The Sentinel-1 water extraction algorithms are described. Sensitive aspects like shadowing in mountainous regions are addressed (shadow in radar images could easily be classified as water). To validate the results, the outputs of these algorithms are then compared with a 10m resolution water index derived from Sentinel-2 images. The best water mask is finally used to produce Water Fractions within the Sentinel-3 footprints of collocated and tightly codated Sentinel-3 SRAL acquisitions. The results are illustrated on difficult cases such as those found along the Brahmaputra River.

This work, performed under ESA/SEOM SHAPE contract 4000115205/15/I-BG, highlights the great synergy potential of the Sentinel-1, 2 and 3 missions to improve the inland water SAR altimetry processing. It could be replicated to LRM altimetry missions and the concomitant imagers as well. Improving Water Level time series will permit assimilation into models such as HYPE to produce improved Water Discharge. This is one of the main objectives of the SHAPE project.

A3.1-0018-18 IMPROVING STREAMFLOW ESTIMATES OF THE RAPID RIVER ROUTING MODEL WITH DATA ASSIMILATION

Charlotte Emery, charlotte.emery@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Cedric David, cedric.david@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

The increasing availability of remotely-sensed observations of surface water enables regional or global monitoring of rivers. However, the current (and expected) measurements still have a sparse spatiotemporal coverage. Hydrological models are able to predict river streamflows at finer scales but those estimates suffer from non-negligible uncertainties. This motivates the merging of space-based observations with computer models of rivers through data assimilation. The use of data assimilation allows to produce consistent, and hopefully improved, estimates of terrestrial hydrology variables that fill the spatiotemporal gaps in observations. The river routing model RAPID (Routing Application for Parallel Computation of Discharge) is based on the Muskingum method and estimates river streamflow over large scale with high computational efficiency. The relatively simple model physics implies that RAPID simulations could be significantly improved by including a data assimilation capability. Here we present the developments of such data assimilation approach where the simulated streamflows are improved through the assimilation of streamflow observations. Given the linear and matrix-based structure of the model, we chose to apply a classical Kalman filter, hence allowing for the preservation of high computational speed. In this study, we develop and test the assimilation framework using in situ measurements at continental scales. The preliminary results demonstrate the feasibility of the approach which is designed to ultimately leverage altimetry measurements from existing (e.g. EnviSat, Jason 2) and upcoming satellite missions (e.g. SWOT), and be applied globally.

A3.1-0019-18 ENHANCING FLOOD FORECASTING AND RIVER BASIN PLANNING IN THE LOWER MEKONG USING SATELLITE-BASED LAND USE AND PRECIPITATION INFORMATION

Farrukh Chishtie, farrukh.chishtie@adpc.net

Asian Disaster Preparedness Center, Phayathai, Thailand

The Lower Mekong countries suffer from devastating and frequent flooding. Agencies exist at regional and national level who are mandated to provide flood forecast and warning information to the public, typically through utilizing flood models. The flood models require a range of input data at different temporal and spatial resolution, but those are hardly available in the region. Both rural and urban populations rely on weather forecast and flood early warning to take preemptive action and to quickly respond to flood events. Hydro-meteorological data such as precipitation and stream gauge are critical elements in flood forecasting as well. Countries such as Cambodia are hampered in their ability to produce reliable and accurate flood forecasts due to the sparse hydro-meteorological observation network in the country. An important input to river basin models at a regional level is land use data from countries. Challenges often arise when different classifications of crop-types and land cover typologies are defined by national agencies, while gaps in data frequency and accuracy also existed. Currently, the regional flood model in the Lower Mekong by the Mekong River Commission is using a compiled dataset from 2010, which no longer reflects the rapid land use change that has occurred in the region till now, leading to inaccuracy in flood modeling outputs. This study addresses the regional needs to improve flood forecasting capability significantly through the SERVIR-Mekong's Land Cover Mapping System (LCMS) providing custom and harmonized land use datasets and map products, and the Virtual Rain and Stream Gauge Information System (VRSGIS) addressing data sparsity through the addition of near-real time gridded rainfall datasets from the Global Precipitation Mission as well as stream water levels from available satellite altimetry missions including recently launched Sentinel-3 mission. Use of these additional data will increase accuracy of the existing hydrological, hydrodynamic and basin simulation models in the Lower Mekong.

A3.1-0020-18 EVALUATING TERRAIN STABILITY IN STEEP TERRAINS USING DOWNSCALED SMAP DATA

Juby Thomas, thomasjuby@outlook.com Delhi University, Delhi, India

Manika Gupta, manikagup@gmail.com Delhi University, Delhi, India

Soil moisture in the vadose zone, typically in the top layer is a key variable in terrestrial cycle. Its temporal and spatial variability over steep terrains affect partitioning of precipitation into infiltration and runoff, hence the terrain stability. This work aims at studying soil moisture - atmosphere - terrain stability associations along the steep terrains of Himalayas by considering the static (Slope, soil type, and land cover) and dynamic (precipitation and root soil moisture) factors. Though rainfall induced slope failures are common in the study area, shallow landslides are not less in number and are predominantly influenced by antecedent soil moisture content. Soil Moisture Active Passive (SMAP) using passive microwave techniques, L-band frequency, which minimizes the impact of vegetation on the soil parameter retrievals, have shown good promise for global mapping of near-surface (top 5cm of the soil profile) soil moisture at a spatial resolution of 25 to 40 km and a revisiting period of 2 to 3 days. With the help of process-based models and data assimilation schemes this top soil moisture is further extended to the root zone (top 1 m). Recent studies have suggested that the performance of available Radiative Transfer Models (RTMs) used for satellite soil moisture algorithms are not optimum under highly heterogeneous landscape conditions and vary with hydro-climate. The available models and algorithms available globally for terrain stability analysis are at coarser level. Since the landslides are local phenomena which are chiefly controlled by in situ parameters, SMAP based soil moisture data is downscaled to an appropriate level. In order to downscale the SMAP soil moisture product, MODIS-derived Normalized Difference Vegetation Index (NDVI) and surface temperature (Ts) are used as conditioning attributes. These two variables are derived for each 1km sub-pixel in the 36km SMAP footprint soil moisture data. Fang et al. (2013) constructed lookup curves between daily surface temperature difference and daily average soil moisture from the Global Land Data Assimilation System (GLDAS) for different NDVI values (derived from the Advanced Very High Resolution Radiometer [AVHRR]) for a 30year period (1979-2008). Based on the collocated MODIS based NDVI and Ts, and the established lookup curves, the SMAP soil moisture data is downscaled to 1km sub-pixels. With downscaled SMAP data along with static and dynamic factors, a threshold of soil moisture content, at which slopes fail, is determined and the vulnerable zones are demarcated spatially and temporally.

A3.1-0021-18 EVALUATION OF HIGH RESOLUTION GRIDDED PRECIPITATION PRODUCTS AND COMPARISON WITH THE SIMULATED PRECIPITATION OBTAINED FROM WRF MODEL IN REGIONS OF NORTH WESTERN HIMALAYA

Adrija Roy, adrijaroy1994@gmail.com

Indian Institute of Remote Sensing, Dehradun, India Praveen K Thakur, praveen@iirs.gov.in

Indian Institute of Remote Sensing, Dehradun, India Bhaskar R Nikam, bhaskarnikam@iirs.gov.in

Indian Institute of Remote Sensing, Dehradun, India

Water is the essence of life in all forms in earth. The hydrological cycle is defined as the process of storage and movement of all available amount of water on earth. A main component of water cycle is precipitation. Extreme precipitation events are responsible for flood like situations, on the contrary, deficiency in rainfall results in droughts in the regions. In recent years, simulations and projection of weather conditions to future, with Numerical Weather Prediction (NWP) models like Weather Research and Forecast (WRF), has become an imperative component of research in the field of atmospheric science and hydrology. The validation of modelled forecast from WRF model configuration and estimating bias of the modelled output is of utmost importance in case of generating weather prediction. This study presents an all-inclusive assessment of 5 high spatial resolution gridded precipitation products including satellite data products and also climate reanalysis product as compared to WRF precipitation product. The study was performed in river basins of North Western Himalaya in India extending from latitudinal extent of 29° to 36.5° N and longitudinal extent of 72.5° to 83.5° E. The basins in North Western Himalayan region like catchment areas of Indus, Beas, Sutlej, Chenab, Jhelum, Ravi, Yamuna and Upper Ganga, experience frequent floods and rainfall extreme conditions. Accordingly, performance of WRF model is evaluated through an extensive comparison of the produced forecast with the other datasets and also comparing with observational gridded (0.25°×0.25°) precipitation data from Indian Meteorological Department (IMD). Other products include version 7 TRMM (Tropical Rainfall Measuring Mission) Multi Satellite Precipitation Analysis (TMPA) 3B42 product (0.25°×0.25°), Global Precipitation Measurement (GPM) product (0.1°×0.1°) and Climate Hazards Group Infrared Precipitation with Station data (CHIRPS) product having a finer spatial resolution of 0.05°. Moreover, climate reanalysis rainfall product at 0.50° and 0.25° resolution from ERA Interim is also used. Analyses were carried out on a daily scale. Evaluations were based on watershed based zones and also on topography based zones in NWH. Forecast evaluation parameters like Bias, Mean Absolute Error, Root Mean Square Error, False Alarm Ratio, Probability of False Detection, and Probability of Detection are estimated for the zones classified as mentioned before. Threshold of rainfall amount were considered as 10mm and 30mm on different group of analyses, and the results found to be similar. TMPA and CHIRPS products were found to be most resembling with the observations. All products showed better performance in the higher latitudes i.e. in planes of Upper Ganga and Yamuna basin and also in parts of Indus basin. Discrepancies found to be increasing with topographical variation i.e. in hilly regions of Beas basin and western part of Sutlej and Chenab basins. GPM product shows greater deviation from the actual precipitation by underestimating the values of precipitation. ERA Interim product is very much identical to the modelled precipitation values of WRF. This study can be used for identifying suitability of WRF simulated data and assessing performance of other rainfall datasets as well.

A3.1-0022-18 INTERCOMPARISON BETWEEN AQUARIUS AND SMOS BRIGHTNESS TEMPERATURES FOR HETEROGENEOUS LAND AREAS

Amparo Benlloch, ambenca@alumni.uv.es University of Valencia, Burjassot, Spain Enrique Navarro, enrique.navarro@uv.es University of Valencia, Burjassot, Spain Ernesto Lopez-Baeza, ernesto.lopez@uv.es

University of Valencia, Burjassot, Valencia, Spain

This paper shows a comparison between ESA SMOS (Soil Moisture Ocean Salinity) and NASA Aquarius brightness temperatures during the time in which both missions coincided observing in space.

Intercomparison between Aquarius and SMOS brightness temperatures (TBs) over land surfaces is more challenging than over oceans because land footprints are more heterogeneous. The different spatial resolutions make the comparison difficult and this has motivated the application of different approaches (purely geometrical, geophysical and more purely physical) which have been evaluated over nine different continental and marine areas with different degree of homogeneity or heterogeneity. The metrics used have been (i) the method of the areas where the SMOS pixels TBs are weighted averaged within the Aquarius footprint (ii) the method of land uses where the averaging weights are obtained from the different land uses within the respective instruments (iii) the TVDI (Temperature Vegetation Dryness Index) method where the weights are obtained from the different degrees of dryness/wetness of the respective surfaces and (iv) the method of the gain matrix where the weighting factors are obtained from the antenna pattern of both radiometers. Other significant differences between both instruments have naturally been considered such as the fact of SMOS consisting of an interferometric aperture synthesis radiometer and Aquarius a real aperture one, the different overpassing times over the areas observed, etc.

Significant and innovative results have been obtained when using the antenna pattern of both instruments. The SMOS data used correspond to CATDS (Centre Aval de Traitement des Données SMOS) level-3 brightness temperatures with the incident angle of 27,5º and Aquarius data correspond to brightness temperatures acquired by its inner beam. Horizontal and vertical polarisations are considered in both configurations.

As expected, the gain matrix method achieves better results, with considerably reduced errors in all experimental areas and for both polarisations. The TVDI method utilizes complementary data (LST and NDVI) from MODIS and it has the advantage that it considers the dynamical aspects of the evolution of the surface, naturally over continental surfaces, and this represents a significant advantage in front of the static methods of the areas and of the land uses.

A3.1-0023-18 SURFACE BIOLOGY AND GEOLOGY WITH IMAGING SPECTROSCOPY

Rob Green, rog@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

On the 5th of January 2018, the 2017 Earth science Decadal Survey was released titled, “Thriving on Our Changing Planet A Decadal Strategy for Earth Observation from Space.” This 700 page document was developed over more than two years with broad input from the Earth science and applications communities. Five targeted observables are indicated as observing system priorities. One of these is designated surface biology and geology. In this category, a set of science and applications targets are identified including: ground/water temperature, snow reflectivity, active geologic processes, vegetation traits and algal biomass. The candidate measurement approach is described as, “Hyperspectral imagery in the visible and shortwave infrared, multior hyperspectral imagery in the thermal IR.” This paper reviews some of the key new science and applications objectives, and outlines some measurement approaches that could be used to address this guidance in the area of global visible to short wavelength infrared imaging spectroscopy.

A3.1-0024-18 COMBINING REMOTE SENSING, ECOPHYSIOLOGY, AND MULTI-SCALE MODELING TO MANAGE RESOURCES IN AQUATIC ECOSYSTEMS IMPACTED BY ENVIRONMENTAL VARIABILITY

David Bubenheim, david.l.bubenheim@nasa.gov

NASA Ames Research Center, Biosphere Science Branch, Moffett Field, California, United States

The California Sacramento-San Joaquin River Delta is the hub for California's water supply and supports important ecosystem services, agriculture, and communities in Northern to Southern California. Expansion of invasive aquatic plants in the Delta coupled with impacts of changing climate, long-term drought, shifting land use, and variations in water flow and water quality are detrimental to water management, commerce, and the ecosystem complex in the San Francisco Bay/California Delta. NASA Ames Research Center and the USDA-Agricultural Research Service partnered with the State of California to develop science-based, adaptive-management strategies to understand the relative response for invasive aquatic plants to these environmental variations and balance resource management in the Sacramento-San Joaquin Delta. The project combines remote sensing, watershed land use models, newly defined environmental response of invasive aquatic plants to climate, and spatial distribution/biomass density mapping and water quality to study ecosystem response to climate and aquatic plant management practices. Specific mapping tools developed utilize satellite and airborne platforms to provide regular assessments of population dynamics on a landscape scale and support both strategic planning and operational decision making for resource managers. Spectral analysis is targeted to determine composition and relative proportions of individual species spatially across plant communities. Water flows to the Delta primarily through the San Joaquin and Sacramento River watersheds; quality of that inflow water is modeled using the Soil-Water Assessment Tool (SWAT). A modified SWAT tool customized to account for unique landscape and management of agricultural water supply and drainage within the Delta addresses quality changes within the Delta. Localized plant distribution and environmental parameters couple with plant response to provide assessment of aquatic plant ecosystem function as a result of variation in factors in and around the Delta. On-the-water validation and operational utilization of these tools by management agencies are improving decision making, management effectiveness and efficiency in the region and provide insight regarding the merging of remote sensing, ecosystem modeling, and functional component assessment tools to aide land and water resource managers make science-informed decisions regarding management and outcomes.

A3.1-0025-18 CLASSIFICATION OF MICRO-TOPOGRAPHICAL DISTRIBUTION IN THE ILI DELTA OF BALKHASH LAKE BY ALOS MULTI-SENSOR DATA

Yasunori Nakayama, nakayama@chs.nihon-u.ac.jp Nihon University, Tokyo, Japan

Kunihiko Endo, endo@chs.nihon-u.ac.jp Nihon University, Japan

Toshihiko Sugai, sugai@k.u-tokyo.ac.jp University of Tokyo, Tokyo, Japan

Authors are investigating wide-range environmental change in Central Asia by the analysis of multi satellite data with the field survey information. Particularly, based on the water area fluctuation analysis result of the closed lakes in Central Asia by satellite data, authors are investigating environmental change situation for a long period. In Balkhash Lake which is one of the typical closed lakes in Central Asia, it was suggested that anthropogenic impact is stronger and natural factor is also added to it in recent years. However, the remains of the lake water level thousands of years ago being wetness compared with the present are left as micro-topography along a lake shore line and in the delta of the Ili River as a main inflow river. If the age of this micro-topography is obtained, the history of geomorphological formation accompanying the climate change during the last thousands to tens of thousands of years will be grasped. In this study, several micro-topographies of different formation year reflecting the past environmental change situation were classified in Ili Delta spreading in the middle and the lower streams of the Ili River as the maximum inflow river of Balkhash Lake by using the multi observational data of PALSAR, PRISM, and AVNIR2 of ALOS. Specifically, landcover classification depending on sediment, and distribution of vegetation and sand dune was firstly carried out by ALOS/PALSAR data. Next, classification of the micro-topography reflecting sand hill or terrace distribution was performed by the high spatial resolution and highly precise DEM which were mainly generated from ALOS/PRISM stereo pair data. In this process, comparison and verification with the public opened existing DEM data such as SRTM or GDEM, and field topographical survey result were also carried out. Finally, the subdivided classification of the micro-topography in the Ili Delta was also tried by using the pansharpened image data derived from ALOS/AVNIR-2 and PRISM data. As a result of this study, the extraction and classification of several kinds of micro-topographies for past different age were carried out by the comparative analysis of the seasonal ALOS/PALSAR data and the high spatial resolution DSM generated from the ALOS/PRISM stereo pair data. Furthermore, restoration of the history of geomorphological formation of the Ili Delta during the last several hundred to thousands of years was tried based on reference of the pansharpened image and field survey results to the geomorphological classification image.

A3.1-0027-18 FULL POLARIMETRIC ALOS-2/ PALSAR-2 ANALYSIS FOR SHORELINE DETECTION

Tomohito Asaka, asaka.tomohito@nihon-u.ac.jp Nihon University, Narashino, Chiba, Japan Takashi Nonaka, nonaka.takashi@nihon-u.ac.jp Nihon University, Narashino, Chiba, Japan Yuuki Uchida, uchida.yuuki@nihon-u.ac.jp Nihon University, Narashino, Chiba, Japan Keishi Iwashita, iwashita.keishi@nihon-u.ac.jp Nihon University, Narashino, Chiba, Japan

Toshiro Sugimura, sugimura.toshirou@nihon-u.ac.jp Nihon University, Narashino, Chiba, Japan

Hiroyuki Wakabayashi, wakabayashi.hiroyuki@nihon-u.ac.jp Nihon University, Koriyama, Fukushima, Japan

Shoreline erosion results from any number of factors, including a decrease in sand supply from rivers, storms, simple inundation of the land by rising sea levels, or ground deformation. To evaluate the actual erosion conditions, we need current shoreline data. Advanced Land Observing Satellite 2 / Phased Array type L-band Synthetic Aperture Radar 2 (ALOS-2/PALSAR-2) data is expected to continue updating the data archives related to national land and infrastructure information. Full polarimetric ALOS-2/PALSAR-2 data observed with below-30°off-nadir angle and with the synthetic aperture radar (SAR) beam facing the opposite direction of landward waves produced appropriate images to detect the shoreline of a sandy coast in our previous study. In this study, we aimed to evaluate full polarimetric ALOS-2/PALSAR-2 data observed on January 12th, 2016 for sandy coast and rocky coast shoreline detection. We applied the Canny edge detection algorithm to detect the boundary between sandy or rocky coast and sea area with surface scattering power images (Ps), double-bounce scattering power images (Pd), volume scattering power images (Pv), and helix scattering power images (Ph) derived from the full polarimetric ALOS-2/PALSAR-2 data. The Ps, Pd, Pv, and Ph images are calculated by the four-component scattering model. Through comparative verification of shoreline data from medium-resolution optical satellite imagery (Terra/ASTER observed on March 2nd, 2016), we determined that full polarimetric ALOS-2/PALSAR-2 data could be used to detect the approximate shorelines of both a sandy coast and a rocky coast.

A3.1-0028-18 GRAVITY AS A MEASURE OF CLIMATE CHANGE

Byron Tapley, tapley@csr.utexas.edu

Center for Space Research, U. of Texas at Austin, Austin, Texas, United States

The interactions of the Earth System components are a significant contributor to current weather and longer climate trends. The interactions involve mass change that involve both energy and momentum. Water movement at diurnal, monthly, annual and decadal periods is a significant part of this exchange. Phenomena associated with these interactions involve mass change related to continental surface and sub-surface water storage (rivers, lakes, ground water), snow cover and polar and mountain ice sheets) as well as change in the ocean and atmospheric mass. Understanding these interactions and their consequences is essential to forecasting future states of the Earth System.

The mass change events involved in these phenomena have an associated gravity change signal which can be measured as a means of both understanding and monitoring these interactions. To fully understand the signal, repeated global and near synoptic measurements of the mass variations are necessary and a satellite-based observation capability is the only feasible approach for satisfying this requirement. The Gravity Recovery and Climate Experiment (GRACE) mission was conceived as a response to the need for such satellite-based measurements. The objective of the GRACE mission is to improve our understanding of the Earth by making pioneering measurements of the gravity signals associated with mass exchange within and between the Earth System components.

Launched on March 17, 2002 with a proposed mission life of 5 years, the GRACE mission ended on October 12, 2017 after providing paradigm shifting measurements for over 15 years. This presentation will describe the mission data set and its contributions to climate change investigations involving change in global sea level, terrestrial water storage, continental aquifers, surface and deep ocean currents, polar ice mass and the mass redistribution associated with large earthquakes and post glacial rebound. The totality of the contributions to studies of Earth system dynamics under-score both the role of the mass change as an essential climate variable and the importance of continuing the measurement record initiated by the GRACE mission. This critical role will be fulfilled by the GRACE Follow On mission, which is scheduled for launch in the late spring 2018.

A3.1-0029-18 REMOTE SENSING TECTONIC AND GROUNDWATER PROCESSES IN CENTRAL CALIFORNIA USING ALOS-1/2 AND SENTINEL-1 INSAR

Zhen Liu, zhen.liu@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Paul Lundgren, paul.r.lundgren@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Cunren Liang, cunrenl@caltech.edu

California Institute of Technology, Pasadena, California, United States Thomas Farr, thomas.g.farr@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

The improved spatiotemporal resolution of surface deformation from recent satellite sensors provides a great opportunity to better constrain and understand both tectonic and non-tectonic processes. In central California the primary plate boundary fault system (San Andreas fault) lies adjacent to the San Joaquin Valley (SJV), a vast structural trough that accounts for about onesixth of the United Sates' irrigated land and one-fifth of its extracted groundwater. The central San Andreas fault (CSAF) displays a range of fault slip behavior with creeping in its central segment that decreases towards its northwest and southeast ends, where it transitions to being fully locked. Despite much progress, many questions regarding fault and groundwater processes in the region still remain. In this study, we combine satellite InSAR and in-situ GPS to image fault and anthropogenic deformation. We performed a synoptic InSAR time series analysis using Sentinel-1, ALOS-1/2 interferometry. We estimate azimuth mis-registration between single look complex (SLC) images of Sentinel-1 in a stack sense to achieve accurate azimuth coregistration between SLC images for low coherence and/or long interval interferometric pairs. We show that it is important to correct large-scale ionosphere features in ALOS-2 ScanSAR data for accurate deformation measurements. In addition to fault creep, the L-band ALOS, and especially ALOS-2 ScanSAR interferometry, show large-scale ground subsidence in the SJV due to over-exploitation of groundwater. Groundwater related deformation is spatially and temporally variable and is composed of both recoverable elastic and non-recoverable inelastic components. InSAR time series are compared to GPS and well-water hydraulic head in-situ time series to understand water storage processes and mass loading changes. We present model results to assess the influence of hydrological processes on surface deformation, fault mechanics and implication for regional earthquake hazard.

A3.1-0030-18 THE GFZ GRACE RL06 LEVEL-2 AND ASSOCIATED LEVEL-3 DATA PRODUCTS

Frank Flechtner, frank.flechtner@gfz-potsdam.de

German Research Centre for Geosciences, Potsdam, Germany

The GFZ German Research Centre for Geosciences as part of the GRACE Science Data System (SDS) is currently reprocessing the complete GRACE mission data. This new Level-2 data release (RL06 in the SDS nomenclature) will incorporate updated standards and background models as well as an updated processing strategy in order to take care of limitations known from the current GFZ RL05a time series.

Amongst others changes from RL05a to RL06 comprise: (1) a reprocessed GPS constellation consistent with ITRF2014/IGS14; (2) reprocessed RL03 Level-1B products for K-band and star camera instrument data; (3) updated models for ocean tides (FES2014) and Atmosphere and Ocean Dealiasing (AOD1B RL06); (4) modified parameterization of orbit and instruments.

The resulting 15+ year RL06 time series of monthly GRACE Level-2 spherical harmonics with its underlying processing standards will then serve for the continuation with GRACE-FO (Follow-on) data expected for late spring 2018. It will also be the basis for the Gravity Information Service (GravIS) jointly developed by a team of GFZ, the Alfred-Wegener-Institute Bremerhaven and TU Dresden where users can download dedicated Level-3 products for hydrological, oceanic and polar research activities.

The presentation will report on the reprocessing status and show examples of the new GRACE RL06 gravity field products and (if already available) first results of GRACE-FO. In addition, an overview of the GravIS web portal will be given and examples of the latest Level-3 products will be shown.

A3.1-0031-18 SEISMICITY AND GPS OBSERVATIONS FOR STUDYING CRUSTAL DEFORMATION AND GEODYNAMICS IN AND AROUND EGYPT

Salah Mahmoud, salah.mahmoud@nriag.sci.eg

National Research Institute of Astronomy and Geophysics (NRIAG), Helwan, Egypt Robert Reilinger, reilinge@erl.mit.edu

Massachusetts, United States

Simon McClusky, reilinge@erl.mit.edu Massachusetts, United States

Egypt has suffered from a numerous of destructive earthquakes such as Kalabsha earthquake (1981, Mag 5.4) near Aswan city and the High dam, Dahshour earthquake (1992, Mag 5.9) near Cairo city and Aqaba earthquake (1995, Mag 7.2). As the category of earthquake damage includes all the phenomena related to the direct and indirect damages, the Egyptian authorities do a great effort to mitigate the earthquake disasters. The seismicity especially at the zones of high activity is investigated in details in order to obtain the active source zones. Since the year of 1994 till now, the geodetic observations by means of Global Positioning System (GPS) were applied instead of the terrestrial ones to cover some other regions of the country. These regions include Sinai, Gulf of Suez, Greater Cairo, Aswan and the Middle part on the River Nile. Data adjustment and analysis of the repeated GPS campaigns from the different networks using Bernese Software prevailed significant movements which may help in more understanding the geodynamics of these regions. In the meantime, GPS measurements of crustal motions for 189 sites extending east-west from the Caucasus Mountains to the Adriatic Sea and northsouth from the southern edge of the Eurasian plate to the northern edge of the African plate were carried out and Estimate of plate motions at stations located at different plates were determined. From the previous results, we could find there are some correlations between the computed surface deformation and the earthquake occurrences in Local and regional scales. In the regional scales, the Hellenic arc is the region which shows very well this correlation. While in the Local scales, there are some regions in Egypt such as Sinai, Aswan, Greater Cairo and Middle part of the Egypt around the River Nile. We also use the results of computing crustal deformation by means of GPS in studying the stabilities of any area for the purpose of establishing new strategic project and in planning for the constructions of new cities.

A3.1-0032-18 KINEMATICS OF THE SUEZ-SINAI AREA FROM COMBINED GPS VELOCITY FIELD

Salah Mahmoud, salah.mahmoud@nriag.sci.eg

National Research Institute of Astronomy and Geophysics (NRIAG), Helwan, Egypt Grazia Pietrantonio, grazia.pietrantonio@ingv.it

Istituto Nazionale di Geofisica e Vulcanologia, Rome, Italy Federica Riguzzi, federica.riguzzi@ingv.it

Istituto Nazionale di Geofisica e Vulcanologia, Rome, Italy Roberto Devoti, roberto.devoti@ingv.it

Istituto Nazionale di Geofisica e Vulcanologia, Rome, Italy

A combined GPS velocity solution covering a wide area from Egypt to Middle East allowed us to infer the current rates across the main, already well known, tectonic features. We have estimated 126 velocities from time series of 90 permanent and 36 non-permanent GPS sites located in Africa (Egypt), Eurasia and Arabia plates in the time span 1996-2015, the largest available for the Egyptian sites. We have combined our velocity solution in a least-squares sense with two other recent velocity solutions of networks located around the eastern Mediterranean, obtaining a nal IGb08 velocity eld of about 450 sites. Then, we have estimated the IGb08 Euler poles of Africa, Sinai and Arabia, analyzing the kinematics of the Sinai area, particular velocity proles, and estimating the 2D strain rate eld. We show that it is possible to reliably model the rigid motion of Sinai block only including some GPS sites located south of the Carmel Fault. The estimated relative motion with respect to Africa is of the order of 2-3 mm/yr, however there is a clear mismatch between the modeled and the observed velocities in the southern Sinai sites. We have also assessed the NNE left shear motion along the Dead Sea Transform Fault, estimating a relative motion between Arabia and Africa of about 6 mm/yr in the direction of the Red Sea opening.

A3.1-0033-18 ASSESSMENT OF TEMPERATURE VEGETATION DRYNESS INDEX (TVDI) AND REGIONAL WATER STRESS INDEX (RWSI) FOR DROUGHT MONITORING IN SINDH

Rao Muhammad Zahid Khalil, zahidkhalil.rao@gmail.com Institute of Space Technology, Karachi, Pakistan

Badar Ghauri, b_ghauri@yahoo.com

Institute of space technology,Pakistan, Karachi, Pakistan

Drought is one of the most complex and least understood phenomena in all-natural hazards. Intense drought periods impacted the livelihoods, crop destruction, human deaths, killed thousands of livestock and pushed peoples to migrate other areas. The drought has hit Indus basin historically from 19th to first half of the 20th century. It ranked 3rd in the frequency of significant hazards of Pakistan according to United Nation Disaster Risk Management. Historical data indicate that the province of Balochistan and Sindh frequently suffered from drought as compared to Punjab and KPK. Since the evaluation of satellite land observation data, numerous investigations have been done to monitor the occurrence and severity of drought using numerous satellite remote sensing based indices. Of these indices, Temperature Vegetation Dryness/Drought Index (TVDI) has been extensively used because of its easiness and accurate monitoring. But recently the application of TVDI has been questioned due to many limitations as it is based on the theoretical concept of the direct correlation between Land surface temperature (LST) and Normalized difference vegetation index (NDVI). Therefore, the selection of suitable index or model for drought monitoring has great importance in order to achieve effective drought monitoring management which results in increased agricultural production and economic development. In this study, the potency of TVDI was investigated, that calculated with modified methodology unlike the many studies using five different vegetation indices (VIs) i.e., NDVI, ANDVI, EVI, SAVI, MSAVI, by comparing it with Regional Water Stress Index (RWSI), an evapotranspiration based index having relatively clear physical meaning and high precision measurement. The northwest portion of Sindh which include Larkana, Qambar Shahdadkot, and some portions of Jacobabad, Dadu, Naushahro Feroze, Khairpur, and Shikarpur was selected as the study area to cover up all land cover types from no vegetated land (bare) to fully vegetated land. Landsat scenes of four different years (1998, 2000, 2014 2017) of the same month (February) were used for all the processing to derive vegetation indices, LST, TVDI, and RWSI. The relationship among TVDI, RWSI, soil moisture and Standard precipitation index (SPI) were also examined. Results indicate that: (1) LST and VIs showed negative relationship in most of the cases except in the case of dense vegetation in 2000 due to the prevailing of severe drought episode at that particular year; (2) The relationship between TVDIs and RWSI were found to be weakened when RWSI > 0.85, which deduces that TVDIs are appropriate for assessing and monitoring light drought, normal, and wet conditions, but not for severe drought conditions; (3) SPI and soil moisture had better significant relationship with RWSI than TVDIs, indicating that RWSI is more reliable and appropriate index for monitoring and assessing drought in this region. This study helps to enhance the drought monitoring capabilities which allows decision makers to make more knowledge-based decisions to reduce the impacts of drought.

A3.1-0034-18 RIVERINE FEATURE EXTRACTION AND VULNERABILITY ASSESSMENT TOWARDS ECO-FRIENDLY TOURISM SITES DEVELOPMENT

Kuldeep ., kesu1001@gmail.com

Indian Institute of Technology Roorkee, Roorkee, India

Texture plays a very vital role in feature extraction from remote sensing satellite images. Texture is an important visual property that is used to characterize the natural and artificial images which make it a very useful feature for image analysis. High resolution satellite images contains abundant textural information which is very helpful for making distinction between the objects with similar spectral reflectance. The main objective of the proposed research is twofold (i) automatic identification of riverine features (island, water and sand) based on their textural information from high resolution remotely sensed data using object based image classification.

(ii) To assess the vulnerability of each river island towards flooding using 2D hydrodynamic model and SAR data. The GLCM based textural features are extracted to be used with image classification. The implementation and execution of flood mapping, monitoring and management applications has become easier with the availability of SAR data with all weather, day and night capabilities. In this study, the exploitation of the SAR dataset for hydraulic modelling and disaster management has been highlighted using feature extraction techniques for water area identification and water level extraction within the floodplain. The availability of high precision digital elevation model generated from the Cartosat-1 stereo pairs has enhanced the capability of retrieving the water depth maps by incorporating the SAR derived flood extent maps. This paper illustrates the flood event on June 2013 in Ganga River, Uttarakhand, India. Water levels that were computed by carrying out the modelling using hydraulic model in HECRAS also suggest that the water surface profiles provided by the combined use of topographic data and SAR accurately reflect the true water line. The outcome of the research can further be utilized in various application including river morphology, flood mapping, tourism infrastructure planning etc.

A3.1-0035-18 APPLICATION OF MULTIPLE REMOTE SENSING TECHNIQUES FOR DELINEATING GLACIER LAKE BOUNDARIES IN NORTHERN PAKISTAN

Badar Ghauri, b_ghauri@yahoo.com

Institute of space technology,Pakistan, Karachi, Pakistan Maha Qaiser, istncrg@gmail.com

Institute of Space Technology (IST), Islamabad, Karachi, Pakistan Muhammad Shafiq, istncrg@gmail.com

Pakistan

Glaciers are the best indicators of climate change in any region. In view of the facts that glaciers are being depleted in south Asian region, application of an accurate remote sensing (RS) technique to map a glacier lake is the needed when many researchers claim to have better results using a particular RS method. We report here the mapping of one of lakes at the bottom of Hisper Glacier using satellite. The Landsat 8 data obtained from USGS were used for Sept.1990, March 2000, June 2010, May 2016 and march 2017 alongwith SRTM DEM. A number of lakes were demarcated using band ratios, NDWI and pan sharpening techniques. A number of lakes were demarcated using band ratios, NDWI and pan sharpening techniques. By comparing all these techniques, Panchromatic Sharpening Enhancement Technique provided the best result in visual interpretation. Then Unsupervised Classification since each water class was spectrally differentiated though it was hard to reclassify the polygons but results which were obtained were all satisfactory. In the last, NDWI and Band Ratio, the results obtained by using NDI were better than Band Ratio separating water from other classes. Coversely, Band Ratio mixed all the classes making harder for the user to interpret the differences and distinguish among water related classes.

A3.1-0036-18 INTERGRATING GIS AND SCS-CURVE NUMBER FOR ESTIMATING RUNOFF COEFFICIENT

Ramsha Muzaffer, ramsha.muzaffer@ymail.com Institute of Space and Technology, Karachi, Pakistan

Rao Muhammad Zahid Khalil, zahidkhalil.rao@gmail.com Institute of Space Technology, Karachi, Pakistan

Sumera Zafer, sumaira.zafar_ncrg05@ist.edu.pk Institute of Space Technology, Karachi, Pakistan

ABSTRACT: This study is an attempt to integrate Geographical Information System and SCSCurve Number for estimating runoff coefficient. Basic element in estimation of rainfall runoff depth is watershed management, which is determined by runoff coefficients. It is one of the most important factor for hydrologic designs such as dams and small ponds. Factors affecting the runoff coefficient value for a watershed are the land use, the soil type and the slope of the watershed and rainfall data. Soil Maps generated using Soil Map obtained by Geological Survey of Pakistan and then digitized using Arc GIS. The slope is another essential factor for runoff Index which had been calculated using 30m ASTER Dem. Land Use Land Cover (LULC) data is obtained by Open Street Map as shape file. CN-Grid HSG (Hydrologic Soil Group) developed to further integrate LULCs and the CN Lookup table for HSG. Intersection performed with each soil group (A, B, C and D) against all LULC. Study area only comprises of soil group 'B', therefore, the CN numbers were only assigned to group B, and for other soil groups the value was set at zero. Rainfall data was acquired from Pakistan Meteorological Department (PMD). SCS curve number method developed USA Soil Conservation service "SCS" (now called Natural Resources Conservation Service-NRCS) a division of US Department of Agriculture. The major objective of the study is to determine the potential runoff coefficient and runoff depth for Karachi.

INTRODUCTION or planning and management of land and water resources, watersheds are the fundamental units to be considered [1]. In urban centers like Karachi city, these watershed supports agricultural activities in its sub-urban areas. Karachi is the biggest city of Pakistan, facing a continuous population growth and urban expansion in its northern, northeastern and northwestern regions [2]. Within Karachi jurisdiction, three major river basins of Malir, Hub, and Lyari Rivers play their role in draining the storm water from the city and recharge ground water. In spite of having extensive network of natural streams, these streams do not have any flow gauges that's why the runoff data is not available. Karachi receives its maximum rainfall during monsoon and average rainfall range from 10mm to 150mm according to the Normal (1985 -2014) data provided by the Pakistan Meteorological Department (PMD). Karachi also receives little rainfall from western disturbances during winter. These natural streams are nonperennial and only active during the rainfall. That is why the agricultural activities in suburban areas of Karachi is mainly dependent on the ground water (recharged during the rainfall). The heavy rainfall of monsoon period is mostly converted into runoff and a huge part of this just gone to the Arabian Sea. But with the harvesting of this rainwater, it is possible to sustain the water resources in suburban areas of Karachi, so the water for agricultural activities would be available for a longer time period. Estimation of rainfall runoff depth is one of the basic elements in watershed management, which is determined by runoff coefficients [3]. Rainfall depth is also important for hydrologic designs such as dams and small ponds. Runoff coefficient is the portion of rainfall which converted into direct runoff during a rainfall event [4]. It can be defined as the ratio of the runoff depth to rainfall depth or as the ration of peak runoff rate to rainfall intensity for the time of concentration [5] These runoff coefficients are also used understand the recurrent interval of floods in an hydrologic or climatic regime [6]. The runoff coefficients varies with the change in topography, landuse/landcover, soil type and it moisture content. The Natural Resource Conservation Service (NRCS)'s curve numbers (CN) represent the runoff potential of a basin based on hydrologic soil group, landuse, and hydrologic conditions of the study area. To calculate CN for a specific area, the information regarding its land use/cover, soil type, and antecedent soil moisture condition (AMC) are to be known [7]. In NRCS curve number method (popular with its previous name SCS-CN), it is assumed that rainfall occurred uniformly during the storm. The SCS-CN method is a rainfall-runoff method based on the basic concept that when rain falls in a basin, it converts into surface runoff after initial losses or initial abstractions. These losses include interception due to vegetation and pavements that restrict the rainwater to penetrate into the ground immediately after the rainfall, surface water storage (lakes, ponds, and depressions), and water infiltrated into the ground [1]. The range of CN values is from 30 -100. The lesser values show high infiltration and low surface runoffs. On the other hand, a higher CN value indicates lower infiltration rate producing higher surface runoffs. The major objective of the study is to determine the potential runoff coefficient and runoff depth for Karachi BACKGROUND

STUDY AREA AND MATERIALS Karachi district of sindh-Pakistan was selected for this study. Karachi is the major city of Pakistan and provincial capital of Sindh. To estimate the runoff coefficient of Karachi a number of data-set were used, including Shuttle Radar Topographic Mission (SRTM) Digital Elevation Model (DEM), Soil map, Rainfall Data and, Land-use/Land-cover (LULC) data from Open Street Map (OSM).

METHODOLOGY A. Data preparation 1) Soil map Soil map of the study area was obtained from Geological Survey of Pakistan (GSP) and then converted to shapefile. Soil data provided by GSP have detailed information of soil physical and chemical properties of topsoil (0-30 cm). There are four Hydrologic Soil Groups (HSGs), A, B, C, and D. According to USDA-SCS (1988) HSG A has the minimum runoff potential and D has the maximum. In Karachi major soil texture is loam which belongs to 'Group B' of the HSG, having moderate runoff potential [78].

2) Landuse/Landcover (LULC) For this study we need a detailed LULC data, that's why this data is obtained by OSM as shapefile.

3) Digital Elevation Model (DEM) SRTM DEM acquired from USGS website to calculate the slope of the study area. Slope is one of major parameters which determine the runoff coefficient of the study area. B. CN-Grid Generation To calculate the curve number for each LULCC, a CNGrid was generated. For the CNGrid generation HSG (Hydrologic Soil Group), LULCs and the CN Lookup table for HSG were used [8]. To calculate the percentage of each soil group (A, B, C and D) against all LULC, Soil groups were intersected with LULCs. The CN Lookup table consist all the values of CN for each LULC according to the soil group. In the study area only 'B' soil group was present, therefore, the CN numbers were only assigned to group B, and for other soil groups the value was set at zero. C. Rainfall runoff Rainfall data was acquired from Pakistan Meteorological Department (PMD). SCS curve number method developed USA Soil Conservation service "SCS" (now called Natural Resources Conservation Service-NRCS) a division of US Department of Agriculture. This is one of the common method used to compute peak runoff rates and volumes of small and ungauged streams [9][10]. The SCS Runoff Curve Number used to simulate rainfall-runoff response in Karachi due to 24-hr storm events. According to SCS curve number, the runoff from a rainfall event starts after initial losses. Initial losses include evaporation, absorption, transpiration and surface storage, called 'initial abstractions (Ia). The variable 'Ia' also includes interception losses due to vegetation and paved surfaces which restrict the rainfall from reaching the ground instantly after it occurs. The surface storages losses are water bodies such as ponds, lakes, depressions and infiltration of rainwater to the ground [11]. In SCS method Ia is assumed to be about 20 percent of the potential maximum retention (Eq. 01), whereas, the potential maximum retention (S) is calculated using Eq. 02 ???????? = 0.2 ???? Eq. 01 ???? = ???? (100/???????? 1) Eq. 02 Where: Z = 10 for English measurement units or 254 for metric units CN = Runoff Curve Number CN value depends on soil type, landcover, and Antecedent Moisture Condition (AMC) of the study area. Equation 03 represents a relationship between the accumulated rainfall and the accumulated runoff.

???? = (???? ????????)2/(???? ????????) + ????) Eq. 03 Where: Q = directly accumulated runoff (inch or mm) P = accumulated rainfall or maximum potential runoff in inches or mm (24- hr storm depth versus rainfall frequency) Ia = initial abstraction (includes surface storage, evaporation, interception, and infiltration before the occurrence of runoff (in or mm) S = maximum potential soil moisture retention after runoff begins (inch or mm) D. Runoff coefficient Annual runoff coefficient per pixel derived using Equation 04, K= yearly (seasonal) total runoff (mm) / yearly (seasonal) total rainfall (mm) IV. RESULTS AND CONCLUSION Remote sensing data along with ground information helps a lot in SCS-CN model. Products like drainage pattern, catchment, land use/land cover of Remote Sensing can have integrated with GIS for watershed management. Estimation of Runoff coefficient in this process is very important as it is one of the most important parameters in hydrologic design. This study can also help in identification of runoff coefficient of areas whose observed runoff records are not available.

A3.1-0037-18 IMPACT OF NEW URBAN SCHEMES ON NATURAL STREAMS OF KARACHI

Sumaira Zafar, sumaira.zafar_ncrg05@ist.edu.pk

Institute of Space Technology (IST), Islamabad, Karachi, Pakistan

Pakistani social activist, director of the Orangi Pilot Project Research and Training Institute Ms Parveen Rehman said that "Development doesn't come from concrete! It comes from human development." Landuse planning and development is one of the key feature of urban centers. This landuse planning has a direct impact on landuse patterns and eco-environmental quality of the area. Landuse planning is a systematic analysis of land suitability and its alternative use. For landuse planning the best choice of land is that which fulfills the present social need but without disturbing the environment of area. Residential development processes in the urban-rural fringe of mega cities has major environmental consequences. Karachi, Pakistan is one of fastest growing urban centers of the world, but this fast-growing population has also been associated with increasing pressure on ecosystems and their individual components. In 1993 only 08% of the city area was developed which is now 21% of the total city area. These development processes have influence on socio-economic, political and environmental situation of the city. The conversion of fertile agricultural land and natural ecosystems into built-up area bring negative ecological impacts. One recent study shows that the urbanization is also going to cause recurrent flash floods in Karachi city which will cause damages in terms of livelihood and assets. The damages by these floods is just not due to heavy rainfalls but because urban development acts as barriers to natural major stream networks and hamper the flow of rainwater to the riverbeds. This study also aims to analyze the impact of one of the well-known real state scheme "Bahria Town Karachi" on natural landcovers. Bahria town is located in the northern part of Karachi almost covering an area of 44,000 Acres. In a newspaper article urban development expert and town planner Mr. Arif Hasan reveals that according to the first master plan of Karachi (1953) the rural area around Karachi were previously reserved for agriculture and the status was unchanged in the revised plans of 1958, 1989 plan for 2000. Bahria town Karachi also responsible for displacement of villages located in the area of prior to the development of the project. About 45 goths (villages) residents were displaced. Figure 01 shows the map and list of the villages which were affected due to Bahria town. In spite of having all the controversies the new town is also responsible for deteriorating the natural landcover and natural streams bed in the area. A previous study related to blockage of stream networks in Karachi reveals that the town is encroaching the riverbeds which in turn will affect the river flow and also ground water recharge. This research aims to study the detailed impacts of Bahria town development on the natural and semi natural environment of the city. For this study Landsat ETM+ and Landsat data for the year of 2000 and 2017 were collected. Landsat is one of the satellite program providing extensive remote sensing data free of cost. Landsat data have been proved valuable for many urban related studies.

A3.1-0038-18 DROUGHT ASSESSMENT USING SATELLITE DERIVED METEOROLOGICAL PARAMETERS AND NDVI IN POTOHAR REGION

Saad Ul Haque, saad_haq@hotmail.com Institute of Space Technology, Karachi, Pakistan

Pakistan faces a number of severe meteorological droughts due to various meteorological variations such as rainfall, air quality and related climate changes. The study area namely as and due to its unique topography, it lacks the network of canals system. Multi-temporal MODIS NDVI product 16-days composite for year 2000-2013 was used to identify any drought period in study area i-e, Potohar Plateau in the north of Pakistan. There was an unexpected decrease in NDVI value in 2009-2010, which caused a short term drought. The minimum mean value for NDVI observed was 0.268 for the whole decade, where mean departure from minimum NDVI value was 0.063 reducing it to a value of 0.20. Meteorological parameters derived from NCEP satellite data such as Precipitation, Max. Temperature, Min. Temperature, Humidity and Solar Radiation were assessed for drought sensitivity for the past drought period 2009-2010. Further precipitation based drought index, known as the Standardized Precipitation Index (SPI) was also derived for 6 months. Maps for each parameter showing its intensity trend were generated for the drought period. For further investigation, the relationships between meteorological parameters were examined. A negative relationship between NDVI and SPI, in month of October was observed that triggered the condition of drought. A decreasing trend was also observed in relationship between NDVI and humidity. Further, Fuzzy Overlay analysis was performed after generation of Fuzzy membership function of these meteorological parameters. VCI was derived from NDVI that estimates the vegetation health. Finally, overall drought severity map was generated by combining VCI and Fuzzy overlay of meteorological parameters. This map gives a significant understanding about the areas under various degrees of drought stress.

A3.1-0042-18 TOWARDS CHARACTERIZING INUNDATION DEPTH UNDER DIFFERENT LAND COVER TYPES WITH L-BAND SAR IMAGERY

Guy Schumann, gjpschumann@gmail.com

Remote Sensing Solutions Inc/University of Colorado Boulder, Monrovia, California, United States

Van Dang, justplainvan@gmail.com

Remote Sensing Solutions, Monrovia, California, United States Jung-Rack Kim, kjrr001@gmail.com

University of Seoul, Korea

Information derived from imagery acquired with instruments onboard satellites, aircrafts or drones can be used in many applications and help advance our understanding of environmental processes. This has been demonstrated in many research studies to date, however, in many cases, remote sensing cannot measure directly the variable that is of greatest interest. In the case of flooding for instance this would be clearly flow velocities along with floodplain inundation depths since those two parameters actually constitute hazard during an event. Yet, it is not possible to measure either one of those parameters from satellites (at least not until now). Therefore, it is necessary to derive the best possible proxy or try to characterize the "unmeasurable" parameters in the best possible way. In an attempt to add to the current advances in remote sensing of floods, we demonstrate that it is possible to characterize inundation depth under different land cover types with ALOS-2 PALSAR L-band SAR images acquired during the 2015 January flooding season in the Lower Zambezi Basin. We believe that the results are robust enough for extrapolation and generalization but acknowledge that more studies of this type are needed to reach a consensus on the value of the findings.

A3.1-0043-18 SEA WATER INTRUSION AND INUNDATION MAPPING ALONG COAST OF KARACHI USING SPATIAL TECHNIQUES; AN IMPLICATION FOR RECENT ADVANCES AND FUTURE CHALLENGES.

Yasmin Raza, yasmeen_raza2211@hotmail.com

Geological Survey of Pakistan, Karachi, KARACHI, Pakistan Rao Muhammad Zahid Khalil, zahidkhalil.rao@gmail.com Institute of Space Technology, Karachi, Pakistan

Karachi Metropolitan, which is not only the most populous and biggest industrial base but also the largest coastal abode of Pakistan. The groundwater conditions in the coastal area of Karachi has experienced rapidly changing trends surrounded with the intensity of extreme events in the region due to global warming, the imbalance between fluvial and marine hydrodynamics which in turn provoke to seawater intrusion towards coastal groundwater aquifers.This project is developed with aims to delineate the effected invaded areas of Karachi by sea water and portrays it through inundation mapping using spatial techniques. The aim of the study is to investigate the mapping of seawater intrusion in Karachi area and adjoining coastal aquifers. Physiochemical analysis has been performed for different samples collected from coastal and adjacent areas of Karachi. Existing hydrogeology and resistivity data have been integrated with physiochemical to spatially analyze the distribution of intruded saline water within aquifers. For mapping vulnerability of aquifers, GALDIT model has been used by incorporating different parameters. Generally, there are three aquifers has been reported from the resistivity field curves within a depth of about 120 meters in consolidated aquifer material. The depth of first confined aquifer in sandstone of Gaj formation ranges between 6-40 meters, second confined aquifer 25 and 90 meters while third one may encounter at a depth between 45- 110 meters. These confined aquifers are found in sandstone and siltstone of lower Mancher or upper member of Gaj formation. Karachi can be divided hydro-geologically into Lower Malir Basin, lower Gadap and some part of the eastern lower Hub basin. These basin exhibits an average gradient of 3m/ km from NE to SW direction. Based on hydro-chemical data, deep groundwater has a higher value of electrical conductivity (range: 5.1 - 19.1 ms/cm), salinity (range: 2.7 - 7.4 ppt) as well as Chloride concentration (range: 1480 - 6034 ppm) and SO (range: 144 -2221 ppm). In Malir basin, South-Eastern part of Karachi, the confined aquifer reported to hosts a mixture of rainwater as well as trapped sea water, through intrusion under natural infiltration conditions, while aquifers of upstream regions indicates that the source of water might be saline water, which significantly arises from nearby industrial unit having High concentrations of Cl (6034 ppm) and SO (221 ppm), coupled with slightly alkaline pH values. Hence, in the light of all physio-chemical data integrated with hydrogeological assessment and the result of GALDIT model, it can be concluded that immediate South and South-Western part of Karachi has much more vulnerable aquifers for saline sea water intrusion as compared to the upstream region.

A3.1-0044-18 REMOTE SENSING OF CRYOSPHERE: ESTIMATION OF GLACIER MASS BALANCE IN THE ANDES AND IN THE US

Shrinidhi Ambinakudige, ssa60@msstate.edu

Mississippi State University, Mississippi State, Mississippi, United States Pushkar Inamdar, pi35@msstate.edu

Mississippi State University, Starkville, Mississippi, United States Lucy Dixon, dixonlucyk@gmail.com

Mississippi, United States

Glaciers are the key components in understanding rapid changes in climate. A continuous measurement of glacial extent, mass and velocity is therefore a key to the understating of the climate change. The main purpose of this paper is to analyze the glacier mass balance in the Andes and in the US using various remotely sensed data. Specifically, we analyzed the mass balance of glaciers in the Southern Andes (Chile and Argentina) using Shuttle Radar Topographic Mission (SRTM) with the elevation footprints from the Geoscience Laser Altimeter System (GLAS-ICESat) campaign. Further, we analyzed a multi-decadal analysis of glacial mass balance, glacier retreat and glacial lake expansion in the Northern Patagonia using Landsat (TM, ETM+ and 8) and ASTER satellite. Finally, we studied melting patterns of snow cover in the Sierra Nevada and Mt. Shasta regions in California using ASTER DEM and Landsat ETM+ satellite images. In the Southern Andes, our analysis showed a negative mass balance of glaciers in the Cordillera Darwin Icefield and North Wet regions with very low uncertainty in the estimation. In the South Patagonian Icefields and Dry Central regions, mass balance was also negative, but with higher uncertainties in the estimation. In the North Patagonian Ice Fields, San Quintin glacier experienced the highest retreat. Glacial lake area increased and additional glacial lakes were formed during the study period. Some glaciers such as Nef glacier recorded mass gain, but glaciers such as HPN-4 lost mass. In California, a remarkable reduction in snow cover extent of about 80% between 2000 and 2015 was observed in the studied watersheds.

A3.1-0045-18 SYNERGESTIC UTILIZATION OF EARTH OBSERVATIONS BY INTEGRATIVE USE OF VARIABLE INFILTRATE CAPACITY MODEL AND RUNOFF ROUTING MODEL FOR FLOOD MONITORING AND FORECASTING

Vikrant Maurya, vikrant.maurya18@gmail.com Delhi University, New Delhi, India

Manika Gupta, manikagup@gmail.com Delhi University, Delhi, India

India is one of the worst flood-affected countries in the world and accounts for 20 % of global death count due to floods. Floods occur mostly during southwest monsoon starting from June to September. About 40 million hectares of land in the country is prone to floods as per National Flood Commission, 2007. The annual average of land area and crop area affected due to flood is about 18.6 million hectares and 3.7 million hectares respectively. The most floodprone areas in India are the Brahmaputra and Ganga River basins in the North and Northeast India. The impact of flood in India is high due to lack of reliable flood monitoring, forecasting and insufficient resources. A reliable flood monitoring and forecasting system is of paramount importance for hazard mitigation and management. Hydrologically oriented Land Surface Models, such as Variable Infiltration Capacity model (VIC), are coupled with runoff routing models for better monitoring and forecasting. VIC model can use any combination of daily or sub-daily meteorogolical forcings, from point observations, gridded observations, or reanalysis fields. At minimum, VIC requires daily (precipitation, max/min air temperature, and wind speed). The VIC model has been successfully applied for many hydrological simulations and water resource management studies, including flooding (Hamlet and Lettenmair, 2007; Hamlet et al., 2010; Elsner et al., 2010; Voisin et al., 2011). The meteorological input parameters for flood monitoring and forecasting are the most critical for the model and can be obtained through satellite remote sensing with relatively high spatio-temporal resolution. The model can give good results for lower latitude basins with few dams (Wu et. al., 2014). The present study focuses on the flood monitoring and forecasting using integrated LSMs and runoff routing model for the downstream areas of the Brahmaputra and Ganga River Basin by using the current state of meteorological and hydrological modelling capabilities and try to fill the knowledge gaps within the scope of study.

Globally floods are one of the most frequent and most damaging disasters in terms of loss of property and human life. India is one of most affected country in the world affected by flood disaster on annual scale, second only to Bangladesh. In India, North Western part of country is dominated by Himalayan Mountains and flooding in these areas is different as compared to other low relief and plains areas of India in terms of source of floods, travel time and volume of floods. In North Western Himalaya (NWH) most of the floods are flash floods caused by high intensity precipitation or more popularly known as cloud burst. The presence of moraine dammed glacier lake also possess high threat of Glacier Lake Outbursts Floods (GLOF) in this area, as demonstrated by 2013 Kedarnath floods. The other source of floods can be breaching of landslide dammed artificial river lakes. In all these cases, the time of travel of flood water from source to outlet or human habitation located along these river valleys is only few minutes to few hours. Hence, any flood warning activity in NWH should be done by taking into consideration all these unique factors. Current study has used 3-day advance weather forecast in NWH using double nested domain of Weather Research and Forecasting (WRF) model (9 km for outer domain and 3 km for inner domain) for entire monsoon of 2015, 2016 and 2017. The model is run using National Centre for Environmental Prediction (NCEP) Global Forecasting System (GFS) 0.25 degree data as initialization state. The WRF outputs were at 3hourly time scale. Based on historical and current data of Indian Meteorological Department (IMD) 0.5 degree daily rainfall grids, validation of few events of 2013-2017 monsoon has been done, giving simulation accuracy of WRF in rainfall prediction above 100 mm of 60%, but overall pixel wise correlation coefficient R2, is low at 0.2-0.3. Accuracy assessment of WRF simulations of 2017 is under progress. The forecasted precipitation of every three hours is used hydrological modelling system (HMS) and variable infiltration capacity (VIC) model for flood hydrograph generation at various outlets of study area. Currently, part of Beas river basin, Upper Ganga basin upto Haridwar and Yamuna basin upto Poanta Sahib are tested for near real time flood forecasting. Limited validation of simulated river flow hydrograph for Uttarkashi and Joshimath sites are done using historical data of 2005-2007 monsoon using Central Water Commission (CWC) discharge data with R2 of 0.6-0.7 for two stations. The output of hydrological models in terms of flood hydrograph is used for flood inundation scenarios along river reaches using 1-D HydroDynamic (HD) modelling to see the probable areas which can come under flood inundation. In 2015 monsoon, the flood event of 05 to 08 August 2015 in part of Beas river basin in Mandi District of H.P. near Dharampur has caused very high damages. Similarly in Late June and Early July 2016, an extreme rainfall event caused flash floods in Pithoragarh region of Uttarakhand, UK. These events were also forecasted well in advance of three days by WRFARW model. During the non-flood season the cloud free cartosat-1 images of upper Ganga basin has been acquired before and after 2013 flood disaster to map the flood affected areas of this area. The Majors Rivers of NWH are also selected to make buffer of 100m, 200m and 500m on both sides to identify and map the flood vulnerable areas. Flood frequency analysis considering 25, 50, and 100 years floods also being done along with DAM break and GLOF modelling of vulnerable lakes of study area to identify the flood vulnerable areas using geospatial modelling approach. In this method, flood inundation scenarios (actual or frequency based) is overlaid with Land Use Land Cover (LULC), roads, settlements etc. to identify probable flood hazards areas. Next, based on class and present conditions of buildings, roads or crop/forest type, the overall vulnerability of area to flooding is assessed. The test sites of this detailed flood vulnerability study are few sites in NWH such as critical river stretches of Mandakini river basin, upper Ganga and Yamuna basin and parts of Beas river basin and later all areas of NWH will be covered. This study shows how an integrated approach can be used for flood early warning and vulnerability assessment in mountainous areas.

A3.1-0048-18 APPLICATION OF SATELLITE DATA COLLABORATING WITH VIC MODEL FOR IDENTIFICATION OF WATER SCARCE REGIONS OF INDIA

Pankaj Sharma, pankajhrc29@gmail.com

University of Delhi, Delhi-110007, India, DELHI, India Manika Gupta, manikagup@gmail.com

Delhi University, Delhi, India

Drought is a complex, slow onset phenomenon of ecological challenges that affect people more than any other natural hazard. Drought cause serious economic, social and environmental losses. Drought in India is a regular event occurring almost every year in some Indian states. Because droughts are a normal part of virtually any climate, it is important to develop plans to reduce their impact. In order to identify and classify drought-prone and drought-affected regions, variables such as evapotranspiration, runoff, and soil moisture storage have been retrieved through Variable Infiltration Capacity (VIC) land surface hydrological model and hydrological drought index is calculated from simulated soil moisture. Soil moisture data is analyzed from a retrospective simulation from 2005 to 2018 are used to develop probability distributions of monthly average soil moisture, and the relative position of soil moisture fields. Meteorological data such as precipitations and temperature are based on Central Forecast System (CFS), Indian Institute of Tropical Meteorology (IITM). Other meteorological forcing parameters such as wind direction, specific humidity, shortwave and longwave radiation have been extracted from the Extended Range Prediction System, IITM. Further, modeled data is validated with available in situ soil moisture observations for Varanasi during the period Sep 2017-April 2018. Temporal variation of drought in affected regions have been identified with high spatial resolution to ensure that drought index is able to allow for the effects of short-term changes in meteorology as well as longer-term climate variations and resolve the high spatial variability in soil moisture and drought occurrence.

A3.1-0049-18 FLOOD SIMULATION AND INUNDATION MODELLING USING HYDROLOGICAL MODEL AND HAND TOOL FOR JHELUM RIVER BASIN

Flood is one of the most destructive natural hazards that cause damage to human settlements and natural environment. In the past years, India has been largely affected from the flood during monsoon season such as 2008 and 2014 devastating flood in Bihar and Jammu and Kashmir etc. A study has been done to simulate the flood discharge and flood inundation in the Jhelum River Basin of geographical area 9,472.14 Sq. Kms. Since, several flooding events have been occurred in the Jhelum River basin in the past years such as 1948, 1950, 1957, 1959, 1969, 1976, 1988, 1992,2002,2004,2010 and 2014 etc. According to report of 11th planning working group of planning commission, India, total 45.640 million hectares area of the country is flood prone and out of which 0.514 million hectares lie in the Jammu and Kashmir that is 2.3 % of total geographical area. In the Lawrence Report (1895), it has been stated that there was a major flood occurred in July 1893 in this basin due to 52 hour continuous rainfall that had caused damage to 25,426 acres of crop land and 2,225 houses in Jammu and Kashmir. The Jhelum River basin is the sub-basin of the Indus River Basin originates from the spring called Chashma Verinag. The total geographical area of this river basin 34,775 Sq. Kms. according to India WRIS (Water Resources Information System). ALOS PALSAR Digital Elevation Model (DEM) of 12.5 m resolution has been used to delineate the river basin. The outlet chosen for the delineation of this basin in the downstream of this river at Asham gauging station lie in the Bandipora district of Jammu and Kashmir. Apart from this, there are two other gauging stations have been chosen for the validation and calibration of the results, one at RamMunshibagh in the Srinagar district and other at Sangam in

the Anantnag district which lie in the middle stream and upstream of the Jhelum River. The vertical accuracy of ALOS PALSAR DEM and Cartosat-1 DEM have been also compared using ground truth data to obtain the suitable DEM for this area. The Geospatial Hydrologic Modelling Extension (HEC-GeoHMS) extension in ARC-GIS software has been used to delineate the basin and the HEC-HMS software has been used to simulate the flood discharge. The threshold value has been used to delineate stream is 100 Sq. Kms. The Tropical Rainfall Measuring Mission (TRMM) 3B42RT rainfall data and the (European Reanalysis) ERA-INTERIM temperature data of from 15th August 2014 to 30th September 2014 has been used for the simulation. The simulation has been run from 15th August 2014 to 30th September 2014 as Hydrologic Engineering Center's-Hydrologic Modelling System (HEC-HMS) software is storm specific. The Soil Conservation Service (SCS) curve number has been used for simulation of run-off and the Muskingam-Cunge method has been used for the routing. The Value of Curve Number (CN) varies from 0-100. Higher the CN value, higher will be the run-off. The Gumble's method has been used to calculate the 2 years 24 hour rainfall that has been used as an input in the TR-55 excel sheet generated by HEC-GeoHMS. The temperature index method has been used in the HEC-HMS to simulate the snow melt. The Height Above Nearest Drainage (HAND) tool has used to generate the inundation map at various threshold value such as 2m, 3m, 4m and 5m respectively. The RISAT-1 images of date 08th Sep 2014, 10th Sep 2014, 20th Sep 2014 and 21st Sep 2014 has been processed for Flood mapping and to obtain the duration of flood. The 10th Sep 2014 RISAT-1 image show more flood than others. The Outflow obtained from hydrological simulation shows maximum discharge of 11,529.10 Cumec at Asham gauging station on 04th Sep 2014 and maximum discharge of 8,252.70 Cumec and 4,988.20 Cumec at RamMunshibagh and Sangam on 5th Sep 2014. The Observed discharge data of these gauging stations obtained Irrigation and Flood Control Department, Kashmir has used for calibration and validation. The outflow obtained can be used for hydrodynamic modelling to obtain flood hazard, vulnerability and risk analysis that can be further used to generate the evacuation plan during flood.

A3.1-0050-18 AFRICAN GEODETIC REFERENCE FRAME AND FIRST RESULTS FROM GNSS NETWORKS IN AFRICA

Salah Mahmoud, salah.mahmoud@nriag.sci.eg

National Research Institute of Astronomy and Geophysics (NRIAG), Helwan, Egypt Richard Wonnacott, rwonnacott@gmail.com

National Geospatial Information, Cape Town, South Africa Hussein Farah, farah@rcmrd.org 3.Center for Surveying and Remote Sensing, Nairobi, Kenya, Kenya

The African Geodetic Reference Frame (AFREF) is conceived as a unified geodetic reference frame for Africa. It will be the fundamental basis for the national three-dimensional reference networks fully consistent and homogeneous with the International Terrestrial Reference Frame (ITRF). When fully implemented, its backbone will consist of a network of continuous, permanent GPS stations such that a user anywhere in Africa would have free access to, and would be at most 1000km from, such stations. Full implementation will include a unified vertical datum and support for efforts to establish a precise African geoid, in concert with the African Geoid project activities. The realization of AFREF has vast potentials for geodynamics, geodesy, mapping, surveying, geoinformation, earthquakes, natural hazards mitigation, earth sciences, etc. Its implementation will provide a major springboard for the transfer and enhancement of skills in surveying and geodesy and especially GPS technology and applications. AFREF is, therefore, an African initiative to unify the geodetic reference frames of Africa based on the ITRF through a network of Global Navigation Satellite System (GNSS) base stations at a spacing such users will be at most within 1000 km of a base station. First Reference Frame Solution of about 80 geodetic GPS stations in Africa has been started in February 2014 at some processing centers in Europe and Africa. Results of independent solutions being developed by various African scientific teams: Hart RAO, South Africa, Ardhi University, Tanzania and SEGAL, University of Beria Interior, Portugal, show an accuracy of aligned ITRF 2008 using 42 IGS stations in E and N components with 3.0 mm and in U component 7.5 mm.

A3.1-0051-18 ESTABLISHMENT OF VLBI FOR THE MEXICAN ASTRONOMICAL GEODESICAL NETWORK (RAGN)

Daniel Mendoza, danila@uas.edu.mx

Centro de Astronomia de la UAS, Culiacan, Mexico

Autors:

Viktor I. Krilov, Daniel Mendoza A., Julio Saucedo M., Tatiana N. Kokina, Isidro Martínez.

The RAGN serves as a unique analytical reference framework that coordinates all the scientific and technical measuremens of the mexican country. It determines its dimensions and combined with other countries networks provides the basis to define the reference ellipsoid parameters as well as to study the Earth as a planet. The RAGN helps in the control of artificial satellites (SAT);furthermore, it provides the basis to study the deformation of the Earth's crust in the country.

The RAGN in México was developed in roughly three periods. In the first, from1915 to 1965, it was dependent on optomechanical methods of triangulation and polygonation. In the second, at the end of the 1970's, the RAGN was adjusted to the "Transit Satellite System". In the third epoch which started at the beginning of the 1990's, with the help of the "Navigation Global Positional System" (NAVSTAR), the current "National Satellital Geodesic Network" (RGNS) was implemented.

The Mexican territory sits on a very active sismic zone in which several tragical earthquakes have ocurred in the last 80 years. After an earthquake technoscientific studies have to be made to determine the deformation of the vertices of the RGNS. This work proposes a way to quickly determine the changes of coordinates of the vertices via an intercalated VLBI to the RGNS. One of the radiotelescopes could be the Large Millimeter Telescope Alfonso Serrano (LMT), located in Sierra La Negra, Puebla, while the second could be located in Mexicali, Baja California, on a point of the RGNS. The method to be used compares the two RGNS coordinates referenced to te VLBI in a time when the Earth's surface is stable in México. After an earthquake the adjustment of the coordinates is calculated. The observational methodology for the VLBI and the RGNS, how they are linked as well as the least squares method to adjust over the reference ellipsoid are presented.

A3.1-0052-18 THE 2017-2027 NATIONAL ACADEMIES DECADAL SURVEY FOR EARTH SCIENCE AND APPLICATIONS FROM SPACE: AN OVERVIEW OF THE REPORT

Arthur Charo, acharo@nas.edu

National Academies of Sciences, Engineering and Medicine, Washington, District of Columbia, United States

Waleed Abdalati, waleed.abdalati@colorado.edu University of Colorado, Boulder, Boulder, United States

A pre-publication version of the final report of the 2017-2027 National Academies' decadal survey for Earth Science and Applications from Space ("ESAS 2017") was delivered to its agency sponsors on December 31, 2017; publication of the edited version is expected in Spring 2018. Like the inaugural survey, which published its final report in 2007, ESAS 2017 was requested by NASA, NOAA, and the USGS. The survey's overarching objective was to develop consensus recommendations from the environmental monitoring and Earth science and applications communities for an integrated and sustainable approach to the conduct of the U.S. government's civilian space-based Earth observation programs. The survey co-chairs will review the report's findings and recommendations and discuss its implementation. A PDF of the report is posted at www.nas.edu/esas2017 where details about the survey may also be found.

A3.1-0053-18 TEMPORAL REGULARISATION FOR MERGING OPTICAL, THERMAL AND SAR DATA

Maxim Chernetskiy, m.chernetskiy@ucl.ac.uk

University College London (UCL), London, United Kingdom Mathias Disney, mathias.disney@ucl.ac.uk

University College London (UCL), London, United Kingdom Marcel Urban, marcel.urban@uni-jena.de

Friedrich Schiller University Jena, Jena, Germany Christiane Schmullius, c.schmullius@uni-jena.de Friedrich-Schiller-University (FSU) Jena, Jena, Germany

Changes of Earth surface can have different nature and can influence different domains of electromagnetic spectrum. Using different domains as an input to an advanced machine learning methods can help in detection of comprehensive changes of earth surface. One of main complications in combining different Earth Observation (EO) data streams is a requirement of common time and space resolution. This can be archived by merging observations that were made by different EO sensors. Merging is typically involves some kind of spatio-temporal interpolation. However, applying interpolation can increase uncertainties due to different spectral properties of adjacent pixels. This in turn can dramatically influence further processing of data streams such as classification or change detection. This issue can be solved by propagation of uncertainties through whole processing chain. Therefore one of the requirement for this study is using a method which permits estimation of EO uncertainties. So we need to provide gap free time series of Earth Observation (EO) data with their associated uncertainties. In order to normalise reflectance, fill gaps due to cloudiness and calculate uncertainties we use temporal regularisation which is based on Bayesian inference. We exploit temporal regularisation which allows filing gaps in the time series of parameters and explicitly characterise the output uncertainties. So we combine data across wavelengths, including optical and microwave (with different spatial and temporal properties), into a common observation vector. We use these data to generate optimally smoothed and filtered time series of reflectance, albedo and backscatter, as the core SSV output, with consistent uncertainties (key for use in further quantitative modelling and change detection chain, particularly attribution). We use MODIS daily reflectance, Sentinel 1 observations, thermal (MODIS LST) and historical microwave (ENVISAT ASAR).

A3.1-0054-18 GPS REFLECTOMETRY MONITORING OF THE UNDULATING SEA SURFACE LEVEL: NUMERICAL SIMULATIONS AND ERROR MITIGATION APPROACHES

Yaroslaw Ilyushin, ilyushin@physics.msu.ru

Moscow University, Physical Department, Moscow, Russia Artem Padokhin, padokhin@physics.msu.ru

Lomonosov Moscow State University, Moscow, Russia Nikita Tereshin, nikita.tereshin@gmail.com Lomonosov Moscow State University, Moscow, Russia

Dramatic changes in the natural environment, observed in the present epoch, are threatening and can be dangerous for the future of the whole world human population. Systematic monitoring of these global changes is now critical for detection of log periodic variations and long term trends such as global warming, polar ice melting, raising of the ocean level etc. Extensively developing technologies of observation of the Earth from space provide excellent possibilities for remote measurements of key physical parameters of the atmosphere, ocean and land surface. GPS reflectometry [1] is a relatively cheap technique for in situ measurements of the sea level surface, which can be implemented both at coastal stations of geodetic GPS-networks and specially organized observatories of global environmental monitoring. This technique, however, suffers from errors caused by rapid sea level perturbations, e.g. wind generated waves which can introduce not only random but also systematic biases in the measured data.

In this study, numerical simuilation of reflections of navigational space-borne radio beacons from undulating sea surface is performed at the main frequency of the Global Positioning System (GPS) L1 (1575.42 MHz). Electromagnetic field has been simulated with the Finite Difference in Time Domain (FDTD) technique [2] for different model spectra of the sea waves. Impact of the surface waves on the mean sea level estimate at the monitoring station location is investigated. Random and systematic errors, in particular related to partial shadowing of the undulating surface at low grazing alngles of the sounding wave coming from a GPS beacon, are evaluated and estimated.

Approaches to mitigation of the observational errors using auxiliary support data, including local sea waves spectra recorded in situ, context images/footage video of the surrounding aquatory, local weather conditions (wind speed and so on) are discussed.

The research is carried out using the equipment of the shared research facilities of HPC computing resources at Lomonosov Moscow State University [3]. Support from Russian Science Foundation with the grant 17-77-20087 is kindly acknowledged.

A3.1-0055-18 GIS AND REMOTE SENSING BASED FEATURE EXTRACTION FOR TOPOGRAPHIC MAP UPDATING IN SYLHET CITY, BANGLADESH

Shiblee SM Sujauddin Pathan, suja5444@yahoo.com Survey of Bangladesh, Dhaka, Bangladesh

Tan Yumin, tanym@buaa.edu.cn Beihang University, Beijing, China

Regular and timely updating works of Topographic map is a major concern for the Mapping Organizations around the World. The usual operations for updating such maps include, acquiring High resolution satellite data that is faster in acquisition but costlier and Aerial photography that demands both longer time and higher cost. Both are acquired and processed in Survey of Bangladesh (The National Mapping Agency of Bangladesh) for generating and updating topographic maps. But, they are done in irregular basis, as the financial aspects for acquiring Satellite data or Aerial Photo, often, do not allow to go for regular and timely updating works. Satellite data from open sources could do the balance in this aspect. Problem is about the resolution of those images which are not enough to bring out necessary topographic details.

Taking this as paradigm, an attempt has been taken in this study for updating topographic map using open sources medium resolution satellite data and involving Geospatial techniques. One of the most recent and cloudless Landsat 8 data is taken to update 1:250,000 scales topography map of the study area Sylhet City, Bangladesh. More concentration has been given into the methods rather than the generalization and digitization works.

The research work started with feature extraction from the open sources data. Preprocessing works involved layer and spectral band compilation and transforming the coordinate system as similar to the coordinate system that is used in survey of Bangladesh. Level 1 data from Landsat TM is used that has both Geometric and radiometric rectifications. LULC classification is done following supervised classification with Maximum Likelihood technique. After validating the accuracy of the feature extraction quantitative and percentile statistics are brought out while processes have been followed for the map features after combining them to the similar features of open sources. To bring the map scale for its suitability to the open sources resolution the existing map of 1:25,000 scales have been compiled and then generalized to a smaller scale of 1:250,000. Both the statistics of Map and open source features are then compared to detect the changes occurred during the study span of recent five years (2010 to 2015). Finally, an insertion and deletion guide is prepared that led to the preparation of updated map of one of the features as test case. In the process, two sets of specification i.e. Specification for Map Generalization and Specification for Map Updating have also been prepared.

A3.1-0056-18 STUDY ON SPATIAL VARIABILITY OF LAND SURFACE VARIABLES AND HEAT FLUXES DURING THE HIWATER CAMPAIGN

Xiaozhou Xin, xinxz@radi.ac.cn

Institute of Remote Sensing and Digital Earth, Chi, Beijing, China
Xiaozhou Xin, xinxz@radi.ac.cn

Institute of Remote Sensing and Digital Earth, Chi, Beijing, China
Xiaojun Li, kdxiaojun@126.com

Institute of Remote Sensing and Digital Earth, Chinese Academy of Sciences, Beijing, China

Surface heterogeneity, including the inhomogeneity of landscapes and surface variables, significantly affects the accuracy of evapotranspiration (ET) (or LE, i.e., latent heat flux) estimated from remote sensing satellite data. The method of using frequency distributions or generalized probability density functions (PDFs) which is called the “statistical-dynamical” approach is a good way to correct the ET or LE estimation error from the perspective of remote sensing model. However, implementing a PDF for each land-surface characteristic would greatly increase the complexity of this type of parameterization, as well as the computational burden of the model. To address this issue, the objective of this study is to analyze the temporal variation of turbulence heat flux heterogeneity and heterogeneity of surface variables, and attempts to find the most closely related surface variables associated with heterogeneity of turbulent heat flux. A mathematical expression method (i.e., entropy) was used to express the heterogeneity of the surface variables caused by the fluctuation of the surface variable values. Based on the airborne data and surface observation network data from Heihe Watershed Allied Telemetry Experimental Research (HiWATER), this study introduced a grey relational analysis and combined it with entropy to analyze the heterogeneity temporal variation relationships of each surface parameters. The results reveled entropy can be used to compare the spatial heterogeneity of different surface variables, and the heterogeneity of the most variable exhibits approximately parabola with the change of solar zenith angle. For albedo, not only its value presents a “bowl shape” diurnal changes, its heterogeneity also showed a similar “bowl shape” changes. By constructing a grey relational system under different weather conditions, we find that the heterogeneity of surface radiation temperature and soil moisture are the factors that must be taken into account in the construction of LE or ET calculation model for heterogeneous underlying surfaces.

A3.1-0057-18 AN ASSESSMENT ON THE QUALITY OF SURFACE SENSIBLE HEAT FLUX DERIVED FROM RE-ANALYSIS DATA BASED ON STATION OBSERVATIONS IN NORTHWEST CHINA

Liantong Zhou, zlt@mail.iap.ac.cn

Institute of Atmospheric Physics, Chinese Academy of Sciences, Beijing, China

The present study compares the seasonal and interdecadal variations of surface sensible heat flux over Northwest China between station observations and the ERA-40 and NCEP-NCAR reanalysis datasets for the period 1960-2000. While the seasonal variation of sensible heat flux is consistent between station observations and the two reanalysis, both the surface-air temperature difference and surface wind speed show remarkable systematic differences. The sensible heat flux displays obvious interdecadal variability that is season-dependent. The ERA-40 sensible heat flux in spring, fall, and winter shows interdecadal variations that are similar to observations. The NCEP-NCAR reanalysis sensible heat flux variations are inconsistent with and sometimes even opposite to observation data. While the NCEP-NCAR reanalysis surface wind speed shows interdecadal changes consistent with station observations, the surface-air temperature difference variations are very different from station observations. For the ERA-40, almost no consistency can be identified in the surface-air temperature difference and surface wind speed variations except for the temperature difference in fall and winter. These inconsistent pose a major obstacle to the application of the reanalysis surface sensible heat fluxes for climate studies.

A3.1-0058-18 MONITORING UNDERWATER ARCHAEOLOGICAL SITES WITH LIDAR

Carlos Eduardo Thompson Alves De Souza, carlos.e.thompson@outlook.com Brazil

The paper focuses on use of Light Detection and Ranging (LiDAR) technology in understanding the underwater archaeology in Brazil, primarily in City of Rio de Janeiro, the world's largest market for geophysics.

A3.1-0059-18 LAND-USE PLANNING WITH MINIMIZING UNEMPLOYMENT USING GIS AND LINEAR PROGRAMMING

Rao Muhammad Zahid Khalil, zahidkhalil.rao@gmail.com Institute of Space Technology, Karachi, Pakistan

Geographic Information System (GIS) is now being used as a primary tool for a vast variety of land-use and earth science application. In this paper, Linear programming (LP) is used as a means for geo-spatial simulating in GIS. In spite of that LP is not exactly a spatial method, but it can be integrated to GIS for solving spatial problems. An example of the integration of LP in land cover/land use planning is illustrated, with reducing unemployment as the main objective. The Northern portion of Hyderabad, Sindh, Pakistan was selected as a study area for land-use planning. The objective of minimizing unemployment is restraint by the three sets of limitations, (a) Ecological, which insist upon to remain unchanged at least 75% of the forest during the land-use planning or modification, (b) Technical, which limits the placement of modified or new land-uses to the highly suited areas, i.e. Newly developed urban areas will be restricted to those areas where three requirements were satisfied: in-between 200-500 meters of urban land, 0.5km away but less than 2km from the road, and in-between 2km to 7km from the river, and (c) Financial constraint includes the amount of 2500 million rupees that is presumed to be available for the transformations of land-use. The required information was obtained by developing thematic layers, that include Land use/Land cover, elevation, and slope layers, derived from satellite imagery (Landsat 8) and SRTM DEM respectively, and Economic data that includes the requirement of labor and capital for transformation. These limitations were formulated as constraints according to LP technique to get the optimal solution. LP-model was solved using software named 'LINDO'. It gave the results in numeric values. The results were mapped out using auxiliary variables. This paper guides that LP is an appreciated mean for modeling land-use/land-cover using GIS framework. LP is also capable of solving different planning situations, by changing coefficients of the objective function and constraints both. The combination of GIS to LP has been reflected here as a technique for data assembling and mapping the outcomes. More attempts should be done to further enhance the spatial domain of the linear programming problems by taking out some more work on this ground.

B0.1-0001-18 THE EXOPLANET CLOUD ATLAS

Peter Gao, gaoliu2000@gmail.com

University of California, Berkeley, Hayward, California, United States

Clouds have been readily inferred from observations of exoplanet atmospheres, and a trend is beginning to emerge where hotter planets appear “clearer” than cooler ones, though there is significant scatter in the data. Equilibrium condensation calculations suggest a myriad of species - salts, sulfides, silicates, and metals - could condense on these worlds, but how they form and evolve as clouds is uncertain. The behavior of clouds - their formation, evolution, and equilibrium size distribution - is controlled by cloud microphysics, which includes processes such as nucleation, condensation, and evaporation. In this work, we explore the cloudy exoplanet phase space by using a cloud microphysics model to simulate a suite of cloud species ranging from cooler condensates such as KCl/ZnS, to hotter condensates like iron and corundum. We investigate how the cloudiness and cloud particle sizes of exoplanets vary due to temperature, metallicity, and gravity, and how these changes may be reflected in current and future observations. We are able to reproduce the observed trend in cloudiness with temperature, as well as an apparent minimum in cloudiness at 1300 K, which could be due to the sinking of silicate and iron clouds into the deep atmosphere. In addition, we make predictions on the magnitude of cloud spectral features at JWST MIRI wavelengths to investigate how we can use these features to characterize exoplanet clouds.

B0.1-0002-18 MAPPING EXOPLANET CLOUDS WITH HIGH-DISPERSION SPECTRO-POLARIMET

Antonio García Muñoz, garciamunoz@astro.physik.tu-berlin.de Technical University Berlin, Berlin, Germany

Polarization is an under-exploited technique in the investigation of exoplanet atmospheres. A polarization detection, particularly if extended over a broad spectral range, can potentially set valuable constraints on the gas and clouds in an exoplanet atmosphere that is not possible through brightness-only observations. I will present simulations that show that the polarization of a spatially unresolved exoplanet may be detected by cross-correlating high-dispersion linear polarization and brightness spectra of the planet-star system. In this approach, the Doppler shift of the planet-reflected starlight facilitates the separation of the signal from other polarization sources, including the star, the interstellar medium and the terrestrial atmosphere. I will elaborate on the case of close-in giant exoplanets with non-uniform cloud coverage, in which cases the hemispheres east and west of the sub-stellar point will produce different polarizations. The simulations show that high-dispersion polarimetry can separate some of the proposed cloud scenarios and, in particular, set additional constraints on the cloud particles optical properties.

B0.1-0003-18 APPLICATION OF TERRESTRIAL GLINTS TO EXOPLANET STUDIES

Jiazheng Li, jiazheng@caltech.edu

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Yuk Yung, yly@gps.caltech.edu

California Institute of Technology, Pasadena, California, United States

Glints, small flashes of reflected light, found in images taken by spacecraft observing the Earth, are generally believed to be due to specularly reflected solar radiation. These glints have been found over both ocean and land. We show that glints over land are due to specular reflection off horizontally oriented ice platelets floating in the air, while glints over ocean have contributions from reflection off both platelets floating above the ocean and ocean waves. Although glints only cover a small proportion of the Earth's surface, they are highly polarized. We use a radiative transfer model to simulate different kinds of glints and to explore their properties. Exoplanets with specularly reflecting materials like icy cloud, surface ice and water could generate light variations that are very different from those with clear atmospheres. For example, rocky, Earth sized exoplanets in the TRAPPIST-1 system are now thought to contain up to 5% of their mass in water (Grimm et al, 2018), which could be observable as clouds, surface oceans or ice. This technique of comparing observations of terrestrial glints with model simulations may provide new information relevant to the search for habitable exoplanets.

B0.1-0004-18 GASEOUS ENVELOPES OF HOT JUPITER EXOPLANETS

Dmitry Bisikalo, bisikalo@inasan.ru

Institute of Astronomy of the RAS, Moscow, Russia Alexander Cherenkov, cherenkov@inasan.ru Institute of Astronomy of the RAS, Moscow, Russia Pavel Kaygorodov, pasha@inasan.ru

Russia

Hot Jupiter exoplanets have a number of outstanding features, caused mostly by their proximity to the host star, e.g.: gas outflowing from the planet's atmosphere to the star, as it happens in close binary stars. In addition, the short distance between the planet and the star results in a large planet's orbital velocity. If this velocity exceeds the local sound speed a bow-shock forms ahead of the planet. Gas dynamic and MHD modeling shows that, if the dynamical pressure of the stellar-wind is high enough to stop the outflow from the vicinity of the inner Lagrangian point, a quasi-closed non-spherical envelope, bounded by the bow-shock of a complex shape, forms in the system. In this report we discuss possible types of gaseous envelopes of hot Jupiters and compare their properties with available observations. We also consider the variations of flow patterns in the gaseous envelopes, occurring under the action of coronal mass ejections.

B0.1-0005-18 MODELING INSTRUMENTAL SYSTEMATICS IN TRANSMISSION SPECTRA FROM FORS2 USING GAUSSIAN PROCESSES

Raissa Estrela, rlf.estrela@gmail.com

Universidade Presbiteriana Mackenzie/CRAAM, Sao Paulo, Brazil Elyar Sedaghati, esedagha@eso.org

ESO, Santiago, Chile

Several transiting exoplanets, from Hot Jupiters to Super-Earths, are having their atmospheres investigated using the most powerful technique to date: transmission spectroscopy. This technique measures the wavelength-dependent absorption of starlight by the planet's atmosphere during a transit revealing the atmospheric composition. However, instrumental systematics can significantly affect the transmission spectra leading to some spurious detections. This is an important issue that has been overlooked in the scientific community due to the presence of instrumental systematics produced by many instruments (Hubble/NICMOS, FORS2, etc). The recently introduced technique of using Gaussian Processes (GP), also widely used in machine learning and Bayesian regressions, has been successfully used to model systematic or correlated noise and to infer accurate planet-to-star ratios and realistic precisions. In this work we develop a technique using such GPs to better analyse systematic trends in exoplanet transmission spectra taken in either MOS/MXU modes caused by the GRIS600zgrismof F ORS2. Our method can provide an effective tool to interpret transmissions signals in fut

B0.1-0006-18 ATMOSPHERIC RADIATION INTERACTION SIMULATOR (ATRIS): VALIDATION AND FIRST RESULTS

Saša Banjac, banjac@physik.uni-kiel.de

Christian-Albrechts-Universität zu Kiel, Kiel, Germany Konstantin Herbst, herbst@physik.uni-kiel.de

Christian-Albrechts-Universität zu Kiel, Kiel, Germany Bernd Heber, heber@physik.uni-kiel.de

Christian-Albrechts-Universität zu Kiel, Kiel, Germany

During the next five years, considerable advancements in observational capabilities within the field of exoplanetary science are expected. In particular, upcoming missions, like the JWST and the E-ELT, will make it possible to further characterize the habitability of exoplanets orbiting M-dwarfs and K-stars, by determining the atmospheric composition using the transit spectroscopy method. In such systems, the expected resolution could be enough to detect substances produced by biological processes (biosignatures). Still, careful interdisciplinary analysis is necessary (physics, chemistry and climate), in order to account for possible false-positives and false-negatives. Furthermore, the high cost and limited life time of such missions make it obligatory to perform parametric studies to better understand the expected range of spectral signatures and thus enable a more efficient use.

Here we present the Atmospheric Radiation Interaction Simulator (AtRIS), a new Geant4- based code tailored specifically to enable parametric studies of radiation propagation through exoplanetary atmospheres. The main purpose of AtRIS is to calculate the electron-ion pair production rates, which are necessary as input for atmospheric chemistry models. However, AtRIS can also provide detailed information about the secondary particles that can be used to, for example, investigate the radiation environment at surface and thus directly characterize the habitability. We present validation studies against Earth measurements and first results.

B0.1-0007-18 INTERACTION OF COSMIC RAYS WITH ASTROSPHERES AND HABITABILITY PROBLEM

Andrei Sadovski, asadovsk@rssi.ru

Space Research Institute (IKI), Russian Academy of Sciences, Moscow, Russia Alexei Struminsky, astrum@iki.rssi.ru

Space Research Institute (IKI), Russian Academy of Sciences, Moscow, Russia Maria Zharikova, mariazharikova@yandex.ru

Space Research Institute (IKI), Russian Academy of Sciences; Moscow Institute of Physics and Technology, Moscow, Russia

The Kepler discoveries of terrestrial extrasolar planets candidates started the discussions of life conditions and possible conditions for habitable zone. Unfortunately, star winds and cosmic rays were almost omitted in consideration despite the fact that they are one of the main factors defining the space weather near Earth. It is important to know and be able to estimate fluxes of galactic and stellar cosmic rays (GCR and SCR) at different stages of evolution of stars and planetary systems. Previously the estimations were made about star wind properties and star and galactic cosmic rays near Proxima Centauri and Proxima b and Trappist system. Already the simplest models, which were derived for the Sun in 1950th–1960th, give the reasonable results for the star wind parameters and conditions on the orbit of Proxima b. We generalize these models for different astrospheres including hot O-B and A stars and try to estimate the possible star wind fluxes, astrosphere parameters and cosmic rays' fluxes and fluences taking into account values of the magnetic fields, coronal temperatures etc. Obtained results will be compared with Earth's and Archean Earth's conditions.

B0.1-0008-18 HABITABLE WORLDS IN MULTIPLE STAR SYSTEMS

Siegfried Eggl, siegfried.eggl@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Max Popp, max.popp@mpimet.mpg.de Ecole Polytechnique, Palaiseau, France

A large fraction of stars in our galactic neighborhood have close stellar companions. It is, therefore, not surprising that some of the best candidates for habitable worlds discovered so far populate a multiple star system (e.g., GJ 667). Given the presence of multiple sources of radiation as well as the gravitational pull of additional stars, one may wonder whether terrestrial planets can retain Earth-like conditions in such systems. In this contribution, we show that planets can indeed remain habitable in multi-star environments. The size of the habitable zone strongly depends on a planet's "climate inertia", however. The latter is a measure of how effectively an Earth-like planet's atmosphere and oceans can buffer changes in insolation. Recent results of the first 3D climate simulation of a water-rich circumbinary planet indicate that signatures of the orbit and consequent insolation forcing are mirrored in most climate indicators such as global surface temperature and precipitation.

B0.1-0009-18 C5H9N ISOMERS: SIGNALLING POTENTIAL BRANCHED CHAIN INTERSTELLAR MOLECULAR SPECIES

Emmanuel Etim, emmaetim@gmail.com

The astronomical observation of isopropyl cyanide further stresses the link between the chemical composition of the interstellar medium (ISM) and molecular composition of the meteorites in which there is a dominance of branched chain amino acids as compared to the straight. However, observations of more branched chain molecules in ISM will firmly establish this link. In the light of this, we have considered C5H9N isomeric group in which the next higher member of the alkyl cyanide and other branched chain isomers belong. High-level quantum chemical calculations have been employed in estimating accurate energies of these isomers. From the results, the only isomer of the group that has been astronomically searched, n-butyl cyanide is not the most stable isomer and therefore, which might explain why its search could only yield upper limits of its column density without a successful detection. Rather, the two most stable isomers of the group are the branched chain isomers; tert-butylnitrile and isobutyl cyanide. Based on the rotational constants of these isomers, it is found that the expected intensity of tert-butylnitrile is the maximum among this isomeric group. Thus, this is proposed as the most probable candidate for astronomical observation. A simple LTE (local thermodynamic equilibrium) modelling has also been carried out to check the possibility of detecting tert-butyl cyanide in the millimetre-wave region.

Understanding the origin of life is a long-standing problem and we are curious to know how life emerged in the universe. Very recently, Altwegg et al. (2016) showed that in a Jupiter family comet, 67P/Churyumov-Gerasimenko, the ratio between methylamine and ethylamine (precursor of glycine) 1 to 15. Vuitton et al. (2006) determines the abundance of many nitrogen-bearing molecules (HCN, HC3N, CH3CN, NH3, C2H3CN, C2H5CN, and CH2NH) in the upper atmosphere of Titan. The present atmosphere of Titan resembles the primeval atmosphere of Earth and thus is thought to be very important for the abiotic synthesis. Synthesis of simple and complex biomolecules or their precursors in the molecular cloud can be transferred to protplanetary disk or comet or further into the future planet. Here, we investigate six isomeric groups containing at least one aldimine or amine to review the presence of them within the ISM. We calculate chemical abundances of amines and aldimines for both isothermal and warm-up condition, enthalpies of formation, optimized energies, and expected intensity ratio to find out the most viable candidates for the future astronomical detection. We found that in the isothermal phase, the methylamine-to-ethylamine ratio is 17.7 in the ice phase, which is very close to the observed value (Altwegg et al. 2016).

B0.1-0011-18 TIDAL EFFECTS (AND EXTINCTIONS) BY PASSING PLANETS AND-OR MINI-MOON BLACK HOLES IN OUR SOLAR SYSTEM

Daniele Fargion, daniele.fargion@roma1.infn.it

Physics Department, Rome University 1, INFN Rome 1,, Rome, Italy

The Earth has been formed by a huge mini-planet collision forming our Earth surface and our relic Moon today. Such a central collision hit was statistically rare. A much probable skimming or nearby encounter by other moons or planets had to occur more often. Indeed several observations suggest that many planetary-mass objects may be present in the outer solar system between the Kuiper belt and the Oort cloud. Gravitational perturbations may occasionally bring them into the inner solar system. Their passage near Earth could have generated gigantic tidal waves, large volcanic eruptions, sea regressions, large meteoritic impacts and drastic changes in global climate. They could have caused the major biological mass extinctions in the past in the geological records. For instance a ten times a terrestrial radius nearby impact scattering by a peripherical encounter by a small moon-like object will force huge tidal waves (hundred meter height), able to lead to huge tsunami and Earth-quake. Moreover the historical cumulative planet hits in larger and wider planets as Juppiter, Saturn, Uranus will leave a trace, as observed, in their tilted spin axis. In addition a large fraction of counter rotating moons in our solar system probe and test such a visiting mini-planet captur origination. Finally the Earth day duration variability in the early past did show a rare discountinuity, very probably indebt to such a visiting planet crossing event. These far moons in rare trajectory toward our Sun by their cannibal capture, might fed in the past thousands of such events, explaining sudden historical (solar and terrestrial) temperature changes. Similar effects (and a few surprising additional ones) are occuring also when hypothetical moon-mass like mini Black Hole (BH), that are acceptable candidate for cosmic Dark Matter mass, are crossing nearby our plane and-or are crossing inside planets like Juppiter or the Sun.

B0.1-0012-18 FROM SOLAR TO STELLAR FLARE CHARACTERISTICS - A NEW SIZE DISTRIBUTION FOR KAND M-DWARF STAR FLARES

Konstantin Herbst, herbst@physik.uni-kiel.de

Christian-Albrechts-Universität zu Kiel, Kiel, Germany Athanasios Papaioannou, atpapaio@astro.noa.gr

NOA - National Observatory of Athens, Penteli, Greece Saša Banjac, banjac@physik.uni-kiel.de

Christian-Albrechts-Universität zu Kiel, Kiel, Germany Bernd Heber, heber@physik.uni-kiel.de

Christian-Albrechts-Universität zu Kiel, Kiel, Germany

Main sequence Kand Mstars are likely targets when it comes to hunting habitable (Earthlike) planets. However, their strong stellar activity, alongside high UVand X-ray intensities, will also produce high-energy particle fluxes which may be harmful to possible life. By now proton fluxes cannot be measured on Kand Mdwarf stars. Due to the fact that observations have shown that solar flares and active M dwarf stars obey common relationships (see, Butler et al., 1988), the measured stellar X-ray (flare) intensities can be used as a proxy for the proton fluxes of the most intensive flares.

The connection between solar energetic proton events and X-ray flares has been the focus of many studies over the past twelve years. In the course of these investigations, several peak size distribution functions based on GOES measurements of both quantities have been developed (see, e.g., Belov et al., 2005; Belov et al., 2007; Cliver et al., 2012). Here we compare the existing peak size distribution functions covering C to > X10 class flares to GOES measurements and extend the investigation down to "Q" (Quiet, 1010W/m2) X-ray flare intensities by utilizing SphinX data covering X-ray flare measurements during the solar minimum conditions in 2009. Using all observational evidence at hand, we develop a new peak size distribution function. Furthermore, we investigate the impact of the newly developed peak size distribution function for Kand M-dwarf stars and show that previous studies underestimate the stellar proton flux by roughly one to four orders of magnitude.

B0.1-0013-18 ON THE CORRELATION BETWEEN PARTITION FUNCTION AND ASTRONOMICAL OBSERVATION OF INTERSTELLAR ISOMERS

Emmanuel Etim, emmaetim@gmail.com

Federal University Wukari, Taraba State, Nigeria, Wukari, Nigeria Elangannan Arunan, arunan@iisc.ac.in

India

The unsuccessful astronomical searches for some important astrophysical and astrolobiological molecules like the amino acids and the few number of known cyclic interstellar and circumstellar molecules have been linked to the large partition function of these molecules. This letter reports an extensive investigation of the relationship between partition function and astronomical observation of interstellar isomers using high level quantum chemical calculations.120 molecules from 30 different isomeric groups with at least one known interstellar molecule from each group have been considered. Partition function and thermodynamic stabilities are determined for each set of isomeric species. From the results, there is no direct correlation between partition function and astronomical observation of the same isomeric species. Though interstellar formations processes are generally controlled by factors like kinetics, thermodynamics, formation and destruction pathways. However, the observation of the isomers seems to correlate well with thermodynamics. For instance, in all the groups considered, the astronomically detected isomers are the thermodynamically most stable molecules in their respective isomeric groups. The implications of these results in accounting for the limited number of known cyclic interstellar/ circumstellar molecules, unsuccessful searches for amino acid and the possible molecules for astronomical observations will be presented.

B0.2-0001-18 A CONSOLIDATED VIEW OF SCIENCE WITH SMALLSATS/CUBESATS

Cinzia Zuffada, cinzia.zuffada@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, 8099, California, United States Julie Castillo-Rogez, julie.c.castillo@jpl.nasa.gov

California Institute of Technology, Pasadena, CA, United States Marco Quadrelli, marco.b.quadrelli@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, 8099, California, United States

This paper takes a look at what science can be achieved by SmallSats and CubeSats. Here, we assume that CubeSats are in the range of 4 to 25 kg (3U to 12U), and SmallSats are in the range 25 to 100 kg. In recent times, there has been a strong impetus to determine not only the technological capabilities of CubeSats and SmallSats, but also their potential to be used as science platforms beyond proof-of-concepts demonstrations. More specifically, quantification of science return vs. cost and risk is being assessed at JPL via ongoing decadal-class science concepts and new ideas for the next Planetary Science Decadal Survey. Due to the low cost of SmallSats and CubeSats, new modalities of scientific observations are possible, specifically exploiting the concepts of constellation or formation, and of sensor disaggregation [2]. With constellations and formations of CubeSats and SmallSats, a few significant general characteristics emerge. For example, instrument resolution (strength, direction) is dictated by spatial sampling in the measurement, leading to novel constellation types. High sensitivity in the frequency band of interest is dictated by temporal sampling, leading to novel requirements in instrument bandwidth. Exploiting such reachness in spatial and/or temporal sampling allows for observations of physical processes thus far precluded, such as highly dynamic changes needing high resolution. From the engineering standpoint, the advantage of large scale distribution of small spacecraft is that a large number of nodes leads to considerations of robustness, and potential graceful degradation. The potential for extended field mapping is enabled by different types of measurement colocation vs. non-colocation. High resolution on the ground is proportional to wavelength and aperture size, while orbit design considerations pose limits on frequent revisit and coverage, thus leading to new remote sensing approaches, keeping in mind that the need for a flexible scan area or for continuous dwell results in more or less demanding pointing considerations. The tracing of science to measurement types and mission requirements for three Planetary Science themes: Building New Worlds, Planetary Habitats, Solar System Workings, is discussed in the paper. Similar flow-down is being carried out in other science domains, such as Heliophysics, Astrophysics, and Earth Science, thus providing a systematic approach at tracing science across all disciplines of

interest. Acknowledgments: This research was carried out at the Jet Propulsion Laboratory, California Institute of Technology, under a contract with the National Aeronautics and Space Administration.

B0.2-0002-18 NASA'S SPACE LAUNCH SYSTEM: SECONDARY PAYLOAD ACCOMMODATIONS IN BLOCK 1 AND BEYOND

Kimberly Robinson, kimberly.f.robinson@nasa.gov

NASA Marshall Space Flight Center, Marshall Space Flight Center, Alabama, United States Andrew Schorr, andrew.a.schorr@nasa.gov

NASA, Marshall Space Flight Center, Alabama, United States Terrie Gardner, terrie.m.gardner@nasa.gov

NASA, Marshall Space Flight Center, Alabama, United States Beverly Perry, beverly.a.perry@nasa.gov

NASA, Marshall Space Flight Center, Alabama, United States

Launching from pad 39B at Kennedy Space Center no earlier than December 2019, NASA's Space Launch System (SLS) will send the Orion crew vehicle to a distant retrograde lunar orbit in order to test and validate the new systems developed for SLS, Orion and Kennedy Space Center's Exploration Ground Systems (EGS). In addition to these primary mission objectives, the first integrated fight of NASA's new deep space exploration system, Exploration Mission-1 (EM-1), offers accommodations for 13 6U CubeSats, which will be deployed in deep space after Orion separates from the SLS Interim Cryogenic Propulsion Stage (ICPS). In 2017, the SLS Program, managed by NASA's Marshall Space Flight Center (MSFC) in Huntsville, Alabama, completed the ICPS and delivered it to the EGS Program, which has responsibility for stacking and launch operations. The 13 EM-1 secondary payloads will reside in the Orion Stage Adapter (OSA), which connects the ICPS to Orion's spacecraft adapter. The OSA is essentially complete with preparations being made for transporting the hardware to Kennedy Space Center with accommodations for secondary payload dispensers and with the secondary payload avionics unit installed.

The rest of the Block 1 SLS vehicle has completed manufacturing and is being outfitted for flight, including the 212-foot core stage. Boeing is building the core stage at Michoud Assembly Facility near New Orleans, Louisiana. Propulsion for the heavy-lift vehicle is supplied by twin five-segment solid rocket boosters, being built by Orbital ATK, and four RS-25 engines supplied by Aerojet Rocketdyne. The four RS-25 main engines, and their new computerized controllers are complete for EM-1. Those engines will be integrated into the completed core stage and fired simultaneously at NASA's Stennis Space Center during a "green run" test, scheduled for 2019. The Block 1 vehicle will have the capability to launch at least 70 metric tons (t) of payload. A more powerful configuration, Block 1B, will be available in the 2020s, and will provide incremental performance improvements that will boost the vehicle's capabilities to at least 32 t to trans-lunar injection (TLI) in the crew configuration and at least 37 t to TLI in the cargo configuration. Block 1B will offer an 8.4 m fairing; other fairing sizes are being studied. Block 1B will offer more accommodations for smallsats on a payload adapter than Block 1 provides in the OSA. A variety of CubeSat sizes from 6U to 27U may be accommodated in Block 1B. The smallsat payloads selected for EM-1 include NASA research experiments and spacecraft developed by industry, international partners and academia. The payloads are: Near Earth Asteroid (NEA) Scout, Lunar Flashlight, BioSentinel, Lunar Icecube, LunIR, the CubeSat 2 Mission to Study Solar Particles (CuSP), LunaH-Map, ArgoMoon, the EQUilibriUm Lunar-Earth point 6U Spacecraft (EQUULEUS), and the Outstanding MOon exploration TEchnologies demonstrated by Nano Semi-Hard Impactor (OMOTENASHI). In addition, three CubeSat payloads that have completed the final ground tournament of NASA's Cube Quest Challenge and are now competing for further prizes are manifested on EM-1: Cislunar Explorers, from Cornell University in Ithaca, New York; the University of Colorado-Earth Escape Explorer (CUE3) and Team Miles, of Tampa, Florida.

This paper will provide an overview of the status of the SLS Block 1 launch vehicle and an overview of the 13 EM-1 6U payloads. Work on the Block 1B vehicle is already underway, which will offer more space for smallsats; those planned accommodations will also be discussed.

B0.2-0003-18 SMALL SATELLITES FOR SPACE SCIENCE (4S) COSPAR ROADMAP

Robyn Millan, robyn.millan@dartmouth.edu

Dartmouth College, Hanover, New Hampshire, United States Rudolf Von Steiger, vsteiger@issibern.ch

International Space Science Institute, and University of Bern, Bern, Switzerland Julie Castillo-Rogez, julie.c.castillo@jpl.nasa.gov

California Institute of Technology, Pasadena, CA, United States Bhavya Lal, blal@ida.org

IDA Science and Technology Policy Institute, Washington, District of Columbia, United States COSPAR Roadmap Study Team: Small Satellites for Space Science

Rudolf Von Steiger, Robyn Millan, Julie Castillo-Rogez, Bhavya Lal, David Klumpar, Alan Title, Rene Fleron, Maurice Borgeaud, Meir Ariel, Anna Gregorio, Stefano Campagnola, Malcolm McDonald, Klaus Schilling, Kirsti Kauristie, Ji Wu, James Park, Sergey Bartalev

In 2016, COSPAR commissioned an international scientific roadmap on Small Satellites for Space Science (4S), focusing particularly on CubeSats and CubeSat-technology enabled small satellites. The report is motivated by recent progress and results summarized in a published paper (Zurbuchen, von Steiger et al., Performing High-Quality Science on CubeSats, Space Research Today, Vol. 196, pp. 10-30, August 2016) and a study by the US National Academies (Zurbuchen, Lal, et al., Achieving Science with CubeSats: Thinking Inside the Box, The National Academies Press, Washington, DC, 2016).

The roadmap has been developed by a study team that covers a broad range of scientific and technological disciplines, from Earth to planetary science, and from solar system science to astronomy. The team is composed of scientists and engineers working in universities, public research institutions and industry. The report is structured into three main parts:

I. Our Neighborhood: current status of technology and scientific potential of small satellites and CubeSats II. Visions for the Future: potential ideas for what small satellites could be used for in the future III. Challenges to Further Development and Progress, and Ways to Overcome Them: roles of agencies, industry, policies, international collaboration and exchange

In this presentation, members of the study team will give an overview of the roadmap and summarize the findings of the study team, concentrating on the parts relating to planetary science in particular. The final report is intended to be of value to space agencies internationally and their supporting governments, as well as non-profits and other private sector organizations that would be interested in promoting global smallsat-based missions.

B0.2-0004-18 CIS-LUNAR OBJECT DETECTOR WITHIN THERMAL INSULATION (CLOTH) FOR THE 6U CUBESAT EQUULEUS

Hajime Yano, yano.hajime@jaxa.jp

Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, Kanagawa, Japan

Takayuki Hirai, hirai.takayuki@perc.it-chiba.ac.jp Chiba Institute of Technology, Chiba, Japan Masayuki Fujii, mfujii@fam-science.jp

FAM Science, Japan

Kazuyoshi Arai, arai@hosei.ac.jp Hosei University, Tokyo, Japan Keith Nelson, kanelson@mit.edu

MIT, Cambridge, Massachusetts, United States EQUULEUS-CLOTH Team

Hajime Yano (JAXA/ISAS), Takayuki Hirai (Chiba Institute of Technology), Masayuki Fu- jii (FAM Science), Kazuyoshi Arai, Hiroyuki Mochizuki, Eigo Ishioka, Ritsuko Jitsukawa, Haruki Nakano (Hosei University), Keith Nelson, Christopher Schuh, Steve Kooi, David Veysset, Mostafa Hassani Gangara, Rick Binzel (MIT)

The Cis-Lunar Object Detector within Thermal Insulation (CLOTH) is a hybrid instrument between multi-layer thermal insulation and piezoelectric film sensor onboard the 6U cubesat EQUULEUS, which is scheduled for launch in the late 2019. The engineering purpose of this instrument is to game-change dust measurement in space by making it possible even with cubesat class spacecraft, which are usually impossble to secure large detection area of a dedicated dust sensor. The scientific purpose is first to measure dust flux in the Earth-Moon lagrange 2 (EML2) region by distinguishing between background sporadic meteoroids and potential EML2 dust population by impact signature characteristics due to respective impact velocities. For data interpretation, impact calibration experiments are conducted with ground facilities for the two distinct velocity regimes.

B0.2-0005-18 THE LUNAR POLAR HYDROGEN MAPPER MISSION

Craig Hardgrove, craig.hardgrove@asu.edu

Arizona State University, Tempe, Arizona, United States

Results from previous orbiter missions to the Moon have identified the presence of water/frost within permanently shadowed regions (PSRs) at the poles, however, there remains uncertainty about the bulk (non-surficial/frost) abundance of these enrichments and whether these smallscale enrichments are pervasive throughout lunar south pole PSRs. Placing constraints on the bulk hydrogen abundance within PSRs will help point to specific processes and delivery sources for polar volatiles, and can help resolve mechanisms operating over long time scales (e.g. solar wind) from other, much shorter time scale delivery mechanisms (e.g. passing asteroids or comets). Small-scale bulk hydrogen abundance maps can also be correlated with other polar datasets (i.e. temperature) to help untangle the relationship between volatile distributions and other surface properties. Hydrogen enrichments between 500 to 600 ppm at a spatial scale of 5-15 km could provide robust evidence for discerning hypotheses regarding transport processes of polar hydrogen enrichments.

The Lunar Polar Hydrogen Mapper (LunaH-Map) is a 6U CubeSat selected for flight on the Space Launch System (SLS) Exploration Mission 1 (EM-1) under NASA's Small, Innovative Missions for Planetary Exploration (SIMPLEx) program. The LunaH-Map spacecraft is equipped with gimbaled solar arrays, 3 reaction wheels, a star tracker, an X-Band radio, a command and data handling system, power control system, neutron spectrometer array, and a low-thrust propulsion system. The current mission science phase achieves 282 orbits over two lunar days and preliminary analysis of the miniature neutron spectrometer (Mini-NS) sensitivities shows the mission will be capable of identifying small-scale (<15 km^2) regions of hydrogen enrichments on the order of 600ppm +/- 120ppm. Communication with Earth will be achieved via the Iris radio, to be used on the MarCO spacecraft at Mars, and will be coordinated with the Deep Space Network. Spacecraft operations, telemetry and science data analysis will be conducted at the Mission Operations Center at Arizona State University (ASU). After deployment from SLS EM-1, LunaH-Map will maneuver and perform a lunar flyby targeting the EarthMoon L2 point and eventual capture by the Moon within two months. Upon lunar capture the spacecraft will spiral down to an elliptical low-altitude science orbit with perilune at the South Pole. During the science phase, the Mini-NS will measure neutron counts about the perilune (lowest altitude passes) of each orbit to enable the mapping of hydrogen enrichments within permanently shadowed regions (PSRs) at spatial scales less than 15 km. The mean perilune altitude is designed to achieve between 10 to 15 km above terrain poleward of 85°S throughout the science phase, but will vary depending upon the final SLS EM-1 launch date and trajectory. The SLS EM-1 launch trajectory will directly impact the parameters of the science orbit of the LunaH-Map spacecraft. The resulting

perilune altitudes and science phase ground tracks will determine the maximum achievable spatial resolution and sensitivity of hydrogen enrichments within south pole PSRs.

B0.2-0006-18 ACHIEVEMENTS AND FUTURE PLAN OF INTERPLANETARY CUBESATS AND MICRO-SATS IN JAPAN

Ryu Funase, funase@space.t.u-tokyo.ac.jp University of Tokyo, Tokyo, Japan

Tatsuaki Hashimoto, hashimoto.tatsuaki@jaxa.jp

Institute of Space and Astronautical Science, Japan Aerospace Exploration Agency, Kanagawa, Japan

This paper introduces Japanese achievements and future plans of CubeSats and Micro-Sats for deep space exploration.

As the first step toward deep space missions by such tiny spacecraft, University of Tokyo and Japan Aerospace Exploration Agency (JAXA) developed the world's first deep space microspacecraft PROCYON. Its mission objective is to demonstrate a micro-spacecraft bus technology for deep space exploration and proximity flyby to asteroids performing optical measurements. PROCYON was launched into the Earth departure trajectory on December 3, 2014 together with Japanese asteroid sample return mission Hayabusa-2. PROCYON successfully completed the bus system demonstration mission in its interplanetary flight.

Currently, Japan is not only pursuing the improvement and utilization of the demonstrated micro-sat deep space bus system with a weight of tens of kg or more for more practical scientific deep space missions, but also trying to develop smaller spacecraft with a weight of less than tens of kg, namely CubeSats, for deep space exploration. We are developing two self-contained 6U CubeSats for the rideshare opportunity on the USA's SLS EM-1 mission, one of which (EQUULEUS) will fly to a libration orbit around Earth-Moon L2 point and perform scientific observations of the Earth and the Moon, and the other (OMOTENASHI) is planning to perform "semi-hard" landing on the moon by using a solid rocket motor onboard.

We are also seeking the possibility of CubeSats which is carried by a larger spacecraft to the destination and supports the mission by taking advantage of its low-cost and risk-tolerable feature. As an example of such style of CubeSat missions, we are studying a CubeSat for close observations of an asteroid, which will be carried to the target asteroid by a larger mother spacecraft. This CubeSat is released from the mother spacecraft to make a close flyby for scientific observations, which is difficult to be performed by the mother spacecraft if we consider the risk of the collision to the target asteroid or dust particles ejected from the asteroid. In order to utilize the large deep space maneuverability of the mother spacecraft, the CubeSat is retrieved by the mother spacecraft after the close flyby observation and it is carried to the next target asteroid to realize multiple asteroids flyby exploration.

B0.2-0007-18 THE LUNAR ICECUBE EM-1 MISSION: PROSPECTING FOR LUNAR WATER ICE

Busek Space Propulsion, Natick, Massachusetts, United States

Lunar IceCube, a 6U CubeSat designed to prospect for water in solid (ice), liquid, and vapor forms and other lunar volatiles (i.e. OH, H2S, CO2 and CH4) from a low-perigee, highly inclined lunar orbit, was selected by NASA's Advanced Exploration Systems (AES) for a flight opportunity on Exploration Mission -1 (EM-1). The mission is a partnership between Morehead State University, NASA Goddard Spaceflight Center (GSFC), the Jet Propulsion Laboratory (JPL), and the Busek Space Propulsion Company. Lunar IceCube will be deployed by the Space Launch System (SLS) and uses an innovative RF Ion engine to achieve lunar capture and a science orbit (inertially locked, highly elliptical, 100 km periapsis) to investigate the distribution of water (water ice, water vapor, water components) and other volatiles. These volatile distributions will be investigated contextually, as a function of time of day, latitude, and regolith composition in the context of mineralogy. IceCube will include the Broadband InfraRed Compact High Resolution Exploration Spectrometer (BIRCHES), developed for CubeSats by GSFCa compact version of the successful volatile-seeking OSIRIS-REx Visible and nearIR Spectrometer (OVIRS) and New Horizons Ralph instruments. The mission will address NASA Strategic Knowledge Gaps related to lunar volatile distribution, and will complement the scientific work of Lunar Flashlight and LunaH-Map by focusing on the abundance, location and transportation physics of water ice on the lunar surface at a variety of latitudes, thus not restricted to permanently shadowed regions (PSRs). IceCube incorporates radiation-hardened subsystems, the JPL Iris transponder, and a high power (120W) solar array. The RF Ion engine (Busek BIT-3 Iodine engine) generates significant delta-v (> 1.2 kms-1 for the 14 kg spacecraft) and is one of the primary enabling technologies that will make this and other interplanetary CubeSat science missions feasible. Experts at GSFC are providing trajectory design and modeling, navigation and tracking support, and orbital products.

The primary science objectives of the Lunar IceCube mission are to enable spectral determination of the composition and distribution of volatiles in the lunar regolith as a function of time of day, latitude, regolith age and composition and to provide a geological context for those measurements through spectral determination of mineral components. Although previous missions (e.g. Clementine, Chandrayaan-1, and LRO/LCROSS) discovered various signatures of OH/H2O, they were not optimized for volatile characterization. BIRCHES is designed with the high spectral resolution (5 nm) and wavelength range (1 to 4 m) needed to fully characterize water and other volatiles, and to distinguish forms of water, including ice. Because the emphasis was on maximizing coverage during the nominal mission, even LRO was not designed to provide repeated systematic (by time of day) measurements of representative features at higher and lower latitudes. IceCube is designed to provide such systematic measurements. The mission also has the potential to lend insight into understanding the role of solar wind proton and micrometeorite bombardment in formation, trapping, releasing of water and exosphere formation. The 13 secondary payload CubeSats that will be included on EM-1, including Lunar IceCube, will usher in a new era of solar system exploration with CubeSats and other small satellite platforms.

B0.2-0008-18 SUPERROTATION STUDY IN THE ATMOSPHERE OF VENUS BY MEANS OF BALLOON PROBES.

Advanced explanation of the physical mechanism of superrotation is proposed. The reason is solar light pressure. The atmosphere of Venus was remotely studied for approximately 100 years and with spacecrafts for nearly half a century. As a result, there was a dramatic modernization in terms of views. The main finding is the detection of a unique phenomenon: the superrotation of the atmosphere. For the first time, this was detected from orbit in 1974 via the spacecraft Mariner, and this is the main element of atmospheric dynamics. The superrotation study was conducted in the UV range at altitudes of 65-69 km and in the IR range of 51-59 km, and also, during the course of the experiment, using a VEGA balloon at 53-55 km. At intermediate altitudes, systematic measurements were not carried out. It is proposed to introduce lightweight balloon probes into the atmosphere at different altitudes, but with increased durability. Envelopes are made of metalized PET foil. The payload mass on each probe is 1 kg. The diameter of the envelope depends on the altitude and at an altitude range 50-70 km is within the range of 1-3 meters. The expedition should last approximately 30 Earth days.

B0.2-0009-18 MAPPING OF ATMOSPHERE AND SURFACE OF VENUS THROUGH A ROBOTIC GLIDER VEHICLE

Vipul Mani, mani.vipul14@stu.upes.ac.in

University of Petroleum & Energy Studies, Dehradun, India Vishal Singh, singhvishal0103@outlook.com

University of Petroleum & Energy Studies, Dehradun, India Siddharth Jain, siddharthjain18@gmail.com

University of Petroleum & Energy Studies, Dehradun, India

One of the driving forces of mankind is the "Nahi Jnanena Sadrusham" or "Nothing is Equal to Knowledge", which has been the dynamo of our civilization. Since the dawn of the human civilization, man has looked up to the heavens with wonder about, what is out there! As one of the first planets to be visited by spacecraft, Venus witnessed many failed attempts as missions. This paper attempts to design a robotic mission to the surface of the Venus with the explicit goal of mapping the atmospheric composition and studying the surface. Proper mission architecture and vehicle design will be developed that maximizes the science data return within the predefined cost and schedule. Trade studies on various mission designs at the architecture and system levels will be given to demonstrate the fitness of the chosen mission and system design. It would include vehicle architecture, launch vehicles, science instruments, orbital mechanics, spacecraft subsystem level designs, and other mission level system trades assessed on the bases of benefit, risk, and cost. A detailed description of the scientific approach, including traceability of specific measurements to science objectives, planned observations, the design of the science instruments, and collection periods will be inculcated. Surface experiment operations and communication data plans will be presented briefly. Although many successful missions have previously have descended into the atmosphere of Venus, through this paper, we are presenting a much economical way to reach to Venus, descend into its atmosphere, map its atmospheric composition and land on its surface, and send the data back to Earth. Comprehensive trade study will be given, in order to strengthen the argument behind selection of the sensors. Venus is a necessary waypoint for missions to Mercury and even though the possibility of such a mission is probably nonexistent for this decade, such challenging missions would test the mankind's drive for space exploration. In addition, this paper hopes to establish some general guidelines for such exploring missions.

B0.2-0010-18 FLIGHT MODEL DEVELOPMENT STATUS OF LUNAR IMPACT FLASH OBSERVING CAMERA DELPHINUS ON EXPLORATION CUBESAT EQUULEUS

Shinsuke Abe, shinsuke.avell@gmail.com Nihon University, Funabashi, Japan Masahisa Yanagisawa, yanagi@uec.ac.jp

Ryu Funase, funase@space.t.u-tokyo.ac.jp University of Tokyo, Tokyo, Japan

EQUULEUS (EQUilibriUm Lunar-Earth point 6U Spacecraft) will be the world's smallest spacecraft to explore the Earth-Moon Lagrange2 point (EML2). The spacecraft will be jointly developed by the University of Tokyo and JAXA which will be launched by NASA's SLS (Space Launch System) EM-1 (Exploration Mission-1) in late-2019. The spacecraft will fly to a libration orbit around the EML2 point and demonstrate trajectory control techniques within the Sun-Earth-Moon region. DELPHINUS (DEtection camera for Lunar impact PHenomena IN 6U Spacecraft) is one of the scientific instruments onboard EQUULEUS to observe the Lunar impact flashes and near-Earth asteroids. When a meteoroid impacts the moon at several 10s of km/s, a brilliant flash at the point of impact can be observed as a flash in visible and near-infrared light. The influx rate of interplanetary dusts onto the Earth-Moon surface are essential for understanding solar system evolution and are useful information for the future human space activities in the CisLunar space that is the volume within the Moon's orbit. Thus, it is very important to investigate size distributions, influx rate and daily variation of meteoroids. Lunar impact monitoring has a great advantage to detect large meteoroids in the mass range between 10s of grams and few kilograms corresponding to centimeters and tens of centimeters, which is as a bridge between visual meteors and small asteroids. This paper will describe the Flight Model of DELPHINUS onboard EQUULEUS.

The elemental compositions of lunar mantle and lower crust carry critical clues for the earliest stages of Earth-Moon's formation and evolution. CubeX is a SmallSat mission with a compact, highly radiation-tolerant, focusing X-ray telescope that identifies and spatially maps lunar crust and mantle materials excavated by impact craters, and also serves as a pathfinder for autonomous precision deepspace navigation using X-ray pulsars.

X-ray observations of planetary bodies provide a powerful diagnostic tool for remotely determining elemental abundances including major rock forming elements such as Mg, Al, Si, and Fe since X-ray fluorescence (XRF), induced either by solar X-ray flux or energetic ions, carries decisive signatures of elemental composition. Through high-resolution XRF imaging spectroscopy, CubeX uses selected lunar sites to search for small patches of elusive lunar lower crust and upper mantle material excavated within and around impact craters. Informed with the surface topography from LRO and the gravity data from GRAIL, CubeX's measurements of regional compositional variations of lunar sites such as Schrödinger and South Pole Aitken Basins assist and provide the context for future sample return missions recommended by the Decadal Survey.

CubeX also uses high resolution X-ray imaging and time series measurements to conduct Xray pulsar timing based navigation (XNAV) and to evaluate its performance for deep space navigation, a critical component for small planetary missions. XNAV may enable low-cost autonomous deepspace navigation and has the potential to greatly assist, or even outperform, NASA's Deep Space Network (DSN) or ESA's European Space Tracking (ESTRACK). The Moon's relative proximity enables a straightforward evaluation of the XNAV performance through DSN.

CubeX carries two X-ray instruments: an X-ray Imaging Spectrometer (XIS) and a Solar X-ray Monitor (SXM). The XIS conducts both XRF observations and XNAV operations, while SXM monitors solar X-ray activity during lunar XRF observations. The XIS employs Miniature Wolter-I X-ray optics (MiXO) with high angular resolution (<1 arcmin), whose lightweight small form factor is suitable for low-cost SmallSat missions. The XIS focal plane combines high spectral resolution (<150 eV at 1 keV) CMOS X-ray sensors and a high timing resolution (< 1 usec) SDD X-ray sensor. This novel combination of instruments enables both XRF observations and XNAV operations without moving parts. CubeX rideshares to the Moon as a secondary S/C during the next solar maximum (2023-2027). After insertion into an initial elliptical lunar orbit, CubeX transfers to a science-optimized, low maintenance 6000 km quasi-frozen circular polar orbit for the 1-year science operation.

Marco Zannoni, m.zannoni@unibo.it Università di Bologna, Forlì, Italy

The Ocean Worlds Europa and Ganymede in the Jupiter system and Titan and Enceladus in the Saturn system are primary targets for future exploration given their habitability poten- tial. Many questions regarding their evolution and habitability can be addressed by upcoming missions to the outer Solar System. NASA's Europa Clipper mission will focus on the habitability and evolution of Europa. ESA's JUpiter ICy moons Explorer (JUICE) mission aims to determine the interior and extent of the internal oceans of Jupiter's largest moons: Ganymede, Europa and Callisto, thus providing key constraints on their habitability. In addition, several missions have been proposed within both NASA and ESA to further explore Titan and Enceladus in the Saturn system. Radio science measurements are powerful tools to determine the static and dynamic gravity field of a body, posing constraints on its radial interior structure and assessing mass anomalies. In particular, gravity investigations of the ocean worlds could provide information on the internal dynamics and evolution, ocean properties, crustal thickness and thermal state. Traditionally, the observable quantities used by interplanetary gravity science experiments are obtained by means of spacecraft tracking at microwave frequencies from a ground antenna. The generation of these observable quantities requires the spacecraft antenna to point in the direction of the Earth and to use an onboard coherent radio transponder. Using both of these simultaneously impacts spacecraft resources including mass, power, and attitude control. Moreover, the geometry and the operations of the entire mission must be carefully designed to meet all science requirements, including the ones posed by the gravity experiment, through a complex and expensive trade-off process. In the recent years it was proposed to use smallsat companion missions, dedicated only to specific investigations, to complement the science observations of a traditional larger exploration spacecraft. This represents a promising option since smallsats provide relatively low-cost and versatile platforms for scientific observations. Here we present a mission concept consisting of one or two smallsats to be released in orbit around an ocean world (we use Europa, Titan, and Enceladus as reference scenarios) and capable of globally characterize its gravity field through a combination of Satellite-to-Satellite Tracking (SST) between two smallsats or between one smallsat and the mothership. This mission proposal is intended to complement a traditional larger mission to Europa, Titan or Enceladus. The observables are generated and decimated on-board the smallsats and transmitted back to Earth for data analysis and gravity field reconstruction, using the main mission as a relay spacecraft.

B0.2-0013-18 MARCO: PREPARING FOR INTERPLANETARY FLIGHT WITH SMALL SPACECRAFT

Andrew Klesh, andrew.t.klesh@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States Joel A. Krajewski, joel.a.krajewski@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Brian Clement, brian.g.clement@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

In May of 2018, the MarCO spacecraft will launch alongside InSight, separate from the launch vehicle, and commence independent travel to Mars. The two spacecraft will provide entry, descent, and landing relay communications for InSight as it descends to Mars, demonstrating the capability for low-cost relay during critical missions periods.

As the first flown interplanetary CubeSats, significant trailblazing was required to successfully achieve flight readiness. Much of the technology within MarCO is planned for use with the EM-1 CubeSat missions, including the Iris radio and utilization of the Deep Space Network. Several missions will also utilize other onboard hardware components. Each component went through a flight qualification process leading to integration and test, including thermal-vacuum, vibration, and deployment testing relevant to the expected environment. Additional limited analyses were completed regarding radiation and electromagnetic compatibility.

MarCO is also pioneering meeting planetary protection requirements within the framework of a CubeSat mission. Classified as a Planetary Protection Category III flyby mission, the project is required to address both impact constraints for launch vehicle elements and the potential for contaminating InSight. Meeting these requirements by adopting the contamination analysis and control architecture typically applied to Mars missions would limit the benefits of the low-cost, highly-adaptable CubeSat paradigm. Instead, a strategy comprising bioassays of specific hardware, conservative bioburden estimation, and worst-case vehicle breakup and burnup analyses was employed to ensure Planetary Protection compliance.

Flight operations have been planned to coordinate with the Deep Space Network and the InSight mission, achieving a safe, reliable flight path, which includes multiple trajectory correction maneuvers to establish the Mars flyby trajectory. Given energy and thermal constraints, the MarCO spacecraft have limited opportunities for communications and ranging, and these activities must be balanced with attitude control maneuvers. Operations have been carefully planned to address these concerns.

Overall, the MarCO spacecraft are launching on a novel technology demonstration mission, not required for InSight success, yet paving the way for near-term CubeSat deep space projects. This talk will discuss the strategies used and lessons learned to prepare MarCO for flight, as well as recent flight status.

B0.2-0014-18 AN INTERPLANETARY CUBESAT MISSION TO PHOBOS

Jekan Thangavelautham, jekan@email.arizona.edu University of Arizona, Tucson, Arizona, United States Erik Asphaug, asphaug@lpl.arizona.edu

University of Arizona, Tucson, Arizona, United States Graham Dektor, gdektor@asu.edu

Arizona State University, Tucson, Arizona, United States Mercedes Herreras-Martinez, mherre15@asu.edu

Arizona State University, Tucson, Wyoming, United States Shota Ichikawa, sichika1@asu.edu

Arizona State University, Tempe, Arizona, United States

Martian moon Phobos may hold vital clues to the origin of Mars. The moon exhibits several unique features such as surface striations, arguably due to its being within Mars' Roche limit. Phobos has been suggested as a low delta-v stop-over site and staging base for human missions to Mars. It is feasible to teleoperate Mars surface assets via a base on Phobos. To one day take advantage of Phobos as a strategic location for future human exploration to Mars, much more needs to be known about the moon's origin, composition and surface-properties. CubeSats offer the opportunity to perform low-cost focused science exploration, with rapid turn-around times between multiple missions. The high failure rate of past Phobos missions must be considered when developing future missions, and the cost/risk involved in large missions needs to be carefully weighed.

We propose development of a 6U, 14-kg or 12U, 24 kg interplanetary CubeSat called LOGIC (Low Orbit Geology Imaging CubeSat) that would perform thermal and visible imaging of Phobos at resolutions of 25 m/pixel and 5 m/pixel, respectively. The mission concept of operations is shown in Figure 1. LOGIC is inspired by JPL's INSPIRE and MarCO CubeSats. This CubeSat mission would be a pave the way for a subsequent, larger Phobos surface lander mission. This CubeSat mission to Phobos would provide an unprecedented view of the moon, including coverage of more than 50% of the surface. The spacecraft contains two science instruments, namely the e2V Cires Visible camera and FLIR Tau thermal camera. The spacecraft is powered using a pair of onboard deployable solar panels such as the E-HaWK from MMA Design. The solar panels have 1 DoF of gimballing. The back side of the solar panels contains an X-band reflect-array for communication and will utilize JPL's IRIS v2 X-band radio. The spacecraft will charge 2 Gomspace NanoPower BPX lithium ion batteries with a total energy capacity of 154 Wh.

The LOGIC CubeSat would launch as a secondary payload much like JPL's MarCO CubeSats on a Mars-bound spacecraft and is expected to be ejected once it is on an Earth-escape trajectory. The spacecraft will be propelled using a chemical propulsion unit such as green-monoprop to get into a Mars-insertion orbit. The spacecraft will enter into a highly elliptical orbit much like ISRO's Mangalayaan and perform aerobraking to enter into a co-orbit with Phobos. Alternately, LOGIC can perform elliptical flybys of Phobos to minimize the need for aerobraking. To adhere to planetary protection guidelines, the spacecraft disposal orbit has been designed to avoid probability of collision with Mars or Phobos for 50 years.

Interplanetary CubeSats offer a compelling path forward towards short, focused science missions that act as trailblazers for larger, longer missions. Even if one fails, a CubeSat mission may be assembled with a relatively short turn-around time. Phobos is an excellent target to better understand small-bodies, their origins and compositions, and could be crucial for making a future human mission to Mars a reality.

Radio occultation experiments have been carried out on numerous planetary missions since 1965, when Mariner IV flew by Mars. The observations of radio links from spacecraft to ground stations have yielded valuable information on the structure of planetary ionospheres and neutral atmospheres. By utilizing links from a single orbiting spacecraft, global coverage of the atmospheric measurements can be achieved, but only after extended periods of time, often many months or more. However, following work by the Earth atmospheric community that advanced crosslinks between spacecraft in Earth orbit, the transmitter side being a Global Positioning System GPS spacecraft, crosslink occultations can be envisoned at Mars and other planets. Crosslink occulations between two or three spacecraft can produce much more rapid global coverage that enables examination of the variability of vertical profiles of temperaturepressure and ionospheric electron density profiles on daily, seasonal, and annual time scales. Such small-spacecraft planetary constellations are enabled by recent

advances in small and less costly spacecraft, such as CubeSats. Such smallsat occultation missions offer a means to dramatically improve knowledge of atmospheric structure and dynamics for several planets and the moon Titan.

We report on our studies for a small constellation of Mars satellites that perform atmospheric/ionospheric occultation studies. We developed a science traceability matrix that yielded technical design specifications linked to key science goals such as the atmospheric temperature accuracy and dense geographical/ temporal measurement distribution that would allow global determination of atmospheric variations from diurnal to seasonal scales over the entire planet. Radio link systems scenarios were examined that met the measurement accuracy requirements at maximum spacecraft ranges. We also explored various mission design concepts and an initial Cubesat design that included considerations of cost, size, power, mass, longevity, and radiation tolerance. The occultation data obtained by each smallsat would be relayed to a large orbiter which then sends the data on to the Earth, so the CubeSats themselves are not required to have Earth communication capability. Precision knowledge of the CubeSat orbits is also required to properly interpret the occultation data. This is achieved by Doppler measurements on radio links between the CubeSats before or after each occulation and by occasional radio contact between each CubeSat with the large orbiter whose position and velocity are well known from Earth-based tracking by the Deep Space Network.

B0.2-0016-18 MARS AEROSOL TRACKER (MAT): AN AREOSTATIONARY SMALLSAT TO MONITOR DUST STORMS AND WATER ICE CLOUDS

Luca Montabone, lmontabone@spacescience.org

Space Science Institute, Boulder, Colorado, United States Michael VanWoerkom, mvanwoerkom@exoterracorp.com ExoTerra Resource LLC, Littleton, Colorado, United States Bruce Cantor, cantor@msss.com

Space Science Institute, Boulder, Colorado, United States Michael Smith, michael.d.smith@nasa.gov

NASA/GSFC, Greenbelt, Maryland, United States Francois Forget, forget@lmd.jussieu.fr

CNRS Research Scientist (Chargé de recherche), Paris, France Michel Capderou, capderou@lmd.polytechnique.fr

Laboratoire de Météorologie Dynamique, IPSL, Paris, France

We have elaborated a mission concept to put a SmallSat (up to about 60 kg of mass) in an areostationary orbit around Mars -17,031.5 km altitude above the equator. The planned areostationary orbit would be the first of its kind, offering the unequaled possibility to obtain a novel set of frequent observations over a region of the planet that can extend up to 80° away from the sub-spacecraft point.

The overall goal of this mission concept is to track Martian dust storms and water ice clouds, helping to address the scientific questions: What are the processes controlling the dynamics of dust and water ice aerosols, and promoting the evolution of regional dust storms into planetaryencircling storms?

The SmallSat uses a solar electric propulsion system based on micro Hall-effect thrusters that allow it to reach, optimize and maintain its orbit, dramatically improving its lifetime and control. The propellant is gaseous xenon. The power source is guaranteed by deployable, flexible, high specific power (160 W/kg) solar arrays designed to meet the power needs of the Hall-effect thruster and payload. Communication is provided in the X-band by the JPL IRIS Deep Space transponder in association with a KaPDA antenna.

The payload is comprised of one off-the-shelf visible camera (fixed-focus, narrow-angle lens, 5 MP resolution), and two thermal infrared cameras (fixed-focus, narrow-angle lens, 0.3 MP resolution). The infrared cameras are equipped with filter wheels for selecting multiple spectral ranges, and the uncooled micro-bolometer image sensors are responsive out to 20 µm to include CO2, dust, and water ice absorption lines. Retrievals of aerosol optical depth throughout the local times will provide quantitative observations at a spatial resolution up to 60 km/pixel and temporal resolution up to half an hour, complementing the high-resolution daylight visible images (resolution up to 4 km/pixel).

We have studied three possible mission scenarios: 1) Ridesharing on a primary orbiter mission directed to Mars, with deployment after the initial capture burn (operated by the mothership). This scenario, which limits the use of thrusters, allows for the lowest mass and size; 2) Ridesharing on a primary mission directed to Mars with deployment a few weeks ahead of Mars capture (operated independently from the mothership); 3) An independent journey to Mars all the way from Earth GTO. In all three cases, the duration of the (primary) science mission at Mars is planned for one Martian year.

B0.2-0017-18 MARSCAT: MARS ARRAY OF IONOSPHERIC RESEARCH SATELLITES FORMING THE CONSTELLATION FOR AERONOMY AND TOMOGRAPHY

Edgar Bering, eabering@uh.edu

University of Houston, Houston, Texas, United States

The MARSCAT Mission will be a multiple 6U CubeSat mission to study the ionosphere of Mars. The mission will investigate the plasma and magnetic structure of the Martian ionosphere, including how the ionosphere responds to solar wind dynamics, what small scale structures exist in the lower ionosphere of Mars, and what processes are responsible for the maintainance of the nighttime ionosphere. The Mars transit proposed is piggy back with a major mission, using an on-board thruster burn or a carrier burn for Mars Orbit Injection (MOI).

MARSCAT will make correlated multipoint studies of the ionosphere and magnetic field of Mars. MARSCAT will make in situ observations of the energetic particle flux, plasma density, temperature, and convection in the ionosphere of Mars. They will also make total electron content measurements along the line of sight between any two of two spacecraft. Following the successful exploration of the Mars ionosphere and its interaction with the solar wind and the crustal magnetic field of the planet, there remain several key questions, which will complete a description of the space environment of Mars. The key questions involve the transport properties of the ionospheric plasma, its role in redistributing the plasma and the role of the magnetic field in modifying the plasma motions. A focus for advancing our current understanding may be obtained by addressing the following key questions. How does the ionosphere respond to solar wind dynamics? What small-scale structures exist in the lower ionosphere of Mars? What processes are responsible for the maintenance of the nighttime ionosphere? The key to advancing or understanding lies in using multiple platforms to increase the temporal cadence with which a particular volume of the ionosphere can be sampled. With recent advances in small satellite capabilities it is now possible to consider the deployment of a small satellite constellation to accomplish this task. Suitably instrumented satellites could be carried as a secondary payload to a major Mars mission in much the same way as small CubeSat missions have been successfully conducted in low Earth orbit.

B0.2-0018-18 NEARCUBE: USING AUTONOMOUS 3U CUBESATS TO FLYBY NEAR-EARTH ASTEROIDS

Pablo Machuca, p.machuca@cranfield.ac.uk

CRANFIELD UNIVERSITY, Cranfield, United Kingdom Joan Pau Sánchez, jp.sanchez@cranfield.ac.uk CRANFIELD UNIVERSITY, Cranfield, United Kingdom

CubeSat technology is rapidly evolving and now the first missions beyond low-Earth orbit (LEO) have been planned [1-4]. These first 6U interplanetary CubeSats (<12 kg) will be launched using NASA's Atlas V and its new Space Launch System (SLS), and are designed to observe and land on the Moon, flyby a near-Earth asteroid, flyby Mars in support of NASA's InSight mission, and more.

The use of CubeSats for planetary exploration represents an attractive solution to reduce the development and implementation costs of missions in comparison to traditional spacecraft [5]. However, ground segment operations—which require extensive workforce and the use of large, costly ground stations such as the Deep Space Network (DSN)—remain as one of the key challenges for interplanetary CubeSats, and still represent a very significant (sometimes inviable) fraction of the mission budgets [6]. In response to the current interest in understanding the potential of CubeSats and possible applications for planetary exploration, this work studies the feasibility of autonomously flying by a near-Earth asteroid using a 3U CubeSat (<4 kg).

The proposed mission, which is named Near-Earth Asteroid Reconnaissance using CubeSats (NEARCube), is therefore envisioned as a feasibility demonstration of small-body exploration missions using autonomous and smaller CubeSats than ever before. Considering the current state of CubeSat technology, this work evaluates the flyby altitudes that can be achieved by autonomous CubeSats, and assesses the potential scientific impact that such a mission could have. If proven possible, autonomous 3U CubeSats could provide a low-cost solution to support current efforts to determine initial stages of solar system formation through asteroid exploration (or the primordial sources of organic matter if used for cometary exploration) [13], they could be used to identify potential targets for future missions, to complement the scientific objectives of larger missions, or to support the emerging asteroid mining industry [14], etc.

The NEARCube mission specifically considers the possibility of deploying a CubeSat from a larger spacecraft in a periodic orbit around the first (L1) or the second (L2) Sun-Earth Lagrange points. These points provide a prime location to observe the Sun and outer space, and have been extensively used in the past by mission such as SOHO, Herschel, Planck, or LISA Pathfinder

[7-10]. The James Webb Space Telescope (2019) and Euclid (2020) missions will be launched to L2 in the upcoming years as well [11, 12]. In addition, the span of the mission is limited here to 150 days to confine the demanding implications and systems requirements of long-duration, deep-space travel, and the spacecraft is primarily designed using currently-available off-the-shelf components (for reduced development and implementation costs).

This study is comprised of three overarching parts: (1) a trajectory design and target selection analysis to understand if 3U CubeSats can travel far enough to encounter a near-Earth asteroid, and to identify asteroids that could be flown by in the upcoming years, (2) a navigation and sensitivity analysis to study if a CubeSat could autonomously estimate its position and velocity, and to characterize the accuracy of the flybys and attainable flyby altitudes, and (3) a systems engineering analysis to propose a 3U CubeSat design, recommend potential science payloads, and assess the measurements and scientific objectives that could be accomplished by such a mission.

Preliminary results show that a total of 11 near-Earth asteroids (larger than 100 meters) could be encountered between 2019 and 2025, out of which 6 could be flown by a 3U CubeSat performing autonomous navigation. Flyby altitudes of 500 km are found to be possible with currently available components and an allocated space of approximately 0.8U for the science payload. A variety of scientific instruments are available (including off-the-shelf components), and proposed here for the NEARCube mission. Potential scientific objectives are also assessed, and include performing ultraviolet, visible or infrared imaging spectroscopy, measurements of remnant magnetic fields, or even mass spectroscopy if used for cometary exploration.

This work therefore identifies an opportunity for small-body planetary science using autonomous 3U CubeSats. The mission concept, upcoming asteroid flyby opportunities, and potential scientific merit of the proposed NEARCube mission are presented and discussed here in detail.

We suggest novel strategies for the exploration of planetary objects with very long periods (referred to as LPOs). These bodies include Oort cloud comets, Manx objects and, now, interstellar objects, such as the recently discovered 'Oumuamua [1]. Long-period comets are the most primitive witnesses of the early solar system. Interstellar visitors are suggested to be ejecta of extrasolar planets subject to catastrophic collisions. Hence the scientific value of exploring these objects is unbounded. A very broad range of measurements are sought at these bod- ies. They include the characterization of their physical properties (shape, density, morphology, dynamical properties), composition (elemental composition, mineralogy, isotopes), interior, geological traits that might inform on origin and possible long-term evolution, and interactions, in particular of a coma when it exists, with the solar wind. The corresponding instruments already exist in a small form factor. Encounters with LPOs are challenging to plan. These bodies have a broad range of inclinations and encounter velocities are in excess of 50 km/s. The only attempt to explore a comet with a longer period (75 years) up-close was the encounter with Comet Halley in 1986. Its visit was deemed such an important event that six spacecraft were sent by different space agencies. Similarly, future exploration of LPOs might be best approached by sending a very large number of spacecraft by multiple space agencies, and in a coordinated manner. It is envisioned that up and coming telescopic facilities such as the Pan-STARRS2 Observatory combined with the Pan-STARRS1 telescope, and later the Large Synoptic Survey Telescope (LSST), will enable the discovery of LPOs a decade and more before these objects reach perihelion. This timeline is a priori sufficient to implement and launch spacecraft that may encounter the LPO as it approaches its perihelion. Constellations, formations, and swarms of small spacecraft have been identified as game changers for enabling new space science [2]. In recent times, there has been a tremendous development in regards to the

technology maturation level achieved by smallsats [3]. Smallsats offer a number of advantages, in particular advanced distributed spacecraft architectures that can be used to address the above challenges and enable wholesome science investigations over a short observation window. This includes:

(1) a loose coordination to synthesize a single, large, virtual instrument [4]; (2) innovative distributed, possibly heterogeneous measurement, and data analysis techniques; (3) autonomous operations; (4) communication relay strategies; and (5) novel orbital organization approaches for constellations or more effective swarming and to enable observations from multiple vantage points.

Part of this work is being carried out at the Jet Propulsion Laboratory, California Institute of Technology, under contract to NASA. The authors also acknowledge support form the W. M. Keck Institute for Space Studies.

The Geophysical Reconnaissance Asteroid Surface Probe (GRASP) is a proposed Canadian space mission to explore the surface of a small asteroid. The asteroid lander/rover nanosat spacecraft (12U cubesat) will be brought to a small (< 1 km in diameter) near-Earth asteroid aboard a host mothership spacecraft, which will drop GRASP onto the asteroid's surface. GRASP will carry two geophysical instruments, a novel space gravimeter located in GRASP's central bus structure, and a set of magnetometers located in GRASP's feet. GRASP will use its rockets to hop from one location to another, eventually covering the entire surface of the asteroid, making science measurements at 100 or more surface locations. These geophysical measurements will be used to constrain the asteroid's interior structure and composition, specifically, asteroid mass, density distribution and magnetic susceptibility and will ultimately be applied to (i) answering fundamental science questions about the origin, formation and evolution of the Solar system, (ii) assessing asteroid mining potential, and (iii) asteroid re-direct strategies. Based on forward and inverse models of asteroid surface gravity observations, the mission will result in well constrained asteroid mass and internal density distribution, which is considered a first. In addition to enabling the field of asteroid surface gravimetry, GRASP will also include optical imaging sensors and on-board rover cameras, which in combination with the geophysical data will allow for the development of a comprehensive asteroid composition model.

Bringing a CubeSat that could autonomously navigate in the vicinity of small bodies would be an ideal platform to perform radio-science from multiple locations at low altitudes that are too risky for a mothercraft. The perturbations due to the asteroid during the orbit or multiple flybys of the CubeSat allow the reconstruction of its detailed gravitational field by planetary geodesy and, eventually, the identification of its internal structure. To this purpose, we are developing the BIRDY concept of interplanetary CubeSat, accompanying a mothercraft for planetary geodesy of small bodies (asteroids, comets, satellites). Besides, classical radio tracking can be coupled to other techniques such as space astrometry and VLBI [1]. Interplanetary CubeSats need to overcome a few challenges before reaching successfully their deep-space objectives: link to ground-segment, energy supply, protection against radiation, etc. Besides, the Birdy CubeSat - as our basis concept - is designed to be accompanying a mothercraft, and relies partly on the main mission for reaching the target, as well as on data-link with the Earth. Autonomous navigation could then provide a way to perform a new kind of planetary geodesy, particularly well adapted to small bodies.

Future mission for space exploration or sample return could hence take profit of having accompanying nano-orbiters, as complementary or deported instruments with increased autonomy. Furthermore, in the current context of more and more small satellites being launched in solo or in network/swarms missions, the operational cost of such projects is booming; especially because of the required ground segment. This kind of technology could greatly increase the feasibility of such projects (by moving the decision making to the satellite), for example high frequency imaging of the Earth, Radio Interferometry from space, simultaneous multi-point in situ study of the solar wind, etc. A performant autonomous navigation function for small satellite could hence unlock new scientific missions and commercial applications.

This autonomous attitude and orbit determination and control function (a.k.a autonomous navigation) for small satellites, in addition to radio science fro planetary missions, is currently being developed by a Consortium made of laboratories LESIA and IMCCE from Observatory of Paris in France, and the National Cheng Kung University and ODYSSEUS Space Co., Ltd in Taiwan. Before going to deep-space, and performing planetary science, our project will start with BIRDY-1 orbiting the Earth, to validate the concepts of adopted propulsion, IFOD and orbit maintenance, as well as the radio-science.

Cis-Lunar Object Detector within THermal Insulation (CLOTH) is the micrometeoroid penetration sensor mounted on EQUilibriUm Lunar-Earth point 6U Spacecraft (EQUULEUS), a joint deep-space cubesat mission between The University of Tokyo and Japan Aerospace Exploration Agency (JAXA), which will be launched in the late 2019. This is the first opportunity to reveal the micrometeoroid distribution around the Earth-Moon Lagrange point 2 (EML2). It is expected that CLOTH will detect two components of micrometeoroids during the cruise to EML2 region, i.e. sporadic dust particles originated from the interplanetary space and the EML2 ejecta particles produced by temporary captured orbiters (TCOs). The CLOTH sensor has laminated structure composed of polyvinylidene fluoride film sensors and the multilayer insulation (MLI) of spacecraft. Due to its sensor structure, CLOTH can detect particles that penetrates the outermost layer film of MLI. In this presentation, we report the micrometeoroid detection performance of CLOTH focusing on the damage and penetration of the outermost layer obtained by hypervelocity impact (HVI) experiments and computational simulations. HVI experiments were performed by using the two-stage light gas gun at JAXA/ISAS and the laserinduced particle impact test (LIPIT) facility at Massachusetts Institute of Technology. In the experiments, we used soda-lime glass particles of 4-30 μm diameter accelerated at 1-7 km/s. For complementing the HVI experiments, computational simulation with finite element method in AUTODYN® was performed. From the experiment and simulation results, we revealed the clear difference in detectable impact condition for the two components of micrometeoroids.

Here, we present a cubesat space mission dedicated to the detection and characterization of meteors. The detection of meteors brings information on the flux of meteoroids and space debris in Earth environment and on the nature of the meteoroids that come from two reservoirs: comets and asteroids [1]. Such study brings information on the formation of the solar system. Several methods have been developed from Earth ground and airborne to detect meteors or space debris. However, the advantage of a space mission dedicated to meteors observation is to be able to probe a large volume of the Earth atmosphere and to avoid weather constraints [2]. The primary objective is to assess a robust statistics on meteoroids and space debris that enter into the Earth atmosphere. At present, their fluxes and properties are not yet determined accurately [3]. These estimates will allow to quantify the delivery of extraterrestrial material on Earth, and possible consequences on aeronomy (e.g. noctilucent clouds and atomic layer). These estimations are also crucial to estimate impact risks for artificial satellites during meteor showers. There are several secondary objectives such as to bring information on ablation, fragmentation, rotation processes by photometry variation; to determine the trajectory in connection with Earth-ground network such as FRIPON network developed in France in order to find the dynamical origin of the meteoroid; and to detect other fainter luminous atmospheric. This cubesat is a 3U developed by students from Sorbonne University and the project is presently in phase B [4]. The launch would be scheduled in four years. Support from CNES-JANUS, ESEP, and IDEX Sorbonne Universités are acknowledged.

The promise of CubeSats as a platform for technology demonstration and education has been well understood since the beginning. With ever-advancing miniaturization and flight heritage, CubeSat missions have started to be proposed and flown to address important questions of space science. One such set of missions are the Miniature Tether Electrodynamics Experiments (MiTEE), student-led CubeSat missions developed and operated at the University of Michigan. MiTEE-I is geared towards investigating the electron current collection behavior of a picosatellite end-body and is slated to launch in 2018. MiTEE-II will build upon the lessons learned of MiTEE-I to study the dynamics and control of asymmetric tethered CubeSat systems.

The long-term focus is to develop short (10-30 m) electrodynamic tether (EDT) systems for PicoSats (< 100g) that provide propellantless propulsion for drag make-up and satellite repositioning, support double probe science, and antennas for communications and science.Here we will also present the space science enabled by the MiTEE missions. Langmuir probe implementation techniques and technologies that are being developed to overcome measurement errors induced by the smaller collection profile of Cubesats. These developments enable a wide array of new space science missions when flown on small spacecraft.

B0.2-0025-18 ON-ORBIT PLANETARY SCIENCE USING CUBESAT CENTRIFUGE LABORATORIES

Jekan Thangavelautham, jekan@email.arizona.edu University of Arizona, Tucson, Arizona, United States Erik Asphaug, asphaug@lpl.arizona.edu

University of Arizona, Tucson, Arizona, United States

There are thousands of asteroids in near-Earth space and millions in the Main Belt, offering many mission targets. Yet landing on an asteroid and manipulating its surface material remains a daunting challenge. Current missions to asteroids such as Hayabusa II and OSIRIS-REx will perform touch-and-go operations instead of landing, to limit these risks.

Fundamental research is required to understand asteroid surface behavior, with regard to landing, mobility, and subsurface exploration. Presently we lack even the most basic knowledge, for instance whether they will act as a hard, rugged materials or fluidize like quicksand under modest vibration. The same can be asked of comets and small moons.

Although similar challenges exist for determining the best form of mobility, manipulation and mechanical processing on the Moon and Mars, the milligravity environment is unique and quite challenging to simulate. Therefore we have proposed and have been developing a low cost CubeSat mission called Asteroid Origins Satellite I (AOSat 1) that will operate in Low Earth Orbit (LEO) as a centrifuge science laboratory. The whole spacecraft will spin at 1-2 RPM, giving a 2U research chamber a milligravity environment corresponding to an asteroid the size of Itokawa. Crushed meteorites in the chamber will mimic a layer of asteroid regolith.

This approach provides a low-cost pathway to producing realistic asteroid physical and thermal conditions, for science and for engineering validation. The laboratory is equipped with cameras and piezoelectric actuators to observe and manipulate regolith. Basic experiments are planned to measure the general behavior, friction coefficient, stiction and other parameters that can feed into asteroid surface dynamics simulators. Beyond AOSat 1, our efforts are focused on developing a series of larger, 6U CubeSats with increasingly sophisticated experiments that enable direct simulations of robotic surface landing, manipulation and resource processing/extraction. We have been developing detailed plans for instrumentation to perform penetrometery, excavate, acquire samples, process regolith and extract water.

Centrifuge science laboratories, from CubeSat and larger scales, can be used to recreate the low-gravity off-world conditions of the asteroids, Moon, Mars and other small bodies in the solar system. The laboratories can provide a persistent link to better understand and perform hypothesis-testing of planetary surface processes, being able to fully recreate them in controlled laboratory

conditions on-orbit. Furthermore, this technology can be applied to de-risk next generation spacecraft technology with increased confidence and long-term planning.

B0.3-0001-18 OBSERVING THE OUTER PLANETS WITH ASTROPHYSICAL ASSETS

Amy Simon, amy.simon@nasa.gov

NASA/GSFC, Greenbelt, Maryland, United States Michael H. Wong, mikewong@astro.berkeley.edu UC Berkeley, Berkeley, California, United States

Space-based astrophysical telescopes are a perfect platform for long duration and frequent cadence observations of the outer planets. These missions are optimized for high spatial resolution observations over a large field of view, and often have very long mission lifetimes. Unlike ground-based, or very close planetary, observations, these telescopes can observe a planet over a full rotation cycle or more, often capturing the entire planet within the instrument field of view. These aspects are critical to providing global context for deep space missions. Even more importantly, they allow us to revisit the very dynamic and variable atmospheres of the gas and ice giant planets throughout their long seasonal cycles. This talk will briefly discuss the challenges of observing the giant planets, including how JWST, WFIRST, LUVOIR, and other future astrophysics missions can provide breakthrough planetary science. We also summarize the outstanding recent results from the Hubble Space Telescope Outer Planet Atmosphere Legacy (OPAL) Program, and from the Kepler K2 and Spitzer Neptune observations.

Jupiter's polar X-ray aurora is dominated by a bright dynamic hot spot that is produced by precipitating 10 MeV ions [Gladstone et al. 2002; Elsner et al. 2005; Branduardi-Raymont et al. 2007]. These highly energetic emissions exhibit pulsations over timescales of 10s of minutes and change morphology, intensity and precipitating particle populations from observation to observation and pole to pole [e.g. Dunn et al. 2017]. Surrounding the soft X-ray emission there is an oval of hard X-ray bremsstrahlung from precipitating electrons. The acceleration process/es that allow Jupiter to produce these high-energy X-ray emissions remain poorly understood, but vary with solar wind conditions [Dunn et al. 2016; Kimura et al. 2016] and the soft X-ray emissions are expected to relate to processes on the boundary between Jupiter's magnetosphere and the solar wind.

We present a decade of remote X-ray observations of Jupiter from 2007 to 2017 using the Earth-orbiting X-ray telescopes Chandra and XMM-Newton. We compare these high spatial and spectral resolution X-ray data with in-situ measurements of the solar wind and the Jovian magnetosphere conducted by NASA's New Horizons and Juno spacecraft. Analysing X-ray spectrograms and X-ray auroral videos we probe time-varying accelerations, precipitating particle populations and auroral morphologies and further connect these with their solar wind and in-situ drivers.

Finally, we compare X-ray observations with UV observations to enrich multi-waveband connections and deepen our understanding of how Jupiter generates its highly energetic polar auroral precipitations.

B0.3-0003-18 EVERYTHING UNDER THE SUN: OBSERVATIONS OF SOLAR SYSTEM BODIES FROM HELIOPHYSICS OBSERVATORIES

Karl Battams, karl.battams@nrl.navy.mil

Naval Research Laboratory, Washington, District of Columbia, United States Matthew Knight, mmk8a@astro.umd.edu

University of Maryland, College Park, Maryland, United States

In this presentation, we give an overview of the wealth of solar system bodies observed from the ESA/NASA Solar and Heliospheric Observatory (SOHO) and NASA Solar Terrestrial Observatory (STEREO). With continuing lifetimes now spanning more than 11-years (STEREO) and 23-years (SOHO), the coronagraphs and heliospheric imagers aboard these spacecraft have observed every class of solar system body: all the planets except Uranus and Neptune; dwarf planets Ceres and Vesta; several Jupiter moons, Titan, and our own Moon; dozens of asteroids (minor planets), including active asteroids such as 3200 Phaethon; and, perhaps most famously, more than 3,500 comets.

We will provide a broad introduction to the SOHO and STEREO missions, and the instruments with which we observe solar system bodies. Included in this will be the limitations and constraints imposed upon these observations by instruments that are intended to study only one solar system body (i.e. the Sun). We then briefly discuss some of the science investigations of solar system bodies that have been, or could be, driven by these data. Finally we conclude with a brief preview of solar system observing prospects from the Naval Research Laboratory's Heliospheric Imager instrument (WISPR) aboard the NASA Parker Solar Probe mission, set for launch in 2018.

AKARI, the Japanese satellite mission dedicated to infrared astronomical observations, was the third mission to survey the whole sky at midand far-IR wavelength regions. AKARI was launched in February 2006 and exhausted its liquid helium in August 2007. Together with the all-sky survey at 9, 18, 65, 90, 140, and 160 µm, a number of pointed observations were also made for deep imaging and spectroscopy from the near-infrared to far-infrared. After the exhaustion of the cryogen, near-infrared imaging and spectroscopic observations had continued until 2011 May. Although most of the targets for the AKARI observations were the Galactic and extragalactic objects, the data of the AKARI observations are extremely important not only for the studies of the Galactic and extragalactic sciences, but also for the Solar System sciences on comets, asteroids, TNOs, and interplanetary dust.

With the mid-infrared all-sky survey data, the asteroid catalog using AKARI (AcuA) was produced. It is an unbiased, homogenous asteroid catalog, containing a total of 5120 objects down to a diameter of 20 km in the main belt. Taking advantage of the sky

coverage with the midand far-infrared all-sky map data, AKARI reveals the global and small-scale structure of the zodiacal dust cloud. AKARI detects asteroidal dust bands and a circumsolar ring structure in the zodiacal emission spatial profiles with much higher resolution than IRAS and COBE/DIRBE. These data provide us the information on the dynamical evolution of the Solar System.

AKARI also has a spectroscopic capability in nearand mid-infrared wavelength region. We carried out spectroscopic observations for tens of asteroids and comets in 2.5–5 μm. AKARI detects a clear absorption feature related to hydrated minerals in many asteroids and carbon dioxide in cometary comae. AKARI also made the spectroscopy of the zodiacal emission in the mid-infrared (5.5–12.5 μm) and detects the silicate feature around 10-μm region toward the various ecliptic latitude regions. These data sets are almost the largest spectroscopic database so far and provide us the information on the physicochemical environment in the proto-solar nebula.

AKARI has already provided many precious data sets and scientific outcomes, but it is just the tip of the iceberg. We will summarize the successful results of the AKARI Solar System sciences and introduce ongoing scientific analyses.

B0.3-0005-18 SEARCH FOR SERENDIPITOUS TRANS-NEPTUNIAN OBJECT OCCULTATION IN X-RAYS

Hsiang-Kuang Chang, hkchang@mx.nthu.edu.tw National Tsing Hua University, Hsinchu, Taiwan, China Chih-Yuan Liu, yuanplus@gmail.com

Paris Observatory, Paris, France

Jie-Rou Shang, bandyshang@gmail.com

National Tsing Hua University, Hsinchu, Taiwan, China

Small Trans-Neptunian Objects (TNOs), of kilometer size and below, are too dim to observe directly. Observations of serendipitous occultation events caused by these small TNOs provide a way to study their population properties such as the size distribution. Limited by the effect of diffraction, optical occultation events can be used to explore TNOs only down to kilometer size, while with X-ray ones it can be pushed down to about 30 meters. In this talk I will report our efforts and results of using Rossi X-ray Timing Explorer (RXTE) observations in this endeavor. With the same technique, we also obtained observational constraints to the size distribution of small Oort Cloud Objects without any model assumptions. Feasibilities of observations using facilities like ASTROSAT/LAXPC and Athena/WFI will be discussed.

B0.3-0006-18 SCIENCE OF SOLAR SYSTEM OBJECTS WITH THE GAIA MAPPING MISSION AND THE GDR CATALOGUES.

Daniel Hestroffer, hestro@imcce.fr

IMCCE/Paris observatory, univ. PSL, CNRS, PARIS, France Paolo Tanga, paolo.tanga@oca.eu

Observatoire de la Côte d'Azur, Nice, France Francois Mignard, mignard@oca.eu Observatoire de la Côte d'Azur, Nice, France Gaia CU4-SSO

Berthier, J.; Cellino, A.; David, P.; Delbo, M; Dell Oro, A.; Muinonen, K.; Pauwells, T.; Petit, J-M.; Thuillot, W.

Since the beginning of its scientific programme, in mid-2014, the ESA space mission Gaia has regularly scanned the whole scan, providing astrometry, spectrometry, and spectro-photometry, of about a billion of stars and also Solar System Objects (SSOs). Although it is not specifically designed for observation of moving objects, the Gaia satellite provides photometric and astrometric measurements, with unprecedented accuracy, for a very large number of SSOs, mainly asteroids. The unique capabilities of Gaia allow for the collection of an extensive and homogeneous data set of some 350,000 asteroids (that is almost half of the known population), some planetary satellites, and comets, down to the limiting magnitude of G20.7 mag, at the sub-milli-arcsec and milli-mag level accuracy. Thanks to large number of sources, the systematic character of the survey, and the measurements of metrological precision into play, Gaia will open a new era in asteroid science. Gaia has already started to provide its harvest with the first two Gaia data releases, DR1, published in September 2016. Gaia DR1 did provide positions for about 1 billion stars and proper motion for the Tycho-Gaia TGAS of 2 million stars. The second data release, DR2 to be published in April 2018, will be the major step in the Gaia mission, providing all astrometric parameters (including parallax and proper motion) for a billion stars, in an absolute reference frame - to become the optical ICRF. Gaia DR2 will also provide for the first time epoch astrometry and photometry for about 14000 asteroids from its direct observations, down to magnitude G20.7. The Gaia performance remains excellent over the entire available brightness range. We will present the Gaia data reduction pipeline for the SSOs, within the framework of the Data Processing and Analysis Consortium (DPAC), and the validation process of the DR2 data. We illustrate the peculiar properties of each single observation, as these properties will affect the subsequent exploitation of the mission data. Overall, we expect to derive masses, sizes, average densities, spin properties, reflectance spectra, albedos, as well as new taxonomic classifications for a very large numbers of asteroids. We will discuss the improvement brought by Gaia over 5 years of nominal mission, starting with DR1, and focusing especially on the dynamics of asteroids and other Solar System Objects. This includes use of the catalogue for calibrating future and past photometric and astrometric observations, new perspectives for orbit determination and stellar occultations, detection of small acceleration or perturbations for the asteroids. Also we illustrate the ground-based activity coordinated by the Gaia-FUN-SSO network for follow-up observations of newly discovered Near Earth Object. We will further focus on the areas that will benefit from complementary observational campaigns to improve the scientific return of the mission, and on the involvement of the planetary science community as a whole in the exploitation of the Gaia survey.

B0.3-0007-18 THE PRESENCE OF DUST AND ICE SCATTERING IN X-RAY EMISSIONS FROM COMETS

Bradford Snios, bradford.snios@cfa.harvard.edu

Center for Astrophysics, Cambridge, Massachusetts, United States Jack Lichtman, jlichtman

University of Connecticut, Storrs, Connecticut, United States Vasili Kharchenko, vkharchenko@cfa.harvard.edu

Harvard-Smithsonian Center for Astrophysics, Cambridge, Massachusetts, United States

We present evidence of dust and ice as sources of X-ray scattering emissions from comets. Emission spectra are modeled from first principles using the charge-exchange interaction with solar wind ions as well as coherent scattering of solar X-rays from dust and ice grains. Scattering cross-sections are interpolated over the 1 nm-1 cm grain radius range using approximations based on the optically thin or thick nature of grains with different sizes. Archival comet observations from the Chandra X-ray Observatory are fit with the theoretical emission model. The best fits show charge-exchange to dominate the emission spectral intensity below 1 keV, while dust and ice scattering is the dominant mechanism at energies greater than 1 keV. Grain size dependences calculated from the scattering results are consistent with independent observations and simulations of such systems, and the dust/ice density dependence on grain radius is shown to vary significantly between comets.

B0.3-0008-18 MESSENGER OBSERVATIONS OF THREE COMETS AT SMALL HELIOCENTRIC DISTANCES

During the extended MESSENGER mission, the opportunity arose to make both spectral and imaging observations of three comets: 2P/Encke, C/2012 S1 (ISON), and C/2013 V5 (Oukaimeden). MESSENGER's position in the inner solar system provided a unique view of these comets at small heliocentric distances, and through the efforts of the spacecraft and instrument teams, observing campaigns for these three comets were conducted. Its instrument payload, though not designed with comets in mind, was both capable and flexible enough to provide a variety of observations, including both wideand narrow-angle images, images in different filters, and high-resolution spectra that spanned wavelengths from 100-600 nm. Of particular note are the ultraviolet observations of various atomic and molecular species. These observations are uncommon for comets close to the Sun due to the viewing restrictions of most telescopes in space. We will report on the analyses of the science data that were collected during these observing campaigns, with a focus on the temporal evolution of the coma dust and gas. Equally important, we will discuss the lessons learned from the experience - what worked and what did not - and present suggestions for future observations of the same genre with spacecraft that also were not designed for the task. Such observations are essentially mini-spacecraft missions to the objects involved and thus represent a potentially high science return for a reasonably small impact on the primary mission.

B0.3-0009-18 DETECTION AND CHARACTERIZATION OF MINOR PLANETS USING NEOWISE

Emily Kramer, emily.kramer@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Amy Mainzer, amainzer@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Planetary Science Institute, Tucson, Arizona, United States Roc Cutri, roc@ipac.caltech.edu

California Institute of Technology, Pasadena, California, United States

NEOWISE is the NASA planetary-funded mission that uses data from the Wide-field Infrared Survey Explorer (WISE) spacecraft to detect and characterize moving objects. WISE was originally designed as an NASA astrophysics mission, with the goal of mapping the sky in the mid-infrared to search for the closest stars and the most luminous galaxies.

WISE surveyed the sky in four infrared wavelength bands (3.4, 4.6, 12 and 22-µm) between January and September 2010, when its solid hydrogen cryogens were exhausted. Survey operations continued using the shorter two wavelength bands until January 2011, after which the spacecraft was put in to hibernation. During this phase of the mission, over 158,000 minor planets were detected, including over 160 comets and 34,000 newly discovered minor planets.

In December 2013, the telescope was taken out of hibernation and renamed NEOWISE, with the new goal of detecting, tracking, and characterizing near-Earth objects (NEOs). The restarted NEOWISE mission uses only the shorter two wavelength bands (3.4 and 4.6-µm), and uses the same survey strategy as the original mission. Since the restart of the mission (as of February 2018), over 30,000 solar system small bodies have been observed, including over 800 NEOs, and over 130 comets. NEOWISE thermal infrared measurements have been used to measure diameters for over 22,000 asteroids in the first three years of the restarted mission, with observations and analysis ongoing as of February 2018.

In this presentation, we will discuss an overview of the results of the NEOWISE mission, with a focus on the minor planets detected during the mission.

B0.3-0010-18 PLANETARY SCIENCE WITH THE TRANSITING EXOPLANET SURVEY SATELLITE (TESS)

Elisa Quintana, elisa.quintana@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States

The Transiting Exoplanet Survey Satellite (TESS) is a NASA-sponsored Astrophysics Explorerclass mission that will perform an all-sky survey to search for planets transiting nearby stars. The primary goal of TESS is to discover planets smaller than Neptune that transit stars bright enough to enable follow-up spectroscopic observations that can provide planet masses and atmospheric compositions. TESS is scheduled to launch in Spring 2018 and will be placed in a highly-elliptical 13.7 day orbit around the Earth. In its 2-year prime mission, TESS will monitor about 200,000 main-sequence dwarf stars with four wide-field optical CCD cameras to detect periodic drops in brightness caused by planetary transits. Photometry of these pre-selected targets will be recorded every 2 minutes. TESS will also obtain full-frame images (FFIs) of the entire, four camera field-of-view (24 x 96 degrees) at a cadence of 30 minutes to facilitate additional science. The TESS Mission will have a robust Guest Investigator (GI) Program under which the astrophysics and planetary science community may propose new 2 minute cadence targets and investigations using the 30 minute cadence FFI data. TESS GI awards will enable science in exoplanet, stellar, extragalactic, and solar system science (including solar system planets, asteroids and comets). I will present a post-launch update of the TESS mission and a summary of the approved GI programs, and discuss planned and possible capabilities of TESS during its 2-year primary mission, and potential science for an extended mission.

B0.3-0011-18 SOLAR SYSTEM SCIENCE WITH EUCLID

Benoit Carry, benoit.carry@oca.eu Observatoire de la Côte d'Azur, Nice, France

The ESA Euclid mission has been designed to map the geometry of the dark Universe. Scheduled for launch in 2020, it will conduct a six-years visible and near-infrared imaging and spectroscopic survey over 15,000 deg2 down to VAB 24.5. Although the survey will avoid ecliptic latitudes below 15°, the survey pattern in repeated sequences of four broad-band filters seems well-adapted to Solar System objects (SSOs) detection and characterization.

I will present a study of the impact of Euclid on planetary sciences. For that, I use current census of SSOs to extrapolate the total amount of SSOs detectable by Euclid, i.e., within the survey area and brighter than the limiting magnitude. For each different population of SSO, from neighboring near-Earth asteroids to distant Kuiper-belt objects (KBOs) and including comets, With current survey design, about 150,000 SSOs, mainly from the asteroid main-belt, should be observed by Euclid. These objects will all have high inclination, which contrasts with many SSO surveys focusing on the ecliptic plane. There is a potential for discovery of several 104 SSOs by Euclid, in particular distant KBOs at high declination, which will not be covered by LSST.

I will present the expected Euclid astrometry, photometry, and spectroscopy with SSO properties to estimate how Euclid will constrain the orbits of SSOs, their morphology (activity and multiplicity), physical properties (rotation period, spin orientation, and 3-D shape), and surface composition. Euclid observations, consisting in a suite of four sequences of four measurements, will refine the spectral classification of SSOs by extending the spectral coverage provided by Gaia and the LSST to 2 microns. The time-resolved photometry, combined with sparse photometry such as measured by Gaia and the LSST, will contribute to the determination of SSO rotation period, spin orientation, and 3-D shape model. The sharp and stable point-spread function of Euclid will also allow to resolve binary systems in the Kuiper Belt and detect activity around Centaurs.

In summary, the depth of Euclid survey (VAB 24.5), its spectral coverage (0.5 to 2.0 micron), and observation cadence has great potential for Solar System research. A dedicated processing for SSOs is being set in place within Euclid consortium to produce catalogs of astrometry, multicolor and time-resolved photometry, and spectral classification of some 105 SSOs, delivered as Legacy Science.

B0.3-0012-18 NEW INSIGHTS INTO THE INFRARED SOLAR SYSTEM WITH JWST

Stefanie Milam, stefanie.n.milam@nasa.gov NASA/GSFC, Greenbelt, Maryland, United States John Stansberry, stansber@as.arizona.edu

University of Arizona, Tucson, Arizona, United States Bryan Holler, bholler@stsci.edu

Space Telescope Science Institute, Baltimore, Maryland, United States Heidi Hammel, hbh@alum.mit.edu

AURA, Washington, District of Columbia, United States

The James Webb Space Telescope (JWST) is an infrared-optimized observatory with a 6.5mdiameter segmented primary mirror and instrumentation that provides wavelength coverage of 0.6-28.5 microns, sensitivity 10X to 100X greater than previous or current facilities, and high angular resolution (0.07 arcsec at 2 microns) and low-moderate spectral resolution (R 100- 3000) [1,2]. It offers multiple capabilities through 4 science instruments including: imaging, spectroscopy (slit, IFU, grism/prism), coronography, and aperture mask interferometry. These instruments, along with the telescope's moving target capabilities, will enable the infrared study of solar system objects with unprecedented detail. This presentation features highlights of planned guaranteed time solar system observations with JWST as well as other potential science cases highlighted in a Special Issue of PASP (see [1] and references therein).

B0.3-0013-18 SOLAR SYSTEM SCIENCE WITH WFIRST

James Bauer, gerbsbauer@gmail.com

Department of Astronomy, University of Maryland, College Park, Maryland, United States Bryan Holler, bholler@stsci.edu

Space Telescope Science Institute, Baltimore, Maryland, United States Stefanie Milam, stefanie.n.milam@nasa.gov

NASA/GSFC, Greenbelt, Maryland, United States

NASA's next great observatory, the Wide Field Infrared Survey Telescope (WFIRST), is designed to complement the capabilities of concurrent platforms, such as NEOCam, LSST and JWST, while combining the capabilities of high throughput and high-resolution imaging with a wide field of view. WFIRST will launch in the mid 2020s. Some 20% or more of the observing time has been set aside for a community-based guest observer (GO) program that could address any science topic, and may increase to nearly 100% during an extended WFIRST mission. The GO program and guest investigator (GI; allocated survey science) programs alike can be utilized for an array of solar system science investigations. GI program data may be mined for statistical data of small bodies, particularly main belt asteroids, Jupiter Trojans, and comets. The GO program may be used to search for volatile absorption features on distant surfaces and gas emissions in comets within the 0.6-2.0 µm wavelength region with high spatial resolution. A deep survey with WFIRST could detect objects orbiting at distances greater than 100 AU, a region of the solar system currently beyond the capabilities of any current facilities. We will present the scope of the solar system science capabilities that are achievable with the recently updated design parameters of the telescope.

B0.3-0014-18 PLATFORM CAPABILITIES FOR PLANETARY SCIENCE WITH ASTROPHYSICS ASSETS

James Bauer, gerbsbauer@gmail.com

Department of Astronomy, University of Maryland, College Park, Maryland, United States Stefanie Milam, stefanie.n.milam@nasa.gov

NASA/GSFC, Greenbelt, Maryland, United States Doris Daou, doris.daou@nasa.gov

NASA Headquarters, Washington, District of Columbia, United States

Planetary Science has benefited greatly from observational platforms whose highest priorities have not originally emcompassed the studies of bodies within our solar system. The first meaurements of X-rays from giant planet aurorae and comets, the discovery of comet and asteroid dust trails, and the largest surveys of asteroid and comet diameters were the results of observations using assets originally intended for astrophysical studies. The great observatories, Hubble Space Telescope, Spitzer Space Telescope, and Chandra X-ray observatory, have done a comprehensive array of planetary science investigations, and future assets, such as JWST and LSST, will make further rich contributions. Findings by NASA planetary assessment groups in 2017 encouraged the further use of astrophysics assets by planetary scientists, and the formation and definition of the necessary capabilities for these platforms to support planetary science. To that end, NASA Planetary Science Division has constituted a group to investigate and receive input as to the desired functionalities of future astrophysics assets, with the long-term idea of providing a list of these faculties to inform future missions during the early technical design phases. We will present the progress and preliminary findings from the activities of this group in its efforts to compile a uniform set of basic capabilities and to maximize the yield of Solar System science with future Astrophysics assets while allowing those missions to achieve their Astrophysics priorities.

B0.3-0015-18 OBSERVING THE SOLAR SYSTEM WITH TWINKLE

Billy Edwards, billy.edwards.16@ucl.ac.uk

University College London, London, United Kingdom

Twinkle is a small space telescope conceived to observe spectroscopically hundreds of extrasolar planets over a broad wavelength range. Twinkle will be able to reveal the chemical composition, weather and history of worlds orbiting distant stars. Additionally, the high stability and sensitivity of its instrumentation mean Twinkle could be utilised for observing a multitude of other targets. Twinkle's ability to study Solar System objects has been explored by determining when objects are observable as well as the data quality and resolution obtainable. The targets considered in this work include planets, moons, dwarf planets and asteroids.

It was found that many celestial bodies would have long periods during which they could be observed with observation windows occurring on a periodic basis. Having determined that a target was observable, the SNR for photometric and spectroscopic data was calculated for a given exposure time. For a number of targets, including the outer planets, their large moons and bright asteroids, the model created predicts short exposure times will achieve high quality (SNR > 100), high resolution (R 300, $\Lambda <$ 2.42µm; R 70, $\Lambda >$ 2.42µm) spectroscopic data. For other targets this is found to not be achievable in one observation and thus multiple observations will be required if resolution or data quality cannot be reduced. Very small or distant objects (e.g. the outer dwarf planets, Haumea, Eris) are deemed too faint for Twinkle to obtain photometric or spectroscopic data of reasonable quality (SNR > 10) without requiring large amounts of observation time.

In conclusion, the Solar System is found to be permeated with targets which could be readily observed by Twinkle at visible and near infrared wavelengths.

B0.3-0016-18 INFERRING COMPOSITIONAL INFORMATION OF NEAR-SUN COMETS FROM MULTI-COLOR SOHO LIGHTCURVES

Matthew Knight, mmk8a@astro.umd.edu

University of Maryland, College Park, Maryland, United States Karl Battams, karl.battams@nrl.navy.mil

Naval Research Laboratory, Washington, District of Columbia, United States

Since Solar and Heliospheric Observatory (SOHO) launched in late 1995, more than 3,000 comets have been discovered in its images. The vast majority of these are dynamically related to each other as part of the Kreutz family of "sungrazing" comets and reach perihelion at distances (q) of 1-2 solar radii. Most Kreutz comets are observed for a few hours to days and are destroyed prior to reaching perihelion. The short observing arcs and the comets' low contrast with the sky so close to the Sun generally preclude significant investigations into their compositions.

SOHO's typical observations are made through either a clear or orange filter. Additional color filters are available, but are acquired infrequently. Fortuitously, two bright Kreutz comets have been detected sufficiently early to permit execution of full color sequences during their transit through the SOHO fields of view: C/2011 W3 Lovejoy and C/2012 E2 SWAN. We will report on our analyses of these multicolor lightcurves as a means of inferring compositional information about the comets.

We have developed a model to fit SOHO multi-color lightcurves that incorporates prominent atomic lines (Na, Fe, K, etc.) seen in spectroscopic data of the spectacular Kreutz comet C/1965 S1 Ikeya-Seki, emission features seen in comets at larger heliocentric distances (CN, C2, etc.), and a thermal component due to the extreme heating near the Sun. This allows a cursory inventory of a comets' composition, including estimates of non-volatile metals that are otherwise impossible to constrain without in situ measurements. It may also allow us to probe the extent to which a comets' volatiles have been depleted by previous perihelion passages.

The modeling may yield insight into the scales at which the Kreutz parent comet was heterogeneous. Most Kreutz comets are estimated to be a few to tens of meters in diameter, significantly smaller than estimates for C/2011 W3 Lovejoy. The small Kreutz comets are comparable in size to the boulders observed on the surface of comet 67P/Churyumov-Gerasimenko by Rosetta and the smallest detected fragments of newly split comets, e.g., C/1999 S4 LINEAR and 332P/Ikeya-Murakami. Thus, this study may help to understand the sizes at which cometary fragments are most strongly held together, which may be diagnostic of the characteristic sizes of the planetesimals out of which the bodies in the early Solar System formed.

This work benefited from discussions with the international team "The Science of Near-Sun Comets" led by G. Jones at ISSI (International Space Science Institute) in Bern, Switzerland in 2014-2015. MMK was supported by NASA Outer Planets Research grant NNX13A102G. KB was supported by the NASA-funded Sungrazer Project.

B0.3-0017-18 MONITORING THE EVOLUTION OF COMET 96P/MACHHOLZ 1 FROM ITS LIGHTCURVE

Nora Eisner, neisner1@sheffield.ac.uk

One of SOHO's most surprising comet-related discoveries is the existence of groups of short period comets on low perihelion distance orbits. Two of these groups, the Marsden and Kracht groups, are dynamically related to comet 96P/Machholz 1, an enigmatic object with a perihelion distance of 0.12 AU that makes it unobservable by most Earth-based telescopes around perihelion. Comet 96P has transited the SOHO fields of view during all five of its perihelion passages since 1996, and several faint fragments were observed accompanying it during its 2012 and 2017 apparitions. We report on our analysis of 96P's SOHO lightcurve, its secular evolution over the last 20 years, and on the evidence of ongoing fragmentation that might have produced the new fragments. We also report on our ground-based efforts to characterize 96P using the 4.1-m SOAR telescope. We observed 96P prior to perihelion in July 2017 and have post-perihelion observations scheduled for June and July 2018.

This work benefited from discussions with the international team "The Science of Near-Sun Comets" led by G. Jones at ISSI (International Space Science Institute) in Bern, Switzerland in 2014-2015. NE, MMK, KB, and MSPK were supported by NASA Near Earth Object Observations grant NNX17AK15G.

SPACE STUDIES OF THE EARTH-MOON SYSTEM, PLANETS, AND SMALL BODIES OF THE SOLAR SYSTEM (B)

THE GOLDEN AGE OF SMALL BODIES, SCIENCE AND EXPLORATION (B1.1)

B1.1-0001-18 ROSETTA AT COMET 67P: DECIPHERING THE ORIGIN OF THE SOLAR SYSTEM, THE EARTH AND LIFE

Kathrin Altwegg, altwegg@space.unibe.ch University of Bern, Bern, Switzerland Martin Rubin, martin.rubin@space.unibe.ch University of Bern, Bern, Switzerland

After more than 12 years the Rosetta spacecraft crash-landed on comet Churyumov-Gerasimenko on September 30, 2016. It has traveled billions of kilometers, just to study a small (4 km diameter), black boulder named 67P/Churyumov-Gerasimenko. The results of this mission now seem to fully justify the time and money spent in the last decades on this endeavor. In the talk I will look back on the craziest mission ever flown by the European Space Agency and point out its technical challenges and scientific highlights. We will show how the results of this mission change our understanding about the formation of the solar system, the Earth and finally life itself.

B1.1-0002-18 CATASTROPHIC DISRUPTIONS AS THE ORIGIN OF 67P/C-G AND SMALL BILOBATE COMETS

Images of comets sent by spacecraft have shown us that bilobate shapes seem to be common in the cometary population. This has been most recently evidenced by the images of comet 67P/CG obtained by the ESA Rosetta mission, which show a low-density elongated body interpreted as a contact binary. The origin of such bilobate comets has been thought to be primordial because it requires the slow accretion of two bodies that become the two main components of the final object. However, slow accretion does not only occur during the primordial phase of the Solar System, but also later during the reaccumulation processes immediately following collisional disruptions of larger bodies. We perform numerical simulations of disruptions of large bodies. We demonstrate that during the ensuing gravitational phase, in which the generated fragments interact under their mutual gravity, aggregates with bi-lobed or elongated shapes form by reaccumulation at speeds that are at or below the range of those assumed in primordial accretion scenarios. The same scenario has been demonstrated to occur in the asteroid belt to explain the origin of asteroid families and has provided insight into the shapes of thus-far observed asteroids such as 25143 Itokawa. Here we show that it is also a more general outcome that applies to disruption events in the outer Solar System. Moreover, we show that the porosity is maintained in the process and high-temperature regions are very localized during the impact process, which solves the problem of the survival of organics and volatiles in the collisional process. The advantage of this scenario for the formation of small bilobate shapes, including 67P/C-G, is that it does not necessitate a primordial origin, as such disruptions can occur at later stages of the Solar System. This demonstrates how such comets can be relatively young, consistent with other studies that show that these shapes are unlikely to be formed early on and survive the entire history of the Solar System. A last implication is that observed prominent geological features, such as pits and stratified surface layers, may not be primordial.

B1.1-0003-18 ON THE ORIGIN OF INTERNAL LAYERS IN COMET 67P/ CHURYUMOVGERASIMENKO

Guided by the results of calculations by Tancredi, Rickman and Greenberg (1994, Astron. Astrophys. 286, 659-682) on the propagation of an amorphous-ice to crystalline phase-change front in an amorphous water-ice simulated comet nucleus, we hypothesize that the strata and intra-strata layers seen in the interior of 67P/ChuryumovGerasimenko are the result of the rapid passage (within 2000 y) of horizontally fronts throughout the interior of the comet during its late stage orbital evolution as a Centaur.

The bi-modal rates of propagation of the fronts (an essentially stationary "quiescent" mode over short radial distances alternating with an "active" rapid spurt mode propagation (100 m/y) over much larger distances) lead to the establishment of alternating strata boundaries and the intra-strata layers. The varied structures found within the strata are the result of different modes of fluidization during the active phase. The independence of the layer systems in the lobes (Massironi and 58 colleagues, 2015, Nature 526, 402-405) is explained by the postulated break-up of the comet from a bi-lobate shape into a close binary configuration at the time of onset of crystallization that weakens the surface. Eventually, the comet returns to a physically connected bi-lobate shape well after the crystallization of the interior is complete. This "phasechange mechanism" may eradicate or overprint evidence in the interior structure of the way the comet was originally formed in primitive times.

The structure and composition of cometary nuclei is one of the major unknowns in cometary science. These were the scientific objectives of the Comet Nucleus Sounding Experiment by Radiowave Transmission (CONSERT) aboard ESA spacecraft Rosetta. The knowledge of the interior is important to understand the formation and evolution of comets. CONSERT was a bi-static radar composed of two parts, one on the lander Philae on the comet's surface, and another on Rosetta spacecraft (Kofman et al., 2007). CONSERT operated during 9 hours after the landing and made measurements through the small lobe (head) of 67P/C-G. The analysis and interpretation have been done using measurements of the propagation time of the signal through the comet, the shape of the received signals and then 3D modeling of the propagation through the comet. The modelling and the propagation time inside the comet permit to derive the bulk permittivity value (= 1.27) of the cometary interior (Kofman et al, 2015). Permittivity values for porous mixture of ices and dusts were compared with laboratory experimental values in order to obtain constraints on the possible constituents of the comet nucleus (ices, silicates and organics) and its porosity (70-85%). The minimum required content of carbonaceous material is 75 % in volume. This suggests that comets represent a massive carbon reservoir (Kofman et al., 2015, Herique et al., 2016). The shape of the signal, very close to the shape of the calibration one, shows that the scattering by inhomogeneities in the medium is not observable. This indicates that the interior is homogenous at the scale of few wavelengths (Kofman et al., 2015). 3D simulations of the signal propagation in non-homogeneous media have been run to define the sensitivity of CONSERT to inhomogeneities and to find constrains on the internal structures in terms of size and composition at a scale commensurate with the wavelength. Given the high bulk porosity of about 75% inside the sounded part of the nucleus, a likely model would be obtained by a mixture, at this 3-m size scale, of voids (vacuum) and blobs with material made of ices and dust with a porosity larger than 60%. The absence of any pulse spreading due to scattering allows us to exclude heterogeneity with higher contrast (0.25) and larger size (3m) (but remaining on the few wavelengths scale, since larger scales can be responsible for multipath propagation) (Ciarletti et al., 2017). Properties of meterscale inhomogeneities inside the comet are essential to understand cometary formation. The knowledge of the precise position of Philae on the comet, since the September 2016, permitted to improve the determination of the propagation paths inside the comet and therefore to describe better the interior. The influence of the close environment on antennas lobes and polarization was calculated using the Digital Terrain Model of the landing site and used to study the received signal power. We will describe shortly measurements that explored the interior of the comet, discuss results, their interpretation in terms of the internal structure and composition. B1.1-0005-18 LARGE SCALE MORPHOLOGICAL CHANGES IN THE HAPI REGION ON COMET 67P/ CHURYUMOV-GERASIMENKO

Bjorn Davidsson, bjorn.davidsson@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

The OSIRIS and MIRO Teams

Seungwon Lee, Jet Propulsion Laboratory, California Institute of Technology; Paul von Allmen, Jet Propulsion Laboratory, California Institute of Technology; F. Peter Schloerb, Univ. Massachusetts; Mark Hofstadter, Jet Propulsion Laboratory, California Institute of Technology; Holger Sierks, Max–Planck–Institut für Sonnensystemforschung; Cesare Barbieri, University of Padova; Samuel Gulkis, Jet Propulsion Laboratory, California Institute of Technology; Horst Uwe Keller, Technische Universität Braunschweig; Detlef Koschny, ESA/ESTEC; Philippe Lamy, Laboratoire d'Astrophysique de Marseille; Hans Rickman, Uppsala University; Rafa Rodrigo, Centro de Astrobiologia, International Space Science Institute; The MIRO Team; The OSIRIS Team

The Hapi region is located on the northern hemisphere of comet 67P/C-G at the neck that joins the two lobes of the nucleus. It primarily consists of granular material that is unresolved at 0.35 m/pixel resolution and that forms a smooth surface with small slopes with respect to local gravity. The OSIRIS cameras on the ESA spacecraft Rosetta observed Hapi regularly since its rendezvous with the comet in August 2014. No changes were seen during the first five months in orbit but on December 30, 2014, two spots appeared in Hapi. Over the course of two months they grew gradually into a 110 by 70 meter shallow depression with a depth of about 0.5 meters. We use OSIRIS observations to characterize the morphology and spectrophotometry of the region. We use measurements of the thermal emission of the comet by the MIRO millimeter and submillimeter radiometer in combination with thermophysical modeling to characterize the surface temperature, near surface temperature gradient, and thermal inertia of the region. The formation mechanism of the depression is discussed in view of these empirical data.

The Narrow Angle Camera (NAC) of the OSIRIS imaging system aboard ESA's Rosetta spacecraft has acquired approximately 25000 images of the surface of the nucleus of comet 67P/Churyumov-Gerasimenko at various spatial scales down to centimeters per pixel. The bulk of these images have been obtained in sequences and the combined displacement of the Rosetta orbiter along its trajectory and the rotation of the nucleus allow associating many pairs of images appropriate to stereoscopic viewing. This is achieved by constructing anaglyphs after rotating the images so that the relative shift appears horizontal. The shift is set to limit the parallax to approximately 2° (with a maximum value of 4°) for the foreground so as to avoid image deformation. A time of writing, approximately 1000 anaglyphs have been produced. In addition to offering spectacular stereoscopic views of the nucleus, these anaglyphs allow studying the topography of the nucleus at spatial scales unachievable by DTMs. Further coupling with spectral images, we have been able to locate ice patches at the bottom of several narrow pits which indicate the presence of sub-surface ice at depths of a few meters. These narrow pits are most likely the sources of collimated jets widely seen in the coma of 67PC-G.

The Rosetta mission and the huge amount of data on the comet 67P/CG has given us the opportunity to test and improve in an unprecedented way the models describing the thermophysical properties of cometary nuclei. Using this kind of models and comparing their results with the observations, it is possible to determine the properties of the nucleus surface and how they change with time, and to infer the conditions of the interior, shedding some light on the formation and evolution processes. In this talk the preliminary results will be shown of the interpretation of the surface temperatures derived from the VIRTIS spectrometer. With the help of the thermophysical model and using a feedback process it is possible to interpret the temperatures derived from VIRTIS spectra in order to determine the amount of ice that is present in the surface layers and its variation along the orbit. It is also possible, using the VIRTIS data, to infer other thermophysical properties of the surface such as the porosity and the roughness. The area on which this analysis has been performed is the Imhotep region, selected for its variety of different terrains and structures and the good and continuous coverage along the time of the mission.

The Rosetta Radio Science Investigations experiment (RSI) determined the mass and the degree and order two gravity field of the nucleus of comet 67P/Churyumov-Gerasimenko after arrival in summer 2014 and again before the ultimate end of the mission in fall 2016. The comparison of the two mass values revealed a substantial mass loss by gas and dust of about 10 million tons. The low bulk density of 537 kg/m3 and reasonable assumptions of the compact dust material density implies a high porosity of about 75% and a high dust-to-ice mass ratio of the nucleus body. The ROSINA and MIRO gas observations, however, integrated over the mission time reveal a mass loss by the gas alone which does not allow a high dust-to-ice mass ratio for the material in space beyond a certain distance from the nucleus where the material does no longer fall back to the nucleus. The dust-to-ice mass ratio must be smaller than 1 in order to agree with the total mass loss determined by RSI. Only a small amount of the lifted mass at an active spot on the surface reaches space. Most of the dust mass falls back and is redistributed on the surface.

The Comet Astrobiology Exploration SAmple Return (CAESAR) mission is one of two mis-sions selected for Phase A study by the NASA New Frontiers Program. CAESAR will acquire and return to Earth for laboratory analysis a minimum of 80 g of surface material from the nucleus of comet 67P/Churyumov-Gerasimenko. CAESAR will characterize the surface region sampled, preserve the collected sample in a pristine state, and return evolved volatiles by capturing them in a separate gas reservoir. NASA Goddard provides project management, systems engineering, safety and mission assurance, contamination control, and mission operations. Orbital ATK develops the spacecraft, based on Dawn mission heritage, which like CAESAR uses solar electric propulsion. Cornell University, under the guidance of Principal Investigator Steven Squyres, manages the science team.

Comet sample analyses can provide unparalleled knowledge about presolar history through the initial stages of planet formation to the origin of life. CAESAR's sample analysis objectives ad-dress questions regarding the nature of Solar System starting materials and how these fundamental components came together to form planets and give rise to life.

The CAESAR Camera Suite enables collection of a sample from the surface of comet 67P. When sampling a poorly-explored or unexplored comet, a substantial payload of instruments would be needed to study the nucleus thoroughly enough to allow wise sample selection. By going to a comet that has already be studied in detail by Rosetta, this need is reduced. The guiding principal of the CAESAR mission is that "it is all about the sample". This guiding principle allows our precious and limited resources to be focused on maximizing the scientific value of the returned sample. A set of six cameras collect images to support sample site selection, optical navigation, and documents the sample before, during, and after collection. The Camera Suite also provides images of the geologic context for the sample and documents changes to 67P since the Rosetta encounter.

CAESAR's Sample Acquisition System (SAS) is specially designed to collect a sample of the surface of comet 67P, based on observation by the Rosetta/Philae mission. It contacts the comet surface during a 5-second touch-and-go (TAG) maneuver, mounted on a three-degreeof-freedom TAG Arm. During surface contact, pneumatic jets direct the sample into a 1.5-liter sample container. Direct imaging of the sample container interior verifies sample collection and a load cell in the TAG Arm measures sample mass. Once successful sample collection has been verified, and while the sample is still cold (< -80 °C), the TAG Arm inserts the sample container into the Sample Containment System (SCS), mounted inside the Sample Return Capsule (SRC). The SCS immediately seals the sample, preventing material from escaping into space.

The SCS then slowly warms the sample from the cold temperatures of the collection to the temperature of the comet surface near perihelion. As gases evolve from the solid sample, they pass from the SCS into a 5-liter passively cooled gas reservoir in the Gas Containment System (GCS), also mounted in the SRC, separating them from the solid sample and thereby protecting the solid sample from alteration. Once H2O has sublimated from the solid sample, the GCS is sealed to capture the volatiles it contains, and the SCS is vented to space to maintain the solid sample under vacuum.

The SRC, which is provided by the Japanese Aerospace Exploration Agency (JAXA), lands at the Utah Test and Training Range (UTTR) and the team places it in cold storage immediately. The team transports all recovered hardware to the Johnson Space Center, where the samples are re-moved and delivered to the dedicated CAESAR curation facility. After preliminary examination, samples are made available to CAESAR science team and the worldwide scientific community.

COSIMA was a Time-Of-Flight Secondary Ion Mass Spectrometer (TOF-SIMS) on board the Rosetta spacecraft [1, 2]. During two years, the instrument allowed in situ analysis of the dust particles released from 67P/Churyumov-Gerasimenko before and after the comet's perihelion.

Compared to the previous space missions targeting a comet, COSIMA collected the cometary dust at a lower impact velocity (<10 m.s–1 [3]) that largely preserved the dust chemical properties and part of its physical structure such as the particle porosity [4, 5]. More than 35,000 particles were collected during the mission [6] and about 400, ranging from 50 to 1000 µm in size, were analyzed by TOF-SIMS.

We will report the elemental composition of the cometary dust as deduced from COSIMA measurements [7, 8, 9]. The average elemental composition measured for 67P's dust will be compared to previous results obtained from the Giotto and Vega missions for comet 1P/Halley and the Stardust mission for comet 81P/Wild 2, to the composition of Chondritic Porous Interplanetary Dust Particles (CP-IDPs), and to the CI chondrite composition. The dust collected and analyzed by COSIMA is representative of 67P's non-volatile composition. The average minerals to organics ratio deduced from the TOF-SIMS measurements gives constraints on 67P's surface and nucleus characteristics. The astrochemical implications of COSIMA results will also be discussed with a focus on the high carbon content found in the cometary dust [7].

The isotopic composition of a substance can provide important information about the substance's history, since isotopic fractionation is sensitive to many conditions such as chemistry, temperature, and radiation. The isotopic ratios of elements have been measured in many extraterrestrial materials, such as chondritic meteorites, interplanetary dust particles, and comets. The great majority of such cometary measurements have been in the gas phase, with relatively few measurements in the dust [1, 2, 3]. Here we present measurements of isotopic composition for several elements measured in cometary dust using the COSIMA instrument.

COSIMA was a Time of Flight - Secondary Ion Mass Spectrometry (ToF-SIMS) instrument aboard the Rosetta orbiter that spent approximately 2 years within tens to hundreds of kilometers of the nucleus of comet 67P/Churyumov-Gerasimenko [4, 5]. COSIMA collected 35000 dust particles and fragments from 67P. Practical considerations restricted the number of particles upon which ToF-SIMS analysis was performed to a few hundred, and a subset of these particles will be discussed here. Comparison to measurements of the isotopic composition of other extraterrestrial matter will be made and the implications for the history of comets will be considered.

To interpret Grain Impact Analyser and Dust Accumulator (GIADA) data, we performed dust dynamical numerical simulations with both spherical and non-spherical (spheroids) shapes. This allowed us to analyse how the grain nonsphericity affects the data interpretation. We considered two GIADA observational periods, 19- 27 February 2015 and 13-28 March 2015. Gas parameters of the coma gas field were calibrated with ROSINA measurements. The dust grains are assumed to be out of the near nucleus coma, i.e. where the gas velocity is radial and constant, therefore were either aligned or have random but constant orientation with respect to the gas drag.

We reproduced the terminal velocities, in agreement with the GIADA measurements, using two different spheroidal shapes and spheres. We obtained: 1) that the dust particle shapes which reproduced best the GIADA dust speeds were consistent with the mass versus cross-section relationship found in the GIADA data; 2) different terminal velocities for spherical and nonspherical particles of the same mass; 3)rotational frequencies of the spheroidal particles that best fit the GIADA measurements in these periods.

This research has recently been published (Ivanovski et al. MNRAS 469, S774-S786 (2017) doi:10.1093/mnras/stx3008).

In August 2014 the ESA Rosetta space probe approached less than 100 km to the nucleus of comet 67P/Churyumov-Gerasimenko (67P), when it was at 3.00 AU from the Sun. During the following several months it gathered information on the dusty-gas atmosphere in the immediate vicinity of the nucleus.

We describe the models developed to predict the gas and dust environment of comet 67P and their methods of adjustment to the observational data obtained by Rosetta before its lander Philae landed on 67P surface.

Ideally speaking, the optimization of the gas model would have resulted from a succession of predictions of the local gas parameters along optimal Rosetta trajectories, as well as of the gas parameters inside the field-of-view of the remote-sensing instruments, followed by the comparison with the in-situ and remote-sensing instruments data. This turned out to be impossible for many reasons. Actually, predefined Rosetta trajectories and instrument view directions turned to be non-optimal for adjusting the model parameters. Therefore, we focused on: (1) fitting the measurements performed by the Rosetta Orbiter Spectrometer for Ion and Neutral Analysis (ROSINA - Balsiger H., et al., Space Sci. Rev., 128, 2007) with the gas model, and (2) fitting the dust coma images acquired by the Optical, Spectroscopic, and Infrared Remote Imaging System (OSIRIS - Keller et al., Space Sci. Rev., 128, 2007), taking into account the dust size distribution (Fulle et al., ApJ, 821, 2016) obtained by the Grain Impact Analyser and Dust

Accumulator (GIADA - Della Corte et al., J. Astron. Instrum., 3, 2014), with our dust model. We present the resulting distribution of gas and dust fluxes over 67P surface.

ESA's Rosetta spacecraft had the unique opportunity to be in the vicinity of comet 67P/ChuryumovGerasimenko for 2.5 years, observing the regions of the coma within a few km of the surface and to study the dynamical and physical properties of the emitted dust. In this work, we will present a summary of the dust coma investigations during the pre-perihelion and the perihelion passage, performed by the Visible InfraRed Thermal Imaging Spectrometer (VIRTIS) onboard Rosetta, in the spectral range between 0.2 to 5 m (Coradini et al. 2007). During the pre-perihelion period, the main dust results can be summarized as follows: 1-The general spatial distribution of the dust is strongly correlated with the presence of H2O emission and is significantly different from the distribution of CO2 emission; 2-The sunward radial profiles of the dust show that the dust particles, lifted off the nucleus, are accelerated by the gas in the first 4-5 km and then transit into the free flowing collision-less zone with a 1/ column density profile, where is the distance from the center of the comet; 4- The colour of the dust in the coma has a fairly steep red slope in the VIS of about 9 to 12 ± 1 % per 100 nm and a much shallower slope in the IR with values of 1.7 ± 0.2 % per 100 nm. The colours do not show any spatial variation, nor any variation with distance from the nucleus. This indicates that the dust expelled into the coma from the nucleus is quite uniform, although it could also be that any changes in its composition (Rinaldi et al. 2016). 5- Combining the VIRTIS data with those by GIADA, the dust detector onboard Rosetta, we evaluate the dust size distribution power-law index that is greater than -3.1. This index matches the one determined using GIADA (Della Corte et al. 2016) March 2015 data indicating that the inner coma radiance is dominated by particles larger than 10 m (Rinaldi et al. 2017). During the perihelion period, we focused on the analysis of the outburst events. The outbursts are characterized by a sudden and short increase of the dust emission, from localized areas with variable degree of collimation, followed by a gradual decrease of activity with a life time ranging between 6 to 24 minutes. The quick onset is correlated with a change of the visible dust colour from redder with 15-18 ± 3 %/100 nm, to bluer with values around 7-10 ± 0.3%/100 nm (Rinaldi et al. 2018, in preparation). The combination of VIS and IR dust properties reveals the presence of very small (less than 100 nm) and bright grains in the ejecta that could be formed by silicate material, implying the thermal degradation of the carbonaceous material, or icy grains (Bockelée-Morvan et al 2017). The dust coma from the outburst was found to expand at speeds between 22.2 ±2.2 to 30.2 ±

1.4 m/s for the "big" outbursts and 38.4 ± 2.1 to 64.9 ±10.6 m/s for "mini" ones. The total ejected mass during an outburst event is estimated to lie between 100 to 6000 kg for a duration of 6 - 24 minutes, assuming a size distribution indexes between -2.5 to -3 (Rinaldi et al. 2018, in preparation).

Rosetta noindent From August 2014 to September 2016 ESA's Rosetta spacecraft escorted comet 67P/Chury-umov-Gerasimenko (hereafter 67P) on its journey into the inner solar system and out again. The mission provides, via various dust and gas instruments, unprecedented data on the nature of cometary activity. The determination of the activity distribution on the surface of a comet is a key goal of any mission to investigate the interaction of the comet with the Sun.

noindent As the ice sublimates the gas expands into space it fills the near-nucleus environment. Individual sources of activity have been observed on the surface but it remains uncertain where the bulk of the mass is lost and how the processes that are involved work in detail. There are several reasons for this. First, imaging experiments use the dust as a proxy for the gas activity. Because the optical depth of the dust is orders of magnitude below 1 in all but a few cases, it is not possible to trace dust filament back to the source against the backdrop of the illuminated surface. Second, remote sensing instruments detecting gas emission (i.e. infrared and sub-mm spectrometers) may suffer with limited spatial and temporal resolution. In addition, the spectra lines may be optically thick and the line-of-sight direction usually cuts through inhomogeneous coma (in density or temperature) which further complicates their interpretation considerably. However, as we will show, with good a-priori estimates of coma structures spectral lines can be accurately inverted to provide constraints of the gas coma down to a few hundreds of meters above the surface (e.g. MIRO). The in-situ instruments (e.g. ROSINA, or GIADA) must consider possible biases due to the spacecraft position relative to the nucleus and respective illumination conditions on the surface. For instance, the frequent use of terminator orbits by Rosetta introduced a significant problem because the measured local densities are at points remote from what we assume to be the main direction of outflow, namely near the sunward direction. In addition, the possible inhomogeneities of the outgassing at the surface cannot be detected due to the fact that the rapid gas expansion smoothens the coma. Therefore, measurements taken tens of kilometers above the nucleus surface are rather insensitive and provide only ambiguous results.

noindent The difficulties described above show the need for predictive models that can reproduce multiple measurements in one self-consistent framework. We will present results from our study of diverse Rosetta data sets (including OSIRIS, VIRTIS, MIRO, and ROSINA), constraining the gas emission into the coma and to establish whether the data enable us to reach appropriate conclusions on the activity distribution on the nucleus surface. The models can be used on the one hand to constrain certain properties of the activity and on the other hand they provide clues on the limits of the interpretations of some of the available datasets. We focus here on the time around May 2015 (equinox). While this period is a few months prior to perihelion, the spacecraft was close to the comet, providing a relatively high spacial resolution of the remote sensing observations such that, in principle, they can be more easily linked with the in-situ measurements.

noindentbf Acknowledgement noindent The team from the University of Bern is supported through the Swiss National Science Foundation, and through the NCCR PlanetS. noindent This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 686709 (MiARD project, www.miard.eu). The european Rosetta mission expands upon results of previous missions to comets with the significant improvement of long-term observations. Its two-year mission allows for a detailed study of the evolution of the cometary plasma environment and its dependence on cometary activity as well as solar wind parameters. There have been several previously unobserved features, like low-frequency waves and atypical draping, that have been found to depend heavily on cometary activity. Some features only exist at specific activity levels and others change with it. Here we present a general overview of the magnetic field evolution and the occurence of features such as the diamagnetic cavity as dependent on the outgassing rate. It is found that the classical picture of magnetic field lines draping around the comet is only valid in a very small time interval around the comet's closest approach to the Sun. Further out the draping changes to a kinetic regime and vanishes entirely at large heliocentric distances. However, the magnetic field is often dominated by large scale ($\Delta B/B$ 1) fluctuations which are related to the diurnal variations in outgassing rate. Contrary to that the field strength is primarily given by the solar wind conditions.

We report on the observation by the Ion and Electron Sensor (IES) on board Rosetta of energetic (>1 keV) electrons in the plasma environment of comet 67P. Rosetta was 1.8 AU from the Sun and 100 km from 67P at that time (Dec. 3, 2015). Most of the electrons in the cometary coma are expected to be of solar wind or photoionization origin so they should be at much lower energy than this. Although, during the Vega flybys of comet Halley, 1keV electrons were observed and these have been explained as having been accelerated by lower hybrid (LH) waves resulting from the two-stream instability involving the solar wind and pickup ion flows. These waves resonate with the cyclotron motion of the ions and the longitudinal motion of electrons. We postulate that the energetic electrons we have observed on Dec. 3, 2015 (and intermittently during the rest of that month) are also the result of such a process and that Landau damping causes the abrupt decrease in this energy (also seen at Halley). Studies using measurements by the Langmuir probe instrument (LAP) on board Rosetta identified occurrences of LH waves with frequency the order of several Hz during October and November 2015 although IES did not see high-energy electrons during those periods. However, we frequently do see electrons accelerated to 100s of eV, which could also be the result of acceleration by LH waves produced under other conditions.

Dawn completed its primary mission, achieving all of its Level-1 requirements, in June of 2016 after spending 7 months in a low altitude mapping orbit (LAMO) at 385 km. NASA approved a one-year extension of mission operations (extended mission 1, or XM1) at Ceres to refine the primary mission data sets and obtain repeat observations to look for surface changes. The objectives of XM1, described below, were achieved with sufficient hydrazine remaining on the spacecraft to support continued operations. In October 2017, NASA approved a second extended mission for Dawn at Ceres (XM2), spanning perihelion passage (April 2018), to obtain new high-priority science data until the spacecraft runs out of hydrazine. The two extended mission phases are described here, as well as the science objectives achieved and planned. XM1 began in July 2016 at the LAMO altitude (385 km), where additional observations were made by the Gamma Ray and Neutron Detector (GRaND) for over 9 weeks to improve counting statistics. At the same time, additional off-nadir imaging was obtained to enlarge the data set used to construct a high-resolution topographic model at 35m/pixel. Additional radiometric tracking data contributed to an increase in the resolution of the gravity field to degree and order 18. High-resolution framing camera (FC) color imaging and visible and infrared mapping spectrometer (VIR) spectra were obtained for several high-priority targets, including Occator crater. Dawn then spiraled up to an orbit at 1500 km altitude, equivalent to the first highaltitude mapping orbit (HAMO) in the prime mission, and obtained full 7-filter color mapping with the FC in the south

polar region. Repeat coverage was obtained over the rest of Ceres to compare to the previous HAMO full-color data set. Infrared spectra of high-priority targets (including Juling and Oxo craters) were obtained, which had proved difficult to capture in LAMO. In the third phase, Dawn spiraled up to an elliptical orbit above 7200 km altitude to obtain GRaND background spectra to improve the signal to noise ration of data acquired at low altitude. In the final phase of XM1, the spacecraft ascended and rotated the orbit plane to perform an opposition observation at 20,000 km. The phase curve was obtained down to 0 degrees in the panchromatic and seven color filters. The spacecraft stayed in a high altitude, hydrazine-conserving orbit to complete acquisition of GRaND background data and monitor for solar energetic particles implicated in sputtering a transient exosphere, while the XM2 proposal was being evaluated. In October 2017, NASA approved XM2 at Ceres with the goal of obtaining elemental concentrations with high sensitivity and spatial resolution. Proximity to the target is key to improving the strength of the gamma ray and neutron signals, as well as improving the ability to spatially resolve the elemental variations. Dawn will enter an eccentric orbit with periapsis lower than 50 km, enabling GRaND to directly measure the elemental composition of surface units with spatial resolution at least 7x better than in LAMO. The measurements will occur during a particularly quiet period of solar activity, ensuring the intensity of galactic cosmic rays, used to interrogate the surface, is maximum. Limited longitudinal coverage will be obtained in a resonant orbit that focuses on coverage of Occator crater and its ejecta, while also characterizing the ancient heavily cratered terrains in the north, and large Urvara and Yalode basins in the south. Combining these very low altitude data with the extended background time series will improve the entire GRaND data set and yield a deeper understanding of surface geochemistry, including the concentration and distribution of subsurface ice, as well as the elemental concentration of the ice-free regolith which provides clues about processes that shaped the regolith, crust, and interior. In the course of achieving the low resonant orbit, VIR observations of the better-illuminated southern hemisphere will be obtained, as well as FC color imaging of high-priority targets to obtain new or repeat coverage. Along with the GRaND results, these data will contribute to the goal of testing hypotheses of Ceres' origin and hydrothermal evolution, as well as understanding cyromagmatic processes. Once the spacecraft runs out of hydrazine, it will lose the ability to maintain the solar arrays pointing to the sun, and the spacecraft will lose power. It will continue to orbit Ceres stably in the eccentric orbit for decades to come in accordance with the planetary protection requirements.

A portion of this work was performed by the Jet Propulsion Laboratory, California Institute of Technology, under contract with NASA.

Before the arrival of NASA's Dawn mission, the dwarf planet Ceres was generally considered to be differentiated, with a thin rocky regolith hiding a water-ice mantle tens of kilometers thick, beneath which lay a rock "core" [1, 2, 3]. Models assuming an undifferentiated porous interior were also consistent with available data [4]. Data returned from the Dawn spacecraft have revolutionized our understanding of Ceres' interior structure, composition, and evolution. Framing camera (FC) images revealed Ceres' surface to be heavily cratered, contradicting expectations of an ice-dominated surface morphology in which crater topography is rapidly muted by viscous relaxation [5]. High-resolution shape

models from Dawn indicate that most large craters (>80 km in diameter) are more than 2 km deep relative to the surrounding terrain [6]. Numerical simulation of the evolution of these craters indicates that Ceres' outer "crust" must contain no more than 35% water ice by volume to preserve the observed crater topography [6]. The pre-Dawn conception of a relatively pure ice layer at depth can therefore be rejected. Yet the crust is unlikely to be ice-free. Analysis of latitudinal variations in the topographic power spectrum at low spherical harmonics indicates that power is lower at low latitudes than at high [7]. Thus, viscous relaxation is, in fact, occurring at long wavelengths (>246 km) [7, 8], implying that the viscosity of Ceres' crust is not rock-like. These observations are consistent with Gamma Ray and Neutron Detector (GRaND) measurements of 20% water ice by volume in the top few meters of regolith at high latitudes [9], Visible and Infrared Spectrometer (VIR) detection of small amounts of exposed water ice on Ceres' surface [10], and crater simplecomplex transition diameters similar to icy bodies [11].

Additional constraints on the interior were provided by Dawn's characterization of Ceres' gravity field and shape [7, 12, 13], which indicate that Ceres' is slightly denser than previously inferred (ρ = 2.162 0.008 g/cc) and at least modestly differentiated (normalized mean moment of inertia of C/MR2 = 0.37). Admittance analysis suggests Ceres' outer crust is 40 km thick, with a density of just 1.2-1.4 g/cc, depending on the isostatic model [7]. The deeper interior has a density of 2.4 g/cc [7, 14]. The combination of the low density and high viscosity of the crust places constraints on its bulk composition, which cannot be a simple combination of ice and hydrated silicates. Instead, a significant fraction of the crust (at least 30% by volume) must be one or more strong, but low-density phase, such as salts or clathrate hydrates [5, 7, 8]. The bulk composition of Ceres' crust, which is roughly 33% water ice, 33% salts/clathrates, 33% hydrated silicates (a range of compositions are possible - the fraction of salts determines the amount of silicates) may result from the freezing of a past ocean [15].

In addition to revealing these bulk interior properties, Dawn data has shown that Ceres' crust is heterogeneous over large spatial scales [e.g., 16, 17]. The thickness of Ceres' crust is variable, and several mass anomalies have been identified in association with geomorphic features [7]. Such anomalies might suggest compositional variation: a mascon at Ceres' largest crater, Kerwan, has been attributed to volatile loss and densification of the crust during the impact that formed the crater [18]. Ceres' many tholi (mounds) might also result from subsurface flow of lowviscosity material within the stronger crust: a process analogous to salt tectonics on Earth [19]. In these cases, Ceres' internal heterogeneity is directly manifesting itself in its surface morphology. Testing models of Ceres' origin and evolution, and past and present habitability derived from Dawn's data requires understanding the past and present distribution of volatiles within the interior, which only a new mission to the dwarf planet can provide.

Ceres is the largest body of the Main Belt, which is characterized by a huge abundance of water ice in its interior. This feature is suggested by its relatively low bulk density (2162 kg m-3, Russell et al. 2016, Park et al. 2016) and by several geological and geochemical evidences (specific minerals or salts produced by acqueous alteration, icy patches on the surface, lobate morphologies interpretable as surface flows (De Sanctis et al. 2016, Carrozzo et al. 2018, Raponi et al. 2018, Zolotov 2017 and Schmidt et al., 2017). Ceres is partially differentiated as suggested by its normalized moment of inertia, 0.37 (Park et al. 2016). A typical internal structure proposed for Ceres is: a rocky core (300-350 km), an icy (or muddy) mantle (100-150 km) and a rocky crust some kilometers in depth (eg. Mc Cord Sotin 2005, Neveu Desch, 2015). The temperature gradient across the mantle, estimated through numerical modelling (e.g. McCord Sotin 2005, Neveu Desch 2015) would be large enough to initiate a thermal convection in the mantle. Since the mantle is not uniquely defined from a composition point of view, in this work we explore how the composition and, in particular the "degree" of muddiness of the mantle, can influence the characteristic of thermal convection. We also estimate the thickness of the top conductive boundary layer and the mechanical stress, which can cause its deformation.

The dwarf planet Ceres has been intensively studied since 2015, when the NASA Dawn spacecraft entered its orbit and acquired images by means of a Framing Camera (FC) and a hyperspectral Visible and Infrared Mapping Spectrometer (VIR). Reflectance spectra revealed a cerean crust mainly composed of a dark component, mixed with Mg-phyllosilicates, NH4- phyllosilicates and Mg/Ca-carbonates, creating absorption bands at 2.7, 3.1, 3.4 and 4.0 μm [1]. Colour images showed that Ceres is a heavily cratered rocky body, where complex craters with central peaks are observed to be widespread across its surface. Central peaks form when complex craters with a minimum diameter of 25 km [2] are created. They are composed of subsurface material uplifted by the impact [3, 4]. The material composing the central uplift is termed crater central peak material (ccp) and its spectral analysis can provide information about the composition of the Ceres subsurface. Reflectance spectra of 32 ccps are reported in this work. We observed a relation between the ccps' ages and

infrared spectral slope (between 1.2 and 1.9 μm). This is probably related to a fragmentation of the regolith into finer grains or to differences in composition. The mineralogical composition of ccps is similar to that of the Ceres surface. However, some differences can be noted in ccps located at poleward latitudes and in ccps excavated from deeper layers of the subsurface. Ccps located at poleward latitudes show deeper absorption bands at 2.7 and 3.1 μm, suggesting that subsurface deposits closer to poles are richer in Mgand NH4-phyllosilicates. Furthermore, 3.1 μm band depths are deeper in ccps coming from greater depth of excavation, indicating that the abundance of NH4-phyllosilicates increases with increasing depth in the subsurface. Carbonates are globally diffused in Ceres subsurface, since the 4.0 μm band depth does not show a particular trend at different latitudes or with increasing depth of excavation. Na-carbonates are part of the mineralogical composition of Ernutet, Haulani and Ikapati ccps whose excavation depths are between 6 and 9 km.

The Dawn spacecraft [1] arrived at Ceres in early 2015, the second of its targets, and performed a detailed study of its surface and internal properties. Dawn is equipped with a Visible and InfraRed Mapping Spectrometer (VIR) [2] to study the surface composition of the mission targets. The VIR instrument observed Ceres' surface at different spatial resolutions and revealed the presence of different minerals. The average thermally-corrected reflectance spectrum of Ceres shows several bands in the 2.6-4.2 m wavelength region, at 2.72, 3.05-3.1, 3.3-3.5, and 3.95 m. The most prominent is a strong and narrow absorption centred at 2.72-2.73 m indicative of OH-bearing silicates. The other bands indicate the presence of ammonia bearing species and carbonates [3,4,5,6]. The surface is mainly composed of a dark and spectrally neutral component (carbon, magnetite), Mg-phyllosilicates, ammoniated clays, carbonates and salts. The observed species and their distribution suggest endogenous, global-scale aqueous alteration [7]. While mostly uniform at regional scale, Ceres' surface shows localized areas characterized by different chemical species and/or variations in abundances. Water ice was found in localized small patches, especially at high latitudes [8] in the North hemisphere. In a specific crater, not far from the equator in the southern hemisphere [9], water ice was found to varies with time. Sodium carbonates have been identified in several areas on the surface, notably in Occator bright faculae [10,4] and in many of the bright areas that punctuate the surface of Ceres. Organic matter has been discovered in several places, most conspicuously in a large area close to Ernutet crater [11]. The signature is associated to aliphatic organics. Ceres shows mineralogy and geology dominated by the action of water and other volatile ices mixed with rocks. The surface displays clearly the products of aqueous alteration and ice on the surface and subsurface. Moreover, Ceres shows clear sign of “recent” hydrothermal activity [4]. The presence of ammonia in phyllosilicates and salts [3,4,5] indicates the accretion of volatiles, such as ammonia in the original material from which Ceres formed, suggesting a cold formation environment. Moreover, the presence of organic species on Ceres, mixed with minerals formed by water alteration and hydrothermal processes, suggest a favourable environment for the developing of molecules precursor of biological molecules.

When the Dawn mission explored Ceres from 2015 to 2018, it revealed intriguing bright regions inside the 92-km-diameter Occator impact crater, which were named Cerealia Facula and Vinalia Faculae. Here we synthesize together studies that investigate the driving forces behind the formation of Occator and its faculae, which are presented in a special issue of the journal 'Icarus'. Occator's ejecta blanket, terraces and hummocky floor material formed during and/or immediately after crater formation. The lobate material is interpreted as a slurry of impactmelted water, soluble salts and boulders of unmelted silicates/salts that flowed around the crater interior before solidifying. It is suggested that the central pit formed when an initial liquid water central uplift drained into impact induced fractures. The outer edge of Cerealia Facula is interpreted as a residual salt deposit derived from relatively short-lived impact-induced hydrothermal circulation. The majority of Cerealia Facula is located within the central pit, and is thought to have formed significantly later than Occator, from brines derived from a pre-existing reservoir and/or an impact-induced reservoir. A part of the lobate material was likely inflated by cryomagmatic intrusion, giving it a hummocky texture and forming fractures. It is proposed that brines used these fractures to travel to the surface and form the Vinalia Faculae. The central dome is located in the central pit, along with the majority of Cerealia Facula, and was one of the last features to form in the crater. Small, bright impact craters superpose the faculae, indicating that the faculae have slightly darkened from mixing and/or space weathering. Occator's faculae are the freshest endmember of an evolutionary pathway for Cerean bright regions. Unlike Cerealia and Vinalia Faculae, the majority of bright regions on Ceres are formed from re-excavated material. We find that Ceres is an active world where briny liquids have been mobile in the geologically recent past, driven by either entirely impact-derived or impact and endogenic driving forces. Faculae have likely formed throughout Ceres' history, but Occator's are currently striking because they are geologically young. Part of this work was carried out at the Jet Propulsion Laboratory, California Institute of Technology, under contract to NASA. Government sponsorship acknowledged.

We describe the thermal behavior of some notable features, investigated by the Dawn spacecraft on the dwarf planet Ceres, using thermal infrared data acquired by the Visible and InfraRed mapping spectrometer (VIR), and comparing them with the local geology and mineralogy of those areas. Based on experience gained at Vesta, thermal information at unprecedented spatial resolution is useful in constraining thermophysical properties, which ultimately allow a comprehensive interpretation of the observed features. On Ceres, the feature that displays the largest thermal contrast, both on a regional and local scale, is the 34-km crater Haulani, located in the equatorial region and close to the prime meridian. Its central peak, rim and its nearest ejecta appear cooler than surrounding terrains observed under similar illumination conditions and local solar time. While Haulani is one of the youngest surface features of Ceres (<6 Myr), its thermal contrast is not found in other young craters like Oxo, Juling and Kupalo, making it difficult to invoke age and space weathering as the sole reason for this observational evidence. Rather, the characteristics of the impact event that generated Haulani, which triggered hydrothermal activity in the shallow subsurface, could have exposed material with higher density and/or characterized by different thermal conductivity compared to most of the other surface features.

Bright material units were discovered on Ceres by the Dawn spacecraft during approach in early 2015. The brightest cluster of spots is found in the 92-km complex Occator crater. VIR data acquired in the near infrared revealed that Cerealia Facula (the brighest spot) is made up of an outcrop of anhydrous sodium carbonate, which is the solid residue of crystallization of brines erupted from below. Despite their compositional uniqueness on Ceres, Occator's faculae do not show any substantial thermal contrast at spatial resolutions of kilometers down to a few hundreds of meters, suggesting that albedo does not strongly constrain daytime surface temperature on Ceres.

With an average height of about 4 km, Ahuna Mons is the highest mountain discovered on Ceres, believed to be cryovolcanic in origin. A thermal analysis of Ahuna Mons carried out with VIR highlights that the northern flank and the summit of Ahuna could be inherently cooler than the surrounding regions observed at the same local time. Because surface composition is quite homogeneous within Ahuna Mons, this evidence could be related to a different compactness of the surface regolith in these areas.

Dawn/VIR spectra allowed a safe identification of water ice-rich materials on the surface of Ceres. About a dozen of ice-rich units were discovered in as many craters located poleward of 30°, favored by the peculiar local topography, which allows ice to be shielded from direct sunlight for most of the Cerean day. In this respect, crater Juling is particularly interesting since the the extension of its ice-rich unit has been discovered to change with time, suggesting a potential connection with the sporadic emissions of water and hydroxyl observed from space. Because pure surficial H2O ice would sublime under current thermal conditions on Ceres, where daytime surface temperatures span the range 180-240 K, direct thermal mapping enabled by VIR infrared data can put constraints on the ice loss rate of ice-rich materials, helping us to establish their origin.

B1.1-0025-18 ROUGHNESS OF CERES FROM HIGH-RESOLUTION SHAPE MODELS

Anton Ermakov, anton.ermakov@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States
Ryan Park, ryan.s.park@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

The Dawn spacecraft has been orbiting dwarf planet Ceres since March 2015. Images from the Dawn's Framing Camera (FC) have been used to create shape models of Ceres using stereophotogrammetry [1] and stereophotoclinometry [2,3] techniques. These shape models have since been used for orthorectifcation of the FC images and computing photometric corrections [4], conducting local geomorphologic studies [e.g. 5] as well as constraining the internal structure of Ceres [6,7].

The goal of this paper is to characterize the roughness of Ceres topography at a range of scales. We follow the methodology from [8] to compute scale-dependent roughness. First, we compute differential slopes, which are differences of slopes between two (long and short) baselines. The roughness is then computed as the interquartile width (using 25th and 75th percentiles) of the differential slope distribution within a certain area (0.5circ bins in our case). We computed roughness between the following short and long baselines: 246 meters and 574 meters, 574 meters and 902 meters; 902 meters and 1558 meters. These baselines are multiples of 82 meters (or 0.01circ).

Unlike for the Moon or Mercury, the roughness maps for Ceres do not reveal any large-scale dichotomy, such as, for example, lunar highlands versus lunar maria. The roughness is mostly controlled by regional scale geology. We observe that young craters such as Dantu, Occator, Haulani, Ikapati and Azacca are surrounded by ejecta that is than the surrounding terrains, which suggests a high degree of ejecta fluidization. Curiously, this behavior is different from that of lunar crater ejecta. Lunar craters are often surrounded by rings of smoother proximal ejecta, while distal ejecta becomes rougher with increasing distance from the crater [9]. The difference in the ejecta roughness pattern is likely explained by the different target composition. Indeed, it is likely that Ceres' crustal material, which is volatile-rich, could reach low viscosity or even partial melting upon impact heating. Also, contrary to large lunar basins, Kerwan-the largest and oldest confirmed basin-has no distinct roughness signature. On the other hand, the next two largest younger large basins Urvara and Yalode do have roughness signatures. The younger and smaller of the two-Urvara-has a relatively smooth interior, whereas the bigger and older-Yalode-appears rougher than the surrounding terrains.

In summary, the produced maps reveal that roughness of Ceres' topography is mostly controlled by regional geologic processes. The roughness maps can be used to facilitate the mapping of crater ejecta as well as to determine relative surface ages.

We will report about the discovery of a primordial asteroid family in the Main Belt (Delbo et al. 2017. Science 357, 1026), which was created by the impact break up of a parent body 4 Gyr ago or even earlier. The family was identified by our novel method that searches for a correlation between the distance in orbital semimajor axis of its members from the centre of the family and their size (Bolin et al. 2016, Icarus 282, 290). This size-dependent correlation is due to the asteroid mobility caused by the non gravitational thermal force known as the Yarkovsky effect. The dispersion of the distribution of the eccentricities and inclinations of the orbits of the primordial family members suggests that the family formed before the instability of the giant planets. The family spans the entire inner portion of the Main Belt, contains low-albedo objects most of which have physical properties similar to those of carbonaceous chondrite meteorites, and include most low-albedo asteroids in that area previously unlinked to other families. When the members of this and other families are removed from the inner Main Belt, few asteroids remain that cannot be included in any of the presently known families. We interpret these asteroids as the original inhabitants of the Main Belt, i.e. the planetesimals that formed directly from the accretion of the dust in the protoplanetary disk. These objects could be considered as interesting targets of feature space missions devoted to understand the composition of the first minor bodies that formed in our Solar System.

B1.1-0027-18 SPECTRAL OBSERVATION OF VESTA IN THE MID-INFRARED: A PYROXENE RICH FINE REGOLITH

Vesta has been explored and mapped in detail by the Dawn space mission [1]. The measurements obtained by the VIR spectrometer demonstrated that Vesta is the parent body of the HED meteorites [2] and that there are hemispherical variabilities. In this work we present new telescopic observations of the Vesta asteroid made at the Subaru Telescope by using the COMICS IR spectrometer during 2016 and 2017 campaigns. We applied standard data reduction for the Mid-IR telescopic observations and a thermal model has been applied to retrieve the spectral emissivities. We compared our results with previous observations in the mid-IR, i.e. the ISO telescope with ISO-PHOT instrument [3], the Kuiper Airborne Observatory (KAO) [4] and the Palomar observatory in the framework of the MIDAS project [5]. Unfortunately, the KAO data have not been used because they are not reliable [Cohen, personal communication]. Our results, show that the Subaru spectra have a low spectral contrast, with a S/N of 100-300 and show weak but definitely real features attributable to residual Reststrahlen bands and a Christiansen peak. The latter feature is very different if obtained with Subaru or the ISO data (8.52 and 9.08 m) pointing to a pyroxene and olivine composition, respectively. As matter of fact, olivine is very rare on Vesta and its low abundance [6,7] cannot account for the presence of a Christianesen peak located a that wavelenghts. Nonetheless, the ISO spectrum seems to exhibit other weaker features similar to the Subaru's one. The more robust comparison is with MIDAS observations that similarly to the Subaru spectra, present an emissivity with very low spectral contrast and show at least two weak residual Reststrahlen pyroxene features. However the Christiansen feature in the MIDAS observations is not clear. The footprint of the Subaru spectra point at different location on the surface of Vesta and they show a little variability confirming a light hemispherical differentiation. Finally, our results seem compatible with the presence of pyroxene minerals and a fine grain regolith.

Binary near-Earth asteroid 65803 Didymos is the target of the proposed Asteroid Impact and Deflection Assessment (AIDA) space mission. The mission concept consists of two spacecraft, the

Double Asteroid Redirection Test (DART) spacecraft that would impact the asteroid's satellite and the Asteroid Impact Mission (AIM) spacecraft that would observe the impact.

We used radar observations obtained at Arecibo and Goldstone in 2003, and lightcurve data from Pravec et al. (2006) to model the shapes, sizes, and spin states of the components. The primary is top shaped and has an equatorial ridge similar to the one seen on 2000 DP107 (Naidu et al. 2015). A 300 m long flat region is also seen along the equator. The primary has an equivalent diameter of 780 m (+/- 10 %) and its extents along the principal axes are 826 m, 813 m, and 786 m (10% uncertainties). It has a spin period of 2.2600 +/- 0.0001 h. A grid search for the spin pole resulted in the best fit at ecliptic (longitude, latitude) = (296,

+71) degrees (+/- 15 degrees). This estimate is consistent with the spin pole being aligned to the binary orbit normal at (310, -84) degrees. Dividing the primary mass of 5.24e11 kg (Fang Margot 2012) by the model volume we estimate a bulk density of 2100 kg m-3 (+/- 30 %).

We summed multiple radar runs to estimate the range and Doppler extents of the satellite. We estimated the motion in successive images and used a shift-and-sum technique to mitigate smearing due to translational motion. This boosted the SNRs and allowed us to obtain size and bandwidth estimates of the satellite. The visible range extent of the satellite is roughly 60-75 m at the 15 m resolution of the Arecibo images. Assuming that the true extent is twice the visible extent, we obtain a diameter estimate of 120-150 m. The bandwidth of the satellite suggests a spin period between 9-12 h that is consistent with the orbit period of 11.9 hours and with synchronous rotation.

The large trans-Neptunian objects with radii larger than 400 km are thought to be in hydrostatic equilibrium. Their shapes can provide clues regarding their internal structures that would reveal information on their formation and evolution. Notably, we model equilibrium shapes of moonless trans-neptunian objects assuming homogeneous and heterogeneous interior models by numerically integrating Clairaut's equations of rotational equilibrium expanded up to third order in the geodetic parameter. Indeed, a level of accuracy better than a few kilometers is required for modeling those objects that are rapid rotators. We show that the difference between the equilibrium figures for homogeneous and heterogeneous assumptions can reach several kilometers for fast rotating and low density bodies. Such a difference could be measurable by ground-based and by space techniques.

B1.1-0030-18 EVIDENCE FOR WATER-RICH EXTRA-SOLAR ASTEROIDS

Boris Gaensicke, boris.gaensicke@warwick.ac.uk University of Warwick, Coventry, United Kingdom

Similar to the Earth, many, maybe most habitable exo-planets are probably born dry, and require the delivery of water to provide the opportunity for life to develop. One possible source of delivering surface water to planets are water-rich asteroids such as Ceres. While studying exo-asteroids orbiting main-sequence stars is in its infancy, it has been demonstrated throughout the last decade that the bulk composition of exo-planetary bodies can be accurately measured, in total analogy to Solar-system meteorite studies, from the spectroscopic analysis of white dwarfs accreting debris from tidally disrupted planetesimals. I will discuss the evidence for extra-solar water-rich planetesimals: the water-rich nature of some of these exo-asteroids has been demonstrated through the detection of significant oxygen excess in the accreted material, with respect to the oxygen content expected from metal-oxides. In addition, hydrogen can serve as a long-term tracer of the accretion of water onto white dwarfs as it accumulates near their surface, and I will present statistical evidence that a significant number of old, evolved planetary systems still contain water-bearing planetesimals.

B1.1-0031-18 ASTEROID INTERIOR AND REGOLITH STRUCTURE: TWO RADARS FOR A DIRECT OBSERVATION

Alain Herique, alain.herique@obs.ujf-grenoble.fr

Institut de Planétologie et d'Astrophysique de Grenoble (IPAG), Grenoble, France Wlodek Kofman, wlodek.kofman@univ-grenoble-alpes.fr

Institut de Planétologie et d'Astrophysique de Grenoble/Univ. Grenoble Alpes, CNRS, Grenoble, France

Dirk Plettemeier, dirk.plettemeier@tu-dresden.de Technische Universität Dresden, Dresden, Germany

Our knowledge of the internal structure of asteroids entirely relies on inferences from remote sensing observations of the surface and theoretical modeling [1]. Is the body a monolithic piece of rock or a rubble-pile, how high is the porosity? What is the typical size of the constituent blocs? Are these blocs homogeneous or heterogeneous? The body is covered by a regolith whose properties remain largely unknown in term of depth, size distribution and spatial variability. Is it resulting from fine particles re-accretion or from thermal fracturing?

After several asteroid orbiting missions, theses crucial and yet basic questions remain open. Direct measurements of asteroid deep interior and regolith structure are needed to better understand the asteroid accretion and dynamical evolution and to provide answers that will directly improve our ability to understand the formation and evolution of the Near Earth Asteroids (NEA), that will allow us to model the mechanisms driving NEA deflection and other risk mitigation techniques.

Radars operating at distance from a spacecraft are the only instruments capable of achieving this science objective of characterizing the internal structure and heterogeneity from submetric to global scale for the benefit of science as well as for planetary defense or exploration. Two complementary radars, operating at different frequencies are needed to meet the objectives requirements [1]. The deep interior structure tomography requires a low-frequency radar (LFR) in order to propagate throughout the complete body and characterize the deep interior: this LFR will be a direct heritage of the CONSERT radar designed for the Rosetta mission. The characterization of the first ten meters of the subsurface with a metric resolution to identify layering and to reconnect surface measurements to internal structure will be achieved with a higher frequency radar (HFR). The design of HFR is based on the WISDOM radar developed for the ExoMars mission. The low and high frequencies radars has been redesigned in the frame of the AIDA/AIM phase AB [2,3] and for HERA/ESA mission. These instruments havee been proposed for next M4 and M5 classes European missions. They are under discussion for future mission like SPS/Jaxa to Jupiter Trojans or Discovery missions.

We will present the rationale of asteroid interior investigation, proposed instruments, performances and science return.

Near-Earth asteroid 2012 TC4 approached within 0.00035 au (6.9 Earth radii of Earth's surface) on 2017 October 12. This was one of the closest near-Earth asteroid encounters known in advance and it provided an outstanding opportunity to investigate this object's physical properties. Here we report radar observations obtained between Oct. 9-14 with the 70 m DSS14 and 34 m DSS-13 antennas the Goldstone Deep Space Communications Complex and with the 100 m Green Bank Telescope. 2012 TC4 has an absolute magnitude of 27, suggesting a diameter within a factor of two of 15 meters. Despite its diminutive size, the flyby was so close that we expected to observe extremely strong radar signal-to-noise ratios (SNRs) that would permit imaging at the highest range resolutions currently attainable at Goldstone. Monostatic detection of the asteroid occurred at DSS-14 (8560 MHz, 3.5 cm) on October 9 but at weaker SNRs than expected, possibly indicating that the diameter was significantly smaller than 15 meters. Monostatic DSS-14 delay-Doppler imaging on Oct. 11 at 3.75 m resolution placed only two range pixels on the object. The highest resolution images were obtained on Oct. 12 when transmissions were at DSS-13 (7190 MHz, 4.2 cm) and reception was at Green Bank. The images achieved a range resolution of 1.875 m/pixel that is the finest ever obtained at Goldsone for any near-Earth asteroid. The images reveal an elongated, angular, asymmetric, and rapidly rotating object and place lower bounds on its long and intermediate axes of about 6 x 12 meters. The rotation evident in the images is consistent with the 12 minute period that is prominent in the lightcurves obtained by W. B. Ryan (pers. comm.). The ratio of samesense circular (SC) to opposite-sense circular (OC) polarization, SC/OC, is about 0.6, which probably indicates that this object has an unusually rough surface at decimeter spatial scales. Circular polarization ratios have been obtained for hundreds of near Earth asteroids, and the ratio for 2012 TC4 overlaps the upper end of the values reported for Cand SQ-class NEAs and the lower end for Eand V-class objects. Combined with an effective diameter in the realm of 7-10 meters, the implication is that 2012 TC4 is an optically-bright object. The radar images are suitable for estimation of the 3D shape and spin state, which may have changed due to tides during the extremely close approach. When combined with the area/mass ratio estimated independently from orbit fitting (D. Farnocchia, pers. comm.), the physical model will be used to obtain the mass and the bulk density, information that is generally not available for solar system objects in this size regime.

B1.1-0033-18 GRAVITY FORWARD/INVERSE MODELING OF ASTEROIDS AND SURFACE BOULDERS TOWARD DESIGNING ASTEROID SURFACE GRAVIMETRY

Alexander Braun, braun@queensu.ca Queen's University, Kingston, Canada Oday Dabboor, 16od2@queensu.ca Queen's University, Kingston, Canada Kieran Carroll, kieran.carroll@gedex.com GEDEX Inc., Mississauga, Canada Yaoguo Li, ygli@mines.edu

Colorado School of Mines, Golden, Colorado, United States

Asteroid mass and density distribution are among the most fundamental physical parameters that can contribute towards understanding the origin of the solar system. To date, insufficient information is known about asteroid density and composition. The main techniques utilized for estimating asteroid mass include albedo, photometric, and spectrometric observations. Radio tracking methods have also been used to measure gravitational deflection from orbiting satellites. All of these methods exhibit high uncertainty and low accuracy, in particular for small asteroids. Asteroid surface gravimetry could provide improved measurements of asteroid mass and density distribution. In this study, forward modeling of several asteroid (e.g., Bennu, 25143 Itokawa, 2008 EV5) density models is used to estimate gravity and gravity gradient at the surface. This research aims to quantify the survey requirements for the proposed Gravimetric Asteroid Surface Probe (GRASP) mission. Models of surface gravity from homogeneous and heterogeneous density distributions, including centrifugal acceleration and the effects of surface boulders are studied. Specifically, analysis is conducted on the differences between heterogeneous and homogeneous density models that can be resolved from surface gravity surveys. Results show that boulder effects (volume of 8 m3) on gravity are at the microGal (nanoG) level, which, in principle, are detectable using the latest space gravimeter, however, differences between homogeneous and heterogeneous models impact surface gravity at the milliGal (microG) level. Inverting surface gravity for the boulder mass is not feasible. The gravity differences between homogenous and heterogeneous density distributions are in fact resolvable from surface measurements and inversion models of such data could therefore by used in order to create constrained asteroid density models.

B1.1-0034-18 JAXA/ISAS SMALL BODY EXPLORATION PROGRAM AND MMX

Masaki Fujimoto, fujimoto.masaki@jaxa.jp

Institute of Space and Astronautical Science, Kanagawa, Japan

Ever since the successful return of Itokawa samples back to Earth in 2020, small body exploration including sample return missions has been one of the pillars of the ISAS activities. We have constructed a program for small body exploration which is composed by our L-class missions, M-class missions and participation to grand missions led by foreign agencies (that ISAS cannot afford to lead). The focus as of now is on the small bodies born outside the snow line. The scientific importance of the systematic investigation of these small bodies stems from the idea that they must have played substantial roles in enabling the habitability of our planet, transporting water and other volatiles to the planet was born dry in the inner part of the solar system. MMX, an ISAS L-class mission to be launched in 2024 that will return samples from Phobos, is one of the main constituents of the program. In my talk, I will describe the small body exploration program and put highlight on the MMX mission.

B1.1-0035-18 THE IMPACT OF THE ESA GAIA MISSION IN OUR KNOWLEDGE OF COLLISIONAL FAMILIES

Zoran Knežević, zoran@aob.rs

Serbian Academy of Science and Arts, Belgrade, Serbia

Knowing the asteroid belt is the key to provide a reliable history of our solar system. The main question which has been raised in the last years is: given our available data, does our classification of asteroid into families provide a reliable history of the collisional evolution of our solar system?

We have done huge steps forward, but the real revolution is represented by the ESA Gaia mission. Starting from April 2018, Gaia will provide observations of solar system objects with sub-mas accuracy, completely changing our vision of the asteroid belt.

We present an overview of the main results achieved by the second Gaia data release, focusing our attention especially on cratering families, which are the results of past collisions between asteroids that have produced many small fragments from a large parent body.

We present our classification of cratering families, including their age determination computed mixing dynamical and physical properties that the asteroids share in the same family.

Hayabusa2 is the second sample return mission from an asteroid after Hayabusa mission. The target asteroid is (162173) Ryugu, which is a C-type asteroid. The main science objective is to investigate organic matters and water at the beginning of the solar system. The technological purpose is to maturate the new technology developed by Hayabusa and to develop other new technology for space missions. Hayabusa2 was launched December 3, 2014 by an H-IIA launch vehicle from Tanegashima Space Center in Japan. Just one year later, on December 3, 2015, Hayabusa2 came back to the Earth to execute the Earth gravity assist, which was successfully done and its orbit was changed toward Ryugu. We observed the Earth and the moon by using the remote sensing instruments on board at the Earth gravity assist. Then after three long-term ion engine operations, Hayabusa2 will arrive at Ryugu in June or July of 2018. At first, we will observe Ryugu carefully by using four science instruments (ONC: Optical navigation camera, LIDAR: Lager Altimeter, NIRS3: Near Infrared Spectrometer, TIR: Thermal Infrared Imager) and decide the landing place. Then we will release the lander and rovers, execute touchdown once or twice, and try the experiment of the impactor. Hayabusa2 will leave Ryugu at the end of 2019 and bring back the sample of Ryugu to the Earth at the end of 2020.

B1.1-0037-18 MASCOT ABOARD HAYABUSA2: STATUS OF LANDING PREPARATIONS

DLR - Institute of Space Systems, Bremen, Germany

MASCOT ('Mobile Asteroid Surface Scout') is a 10 kg mobile surface science package on-board JAXA's Hayabusa2 spacecraft, which, by July 2018, will have reached the near-Earth asteroid (162173) Ryugu. MASCOT has been developed by the German Aerospace Center (DLR) in cooperation with the Centre National d'Etudes Spaciales (CNES). The concept of MASCOT is to perform in-situ measurements on the asteroid's surface and to support the Hayabusa2 mission in the sampling site selection. MASCOT is equipped with 4 scientific instruments: a wide angle camera, an IR spectrometer, a radiometer, and a magnetometer.

The data provided by the instruments aboard the Hayabusa2 spacecraft from June till September 2018 will be used to select both, sampling sites for the main spacecraft but also the best landing site for MASCOT. Besides of scientific preferences, the main selection criteria will be illumination (thermal), flight dynamics, visibility from main spacecraft and minimum interference between sampling and landing sites. The landing of MASCOT is scheduled for October 1, 2018.

The paper will give an update of the status of MASCOT operations planning and landing site selection, 3 months before the actual landing.

B1.1-0038-18 THE OSIRIS-REX ASTEROID SAMPLE RETURN MISSION: ANTICIPATING ASTEROID (101955) BENNU

Dante Lauretta, lauretta@lpl.arizona.edu

University of Arizona, Tucson, Arizona, United States Patrick Michel, michelp@oca.eu

Université Côte d'Azur, Observatoire de la Côte d'Azur, CNRS, Nice, France

In May of 2011, NASA selected the Origins, Spectral Interpretation, Resource Identification, and Security–Regolith Explorer (OSIRIS-REx) asteroid sample return mission as the third mission in the New Frontiers program [1]. The spacecraft departed for near-Earth asteroid (101955) Bennu aboard an United Launch Alliance Atlas V 411 evolved expendable launch vehicle at 7:05 p.m. EDT on September 8, 2016, on a seven-year journey to return samples from Bennu. The spacecraft is on an outbound-cruise trajectory that will result in a rendezvous with Bennu this fall. The science instruments on the spacecraft will survey Bennu to measure its physical, geological, and chemical properties, and the team will use these data to select a site on the surface to collect at least 60 g of asteroid regolith. The team will also analyze the remotesensing data to perform a detailed study of the sample site for context, assess Bennu's resource potential, refine estimates of its impact probability with Earth, and provide ground-truth data for the extensive astronomical data set collected on this asteroid [2].

The spacecraft will begin observing Bennu in August 2018, when the asteroid is just bright enough for detection by the PolyCam long-range imager. These first science observations mark the beginning of asteroid proximity operations. The Approach Phase will be followed by Preliminary Survey, which consists of a series of hyperbolic trajectories that cross over the North and South poles and the equator at a range of 7 km. After this phase, the spacecraft will be placed into a 1.5-km orbit, beginning the Orbit-A Phase. In this phase the spacecraft enters into a gravitationally bound orbit about the asteroid. The characterization of Bennu begins in earnest with the Detailed Survey Phase, which requires multiple hyperbolic passes of Bennu to obtain the wide range of viewing angles necessary to characterize the asteroid's global properties. At the end of Detailed Survey, the spacecraft will enter a close orbit around Bennu and commence the Orbit-B Phase, with a focus on global mapping of the topography and gravity field of Bennu. The Orbit-B phase will conclude with a down-select to a primary and a secondary sampling site. These two sites will be the target of a series of low-altitude reconnaissance observations. After selection of the primary site, the mission will enter the Sample Acquisition Phase. The mission has adopted a sampling strategy referred to as Touch-And-Go, or TAG.

TAG uses the momentum of a slow, descending spacecraft trajectory to maintain contact with the surface for a few seconds, just long enough to obtain a sample, followed by a controlled back-away burn. The spacecraft will leave Bennu in 2021 and return the sample to the Utah Test and Training Range (UTTR) on September 24, 2023.

[1] Lauretta et al. (2017) Space Science Reviews 212: 925-984. [2] Lauretta et al. (2015) Meteoritics Plan-etary Science 50, 834-849.

B1.1-0039-18 MICRO-IR AND SEM/EDS ANALYSIS OF CARBONACEOUS CHONDRITE METEORITES IN SUPPORT TO NEXT ASTEROIDAL SAMPLES RETURNED CHARACTERIZATION

Fabrizio Dirri, fabrizio.dirri@iaps.inaf.it INAF - IAPS Rome, Roma, Italy

F. Dirri, M. Ferrari, E. Palomba, A. Longobardo, S. Stefani, A. Rotundi

Multiple analytical techniques are generally applied to characterize returned asteroidal and cometary samples, and meteorites [1,2,3]. Waiting for samples that will be returned from primitive asteroids by Hayabusa 2 and Osiris Rex missions [4,5], we applied Infrared µ-spectroscopy (µ-IR), Scanning Electron Microscopy and Energy Dispersive Spectroscopy (SEM/EDS) on three Carbonaceous Chondrite (CC) meteorites. The analysed CCs are: 1) Murchison (CM2 group); 2) NWA8267 (CM2 group) [6]; and 3) NWA2086 (CV3 group) [7]. These can be considered as possible analogues of space mission asteroid targets, i.e. Bennu (B-type) and Ryugu (C-type). A preliminary analysis was performed by using a Stereo Microscope (Leica M205c), equipped with a digital camera, in order to select sample regions characterized by a significant mineralogical heterogeneity. Successively, the same areas have been analysed by means of a µ-IR Microscope in the spectral range 8-14 µm, and by SEM/EDS. Christiansen features and Reststrahlen bands of the main minerals were identified by means of µ-IR technique while chemical information and high-resolution images of the inclusions were identified by using the SEM/EDS. Combining the results obtained applying these two techniques allowed us to determine the mineralogy of the selected regions. The matrix and chondrules of NWA2086 (CV3) meteorite are composed of olivine and Mg-rich pyroxene The Murchison inclusions composition can be ascribed to olivine, hydrates silicates with low amount of sulphides and iron oxide. The NWA8267 analysed region is composed of low-Ca pyroxene and sulphides. In order to have a comprehensive mineralogical framework of meteorite samples, which will support the returned asteroidal samples characterization, we planned to: 1) analyze additional CCs regions of interest by means of the combined analytical techniques; and 2) compare the CCs spectra from 2 to 4.2 µm with C-type asteroids spectra, e.g. 1 Ceres, 10 Hygeia, to find similar spectral features.

B1.1-0040-18 COMETS - HOW LABORATORY EXPERIMENTS CAN HELP TO UNDERSTAND THEIR FORMATION AND ACTIVITY

Bastian Gundlach, b.gundlach@tu-bs.de

Institut für Geophysik und extraterrestrische Physik, TU Braunschweig, Braunschweig, Germany

In the past years, very successful space missions have significantly improved our knowledge of the origin and activity of comets. These space missions have been supported by a variety of different theoretical models and intensive observational campaigns. However, the support from ground-based laboratory experiments has been limited, although they can provide deeper insights into the physics processes driving the activity of comets.

Comets are believed to have formed in the young Solar System by the gentle gravitational collapse of dust clouds, typically consisting of mmto cm-sized aggregates. Due to the nature of this formation scenario, the nucleus is composed mainly of non-volatile dust (the dustto-ice mass ratio is 4-9), with only minor contributions (in mass) by volatiles. The nucleus apparently consists of intact dust aggregates, which have survived the comet formation process, owing to the small impact velocities during the collapse. For most of their lifetime, comets have orbited the Sun at large heliocentric distances so that they remained almost unaffected by solar radiation. However, gravitational disturbances by the giant planets can change their orbital parameters over time and, thus, comets can get closer to the Sun.

In this case, solar illumination leads to the evaporation of water ice and other volatile species and, thus, a volatile-free dust layer forms, covering the water ice. This desiccated dust layer possesses a low thermal conductivity, a low gas permeability and a very low tensile strength (Pa). As a result, the evaporation of the volatile constituents can lead to the ejection of dust aggregates from the surface. These aggregates are composed of micrometric particles.

Laboratory experiments performed so far were very useful to understand the nature of ice-dust samples under come-tarylike conditions. However, since we have now data from several fly-by missions and more than two years of escorting a comet from the onset of activity throughout the perihelion (activity maximum) and beyond, the picture of gas and dust production has changed. The major changes are 1) that comets can show activity anywhere on their surface,

2) that comets possess a very high dust-to-ice ratio and 3) that cometary surfaces consist of millimeterto centimeter-sized aggregates.

These new insights have changed the requirements needed to carry out state-of-the art comet simulation experiments with realistic sample materials. Thus, a new generation of ground-based laboratory experiments is required to interpret the data gathered by previous space missions (especially by the Rosetta mission) and to support future space missions to comets, or to other icy bodies in the Solar System.

The objective of our laboratory investigations is to investigate the fundamentals of cometary activity, by performing experiments with appropriate comet analogue materials, such as aggregates composed of silicate particles, granular H2O ice and CO2 ice. In order to study the activity of comets in laboratories on Earth, one has to create optimised analogue materials and ensure realistic environmental conditions, in which the samples are studied. In particular, a setup must be designed in which gravity is rendered unimportant. This can be achieved by choosing appropriate aggregate sizes (e.g., smaller than 200 µm in radius) and correspondingly higher gas-production rates (by adapting the temperature of the samples). The ratio between tensile strength of the dust and sub-surface gas pressure can be adjusted to cometary conditions.

B1.1-0041-18 THE DOUBLE ASTEROID REDIRECTION TEST (DART): OVERVIEW AND INVESTIGATIONS

Andrew Rivkin, andy.rivkin@jhuapl.edu JHU/APL, Laurel, Maryland, United States Andrew Cheng, andrew.cheng@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Angela Stickle, angela.stickle@jhuapl.edu

JHU/APL, Laurel, Maryland, United States Cristina Thomas, cristina.thomas@nau.edu

Northern Arizona University, Flagstaff, Arizona, United States Derek C. Richardson, dcr@astro.umd.edu

University of Maryland, College Park, Maryland, United States Olivier Barnouin, olivier.barnouin@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, United States Eugene Fahnestock, eugene.g.fahnestock@jpl.nasa.gov

JHU/APL, Laurel, Maryland, United States Cheryl Reed, cheryl.reed@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, United States

The Double Asteroid Redirection Test (DART) will be the first space experiment to demonstrate asteroid impact hazard mitigation by using a kinetic impactor. At this writing DART is currently in Preliminary Design Phase (“Phase B”), and is part of the Asteroid Impact and Deflection Assessment (AIDA), a joint ESA-NASA cooperative project. The mission is scheduled for its Preliminary Design Review in April 2018, with a transition to Final Design and Fabrication (“Phase C”) afterward.

The AIDA target is the near-Earth binary asteroid 65803 Didymos, an S-class system that will make a close approach to Earth in fall 2022. The DART spacecraft is designed to impact the Didymos secondary at 6 km/s and demonstrate the ability to modify its trajectory through momentum transfer. The primary goals of DART are (1) perform a full-scale demonstration of the spacecraft kinetic impact technique for deflection of an asteroid; (2) measure the resulting asteroid deflection, by targeting the secondary member of a binary NEO and measuring the resulting changes of the binary orbit; and (3) study hyper-velocity collision effects on an asteroid, validating models for momentum transfer in asteroid impacts. The DART Team has identified five broad “investigations” to be addressed by the project: Modeling and Simulation of Impact Outcomes, Remote Observations, Dynamical and Physical Properties, Science Proximity Operations, and Ejecta Dynamics and Evolution.

The DART impact on the Didymos secondary will change the orbital period of the binary by at least 73 seconds, which can be measured by Earth-based optical and radar observations in the post-impact period. The baseline DART mission launches in 2021 to impact the Didymos secondary in 2022 near the time of its close pass of Earth, which enables an array of groundand space-based observatories to participate in gathering data. The AIDA project will provide the first measurements of momentum transfer efficiency from hyper-velocity kinetic impact at full scale on an asteroid, where the impact conditions of the projectile are known, and physical properties of the target asteroid are also characterized. The DART kinetic impact is predicted to make a crater of order 10 meters diameter, depending on target physical properties, but will also release a large volume of particulate ejecta that may be directly observable from Earth or even resolvable as a coma or an ejecta tail by ground-based telescopes.

We will discuss the plans for the DART mission and its investigations.

B1.1-0042-18 THE HERA MISSION: EUROPEAN COMPONENT OF THE ESA-NASA AIDA MISSION TO A BINARY ASTEROID

Patrick Michel, michelp@oca.eu

Université Côte d'Azur, Observatoire de la Côte d'Azur, CNRS, Nice, France Michael Küppers, michael.kueppers@sciops.esa.int

ESA/ESAC, Villanueva De La Canada, Spain Ian Carnelli, ian.carnelli@esa.int

ESA, Paris, France

The European component of the joint ESA-NASA Asteroid Impact and Deflection Assessment (AIDA) mission has been redesigned from the original version called Asteroid Impact Mission (AIM), and is now called Hera. The main objectives of AIDA are twofold: (1) to perform an asteroid deflection test by means of a kinetic impactor under detailed study at NASA (called DART, for Double Asteroid Redirection Test); and (2) to investigate with Hera the changes in geophysical and dynamical properties of the target binary asteroid after the DART impact.

This joint mission will allow extrapolating the results of the kinetic impact to other asteroids and therefore fully validate such asteroid deflection techniques. Hera leverages technology and payload pre-developments of the previous AIM, and focuses on key measurements to validate impact models such as the detailed characterisation of the impact crater. As such, AIDA will be the first documented deflection experiment and binary asteroid investigation. In particular, it will be the first mission to investigate a binary asteroid, and return new scientific knowledge with important implications for our understanding of asteroid formation and solar system history.

The baseline target is the binary near-Earth asteroid (NEA) (65803) Didymos. In particular, its secondary component, called hereafter Didymoon (163 ± 18 m diameter), is the target of the DART mission.

The baseline payload of Hera includes a Framing Camera, a miniaturized LIDAR and for the first time a 6U CubeSat dedicated to asteroid characterization carrying two additional instruments. The spacecraft design allows for 40 kg of additional payload mass. Current options under investigation include the Small Carry-on Impactor proposed by JAXA (a replica of the one on-board the Hayabusa2 mission) and a high-frequency radar for the measurement of subsurface properties. Other options, such as a small lander, can also be considered. A Radio Science Experiment (RSE) will also be performed, which does not involve any additional on-board hardware but only complex on-ground data processing.

Finally, a mission like Hera will certainly fire the imagination of young people and adults, as the science is accessible and understandable to those audiences and is associated with fascinating challenges and goals of planetary defense. The status of the study and payloads will be presented.

B1.1-0043-18 AN OVERVIEW OF THE DESTINY+ MISSION: FLYBY OF GEMINIDS PARENT (3200) PHAETHON AND IN-SITU DUST ANALYSES

Tomoko Arai, tomoko.arai@it-chiba.ac.jp Chiba Institute of Technology, Chiba, Japan The DESTINY+ Team

Masanori Kobayashi, Ko Ishibashi, Fumi Yoshida ,Hiroshi Kimura, Takayuki Hirai, Hong Peng, Hiroki Senshu, Koji Wada, Ralf Srama, Kruger Harald, Junichi Watanabe, Takashi Ito, Katsuhito Ohtsuka, Hikaru Yabuta, Tomoki Nakamura, Masateru Ishiguro, Takfumi Ootsubo, Shinsuke Abe, Mutsumi Komatsu, Keiko Messenger-Nakamura, Scott Messenger, Yasuhiro Kawakatsu, Hiroyuki Toyota, Kazutaka Nishiyama, Takeshi Takashima

DESTINY+ (Demonstration and Experiment of Space Technology for INterplanetary voYage, Phaethon fLyby and dUst Science) is a mission proposed for JAXA/ISAS Epsilon class small program, currently in the pre-project phase (Phase-A) with a launch targeted for 2022. DESTINY+ is a joint mission of technology demonstration and scientific observation. DESTINY+ will conduct a high-speed (33 km/sec), close flyby of Geminids parent asteroid (3200) Phaethon and in-situ dust analyses of interplanetary dust and interstellar dust around 1 a.u. The science goal is to understand the nature and origin of cosmic dust brought to the Earth, in the context of exogenous contribution of organics to the origin of terrestrial life. The mission objectives are two folded: (1) to measure physical properties (velocity, orbit, mass) and chemical composition of dust around 1 au, and (2) to conduct geological observation of Phaethon upon flyby and analyze dust nearby Phaethon. The science observation is conducted with a panchromatic telescopic camera (TCAP), a UV-VIS-NIR multiband camera (MCAP) and a dust analyzer (DDA).

B1.1-0044-18 VISIBLE-INFRARED SPECTRAL CHARACTERIZATION OF 3200 PHAETHON AT ITS CLOSEST APPROACH TO EARTH

Ernesto Palomba, ernesto.palomba@iaps.inaf.it INAF - IAPS Rome, Rome, Italy

Alessandra Migliorini, alessandra.migliorini@iaps.inaf.it INAF - IAPS Rome, Roma, Italy

Chiba Institute of Technology, Chiba, Japan

The asteroid 3200 Phaethon is a peculiar object with a very eccentric orbit with a perihelion located at only 0.14 AU and it has been dynamically associated with the Geminid meteor stream (Gustafson 1989; Williams Wu 1993; Jenniskens 2006, and references therein). Phaethon is a B-class asteroid and it is linked with carbonaceous species and hydrated silicates such as phyllosilicates. Good match of the Phaeton spectra are the aqueously altered CI/CM meteorites (Licandro, 2007) and the CK meteorites (Clark et al. 2010). The asteroid 3200 Phaethon is the target of the Destiny + Space mission, managed by Japanese Space Agency (Jaxa), which will perform a close rendevouz with this asteroid, with the scientific objectives of studying its surface properties and assessing its cometary activity in terms of release of dust and volatiles. The December 2017 Phaethon Earth approach have been a very important event since it was about 10 times closer than any other future approach predicted at least for the next 20 years. In that occasion, we observed the asteroid at the 3.5 mt Telescopio Nazionale Galileo in the spectral interval (0.4-2-5 µm).We obtained three spectra in the Visible from 0.4 to 0.8 µmm, with a strong fringing longward of 0.8 µmm which doesn't allow to use the data between 0.8 and 1 µmm. The spectra are featureless, however, the slope of two spectra agrees well with many previous observations of Phaeton (see e.g. Licandro et al, 2006). One spectra show, instead, a bluer behaviour, similarly to the unique previous observation by Luu and Jewitt (1993). The IR spectrum is almost featureless, with very weak features at the limit of the S/N which at present are under investigation.

OKEANOS (Oversize Kite-craft for Exploration and AstroNautics in the Outer Solar system) is the future mission under study to cruise to the outer solar system using a large-area solar power sail, and to rendezvous with and land on a Jupiter Trojan asteroid for in-depth study there. Jupiter Trojans are the key targets to be explored, because they are mainly volatilerich D/P type asteroids, located beyond the water ice snow line, and possibly originated from the EKBO scattered due to planetary migration. The conditions and materials that were lost in the inner solar system should be preserved there. This mission aims at investigating the origin and evolution of Jupiter Trojans and their materials by direct microscopy and mass spectroscopy of the collected samples. Geologic context of the landing site and the surrounding area will be observed with imaging, NIR and X-ray spectroscopy, and radiometry. The landing site will be selected by global mapping of imagery, NIR and TIR imaging spectroscopy, and ground penetrating radar to understand the global shape, surface geology, mineralogy, degree of hydration, thermo-physical properties, and so on. Gravity (or porosity) and magnetic property of the bulk asteroid to study the interior structure will be also measured by Doppler shifts and magnetic field measurements. Current activity of dust ejection and volatile eruption will be also measured. The details of the mission and instrumentation will be presented.

B1.1-0046-18 LABORATORY ANALOG EXPERIMENTS TO UNDERSTAND THE POSTCOLLECTION ALTERATION OF COMET SURFACE MATERIALS FOR CAESAR

Comet Astrobiology Exploration SAmple Return Mission proposed for New Frontiers 4

The primary goal of the Comet Astrobiology Exploration SAmple Return (CAESAR) mission (Squyres et al. 2018; Hayes et al. 2018) proposed for NASA's New Frontiers 4 program is to bring the first cometary surface materials (dust, organics, and ice) back to Earth for study. This requires storage of the collected solids at temperatures above that of the comet itself during the return voyage and capturing sublimating gases in a separate, cooled container. Warming of the cometary materials in order to drive sublimation could induce changes that are both physical (such as structural changes in the cometary dust grains) and chemical (such as the breakdown or formation of organics or the aqueous alteration of minerals). To prevent such alterations and to interpret the state of the comet surface sample upon retrieval after delivery to Earth, a thorough understanding of the effects on the sample caused by sublimation and exposure to evolved gases is necessary. To this end, we have studied the behavior of H2O transfer under varied conditions of sublimation and collection temperature in an experimental breadboard set-up at NASA GSFC. We have also studied the same process in the presence of a cometary dust analog (fumed silica) in order to determine if any alteration occurs during the exposure to H2O vapor during sublimation. Particles exposed to sublimating H2O were analyzed using scanning electron microscopy (SEM), electron diffraction (EDX), and infrared (IR) spectroscopy. No evidence for alteration was observed. These results will be discussed in terms of their implications for comet surface sample return missions.

Jet Propulsion Laboratory, Pasadena, California, United States

Although comet nuclei appear weak at large scales, the Philae lander first bounced off the surface of 67P, then the MUPUS penetrometer was unable to make its way inside the surface. Both observations suggest the presence of a layer of hard materials at depth. To better understand what this hard layer consists of and how it develops over time, we are developing a new simulation chamber to examine explore correlations between the composition of starting icy comet nucleus analog materials (dust-to-ice ratio, in particular), their thermal properties, their mechanical properties, and their evolution over depth and time. The primary approach is to synthesize porous cometary analogs with a wide range of dust-to-ice ratios, and simulate the variations in insolation they would be subject to along typical Jupiter-Family Comets orbits (scaled to timescales accessible in the laboratory) under high-vacuum conditions using a custom-built lamp with illumination modulation. In this context, "dust" refers to the refractory components of comet nuclei (e.g. silicates, large organic molecules), and "ice" to their volatile components (mostly H2O and CO2 ice in Jupiter-Family Comets). Temperature profiles are measured continuously using a custom-built thermal probe, and 2D time-dependent thermal modeling retrieves the thermal properties and their evolution as function of depth and time.

A custom-built cone penetrometer apparatus measures the strength (resistance to penetration) of the comet analogs at various locations of the sample over the course of each experiment. We will report on the status of development of this new simulation chamber and preliminary results obtained to date.

Previous works based on data provided by the Rosetta/VIRTIS imaging spectrometer demonstrated the occurrence of a water diurnal cycle (De Sanctis et al., 2015) and the occurrence of recently exposed water ice outfalls (Filacchione et al. 2016) on the nucleus of the comet 67P/Churyumov-Gerasimenko well before the perihelion passage. Longobardo et al. (2017) found a systematic 3.2 um absorption band center (shortward) shift following an increase in surface temperature, interpreted as due to cometary activity: high temperatures lead to underlying water ice exposure. In this work, pre-perihelion cometary activity has been further investigated, combining the VIRTIS data with those by GIADA, the dust detector onboard Rosetta. In particular, we considered the measurements performed, from August to December 2014, by two of the three GIADA sub-systems: the Grain Detector System (GDS) and the Impact Sensor (IS). Following Della Corte et al. (2015) we separated the particles in "compact", i.e. high-density particles (IS and GDS-IS detections and GDS isolated detections), and "fluffy" detected as "dust showers" (GDS dust showers), i.e. particles detected only by the GDS and clustered in time (Della Corte et al. 2015; Fulle et al., 2015). A third category is a mixture of the two, detected by GIADA as a compact particle immediately followed by a dust shower (Fulle et al., 2016). For particles detected by both subsystems, velocity, momentum and mass are determined. For particles detected only by the IS, the velocity is inferred by applying an empirical relation (Della Corte et al., 2016). For the third category we assigned a unique velocity given by the compact particle velocity associated with the shower. We retrieved the source region for individual compact particles and for the dust showers coupled with compact particles, assuming a radial trajectory along which the particle: 1) is uniformly accelerated in the first 11 km from the nucleus (i.e. acceleration region, Ivanovski et al. 2017); 2) has a constant speed out of the acceleration region. Our analysis provides the following main results:

1) Good correlation between the two studied categories of particles source regions, i.e. the source of the two different types of particles is likely the same. 2) Correlation between number of particles detected by GIADA and the 3.2 um band shift magnitude observed by VIRTIS in each comet region observed during the considered period, corroborating that the band center shift with temperature is due to the diurnal pre-perihelion cometary activity.

When Rosetta arrived at its target comet 67P/Churyumov-Gerasimenko it first performed a series of distant flybys (100-30 km). During this mission phase the mass of the comets nucleus could be determined by analyzing the RSI radio tracking data. In combination with the volume from images of the OSIRIS camera this resulted in a precise bulk density determination. That already gave first insights into the comets interior structure. The nucleus appears to be a low-density, highly porous dusty body. From bound orbits with distances below 30 km the low degree and order gravity field coefficients could be derived. The gravity field coefficients strongly depend on the nucleus irregular shape and on the interior mass distribution. The shape is very well reconstructed from of the OSIRIS camera images. Various models of the interior nucleus structure and density distributions are used to compute simulated values of the gravity field coefficients. A comparison with the observed coefficients yields the feasibility of the theoretical interior structure. Thus, the gravity field helps constraining models of the internal structure, the composition and also of the origin and formation of the comets nucleus.

The Philae lander on the surface of comet 67P/C-G was finally imaged by the OSIRIS camera onboard the Rosetta spacecraft on September 2, 2016. In this study, we derive an estimate of the mass of the comet from the three CONSERT measurement sequences taken in direct visibility from the lander to the orbiter, and compare it with the mass estimate derived from radio-tracking data of the Rosetta spacecraft from the Earth[1][2]. We also derive updated 3D coordinates for the lander, by taking into account the shape of the comet as a constraint and the 2D a priori coordinates from the OSIRIS images[3].

From August 2014 to September 2016 ESA's Rosetta spacecraft escorted comet 67P/Churyumov-Gerasimenko (hereafter 67P) on its journey into the inner solar system and out again. The mission provides, via various dust and gas instruments, unprecedented data on the nature of cometary activity.

By using state of the art models for the inner gas and dust comae dynamics for the interpretations of Rosetta data sets (e.g. Bieler et al. (2015), Fougere et al. (2016), and Marschall et al. (2016)) we are now able to extend our understanding of the dust emission direction and speed distribution of cometary dust particles. Furthermore the in-situ dust experiments provide data point to determine the dust size distribution (e.g. Fulle et al. (2016), and Merouane et al. (2017)). This expands our knowledge of the dust size distribution we have from other comets (e.g. McDonnell et al. (1987) for 1P/Halley). These results are the basis to determine the trajectories of dust streams within the solar system (e.g. Soja et al. (2015)). Such models can predict the number densities of interplanetary dust particles originating from comets. In this work we will present the effects of our updated input parameters which are informed by

Rosetta measurements on the dynamics of these dust stream. Understanding the dynamics of dust streams is of great importance for our assessment of the risk for interplanetary space craft posed by cometary dust particles. The results of or model can be directly used to estimate this risk by calculating dust impact probabilities.

On 07 June 2016 the Rosetta Ion and Electron Sensor (IES) instrument observed both negatively and positively charged particles approximately 28 km away from comet 67P/ChuryumovGerasimenko. The local He++ energy peak of 1430 eV/e corresponds to the mass-loaded solar wind speed of 371 km/s. At this velocity, the energy-time spectrograms observed negative pickup particles with mass per charge ratios of 1.16 (H-) and 4.12 (He-) between 06:03 and 11:36 UT while the electrons are accelerated to 100s of eV with an energy peak around 200 eV. The IES electron analyzer also indicated charged nanograins a few hours prior to the electron enhancements. A cometary outburst would support the highly localized and temporal nature of these negative particle signatures. Prior to the electron signatures, we found a few probable lower hybrid waves (2 s wave packets) beginning at 5:33 UT. We will investigate whether the lower hybrid waves present

B1.1-0053-18 GRAINS: A NEW NUMERICAL METHOD FOR THE STUDY OF GRAVITATIONAL AGGREGATES

Fabio Ferrari, fabio1.ferrari@polimi.it Politecnico di Milano, 20156, Italy

Michèle Roberta Lavagna, michelle.lavagna@polimi.it Politecnico di Milano, Milano, Italy

The study of small bodies addresses a number of questions relevant for space engineers, planetary scientists and physicists. Near Earth Asteroids (NEA) are a great opportunity for technological and human exploration missions. NEAs can also represent a threat for the planet. The scientific and technological exploitation and the implementation of mitigation actions for hazardous asteroids rely upon our knowledge of their properties. Remote surveys play a fundamental role to estimate asteroid properties, but they can provide very limited information about their internal structure. GRAINS addresses such problem through N-body numerical simulations of gravitational aggregation. This method is suitable to estimate the internal properties of rubble-pile asteroids: gravitational aggregates with very low tensile strength and high level of porosity. The study of aggregation phenomena currently relies on codes optimized for a large number of mutually interacting particles, regardless of their individual shape and rigid body motion. Although not relevant for many applications, this limitation could be relevant for the case of asteroids, as suggested by results of granular dynamics in terrestrial engineering applications. The latter are commonly studied using multi-body codes, able to simulate contact interactions between a large number of complex-shaped bodies, but not suitable for gravitational dynamics. GRAINS is able to joint the advantages of both classes of codes into a single implementation, to reproduce N-body gravitational dynamics between a large number of complex-shaped rigid bodies. In this work, aggregation simulations are presented: favorable conditions leading to the formation of an asteroid are investigated, when starting from a cloud of boulders. The analysis is performed under many degrees of freedom, to include different geometries, physical and dynamical properties of the boulders and final aggregate. The problem to be investigated is twofold: (a) the study of gravitational aggregation dynamics, and

(b) the study of the physical and dynamical properties of the final aggregate. The first aspect includes the analysis and numerical simulation of typical scenarios, for small and medium sized (hundreds of meters) asteroid aggregation, to identify the conditions that lead to the formation of a single or multiple aggregate, or to the dispersion of the particle cloud. The second aspect analyzes the properties of the final aggregate, as a result of the dynamical simulation, which are then studied and classified depending on the initial parameters and simulation scenario.

Preliminary results show good agreement between theory and observation, and confirm the capability of the numerical code to predict natural aggregation phenomena.

B1.1-0054-18 OBSERVATIONS OF H2O EMISSION LINES AT 22235 MHZ OF THE COMET 96P/ MACHHOLZ

Aleksander Volvach, volvach@meta.ua

Crimean Astrophysical Observatory, Yalta, Ukraine Larisa Volvach, volvach@bk.ru

Crimean Astrophysical Observatory, Yalta, Ukraine Svetlana Malashevich, sv.malashevich@gmail.com Crimean Astrophysical Observatory, Yalta, Ukraine

The 22-meter radio telescope of Crimean Astrophysical Observatory has implemented the possibility of carrying out studies of almost all space masers (OH masers, H2O masers, methanol masers, SiO masers), as well as spectral observations in the frequency range from 85 GHz to 115 GHz. These innovations made it possible to begin the study of weaker sources of cosmic maser radio emission including in cometary atmospheres. The observations of H2O emission lines at 22235 MHz of the comet 96P/ Machholz were performed during October 24-31, November 1-5, 2017 with usage of 22-m radio telescope CrAO. Water production rates estimated from intensities of radio and optical lines are compared.

B1.1-0055-18 THE COMPOSITIONAL BEHAVIOR OF THE JUPITER FAMILY COMETS

Kumar Venkataramani, kumar@prl.res.in

Physical Research Laboratory, Ahmedabad, Ahmedabad, India Shashikiran Ganesh, shashi@prl.res.in

Physical Research Laboratory, Ahmedabad, India Umesh Joshi, joshi@prl.res.in

Physical Research Laboratory, Ahmedabad, Ahmedabad, India

The Jupiter family comets 41P/Honda-Mrkos-Pajdušáková and 45P/Tuttle-Giacobini-Kresák were observed using the 0.5m and 1.2m telescopes at the Mount Abu Infra-red observatory(MIRO) during the period of December 2016 to May 2017. The optical spectra of these comets were obtained using the low resolution spectrograph LISA mounted on the telescpoes at MIRO. As expected in the optical region,the comets exhibited a lot of molecular emission bands including CN,C2,C3,CH and NH2. The spatial profiles of some of these molecules were studied using the traditional theoretical model given by Haser. Although, these molecular emission bands are daughter and grand-daughter products, the behavior of their production rates and scale lengths strongly depends on the parent molecules. The parent molecules originate in the subsurface layers of the cometary nuclei. They are influenced by many of the orbital parameters like perihelion and aphelion distances and orbital period, inclination, etc. Both of these low inclination Jupiter family comets have close resemblance (in terms of the above mentioned orbital parameters) to the short-period comet 67P/Churyumov-Gerasimenko studied in detail by Rosetta (few results in MNRAS, Vol. 462, Issue 1, November 2016). Therefore, their study can give vital confirmation on the similarity or otherwise of the Jupiter family comets.

Similar study (Kumar V et al., MNRAS, 2016, 463(2), 2137) has also been done on some of the long period comets like C/2014 Q2(Lovejoy) which had an extremely high orbital inclination of 80 deg (with the ecliptic). Behavior of the different classes of comets gives us an idea of their relative source of origin in the proto planetary disk. Therefore detailed study of the different families of comets will provide information on the homogeneity or heterogeneity of the proto-planetary disk at the early stages of its formation.

This work describes the observations and results from the optical spectrum of the two Jupiter family comets as compared to the longer period Oort cloud comets.

There are numerous debates and models about the source of water and organic compounds on Earth and other terrestrial planets without converging to an agreement. One of the best ways to study this problem is by determining the deuterium-to-hydrogen (D/H) ratios in comets and across the Solar System because there is a gradient in D/H in the solar nebula due to the temperature gradient. The OD/OH in interstellar space measurements is usually around 2×10-5, slightly higher than the Earth's 1.5×10-4 value. The previous notion was that Jupiter family comets (JFC) are formed further away from the Sun, close to Neptune, whereas Oort cloud comets have formed closer in, outside of Saturn. If that proposition is correct, then we should see a trend of higher D/H ratio in JFCs then the Oort cloud comets. This hypothesis, however, is under debate due to mixing values of D/H measurements in JFCs. Our very few cometary D/H measurements suggest a wide range of D/H ratios in the water within Jupiter family objects and preclude the idea that this reservoir is solely composed of Earth ocean-like water. We need not one, or two but several measurements of many comets, as well as observations of many comets over the period of their orbit around the sun and preferably data from the same comets over multiple orbits before we can apply statistics and improve our ability to distinguish between different scenarios. It is not possible to get such statistics using in situ measurements, such as mass spectrometers, and the current remote sensing high spectral resolution spectrometers require large aperture space-born telescopes that can't be solely dedicated to cometary studies. We are proposing to take advantage of a novel technique, Spatial Heterodyne Spectrometer (SHS), to survey cometary D/H at 308 nm. SHS is a high throughput, a reflective two-beam cyclical interferometer that can obtain high spectral resolution spectra (R 100,000) from a narrow bandpass in VIS to UV in a miniaturized format using small aperture telescopes. A key advantage comes in achieving high sensitivity observations using small (<0.5m) aperture telescopes in a dedicated SmallSat. Using SHS in a low cost

(<50M)Small Satina polar orbit around the Earth, SHS will enable us to survey cometary D/Hratiosinmany

B1.1-0057-18 ON THE EXISTENCE OF GROUPS OF METEORITES AND METEORITEPRODUCING METEOROIDS IN ORBITS OF JUPITER FAMILY COMETS

Natalia Konovalova, nakonovalova@mail.ru

Institute of Astrophysics, Tajik Academy of Sciences, Dushanbe, Tajikistan

The possibility of existence of groups of meteorite-producing meteoroids which associate with six known ordinary chondrite meteorites was analyzed. The IAU Meteor Database of Photographic orbits and the other published sources have been used to search for possible groups of related known meteorites and meteorite-producing bolides for which can believe that any bolides survived the atmospheric encounter. A comparison of the orbits of meteorite-producing fireballs with each other and with orbit of known meteorite was carried out. Three criterions of orbital similarity known as DSH criterion Southworth and Hawkins, DDr criterion Drummond and DN criterion Jopek have been used to suggest that this is the group of related bodies. In result six identified groups comprising a total of 95 meteorite-producing meteoroids associated with six known ordinary chondrites were found. The geocentric radiants and orbital elements of meteoroids confirmed sporadic nature and orbits of Jupiter family comets (Tj 3.1) of these events. On the calculated value of the aerodynamic pressure at the height of maximal brightness the bulk densities of studied meteoroids were estimated. As result a value of bulk densities of meteoroids about 1070-1250 kg m-3 were obtained and suggested the carbonaceous composition of meteoroids in these groups. Gravitational perturbations as well as the rotational instability, the impact ejection and thermal fracture of parent bodies of groups of meteorite-producing meteoroids cause to shatter into numerous fragments of different sizes. The resulting fragments form a group of bodies with almost identical heliocentric orbits, which then gradually move towards to Earth-crossing orbit due to orbital resonance with major planets, especially with Jupiter. In groups still can contain potential meteorite-producing meteoroids and this must lend some support to purposeful monitoring of potential members of groups in the identified periods of increased fireballs and meteorites activity by means of both of land fireball network and space tools established on orbital satellites is important for the prevention of danger to the Earth.

B1.1-0058-18 DEVELOPING A GENERAL UNDERSTANDING OF THE EVOLUTION OF COMETARY LANDSCAPES THROUGH NUMERICAL SIMULATIONS

Comets, remnants of the formation of our solar system, typify the remnant, unprocessed materials from which all the larger planets were constructed. Consequently, they represent a window into the initial conditions that proved favorable for the formation of the Earth and life as we know it. With Rosetta's rendez-vous of comet 67P/Churyumov-Gerasimenko (67P) in the summer of 2014, we now have a dataset that permits access to the spatial scales where the processes relevant to small body evolution can be directly observed. These observations have allowed for detailed analyses of morphologies down to the meter scale across the entire nucleus, and have provided a long temporal data set with which to search for changes on the surface, important observations that have given us the opportunity to watch how a comet erodes.

Changes on the surface are driven by outgassing from sublimation of near-surface volatiles, and are expressed on the surface in two forms: large-scale changes to the bulk nucleus via cliff collapse, and small-scale changes contained within the smooth terrain regions that blanket much of the northern hemisphere. Large-scale failure of cliffs generates low thermal inertia, volatile-depleted regolith that acts to slow further bedrock sublimation, allowing for the surface of 67P to retain its relatively primitive topographic form to the current day. Yet, despite their brittle appearance in Rosetta images, with boulder deposits at their base suggestive of mass wasting, there is little evidence of substantial topographic evolution of the cliffs after 67P's perihelion passage. Most changes were within the smooth plains deposits, with only a few observations of cliff failures. As such, we have no knowledge, of the frequency of mass wasting events and how much material may be expected to be removed in any given event.

Numerical landscape evolution modeling offers the possibility to tie Rosetta's many observations to the fundamental physics that drives these processes, and ultimately determine whether 67P evolves gradually, through its jets, or stochastically through large outburst events. Specifically, we utilized the MARSSIM landscape evolution model, which accounts for the thermophysical weathering of a bedrock composed of both volatile and non-volatile materials on a low, variable gravity environment like on 67P. Unlike for other planetary bodies, our simulations use realistic inputs as to the volatility and strength of the bedrock, and insolation rates and initial topography as measured by Rosetta.

Our simulations are designed to test over what time scale(s) 67P's topography evolves, and in what manner (i.e. does the surface erode gradually through its jets, or are sudden, chaotic events the dominant means by which the topography is formed)? These simulations, therefore, allow us to constrain the rates of landscape evolution and the total erosional exhumation on 67P, to directly answer the question as to how its surface evolved despite the current apparent low levels of observed activity. Accordingly, we assess the question of whether 67P's northern hemisphere terrains are primitive or not, and compare directly the erosional processes observed on both 67P, but also erosional processes observed on comets 81P/Wild 2, 9P/Tempel 1 and 103P/Hartley 2. Further, we combine a robust study of transient changes in the smooth regolith terrains, which are expressed as pits, to better constrain both the evolution of this vast smooth regolith cover, and of the volatiles embedded within the near-surface of 67P.

B1.1-0059-18 PLASMA WAVES IN COMETS

Vipin K Yadav, vkyadavcsp@gmail.com

Vikram Sarabhai Space Centre, Trivandrum, India

Plasma waves are a unique feature of space plasmas and have a universal presence in our solar system - planets, some of their satellites and interplanetary medium (IPM) where electrostatic and electromagnetic plasma waves are observed. The plasma environment of Sun also supports the generation of some plasma waves such as Alfven waves which travels a long distance in heliosphere. Plasma waves are predicted to exist in interstellar medium (ISM) and are also believed to exist in many other natural plasma systems such as pulsars, quasars and galaxies.

The plasma environment around a comet is also capable of sustaining plasma waves. Some of these waves are observed in comets Giacobini-Zinner, Halley, Grigg-Skjellerup and Borrelly. Some other comets such as Hyakutake and 67P/ Churyumov-Gerasimenko are also supposed to sustain plasma waves but are yet to be observed. This paper presents a brief review on the plasma wave observations in cometary plasma environment carried out so far and some of its unresolved issues.

B1.1-0060-18 RELATIONSHIP BETWEEN THE FORMATION OF THE ANOMALOUS TAIL OF COMETS WITH METEOROID SWARMS

Abduljalol Safarov, aj_safarov@mail.ru

Tajik National University, Dushanbe, Tajikistan

Of the 80 comets having anomalous tail, it detected 24 comets, which is associated with meteor showers. About 20 comets, observed a significant transient nuclei activity, are able to generate meteoroid swarms that do not intersect the Earth's orbit. It determines the minimum time of formation of the closed meteoroid swarm of comet 6P/d'Arrest, 10P/Tempel 2, 19P/Borrelly, 34D/Gale, 67P/Ch-G and D/1894 F1. It turned out that the most rapidly meteoroid swarm formed from comets 19P/Borrelly, 34D/Gale, 67P/Ch-G, 6P/d'Arrest, D/1894 F1 and 10P/Tempel 2. Time meteoroid swarm formation depends on the velocity of ejection of dust particles comet. This must be taken into account in the preparation of space missions beyond Earth orbit.

B1.1-0061-18 DYNAMICS OF LANDSLIDES ON AN ASYMMETRIC COMET

Leszek Czechowski, lczecho@op.pl University of Warsaw, Warszawa, Poland Konrad Kossacki, kjkossac@igf.fuw.edu.pl

University of Warsaw, Institute of Geophysics, Warsaw, Poland

The phenomenon of landslide is a form of the gravity movement. They play important role in the overall process of erosion on terrestrial planets. Comets and other small celestial bodies have very weak gravity field, so it is believed that probability of such motion is very low. However, data from space missions to comets 9P/Tempe 1 and 67P/Churyumov-Gerasimenko revealed existence of landslides. The causes of landslides are usually related to instabilities of slopes. It is often possible to indicate a few causes of the landslide. Causes are the factors responsible for making the slope unstable. Usually only one factor is a trigger. For terrestrial landslides several causes are usually considered, e.g.: (1) the pressure of water in pores acts usually to destabilize the slope, (2) acceleration of ground motion resulting from earthquakes or impacts, (3) liquefaction of saturated soil, whereby the soil loses its strength in response to an applied stress.

Some of these factors could also trigger the motion [1]. Note that on comets, instead of liquefaction, one can expect fluidization when gas and solid particles form a mixture [2]. On the small bodies of spherical shape the total area of the regions with large slope is limited. The different situation is observed on highly asymmetric bodies [3]. In the present paper we consider comet 67P/Churyumov-Gerasimenko. It is found that the most of the surface (75%) has the slope in the range 0< <40o. The slope in the range 40o < <70o is found on 17% of the surface and on 6% of the surface the slope is 70o< <90o. On 1.6% of the total area of the comet there are overhanging surfaces. Here, we consider slow ejecta as material for the possible landslides. This ejecta could be a result of an internal activity [4, 5] or of impacts. We find that for the velocity 0.3 m s-1 or lower, the ejecta land usually close to the starting point. Ejecta faster than 0.5 m s-1 have complicated trajectories and could land very far from the starting point.

Institute of Space and Astronautical Science, Kanagawa, Japan

Visibleto near-infrared imaging and spectroscopy (e.g. Mars Express OMEGA HRSC; Mars Odyssey CRISM HiRISE) of Phobos reveal two major geologic units: the majority of the surface is covered by a "red" unit, a low-albedo, nearly spectrally featureless unit with a red continuum slope; while a "blue" unit, defined by its slightly higher UVVIS albedo and relatively flatter continuum slope, is more locally distributed and associated in particular with Stickney crater. The red unit may be derived from the blue unit as a result of darkening and reddening by space weathering (e.g. Pieters et al., 2014); however, limited spatial resolution of measurements, the unique orbital environment at Phobos, and its unknown composition are challenges to understanding the true relationship of these two units.

The Phobos gravitational environment presents a set of unique conditions that can inform our understanding of regolith development and maturation for this enigmatic body. Due to its proximity to Mars and its slightly eccentric orbit (e = 0.0151), Phobos experiences librations that lead to local variations in surface gravity slopes. These slopes can vary by up to 2 degrees for every orbital period (7hr 39 min). Using direct numerical simulations of Phobos' regolith, we show that these variations can lead to a small amount of mass-wasting in high-slope regions during every orbit. We find that high-slope regions that experience moderate-to-high variations in surface slopes are correlated with blue geological units on the moon's surface. In particular, we find that this may explain the mass-wasting features that appear on Stickney's eastern ridge and extends eastward towards the sub-Martian point. Our findings suggest a continual shifting of regolith on the surface of Phobos that transforms its surface by exposing fresh sub-surface material.

Using OMEGA observations of blue and red regions of Phobos, we quantify typical slope differences between the units. Leveraging space weathering rates derived from observations of several asteroid families (e.g. Kaluna et al. 2015) that could be compositional analogs to Phobos, we analyze the spectral slope differences between the blue and red units on Phobos and find that blue material would weather to red in 104-108 years. This timescale agrees with our predicted quick refreshing rate due to eccentricity-driven mass-wasting. If blue material on Phobos represents relatively pristine, unweathered regolith, it is difficult to explain the observed absence of mafic absorptions in the context of in-situ formation or the capture of an inner solar system body, which predict the presence of olivine and pyroxene. Rather, Phobos is likely a captured main-belt or outer solar system body.

DESTINY+ (Demonstration and Experiment of Space Technology for INterplanetary voYage, Phaethon fLy-by and dUst Science) is a mission proposed for JAXA/ISAS Epsilon class small program, currently in the pre-project phase (Phase-A) with a launch targeted for 2022. DESTINY+ is a joint mission of technology demonstration and scientific observation. The science mission objectives are (1) to measure physical and chemical properties of cosmic dusts around 1 au and (2) to conduct geological observation of Phaethon upon flyby and analyze dusts nearby Phaethon. Phaethon is known as a parent body of the Geminid meteor shower, the size of which is approximately 6 km in diameter. Phaethon is important as a known source for cosmic dust delivered to the Earth. During the flyby of Phaethon spatially resolved images of Phaethon will be taken by two onboard cameras, the Telescopic CAmera for Phaethon (TCAP) and the Multiband CAmera for Phaethon (MCAP). The relative flyby speed is as high as 33

km/s and the distance at the closest approach is approximately 500 km. The main purposes of the DESTINY+ flyby observation of Phaethon is to understand the geology of a parent body of a meteor shower, and in particular constrain the dust ejection mechanisms from active (i.e., dust-ejecting) asteroids. The specific objectives of the camera observation are taking images for

(1) obtaining the light curve of Phaethon in order to estimate the rotational period, (2) measuring the outline shape of Phaeton, (3) making a 3D shape model of Phaethon, (4) observing the surface geological features of Phaethon including dust ejection features, and (5) observing the surface material distribution of Phaethon. The observations (1) to (4) will be conducted by TCAP, and (5) by MCAP. We will explain the flyby imaging sequence of DESTINY+, and show the conceptual designs of TCAP and MCAP.

B1.1-0064-18 FURTHER ANALYSIS OF TRANSIENT DUST CLOUDS AT L4 AND L5 OF THE EARTH-MOON SYSTEM

Naveed Moeed, naveed.moeed@physics.org

Royal Astronomical Society, CHAPEL HILL, North Carolina, United States John Zarnecki, john.zarnecki@open.ac.uk

Open University Milton Keynes, Milton Keynes, United Kingdom

Dust clouds at the L4 and L5 libration points of the Earth-Moon system as first observed by Kordylewski (1967), continue to provide Earth-based, space-based and in-situ observational challenges. With the last comprehensive study concluded in 2002 (Moeed, 2003), this paper provides an update on the positive and negative observations since. So far, positive observations have shown that the infra-red might offer the best opportunities for detection (specifically in bands between 1.5μm and 8μm). Further study has therefore suggested focusing on ground and space-based infra-red surveys which have serendipitously observed these regions. An analysis of such mission data yields over 8,500 further observations of L4 and L5 (which we take to incorporate a 0.5° region around both points). Some preliminary results from the COBE

(DIRBE) dataset (negative observations) are presented demonstrating an upper limit of 6.31 MJy/sr (Moeed, 2003). The methodology used however is repeatable across all other scans of the area and analysis of all 8,500 scans should yield improved results. The "now-you-see-menow-you-don't" phenomenology of these clouds is also correlated against possible interplanetary dust collisional events (e.g. cometary tails) which could regularly feed these areas.

The solar power sail mission: OKEANOS (Oversize Kite-craft for Exploration and AstroNautics in the Outer Solar system) is a Japanese candidate deep-space probe that will be powered by hybrid propulsion of solar photon acceleration and ion engines. The main scientific objectives are studies of Trojan asteroids in the Jovian L4 or L5 regions. The long distance and period from the launch to the swing-by at Jupiter will give us a good opportunity to explore the solar system between the Earth and the Jupiter to elucidate the solar system disc structure. We define the cruising-phase sciences of the OKEANOS mission as the scientific theme that will be explored or observed from the launch to the swing-by at Jupiter. Candidates of instruments for the cruising phase are: the EXo-Zodiacal Infrared Telescope (EXZIT), the Arrayed Largearea Dust detectors in INterplanetary space (ALADDIN)-2, the MaGnetic Field experiment (MGF)-2, and the GAmma-ray burst Polarimeter (GAP)-2. In this paper, we report scientific purpose and observation plans of them. Zodiacal light observed at visible and near-infrared wavelengths is thought to be sunlight scattered by interplanetary dust. The two-dimensional distribution of zodiacal light reflects the three-dimensional structure of interplanetary dust. However, it is still controversial that how the ratio of asteroid-origin to comet-origin changes by the heliocentric distance. Therefore, the comparison of the radial distribution of zodiacal light and the in-situ dust observation will help clarify the distribution and components of solid particles in our solar system. These results are expected to provide precise distribution of the interplanetary dust in our solar-system discs. The temperature of the solar wind, which depends on the heliocentric distance, has been observed to be greater than that predicted by the adiabatic model. Therefore, the existence of heating processes, such as plasma turbulence or magnetic reconnection, could be predicted. The observation of the magnetic field by the devices separated in the scale of the membrane of the Solar Power Sail provides the resolution of the plasma turbulence on the electron scale. Thus, the intermittent observation of the magnetic field between the Earth and Jupiter would determine the heating mechanism of the solar wind. The synergy of the magnetic field and dust observation may show the interaction between interplanetary dust and solar wind. By analyzing the environments on the dust surface, the chemical evolutions of molecules caused by solar wind and cosmic radiation can be investigated. We are investigating the possibilities to detect gamma-rays and particles from the solar-system shocks.

B1.1-0066-18 INVESTIGATING CERES' SUBSURFACE PROPERTIES THROUGH INTERMEDIATE LANDSLIDES

Kayla Duarte, kduarte3@gatech.edu

Georgia Institute of Technology, Atlanta, Georgia, United States The Dawn Science Team

B. E. Schmidt, H. Chilton, K. Ferrier, K. H. G. Hughson, J. E. C. Scully, H. G. Sizemore, A. Nathues, T. Platz, C. Russell, C. Raymond, J. Wray

Ceres, the largest body in the asteroid belt, is a primary focus of NASA's Dawn mission, partially due to evidence for ice in Ceres' surface and interior. Here we use Dawn Framing Camera data and build on earlier work using landslides to estimate ice content. Previously, three landslide types were identified using morphological criteria: type 1 (T1) have a thick, lobate toe, type 2 (T2) are thin and have a larger run out length than T1 landslides, and type 3 (T3) are more comparable to fluidized ejecta. However, landslides that do not fall cleanly into these groups, termed intermediate (IM), span a continuum between T1 and T2. Looking at these IM landslides allows us to better understand the relationship and progression between T1 and T2 and to identify any unique behaviors.

Our current analysis of IM landslides estimates the friction coefficient of Ceres' near-surface material as the landslide deposit is emplaced via the ratio of landslide drop height to run-out length (H/L). We include both the conventional maximum (max) and our in-progress center of mass (CoM) approximation. To obtain HMax/LMax, we produce a profile graph to attain the max lengths and heights of the feature. HCoM/LCoM measurements are obtained using a profile by estimating the center of mass of the projected preexisting surface and the deposit. We have found some H/L values to be lower than those of mobile clays, suggesting these landslides require friction reduction most likely from ice. Further, the overlapping range of H/L ratios for T1 and T2 flows is reinforced by the continuous range of H/L values for IM landslides. This implies emplacement conditions are not uniquely linked to morphology, and may suggest temperature-dependent behavior. We have also used a volume-area measurement of the scar to describe the flows. This relationship can be used to describe the type of material flowing in the landslide and can help distinguish between the different types using the depths to which the flows fall. This, along with an investigation of physical properties, has been done among the landslides to fill the continuum between T1 and T2. Overall, the major conclusions drawn from IM landslide analyses are 1) the idea that transportation is loosely tied to morphology, 2) that landslides on Ceres progress across a continuum where the distinction of T1 and T2 represent the end member states, and 3) the observation of potential fluidization in the landslides.

Thermal inertia is a fundamental parameter that controls surface temperature variations of airless bodies; being sensitive to the presence of dust, regolith or rock, it can be considered as an indicator of the physical structure and type of the surface material. Ceres and Vesta, the two largest bodies of the main asteroid belt, are important to understand the early stages of solar system and the formation of terrestrial planets; the Visible and InfraRed mapping spectrometer (VIR) onboard the NASA DAWN mission has allowed to measure the surface temperature of these bodies, and a thermal analysis has been done for Vesta's surface, obtaining a map of its thermal inertia. A similar analysis has now been done for Ceres. The thermal inertia is derived by comparing the observed temperatures with the theoretical temperatures calculated with a thermophysical model. The code can simulate different types of material with different thermal conductivity, corresponding to different kind of material (from lunar dust to regolith, in ascending order of thermal inertia); the temperatures are calculated iteratively by varying the values of roughness (a term characterizing topography at subpixel scale) and thermal conductivity class, until observed temperatures are reproduced. Our analysis indicates a low value of the average thermal inertia (up to 20 Jm−2K−1s−1/2), thus confirming again the inversely proportional trend of the thermal inertia as a function of the diameter, observed for many asteroids of the main belt. Much higher thermal inertia values than the average have instead been derived for two small areas, the faculae of the Occator crater and the Haulani crater. The possible causes of these differences will be discussed.

Nar Sulcus is located in the southwest quadrant of Yalode crater on Ceres' southern hemisphere. Geological mapping of the fractured terrain revealed it is composed of two sets of mutually perpendicular fractures.

We test the hypothesis that the topography and morphology of the Nar Sulcus normal faults are controlled primarily by a thin ice-rich elastic layer. We do this by mapping the structures in Nar Sulcus from spacecraft images, comparing their profiles to a single layer flexural-cantilever model for normal faulting similar to the one developed by [1], and analyzing their displacement:length (D/L) ratios using a method similar to the technique described in [2]. This analysis, which is similar to the one conducted on the europan ice shell by [3], estimates the elastic thickness, elastic moduli, and remote stress acting on the faults at Nar Sulcus.

Initial results from the flexural-cantilever model indicate that the elastic thickness of the cerean 'crust' is 700 m, and that its tensile strength is higher than that of pure water ice but much lower than that of even weakly lithified silicate material. The D/L analysis suggests that the remote stress on the Nar Sulcus normal faults is on the order of a few tens of MPa. This remote stress is incompatible with a genesis from static loading, and suggests an active source of uplift [4]. This could plausibly be solid-state diapirism, or laccolith formation due to cryomagma accumulation sourced from either impact melt or endogenic reservoirs [5].

The incorporation of higher resolution terrain models before the COSPAR meeting will provide for more thorough and insightful results.

The two most massive objects in the asteroid belt were explored by the Dawn mission: Vesta (diameter 526 km) was visited from 2011-2012 and Ceres (diameter 940 km) was visited from 2015-2018. Both objects are protoplanets that have likely existed since the beginnings of our solar system. Thus, they can provide valuable inputs into our understanding of the evolution of the solar system. Prior to Dawn's arrival, Vesta was thought to be depleted in volatiles while, in contrast, Ceres was predicted to be volatile rich (e.g. Russell and Raymond, 2011, SSR). However, the discovery of pitted terrain (Denevi et al., 2012, Science) and curvilinear gullies and lobate deposits in impact craters on Vesta (Scully et al., 2015, EPSL) indicated that Vesta, at least locally, might not be as depleted in volatiles as originally thought. Scully et al. (2015) hypothesized that localized deposits of subsurface water ice were heated by impacts, releasing liquid water onto the walls of newly formed impact craters. Under impact-induced transient atmospheric conditions, this short-lived liquid water was proposed to form curvilinear gullies and lobate deposits via a debris-flow-like process. The vaporization of this short-lived liquid water, at the ends of the curvilinear gullies and lobate deposits, was further suggested to contribute to the formation of the pitted terrain. Similar geomorphological features have been observed on Ceres (e.g. Sizemore et al., 2017, GRL), and there is abundant evidence for water ice within Ceres' crust (e.g. Buczkowski et al., 2016, Science; Combe et al., 2016, Science; Schmidt et al., 2017, Nature Geoscience). Here we evaluate the hypothesis of Scully et al. (2015), using both geomorphological analyses and laboratory experiments about the behavior of liquid water under low-pressure conditions. We will present initial results of our geomorphological analyses of curvilinear gullies, lobate deposits and pitted terrain in specific Vestan impact craters, and compare these features to those within Cerean impact craters. In addition, we will discuss our experimental set-up, and present the results of our initial experiments, in which water and brine were exposed to pressures of 10-4-10-5 torr. This work is being carried out at the Jet Propulsion Laboratory, California Institute of Technology, under contract to NASA. Government sponsorship acknowledged.

B1.1-0070-18 BREAK-UP NEAR-EARTH ASTEROID FAMILY 1566 ICARUS AND 2007 MK6

National Astronomical Observatory of Japan, Mitaka, Japan

Many asteroid families have been identified in the main belt while none in the near-Earth asteroids population due to frequent planetary perturbations. Apollo type NEA 2007 MK6 has been suggested to be a fragment of near-sun asteroid (1566) Icarus. In order to examine surface heterogeneity, rotational lightcurve and spectroscopic observations were carried out using US-Japan telescopes and 4.3-m DCT at Lowell observatory for Icarus and 2007 MK6 during 2015-2016 Earth encounters. The visible spectrum of 2007 MK6 was defined as O-type taxonomy. Meanwhile Icarus also has O-type features among average Sq-type surface. This paper will discuss physical evidences for the break-up NEA candidate.

Since the dawn of solar system exploration, cosmic dust measurement by spacecraft has been mainly focused on hypervelocity impacts in cruising phases, fast flybys to target bodies and incoming sporadic dust flux to orbits around planets/satellites. Recently mission opportunities are expanding to rendezvous to small bodies like comets and activated asteroids and other celestial bodies emitting local dust components such as icy plumes of Ceres, Europa, and Enceladus. In such rendezvous missions including Rosetta/Philae to a comet nucleus, spacecraft receives impacts by local dust at much lower velocities than the hypervelocity regime, i.e., well below 1 km/s order. In order to detect impact signals and to derive physical properties of these local dust grains, we must develop a new type of dust detector sensitive enough to lower momentum (i.e., smaller and slower impacting particles) than previous hypervelocity dust detectors. In this study, we started to develop such a new detector by redesigning electronics and data processing programs of the ALADDIN Poly-vinylidene Fluoride (PVDF) film sensor array onboard the solar sail spacecraft IKAROS launched in 2010. The IKAROS-ALADDIN was originally designed for detecting hypervelocity impact signals of as large meteoroids as 10 microns order during the interplanetary cruising between the Earth and Venus orbits. We first added an amplifier circuit just after the IKAROS/ALADDIN data processing unit and conducted single particle impact experiments of 10 to 50 micron glass beads, 20 micron aluminum particles, 30 micron iron particles, 100 micron alumina particles onto the IKAROS-type PVDF film sensors at low to medium velocity ranges, namely 1 to 600 m/s. With the 4 cm^2 effective area of the PVDF sensor, we obtained an empirical relationship between impact momentum and signal profiles. The second step of our development is to distinguish the amplified signals of lower momentum cases from integrated noise signals by reducing multiple noises generated from the sensors, the electronics, and the impact experiment apparatus and by re-arranging an array of amplifiers and noise filters for the data processing unit in order to allow the PVDF sensors to have larger effective areas like the IKAROS-ALADDIN.

B1.1-0072-18 ALL-SKY SPACE INSTRUMENT FOR EARLY DETECTION OF DANGEROUS BODIES IN THE NEAR EARTH SPACE

Alexander V. Bagrov, abagrov@inasan.ru

Astronomical Institute of the Academy of Sciences, Moscow, Russia
Vladislav Leonov, leonov@inasan.ru

Institute of Astronomy of the RAS, Moscow, Russia

The Chelyabinsk meteorite of 2013 attracts interest to small Solar system bodies that can be seen only very close to the Earth. Such objects can reach the Earth only a few hours later their possible detection, so a survey of early warning of dangerous space objects must be based outside of the Earth surface. We propose a simple device that will consist of wide-angle optoelectronic cameras which fields of view cover all sky. If the satellite with such device will be launched to the solar-synchronized orbit and use 3-axis stabilization, any star in sky images will be stable and point-like. Though any moving object will produce moving image, and it can be easily detected. As cameras observe the stable sky, it is possible to use long expositions for increasing limiting power. If we use high-speed lens "CANON EF85mm f/1,8" and full matrix camera like SONY-7Alpha, we can use 100-sec exposition to have 17.5m limiting magnitude. So deem will be comet nucleus with diameter 20 meters at a distance 2 million kilometers. Having velocity 20 km/s it can reach Earth in 30 hours. To avoid the hindering illumination from the Sun, the whole instrument must be placed in the shadow of its solar batteries. Batteries will cover only 10% of the whole sky in the direction, from where less than 1% of natural Solar system objects can appear. From solar-synchronized orbit, the Earth will cover nearly 10% of the sky too, but due to the orbital motion of the satellite maximal duration of invisibility of any coverable point will be just 1/6 of revolution period. So the proposed space instrument will be continuously observing the whole sky without any risk of missing or mixing up the objects of interest.

B1.1-0073-18 DETECTION OF SMALL TRANS-NEPTUNIAN OBJECTS WITH STELLAR OCCULTATIONS AND MIOSOTYS.

Alain Doressoundiram, alain.doressoundiram@obspm.fr Paris Observatory, Meudon, France

Chih-Yuan Liu, chihyuan.liu@obspm.fr Observatoire de Paris, LESIA, Meudon, France Francoise Roques, francoise.roques@obspm.fr France

Miosotys

Chih-Yuan Liu, Francoise Roques, Hsiang-Kuang Chang, Lucie Maquet, Michel Auvergne Frédéric Dauny Andrée Fernandez Bernard Christophe Jean Guérin, Paul Felenbok

We present here a 4 years campaign of search for TransNeptunian Objects by a dedicated ground-based instrument MIOSOTYS (Multi-object Instrument for Occultations in the SOlar system and TransitorY Systems). MIOSOTYS is a fibre-based, high speed photometer which is designed mainly for serendipitously monitoring the occultation events caused by small (D around 1 km) Trans-Neptunian Objects (TNOs) located in the so-called Kuiper Belt. Such occultations reveal the density of small TNOs as far as 40 AU and beyond. Also, they provide information on the size distribution down to hectometer-sized objects. This is a key parameter for better understanding formation processes in this remote region of the solar system. We will describe the instrument and the telescopes as well as the observations conditions, the data reduction and the quality of the data set. We will present the method of search for potentials occultation events and how these events are fitted with synthetic profiles using diffraction patterns. This method, applied to the data set, gives occultation profiles which number is used to deduce the density of TNOs in the sky plane.

B1.1-0074-18 DUST LEVITATION DYNAMICS ON SMALL AIRLESS BODIES

Kristin Nichols, kristin.nichols@colorado.edu

University of Colorado Boulder, Boulder, Colorado, United States Daniel Scheeres, scheeres@colorado.edu

University of Colorado at Boulder, Boulder, Colorado, United States

Increased interest in the exploration of small bodies in the solar system has led to a number of intriguing scientific objectives and mission architectures to these destinations. However, not much is known about the natural surface environment that exist on such bodies, nor what kind of effects our presence near the small body surfaces will have on the dynamics of the dusty regolith there. Thus a model of the small body environment which is able to predict surface conditions is needed for future mission planning and operations. Furthermore, this kind of model can be used concurrently with missions such as OSIRIS-REx and Hayabusa2 to match our predictions with observations in nature.

Using an updated version of the small body environment simulation developed by Nichols and Scheeres (2017) complete with polyhedron gravity model, solar radiation pressure, an electrostatic charging model, and consideration to the cohesive properties of the regolith material, the initial conditions required for particles to separate off the surface of a small body are examined. Such initial conditions provide insights into the charging characteristics and sizes of dust particles that are and are not able to escape from the surface; thereby providing a prediction on the types of charged particles which would remain on the surface and expect to be encountered on exploration missions. Additionally, examination of the charging rate of a dust particle due to currents to and from the grain by the surrounding plasma sheath can be coupled with the rotation rate of the small body and the grain's location on the body to determine if charged dust transport is a primary means of surface development and dynamics on the small body. The electrostatic model used in this simulation employs plasma sheath charging rates by Colwell et al. (2005), while leveraging new experimental and theoretical patched charging model results by Wang et al. (2016) and Zimmerman et al. (2016). Overall this work focuses on modeling the small body surface environment and providing predictions of the fine dust grain population expected to exist on the surface of such bodies, with simulations of how this dust population changes with the natural evolution of the body.

Characterizing the shapes and spin states of near-Earth asteroids (NEAs) is essential both for ruling out potential future Earth impacts and for planning spacecraft missions. Delay-Doppler radar imaging is a powerful technique to characterize NEAs. Radar observations using the Arecibo Observatory and the Goldstone Solar System Radar have provided detailed images of many near-Earth asteroids.

Reconstructing objects' shapes and spins from delay-Doppler data is a computationally intensive inversion problem. Since the 1990s, delay-Doppler data has been analyzed using the SHAPE software (Hudson 1993, Magri et al. 2007), providing shape models of a few dozen NEAs out of the hundreds observed with radar.

SHAPE performs sequential single-parameter fitting and requires considerable computer runtime and human supervision. Multiple-parameter fitting algorithms can more efficiently invert delay-Doppler datasets (Greenberg Margot 2015) and decrease runtime, but extensive human oversight of the shape modeling process is still required. Producing a single NEA shape model typically takes weeks to months. We have explored the application of two techniques to accelerate and better automate delay-Doppler shape modeling: Bayesian optimization and deep neural networks.

One of the most time-intensive steps of the radar shape modeling process is to perform a grid search to constrain the target's spin state. We have implemented a Bayesian optimization routine that uses SHAPE to autonomously search the full space of spin-state parameters. Bayesian optimization yields spin-state constraints with more than a factor of 3 less computer runtime than a grid search and with minimal human supervision. These routines are now being incorporated into radar data processing pipelines at Arecibo.

The shape modeling process could be further accelerated using a deep neural network to replace iterative fitting, quickly providing a good approximation of an asteroid's shape and spin state. However, neural network approaches require training with thousands of known asteroid shapes and corresponding sets of delay-Doppler images - far more than the current radar sample. To overcome this limitation, we have produced a database of simulated radar observations. The current database includes 10,000 artificial shape models mimicking the distribution of known asteroid shapes and simulated delay-Doppler data sets produced using a wide range of spin states and orbits for each of the artificial shapes. The database can be further expanded as needed.

We are now experimenting with training different neural network architectures, with the goal of eventually having a software routine that can produce an approximate shape and spin state model from a delay-Doppler radar dataset almost instantaneously.

This work was supported by the NASA Frontier Development Lab program.

B1.1-0077-18 DYNAMICAL CHARACTERISTICS OF THE SURFACE AND THE ENVIRONMENT AROUND THE ASTEROID 16 PSYCHE

UNESP-Campus de Guaratinguetá, Guaratinguetá, Brazil

The asteroid 16 Psyche, localized in the main belt and having a diameter of approximately 250 km, is thought to be the most massive among the M type asteroids. Observations made from Earth indicated an Iron-Nickel composition. It is believed that this body may be what was left from a metallic core of a protoplanet that would have had a catastrophic collision. Last year, a space mission with the same name, Psyche, was selected by NASA within the Discovery Program. The mission goal is to study the origin of planetary cores based on the exploration of asteroid 16 Psyche. The launch of the mission is planned for 2022 and, after a 4 years journey, it will explore the target for about 20 months. Therefore, a previous good knowledge of the target might be very useful for its planning. In the present work is studied a variety of dynamical aspects related to the surface, as well as, the environment around this asteroid. In our studies was adopted the shape of the asteroid determined by radar observations. The shape is given by a polyhedron of 2292 triangular faces and 1148 vertices. Assuming constant values for its density and rotational period. We used computational tools to explore the gravitational field generated by this asteroid. It was determined a set of physical and dynamical characteristics over the whole surface of the asteroid. Among them were computed and analyzed the altitude, tilt, slope, potential height, potential speed and escape speed. Beyond that, the equivalent spherical harmonics that define its gravitational field were computed and compared with the gravity field obtained via the polyhedron model. In order to explore the neighborhood close to asteroid 16 Psyche, the location and linear stability of the equilibrium points were found. The system has four external equilibrium points and an internal one. Two of the external points are unstable and the other two stable. A set of numerical simulations of massless particles around the asteroid confirmed the stability of these points, and also showed an asymmetry in the size of the stable regions. That information is also relevant in order to estimate regions on the surface of 16 Psyche that might have a higher amount of accumulated particles.

B1.1-0078-18 FREEZING OF AMMONIUM-SODIUM-CARBONATE-CHLORIDE BRINES: IMPLICATIONS FOR THE ORIGIN OF CERES' BRIGHT SPOTS

Subsurface brines on Ceres containing natrite (Na2CO3) and smaller amounts of NH4Cl or NH4HCO3 have been proposed to reach the dwarf planet's surface from an internal reservoir, where the brines freeze and result in bright spots across Ceres. Kinetically frozen solutions containing the likely constituents of Ceres' subsurface brines (ammonium, sodium, carbonate, and chloride ions) were studied via infrared and micro-Raman spectroscopy, where the flash-frozen mixtures were found to preferentially form ammonium chloride and ammonium bicarbonate, even in sodium-dominated solutions. Additionally, sodium chloride only formed when sodium or chloride (or both) were present in excess in the brine solutions. Raman spectroscopy was further employed to analyze the effect of vacuum exposure on these frozen brines over longer periods of time to simulate the surface conditions of Ceres.

Radar observations can provide unique information on the rotation period, size, structure, rotational state, and surface and near-surface characteristics and roughness of Near-Earth Objects (NEOs) such as asteroids. Via measurements of the range

(distance along the line of sight) and velocity along the line of sight, radar observations complement optical measurements of the plane-of-sky motion and enable precise knowledge of the orbits of asteroids. Multiple, sufficiently precise observations can allow orbits to be obtained to the extent that the mass and bulk density of an object can be inferred due to the presence of non-gravitational forces. Further, the orbits of asteroids can be used to assist with mission planning for spacecraft (e.g., as for the OSIRIS-REx and Psyche missions).

Although tons of interplanetary dust and small objects hit the earth every day, asteroids and comets can cause significant damage. Therefore, monitoring these asteroids is very important as it enables the prediction of collision orbits, and consequently, it becomes potentially possible to perturb the object away from the collision trajectory. Moreover, as these objects represent remnant debris from the formation of the solar system formation, studying them is also of scientific interest.

Approximately 5% of asteroid passes are only observable from the southern hemisphere, while suitable transmitters and receivers are almost exclusively located in the northern hemisphere. To extend asteroid radar coverage to the southern hemisphere, three stations in Australia have recently been configured to provide a radar capability to observe asteroids and study their trajectories and physical properties. These stations are the Tidbinbilla Deep Space Network station, and the Parkes and Narrabri stations of the Australia Telescope National Facility.

In this paper, we report on three asteroids, namely 2012 TC4, 1981 ET3 (Florence), and 2017 VR12. 2012 TC4 is of special interest, since the southern hemisphere location allowed observation during closest approach, only 40,000km from Tasmania. The provided results will be based on data collected in Australia using a bi-static radar setting. Data are subsequently processed using a software package created by UNSW Canberra, in contrast to the bulky and specialized receiver/recorders traditionally used for this purpose. We conclude with a discussion of future plans for the Southern Hemisphere Asteroid Radar consortium including more asteroids observable mainly from the Southern Hemisphere to complement the information obtained via DSN in the Northern Hemisphere. We also discuss plans to use multi-static radar and investigate the use of new coded waves to provide enhanced images of the target asteroids.

We report Goldstone radar observations of near-Earth asteroid (NEA) 3122 Florence obtained in 2017. We observed Florence on 14 days between August 29-September 13, dates that straddled the asteroid's closest approach within 0.047 au. With an estimated diameter of about 4.4 km (Mainzer et al. 2011), Florence is among the largest near-Earth asteroids. The radar data reveal that Florence is a triple system that consists of a large primary body and two small moons that revolve around it. The observations yielded an extensive set of delay-Doppler images achieving range resolutions as fine as 75 m/pixel that placed hundreds of pixels on the primary asteroid. At least one large crater, several hundred meters in diameter, is visible in images obtained on Sep. 1, the day of the closest approach. Tracking of features visible in the images confirms the 2.36 h rotation period estimated from lightcurves by Wisniewski et al. (1997). The images suggest the primary has equatorial and polar dimensions of 4.6 and 4.1 km and a low elongation. The shape is sloped in both hemispheres and resembles the primary of the 1999 KW4 binary system reported by Ostro et al. (2006). The dimensions inferred from the radar images are consistent with those estimated from thermal infrared observations reported by Mainzer et al. (2011). Florence is only the third known triple system in the near-Earth asteroid population (after 2001 SN263 and 1994 CC) and it is by far the largest. Preliminary estimates for the diameters of the satellites are 0.2 and 0.3 km, and they orbit the primary with periods of about 7 and 22 hours. The inner moon of Florence has the most rapid orbital period among all satellites of the known binary and triple systems in both NEA and main belt populations. We observed two radar eclipses of the inner moon on Aug. 31 and Sep. 1. We used the measurements of delayDoppler positions of the satellites to estimate the orbital parameters, mass, and bulk density of the system. Due to the three-body nature of the system, we integrated the full equations of motion of the system to fit the radar astrometry estimated from Goldstone and Arecibo images. The orbital fit suggests that the pole of the primary is within 10 deg of the ecliptic longitude and latitude of (78 deg, -85 deg), although we cannot exclude a prograde pole 180 degrees from this point. We obtain a system mass of (7.9 ±

0.2) 1013 kg and a J2 value to 0.092 0.013, where J2 is the second degree zonal harmonic of the gravity field. If we adopt an equivalent diameter of 4.2 km for the primary, then the system mass implies a bulk density of 2 g/cm3, which, for plausible S-class meteorite analogues, is consistent with a porosity of at least a few tens of percent. The J2 value is consistent with the theoretical value calculated for a uniform density oblate object. The radar data were obtained as the asteroid moved 90 degrees on the sky, covered a wide range of subradar latitudes, and are ideal for estimation of a detailed 3-D shape model of the primary.

B1.1-0081-18 KIDNAPPING SMALL SIZE (POSSIBLY ICY) ASTEROID TO DEFLECT THEM AND BUID SAFE HUMAN CURRIER AND MULTI STATION LIFE-RAFT FOR SPACE ENTERPRISE.

Daniele Fargion, daniele.fargion@roma1.infn.it

Physics Department, Rome University 1, INFN Rome 1,, Rome, Italy

We know that any inter-planetary flight for human being is under a severe danger because of the lethal solar flares and their consequent radioactive solar ray showers. The screening for the astronauts by any huge superconducting magnets is too heavy, costly and fragile by many reasons. On the contrary the ability to reach any nearby icy small size (few meter up to a few tens meter size) asteroids, to harbour (by robotic tractors) there a complete undergound screened rooms where to host ecological life systems is the simplest opportunity we face today. This goal may guarantee a natural and safe currier net for future life (and human) stations and or enterprise. The need to deflect such a small size (a few hundreds to several thousands of tons objects) may be achieved by micro robotic nuclear engines tractors, located on the asteroid surfaces, able to dig the asteroid icy surface and to propel it by effective a mass momentum by a few element fountain jet array: the mini asteroids skin (ice, dust) ejections and their consequent bending might drive the asteroid easely to any trajectories, possibly enhanced by planet gravity sling shot. The need for such a wide array of icy asteroid stations, mostly in a robotic ibernated state, it will offer a safe and solid multi station life-raft in our (planetary) wide space sea. Such array will be able to collect material and to guarantee energy stations for future (step by step) short and long human (and living systems) planetary travels. References:

Searching for periodic orbits around those minor bodies suffers from the trade-off: inefficient calculation by using the accurate polyhedral model or partial loss of essential characteristics with over-simplified models. Here a practical method is proposed to overcome the above problem in terms of elongated asteroids. The method is to obtain required initial variables of periodic orbits by using the rotating mass dipole with appropriate parameters, and then local iterations are implemented to obtain the real orbits over an asteroid in the polyhedral model. After introducing the dipole and polyhedral models, detailed procedures of the searching method are listed with five steps. A planar single lobe orbit is then presented to evaluate the effectiveness of the method, regarding the asteroid 216 Kleopatra of the triple asteroid system as a representative elongated body. By applying the above method, ten families of periodic orbits around Kleopatra are identified and discussed with respect to their orbital stabilities and periods. One sample of the sombrero orbit is checked by calculating 1000 hours to examine its orbital behavior. Besides the above orbits, the intriguing head-surrounding orbit is also analyzed even with an unexpected converged solution.

B1.1-0083-18 THE SEMI-ANALYTICAL ANALYSIS OF ORBITAL MOTION AROUND AN ASTEROID WITH THE JOINT EFFECTS OF THE C_20 TERM AND THE SOLAR RADIATION PRESSURE

Jinglang Feng, jinglang@nju.edu.cn Nanjing University, Nanjing, China Xiyun Hou, silence@nju.edu.cn Nanjing University, Nanjing, China Jingshi Tang, jstang@nju.edu.cn Nanjing University, Nanjing, China Lin Liu, lliu@nju.edu.cn

Nanjing University, Nanjing, China

This study develops a semi-analytical method of propagating orbital motion near the equatorial plane of an asteroid, taking into account the joint effects of the asteroid's oblateness (the C20 term), the solar radiation pressure (SRP) and the asteroid's orbital eccentricity around the Sun. In the asteroid-centered frame, the Hamiltonian of the orbital motion is derived with Poincaré variables. It is firstly averaged over the orbital motion around the asteroid, and time-explicit formulas of the evolution of orbital eccentricity are obtained. The second average is performed over the asteroid's eccentric orbital motion around the Sun, and timeexplicit formulas of the evolution of orbital inclination are obtained. Then, the eliminated oscillating terms of the inclination during the second average are recovered by applying the Lie transformation. Compared with numerical integrations, the validity of these solutions for different semi-major axes and different values of area-to-mass ratios is analyzed. This study improves the knowledge of secular orbital evolution around an asteroid. It can be applied to fast prediction of long-term orbital evolutions around near Earth asteroids (NEAs), e.g. characterizing the fate of the orbiting dust/ejecta or the spacecraft especially with large solar sails.

B1.1-0084-18 ON THE SPIN-ORBIT-SPIN COUPLING IN THE BINARY ASTEROID SYSTEMS

Xiyun Hou, silence@nju.edu.cn Nanjing University, Nanjing, China Jinglang Feng, jinglang@nju.edu.cn Nanjing University, Nanjing, China Jingshi Tang, jstang@nju.edu.cn Nanjing University, Nanjing, China Lin Liu, lliu@nju.edu.cn

Nanjing University, Nanjing, China

The well-known spin-orbit coupling usually assumes an invariant mutual orbit between the satellite and the planet (or the planet and the Sun) and usually only considers the second order term of the satellite's (or the planet's) non-spherical gravity and assumes a spherical shape for the planet (or the Sun). Different from this scenario, the two asteroids in the binary asteroid system are usually highly irregular. It may be no longer valid to assume an invariant orbit and only consider the second order term of one single asteroid. Considering higher order non-spherical terms of both asteroids and a varying mutual orbit, a more generous concept — the spin-orbit-spin resonance — was proposed by some researchers. In a general spin-orbitspin resonance, the orbital motion and both asteroids' rotational motions are involved. In the absence of one asteroid's rotational motion, the resonance is reduced to the traditional spinorbit resonance. In the absence of the orbital motion, the resonance is reduced to the spin-spin resonance.

When the two asteroids are close to each other (which is often the case in the current binary asteroid population) and move one eccentric orbits, the strength of the spin-orbit-spin resonances may be so strong that they overlap with each other. This overlap allows the binary asteroid system to transfer between different resonances via the Arnold diffusion. This process provides an efficient way for the orbital energy and the two asteroids' rotational energy to transfer between each other. In this contribution, using tri-axial ellipsoid shape models for the two asteroids and the mutual potential truncated at the 4th order, the spin-orbit-spin resonances are investigated. Their possible implications on the long-term dynamics of binary asteroid systems when combined with the YORP effect are also briefly addressed.

B1.1-0085-18 MOTION IN THE VICINITY OF ZERO-VELOCITY SURFACES ABOUT IRREGULARLY SHAPED BODIES

Dusan Marceta, dmarceta@matf.bg.ac.rs Matematicki fakultet u Beogradu, Belgrade, Serbia Neda Bokan, neda@rect.bg.ac.rs

Matematicki fakultet u Beogradu, Belgrade, Serbia Vanja Petkovic, vanjapetkovic1@gmail.com Matematicki fakultet u Beogradu, Belgrade, Serbia

There is increasing interest for the exploration of the small bodies of the solar system which has recently resulted in number of space missions devoted to these bodies. Also, significant effort has been invested in theoretical analysis of their dynamical environment. This is primarily referred to the development of novel methods for the modeling of gravity field, such as muscons and polyhedral models, which are significantly advantageous comparing to the traditional methods based on the spherical and ellipsoidal harmonic series. Although motion of the particle in such complex dynamic environment cannot be defined in closed form, there is the integral of motion which defines the so-called zero-velocity surfaces (ZVS) which separate the regions in which the motion is possible from those in which it is not (forbidden regions), similarly as in the threebody problem. In this research, we analyze the motion of the particle in the vicinity of these surfaces from the differential geometry point of view, by observing the connection between local geometrical characteristics of the orbit and ZVS when the particle is very close to them. We notice the relations between the curvature and torsion of the orbit and local main curvatures of the ZVS and dependence of these relations on the proximity of the particle to the ZVS. We performed this analysis for the asteroids Bennu and Castalia, for which the accurate shape models are available, and which are also good representatives of oblate and prolate bodies.

SPACE STUDIES OF THE EARTH-MOON SYSTEM, PLANETS, AND SMALL BODIES OF THE SOLAR SYSTEM (B)

PLUTO AND CHARON: THE NEW HORIZONS MISSION RESULTS (B1.2)

B1.2-0001-18 TO PLUTO AND BEYOND: OVERVIEW OF NASA'S NEW HORIZONS MISSION

Harold Weaver, hal.weaver@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States New Horizons Leads

Alan Stern, Glen Fountain, Helene Winters, Thomas Coughlin, Peter Bedini, Carl Engelbrecht, Christopher Hersman, David Kusnierkiewicz, Steven Vernon, Alice Bowman, Yanping Guo, Mark Holdridge, Gabe Rogers, Stewart Bushman, James Stratton, William Gibson, John Andrews, Mark Tapley, Michael Vincent, Tiffany Finley, Joe Peterson, Fred Pelletier, Bobby Williams, Shyam Bhaskaran, Wiliam Owen, Leslie Young, Catherine Olkin, Kimberly Ennico, John Spencer, and the New Horizons Team

The New Horizons mission was selected by NASA in November 2001 to conduct the first in situ reconnaissance of Pluto and the Kuiper belt. The spacecraft was launched on 2006 January 19, received a gravity assist from Jupiter during closest approach on 2007 February 28, and flew 12,500 km above Pluto's surface on 2015 July 14. New Horizons carries a sophisticated suite of seven scientific instruments, altogether weighing less than 30 kg and drawing less than 30 W of power, that includes panchromatic and color imagers, ultraviolet and infrared spectral imagers, a radio science package, plasma and charged particle sensors, and a dust counting experiment. The flyby of Jupiter at 32 RJ in early 2007 provided a 20% boost in spacecraft speed, which cut more than 3 years off the travel time to Pluto and provided an excellent practice planetary encounter, as well as unique science data. The New Horizons flyby of the Pluto system in 2015 provided unprecedented detail on the Pluto-Charon binary and Pluto's four small moons (Styx, Nix, Kerberos, and Hydra, in order of their orbital distance from Pluto). Pluto's surface displays diverse landforms, terrain ages, albedos, colors, and composition gradients. Measurements of Pluto's atmosphere revealed many surprises, including 20 separate haze layers and smaller than expected N2 escape rates. Charon displays evidence of ancient tectonic activity and a giant hood of dark, red material covering its poles. All the small satellites have highly elongated shapes, surprisingly high albedos, and unusual rotational properties. The New Horizons plasma and dust instruments have provided a record of solar wind activity, high energy ions, and dust density along its trajectory from 1.5 AU to 43 AU. The first New Horizons Kuiper Extended Mission (KEM) was approved by NASA in 2016, and the spacecraft is now headed toward a close flyby on 2019 January 1 of the cold, classical Kuiper belt object 2014 MU69, which may be the most primitive object ever visited by a spacecraft. In this paper, we review the journey of the New Horizons spacecraft across the solar system, highlighting both its technical achievements and its unique scientific findings.

B1.2-0002-18 THE GEOLOGY OF THE PLUTO SYSTEM

Jeffrey M. Moore, jeff.moore@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States The New Horizons Geology and Geophysics Imaging Theme Team

W.B. McKinnon, J.R. Spencer, A.D. Howard, O.L. White, O.M. Umurhan, P.M. Schenk, R.A. Beyer, K.Singer, S.A. Stern, H.A. Weaver, L.A. Young, K. Ennico, C.B. Olkin

NASA's New Horizons mission acquired a large set of images and other data making possible thorough geological analysis of landscapes in the Pluto System. Pluto and Charon exhibit strikingly different surface appearances, despite their similar densities and presumed bulk compositions. Systematic investigation, modelling and mapping revealed that much of Pluto's surface is attributed to surface-atmosphere interactions and the mobilization of volatile ices by insolation. Many valley systems appear to be the consequence of glaciation involving nitrogen ice. Other geological activity requires or required long periods of internal heating, such as Pluto's extensive tectonic fabric. The convection and advection of volatile ices in Sputnik Planitia are thought to be powered by present-day radiogenic heat loss. The prominent mountains at the western margin of Sputnik Planitia, and the strange, multi-km-high mound features to the south, probably composed of H_2O, are young geologically as inferred by light cratering and superposition relationships. These multi-km-high mound features might be cryo-volcanoes. Their origin, and what drove their formation so late in Solar System history, is under investigation. East of Sputnik Planitia are large belts of sub-parallel sharp-crested ridges found only at high altitude that are apparently composed of massive deposits of sublimation-sculpted CH_4 ice, referred to as Bladed Terrain. New Horizons found evidence that Bladed Terrain may cover much of Pluto's low latitudes and may have originally formed there in part as a consequence of Pluto's very high obliquity. Currently Bladed Terrain is undergoing net erosion. This observation, along with evidence for formally more extensive nitrogen glaciation, implies that Pluto has undergone significant climate evolution. The dynamic remolding of landscapes by volatile transport seen on Pluto is not apparently evident on Charon's surface. Charon does, however, display a large resurfaced plain and globally engirdling extensional tectonic network attesting to its early endogenic vigor.

B1.2-0003-18 PLUTO'S GLACIERS, GLACIATION, AND IT'S RELATED MYSTERIES

Orkan Umurhan, orkan.m.umurhan@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States Kevin Zahnle, kevin.j.zahnle@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States The New Horizons Geology and Geophysics Imaging Theme Team

O.L. White, W.B. McKinnon, P.M. Schenk, R.A. Beyer, K. Singer, J.R. Spencer, S.A. Stern,

H.A. Weaver, K. Ennico, C.B. Olkin

The New Horizons flyby of Pluto revealed an active low temperature physics laboratory involving volatile ices like N_2 and CH_4 and showcasing geologic features indicative of both present and past glaciation including dendritic networks, U-shaped and alpine valleys, as well as features resembling medial moraines and debris deposition. This talk will review these observations as well as our theoretical understanding of the ability of both N_2 and CH_4 ices to flow on Pluto's surface based on published laboratory assessed rheological properties of these volatiles. We will show some simulations of N_2-ice glacial flow based on the predicted past precipitation of N_2 using global circulation modeling of Pluto's past million year climate. We examine one of several outstanding issues: the puzzle of what processes and scenarios may be responsible landscape erosion on Pluto. We review the leading candidate mechanisms we think may be responsible for erosion of Pluto's surface and, further, shine light on how Pluto's low gravity and relatively low N_2 ice inventory make it difficult to reconcile how these mechanisms can carve km deep valley systems over the course of Pluto's geologic history. We shall discuss one hypothetical solution to this dilemma, namely, that Pluto's surface possibly harbored a far deeper inventory of CH_4 ice deep in its past and that this volume of ice, while present, provided the requisite overburden pressure to drive glacial erosion of Pluto's surface.

The 2.5-km deep, volatile-ice-filled basin named Sputnik Planitia (SP) is central to Pluto's geological, glaciological, and climatological activity. Composed of nitrogen, methane, and carbon monoxide ices, but dominated volumetrically by N2-ice, this ice sheet is organized over much of its extent into cells, typically 10-40 km across, that strongly resemble the surface manifestation of solid state convection. We have previously shown that solid layers of N2 ice >1 km or so thick should convect for Pluto's estimated present-day, steady state radiogenic heat flow (even considering a wide range of uncertainty for the latter). We have also shown that convective overturn in a several-km-thick layer of solid N2(-CH4-CO) can explain the great lateral width of the cells. We have argued that the temperature dependence of N2-ice viscosity implies that the SP ice layer convects in the sluggish lid regime, a unique convective mode heretofore not definitively observed in the Solar System. In this talk we will describe ongoing efforts to understand this convection and its implications, focusing on the questions of the aspect ratio and planform of the convective cells and the implications for the thickness of the ice sheet (depth to the water ice basement), Pluto's heat flow, and the potential for N2-ice melting at the base of the ice sheet.

We perform CITCOM convection calculations in 2-D and 3-D to constrain the depth of this N2 and thus the depth of the Sputnik impact basin and related properties and conditions. For an extended but plausible range of Rayleigh numbers and viscosity contrasts for solid nitrogen, convection can occur in all possible regimes: small viscosity-contrast, sluggish lid, or stagnant lid, or the layer could be purely conducting. Convective dynamics are complicated at the vicinity of regime transitions, thus we conduct a systematic analysis of convection regimes using 2-D convection simulations. Moreover, the conditions at the base of the nitrogen ice sheet are uncertain. It may be directly in touch with the water ice bedrock, or nitrogen-rich melts may be present if the base reaches the melting temperature of nitrogen (63 K). This bottom boundary condition affects the dynamics of the convection system and thus the surface manifestation, which is more prominent in 3-D models.

Sputnik Planitia is a deep, 1150 km x 900 km elliptical basin likely formed by the impact of an 200-km-wide ancestral Kuiper belt object more than 4 billion years ago. Based on depths of smaller, fresher craters formed in Pluto's water-ice bedrock, SP was likely originally no deeper than 10 km, which implies an upper limit of 7 km for the N2-ice sheet today. Preliminary topography determined by photoclinometry on the highest resolution New Horizons LORRI transects indicates the cells themselves are broad domes 100 m high. These topographic profiles are more consistent with greater as opposed to lesser viscosity contrast across the convecting layer. The vertical scale is also indicative of the integrated thermal anomaly (which provides the buoyancy that drives the convection). For N2-ice thermal expansion (which is large), 100 m of uplift is consistent with a temperature contrast of 10 K over a depth of 5 km, and greater thermal anomalies are required as the viscosity contrast increases. It is hard to reconcile these requirements with solely top-down cooling due to climactic temperature variations (small temperature changes), which has been proposed for SP.

Pluto's surface has experienced considerable endogenic and exogenic resurfacing (Moore et al., 2016). The terrains on Pluto represent a variety of ages, from seemingly ancient to surprisingly young. Some of the very young terrains are the result of the volatile ices on Pluto's surface (e.g., the convecting nitrogen-ice-rich plains of Sputnik Planitia). But Pluto also has several examples of more recent activity (terrains with few-to-no superimposed craters), that appear to be primarily made out of non-volatile water ice.

The most prominent examples of potential cryovolcanism are two enormous domes with deep central depressions (Singer et al., 2016). The informally named Wright Mons stands 4 km high and the main mound spans 150 km. The informally named Piccard Mons is approximately 7 km high and 225 km wide. Only a few potential distinct flow features are evident, but the morphology of the areas surrounding Wright and Piccard indicates there may have been multiple episodes of terrain emplacement. There is also an extensive plateau to the west of Wright Mons with a relatively flat surface. This plateau exhibits many large depressions with various morphologies, most of which do not appear to have an impact origin.

Each potential example of cryovolcanism found in the outer solar system is unique, and Pluto and Charon's features expand the information we have to understand this enigmatic process. We will present image, topographic, and composition data for these feature along with geologic mapping results. We will discuss potential formation mechanisms in light of available empirical and model constraints.

Please note some geologic features names used here are informal.

B1.2-0006-18 NUMERICAL MODELING OF PLUTO'S GLACIERS, FROSTS AND ATMOSPHERE TO INTERPRET NEW HORIZONS OBSERVATIONS

Francois Forget, forget@lmd.jussieu.fr

CNRS Research Scientist (Chargé de recherche), Paris, France Tanguy Bertrand, tanguy.bertrand@lmd.jussieu.fr

IPSL, CNRS, Paris, France

On the basis of our experience on the other terrestrial climates of the solar system (Mars, Earth, Titan, Venus), we have developed a hierarchy of models to simulate the climatic processes at work on Pluto: a Global Climate Model to represent the evolution of the 3D atmospheric circulation and surface ices (N2, CH4 and CO) over up to several Earth years, complemented by a 2D volatile transport model able to simulate the evolution of the N2, CH4 and CO reservoirs over several millions years. Such tools are based on universal equations, with the minimum of ad-hoc hypothesis. Yet we found that the modelled Pluto climate system and the evolution of its volatile reservoirs are surprisingly sensitive to a few model parameters such as the ice albedos and deep subsurface thermal inertia. Nevertheless, by choosing selected values we could reproduce many characteristics of the planet observed by New Horizons in 2015, such as the distribution of nitrogen and methane glaciers and frost, the evolution of pressure, many aspects of the Sputnik Planitia ice cap, or the thermal structure of the near surface atmosphere. In this talk we will review what we have learned from these simulations, but also put forward the observations that remains enigmatic and difficult to understand and predict with our physical models.

NASA's New Horizons spacecraft provided the first high-resolution imaging of the surface of Pluto and its moons. The Ralph instrument provides 4-color images (Blue 400-500 nm, Red 540-700 nm, NIR 780-975 nm, CH4 860-910 nm) and near-infrared spectral imaging from 1.25 to 2.5 microns. These data allow us to map the composition of volatiles, like N2, CH4 and CO, across the surface of Pluto as well as non-volatiles like water ice and the tholins. We find that the large basin, Sputnik Planitia, is filled with volatile ices and there is a general latitudinal pattern of composition on Pluto (that is interrupted by the basin of Sputnik Planitia). The north pole

of Pluto is dominated by methane rich ice relative to the more volatile N2 ice, mid-latitudes are dominated by N2 ice, and the equatorial region is dominated by tholins.

Pluto's large moon Charon generally has a more uniform surface composition compared to Pluto. The surface composition is dominated by crystalline water ice. Also seen on the surface of Charon is a feature near 2.2 microns attributed to an ammonia-containing species. Intriguingly, Charon has a dark, red north pole that can be explained by methane escape from Pluto and becoming cold trapped on Charon's pole until it photolyzes during the long artic winter. Two small satellites of Pluto, Hydra and Nix, also show a surface composition of water ice and hydrated ammonia.

These results and their implications will be addressed.

Inferring the composition of Pluto's surface and atmosphere is critical to further understand the origin and evolution of this icy dwarf planet and by extension other trans-Neptunian objects with similar size or smaller. Laboratory experiments suggest that the dark red to yellow color of Pluto is due to the presence on the surface of tholin-like material, which are organic compounds produced through photolysis and radiolysis of native material found on the surface and atmosphere of the dwarf planet. We present a characterization of the tholin material across Pluto's surface through a pixel-by-pixel Hapke modeling of the New Horizons Ralph/LEISA and MVIC data (Reuter et al., 2008). The ultimate goal is to understand whether one or more colored agents are present across the surface and to possibly identify their optical characteristics. This will be of great importance as an input for future laboratory measurements and for understanding the nature of the dark material inside and outside the Pluto forming zone.

Observations of Pluto's atmosphere by NASA's New Horizons spacecraft during its July, 2015 flyby [1] included a REX radio uplink occultation [2]; Alice ultraviolet airglow, solar occultation, and stellar occultations and appulses [3]; LORRI and MVIC images and LEISA infrared spectral-images of the haze [4]; and SWAP and PEPSSI in-situ observations [5]. Concurrent ground-based observations included stellar occultations [6] and ALMA measurements [7]. Together, these paint a picture of an N2-dominated atmosphere with numerous trace constituents, including CO, CH4, HCN, simple hydrocarbons, and more processed hazes. The atmosphere has a spatially variable lower atmosphere/planetary boundary layer that is strongly influenced by the surface temperature and the daily sublimation/condensation cycle [8]; a middle and upper atmosphere with Titan-like haze formation and chemistry [9]; and a cold, loosely bound upper atmosphere with CH4 and N2 escaping by enhanced Jeans escape [10].

New Horizons flew by Pluto in July of 2015, revealing a geologically active world [1] with a complex atmosphere [2]. While Pluto has long been known to have a seasonal atmosphere [3-5], this flyby allowed us to image the atmosphere for the first time at resolutions less than 1

km/pixel and large phase angles up to 170°, revealing distinct haze layers in Pluto's atmosphere [6]. Like Pluto, both Titan and Triton are large icy worlds with complex hazy atmospheres and have been observed at high phase and resolution [7,8]. Herein, we apply a simple radiative transfer model to phase curves from disk-integrated observations of Pluto, Titan, and Triton, at phase angles from 15-170° to determine the single scattering albedo and the Henyey-Greenstein scattering phase function of Pluto's haze particles. From these two parameters and comparison between the three bodies we determine the size and spectral nature of Pluto's haze [9]. We generated phase curves from full disk images of Pluto taken by the Multispectral Visible Imaging Camera (MVIC) in its four color filters. MVIC began observing the Pluto system on April 9th 2015, 96 days before closest approach on July 14th 2015. We limit ourselves to data taken 6.7 days before and after closest approach as images taken before this time show Pluto as only appears as a few pixels on the disk which can exacerbate pointing errors. As MVIC observed the same faces of Pluto multiple times in those 96 days these images are redundant and can be ignored. We perform aperture photometry within the images to find the mean brightness of the atmospheric pixels, <I/F>, by summing all the pixels in the annular aperture, removing the mean dark current, and dividing by the number of pixels on the disk. To determine viewing and phase angles we use the MICE toolkit from JPL's Navigation and Ancillary Information Facility [10]. We similarly determine the phase curves of Titan and Triton using observations from the Imaging Science Subsystems aboard Cassini and Voyager 2 respectively. In addition to disk integrated phase curves, we also generate resolved phase curves for several areas of Pluto. We chose areas with seemingly contiguous compositions and morphologies, and subregions within them were completely illuminated through multiple observations during the flyby. Unsurprisingly Sputnik Planitia is brighter than Cthulhu Regio and the disk integrated value at low phase. However, Cthulhu Regio shows a massive increase in brightness at high phase angles, even brighter than the whole disk. This could be an increase in haze opacity over Cthulhu Regio or inadvertently including pixels off the disk due to pointing errors. Future work will interrogate these two hypotheses.

During the New Horizons encounter of the Pluto system on July 14, 2015, the radio brightness temperatures of Pluto and Charon were measured from three unique perspectives: (1) the dayside on approach, (2) near closest approach to Pluto, and (3) the nightside on departure. The measurements were made using the New Horizons 2.1 m High Gain Antenna (HGA), the spacecraft's X-band receiver at 4.2 cm wavelength, and the on-board Radio Science Experiment

(REX). Pluto and Charon were unresolved by the HGA for the dayside measurements, but the measurements near closest approach scanned two chords across the Pluto disk with a resolution of about 12% of Pluto's diameter. The nightside measurements were recorded in two phases:

a scan across the Pluto nightside, at a resolution close to 50% of Pluto's diameter, during the REX radio occultation experiment (with the HGA pointed toward Earth), and (ii), later in departure, separate full-disk observations of Pluto and Charon. These measurements constitute an ensemble of radio brightness temperatures of Pluto and Charon from both the sunlit and dark hemispheres, and over a variety of surface materials, topography and emission phase angles. Placing these measurements in physical context necessarily involves understanding the emissivity, not only of the surface materials, but also the composition and structure of the subsurface, given the low absorptivity of the materials on Pluto and Charon at 4.2 cm wavelength. Fortunately, the surface material composition on Pluto's dayside was imaged independently at high resolution by the New Horizons on-board infrared imaging spectrometers [1,2], but only to a depth of the order of 0.1 cm. Even so, the emissivity of materials such as tholins and the ices of nitrogen and methane at temperatures in the range 30-40 K is poorly known, and further confounded by the lack of knowledge of the subsurface. With these uncertainties in mind, possible physical temperatures for Pluto and Charon are presented using models of emissivity derived from sparse laboratory experiments and extended via numerical computation. Choices of surface and subsurface composition and structure are further discussed that fit the observations within the constraints of emissivity and physical plausibility. [1] Stern

The scientific objectives of NASA's New Horizons mission include quantifying the rate at which atmospheric gases are escaping Pluto and describing its interaction with the surrounding space environment. The two New Horizons instruments that measure charged particles are the Solar Wind Around Pluto (SWAP) instrument and the Pluto Energetic Particle Spectrometer Science Investigation (PEPSSI) instrument. This presentation describes results from these instruments when New Horizons flew past Pluto in July 2015 at a distance of 32.9 AU from the Sun.

Particle instruments on New Horizons revealed an interaction region confined sunward of Pluto to within 6 Pluto radii with an upstream solar wind stand-off distance of only 2.5 Pluto radii. The surprisingly small size is consistent with an atmospheric escape rate of 4-8 x 1025 CH4

molecules s–1 (considerably less that predicted before the flyby) as well as a particularly high solar wind flux due to a passing compression region. This region is similar in scale to the solar wind interaction with Mars's escaping atmosphere. Beyond Pluto, the disturbance persists to distances greater than 400 Pluto radii downstream.

NASA's New Horizons spacecraft flew past Pluto in July 2015 and will encounter the cold classical Kuiper Belt Object (KBO) 2014 MU69 on January 1, 2019. During the cruise between these two encounters, New Horizons has observed several KBOs and dwarf planets at uniquely high phase angles, as well as Centaurs at extremely high phase angles to search for forwardscattering rings or dust. We will report on the observations obtained with the LORRI framing camera from the start of 2016 to the end of 2017. These cover dwarf planets, classical KBOs, Centaurs, and the previously-reported 3:2 resonant KBO (15810) Arawn (Porter et al. 2016). We will present astrometry and photometry for these objects, in addition to a high-phase rotational lightcurve for 2012 HE85. We also describe and report on the ground-based observations with Subaru Hyper Suprime-Cam (HSC) that enabled these spacecraft observations. These observations are the prototypes for the continuing exploration of the classical Kuiper Belt that New Horizons will resume in August 2018.

B1.2-0015-18 THE NEW HORIZONS KUIPER EXTENDED MISSION: PLANS AND GOALS

Alan Stern, astern@swri.edu

Southwest Research Institute, Boulder, Colorado, United States The New Horizons Team

Harold Weaver, John Spencer, Catherine Olkin, Anne Verbiscer, Joel Parker, Jeff Moore, William McKinnon, Will Grundy, Randy Gladstone, Leslie Young, Dale Cruikshank, Heather Elliott

NASA's New Horizons spacecraft is conducting a first exploration of the Kuiper Belt in its current, approved Extended Mission, which will last through 2021 when the spacecraft reaches 50 AU. The centerpiece of this extended mission is a flyby of the cold classical Kuiper Belt Object (KBO) 2014 MU69 (MU69) on 1 January 2019 UT. This KBO orbits the Sun with a low eccentricity; it will be encountered at a heliocentric distance of 43.2 AU. This will be the first (and only, for the foreseeable future) close look at a cold classical KBO, and the most distant close encounter with any object in history. The nominal close approach distance for the flyby trajectory is 3,500 km, 3 times closer than the 2015 flyby of Pluto by New Horizons. Expected spatial resolutions will be as high as 35 m/pixel for panchromatic imaging, 320 m/pixel for color imaging, and 1.8 km/pixel for 1.25-2.5 μm near-IR spectroscopy. All of these resolutions considerably improve on those achieved at Pluto and its system of satellites. We also plan extensive rotational coverage on approach to MU69, deep imaging searches for satellites and rings, and measurements of microwave thermal emission from the day and night sides. Though neither coma nor activity is expected in such a cold, small body (D 30 km), we will also conduct extensive searches to constrain any such phenomena in visible scattered light, via UV absorption and emission techniques, and using the spacecraft's in situ plasma and dust instruments. We will summarize knowledge of MU69, the scientific objectives of the flyby, as well as the other heliospheric and KBO/Dwarf Planet science New Horizons is performing in this extended mission. We will also outline the exciting planetary science New Horizons can perform in a second extended mission.

B1.2-0016-18 PRESENTING THE NEW HORIZONS MISSION RESULTS TO THE FRENCHSPEAKING WORLD ON JAN 1ST, 2019

Guy Pignolet, guy.pignolet@science-sainte-rose.net Science Sainte-Rose, Sainte-Rose - La Réunion, France Emeline Legros, e.lgs181@gmail.com

Lycee Boisjoly Potier, Le Tampon - La Reunion, France Louana Delcourt, louanadelcourt@yahoo.fr

ENSAM Ecole Architecture, Le Port - La Reunion, France

The results of the mission to Pluto, Charon and MU69 that have been obtained or will be soon obtained with the equipment of the New Horizons spacecraft and the remarkable work of the team of scientists need to be communicated to the science community at large, to the decision makers who support such mission. The story needs also to be told to the public at large, to bring education about the world in which we live, and to foster new vocations and investment in space research. Reunion Island, a French/European state that may compare with Hawaii, located on the opposite side of the world with respect to Pasadena where the mission was initiated, played a minor but yet important role during launch operations in 2006, and a full scale model of the spacecraft is on permanent display for visitors in the city of Sainte-Rose where the Nasa tracking station was hosted. On the occasion of the 1st January 2019 fly-by of New-Horizons over object MU69, educational teams in Reunion Island, in cooperation with global French-speaking media, have plans to extend knowledge about the New Horizons mission and its achievements to the 300 million people of the French-speaking community world-wide.

B1.2-0017-18 SPECTROSCOPIC MEASUREMENTS OF RADICALS IN OUTER SOLAR SYSTEM ICE ANALOGS

Edith Fayolle, edith.c.fayolle@jpl.nasa.gov

NASA Jet Propulsion Lab / California Institute of Technology, Pasadena, California, United States

Paul Johnson, paul.v.johnson@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology/ NASA, Pasadena, United States Stanley Sander, stanley.p.sander@ jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology/ NASA, Pasadena, California, United States

New Horizons instruments are pushing our understanding of outer solar system bodies. LEISA and Alice instruments in particular, are providing and will provide a wealth of spectral information to determine chemical compositions. Pluto and most KBOs surfaces are dominated by N2-ices and smaller amount of CH4, and CO. Based on the laboratory irradiation of outer Solar System ice analogs by photons or energetic particles, CH- and N-bearing radicals are expected to be present and trapped in these icy surfaces due to N2 ice low reactivity. The (non-)detection of radicals would put constraints on the processing history of these icy bodies.

To identify radicals in KBO surface spectra, the electronic and vibrational transitions of these species frozen in N2 matrices at low temperatures (25-45K) need to be measured over a large wavelength range.

In this work, we show the first results from an experimental setup capable of measuring radical spectra in outer Solar System ice analogs from the VUV to the mid-IR. Radicals are produced in a supersonic pyrolysis nozzle by thermally cracking specific reactants in an N2 flow. The radical-N2 beam is further expanded into a vacuum chamber and condensed onto a temperature controlled cryogenically-cooled window. The isolation of radicals by the N2 matrix allows us to perform spectroscopic measurements and derive radical frequencies as well as band strengths. The methyl radical (CH3) has been chosen as proof of concept here and future measurements will be extended to ethyl (CH3CH2), cyano (CN), and methylene (CH2) radicals. These spectroscopic data will allow us to derive local abundances of radicals from observed spectra and understand the specific energetic processing and history of Pluto and other KBOs.

B1.3-0002-18 PROTOPLANETARY DISKS AND THEIR EVOLUTION

Laura Perez, lperez@das.uchile.cl Universidad de Chile, Santiago, Chile

The formation of planetary systems takes place in the gaseous dusty disks that surround young stars during their epoch of formation, known as protoplanetary disks. With the advent of sensitive observations and together with developments in theory, our field is making rapid progress in understanding how planet formation proceeds. In this review, I will describe how the evolution of protoplanetary disks is traced by observations of their dust and gas components, and I will present recent observational results that elucidate key aspects of the planet formation process, particularly focusing on observations at the sub-mm, millimeter, and centimeter-wave regime. This wavelength range is already providing a plethora of new results, thanks to improvements in sensitivity brought forward by VLA and ALMA. Finally, I will discuss different features observed in protoplanetary disks (gaps, asymmetries, spiral structure, etc.) at high angular resolution, and the role these substructures may play during the process of disk evolution and planetary formation.

B1.3-0003-18 NATURE OR NURTURE? THE EFFECT OF RADIATION ENVIRONMENT ON PROTOPLANETARY DISC EVOLUTION

Thomas Haworth, t.haworth@imperial.ac.uk Imperial College London, London, United Kingdom

FRIED (Fuv-Radiation Induced Evaporation of Discs) is a project dedicated to studying the effect of radiation environment on the evolution of protoplanetary discs and any planet formation within them. Do discs subject to strong UV radiation in high mass star forming regions produce different planets to those in quiescent environments? What about in the intermediate regime?

The loss of matter from such discs is set by thermochemistry in the photodissociation (PDR) regime. State of the art photochemical-hydrodynamics is therefore required to model this process, which we have at our disposal using the TORUS-3DPDR code (e.g. Bisbas et al. 2015, Haworth et al. 2016).

In an externally evaporating disc, our models find a competition between the growth and radial drift of grains into small radii (where they might produce planets) and the evaporation of grains from the outer disc. This limits the available mass reservoir for planet formation, but also quickly sees the global solids-to-gas mass ratio rise as grains grow to a size at which they are resilient to stripping by photoevaporation.

I'll illustrate this with our recent work in which we studied the evolution of discs that would have been precursors to the famous Trappist-1 planetary system in different radiation environments (Haworth et al. 2018). Our models imply that photoevaporation requires much higher initial disc masses than canonically expected in order to facilitate formation of the observed 4 Earth masses of planets in this system. I'll also highlight our first evidence of an evaporating disc in a low mass star forming region in the case of IM Lup (Haworth et al. 2017).

Finally, I'll give a preview of upcoming results, including a large publicly available grid of mass loss rates for a range of stellar, disc and UV field parameters. This will permit theorists to include external photoevaporation in disc models, and for observers to make quick instantaneous mass loss rate estimates.

B1.3-0004-18 MAGNETICALLY INDUCED DISK WINDS AND TRANSPORT IN THE HL TAU DISK

Yasuhiro Hasegawa, yasuhiro.hasegawa@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, Wyoming, United States

The mechanism of angular momentum transport in protoplanetary disks is fundamental to understanding the distributions of gas and dust in the disks. The unprecedented ALMA observations taken toward HL Tau at high spatial resolution and subsequent radiative transfer modeling reveal that a high degree of dust settling is currently achieved in the outer part of the HL Tau disk. Previous observations, however, suggest a high disk accretion rate onto the central star. This configuration is not necessarily intuitive in the framework of the conventional viscous disk model, since efficient accretion generally requires a high level of turbulence, which can suppress dust settling considerably. We develop a simplified, semi-analytical disk model to examine under what condition these two properties can be realized in a single model. Recent, non-ideal MHD simulations are utilized to realistically model the angular momentum transport both radially via MHD turbulence and vertically via magnetically induced disk winds. We find that the HL Tau disk configuration can be reproduced well when disk winds are properly taken into account. While the resulting disk properties are likely consistent with other observational results, such an ideal situation can be established only if the plasma β at the disk midplane is β0 = 2 104 under the assumption of steady accretion. Equivalently, the vertical magnetic flux at 100 au is about 0.2 mG. More detailed modeling is needed to fully identify the origin of the disk accretion and quantitatively examine plausible mechanisms behind the observed gap structures in the HL Tau disk.

B1.3-0005-18 VOLATILES FROM THE PRESTELLAR PHASE TO PROTOPLANETARY DISKS

Yuri Aikawa, aikawa@astron.s.u-tokyo.ac.jp University of Tokyo, Tokyo, Japan

In this presentation, I will overview the theoretical and observational studies of volatiles from interstellar gas to protoplanetary disks.

Interstellar space is filled with diffuse gases, which are repeatedly swept by supersonic flows around sources such as expanding HII region and supernova remnants. Molecular clouds are formed in the post-shock region, when the converging flows make the shock wave propagating perpendicular to the magnetic field. While a significant fraction of carbon and oxygen is already depleted in the solid phase (dust grains) in diffuse clouds, the dust grains are coated by the ice mantle, when the visual extinction of molecular gas reaches a few magnitude (i.e. hydrogen column of several 1021cm−2).

As a self-gravitating core is formed, and the molecular gas becomes dense, the collisional timescale of gas and dust, and thus the freeze-out timescale of molecules onto ice mantle become shorter. Prestellar cores are characterized by dense (>105 cm−3) cold (sim 10 K) gas and the freeze out of heavy-element species, including CO, at the core center. Despite the low temperature, the ice mantle is not chemically inert; H atoms can diffuse and hydrogenate atoms and molecules. CO is hydrogenated to form CH3OH, as well as radicals, for example. Observations find vapors of water and various complex organic molecules (COMs), which could be non-thermally desorbed from ice mantle and/or formed via gas-phase reactions of sublimates. The cores eventually become gravitationally unstable and collapse to form stars.

The central region of the core is heated by the contraction and irradiation from the newly formed protostar. Various COMs are formed by radical-radical reactions in the ice mantle in the luke-warm ice mantle and by the gas-phase reactions of sublimates. Emission lines of water, COMs, and other organic molecules are intensively observed towards protostellar cores and a forming protoplanetary disk at the core center.

In the protoplanetary disks, volatiles are again frozen onto grains in the outer cold midplane, while they are in the gas phase in the warm upper layers and inside their snow lines. Emission lines of relatively abundant species are spatially resolved; some lines show ring-like structures, which are interpreted in terms of snow lines, evolutions of dust grains, and the spatial and temporal variations of C/O ratio caused by the cold finger effect. Emission lines of COMs, such as CH3OH, are also detected.

B1.3-0006-18 CONSTRAINTS ON EMBEDDED DISK STRUCTURES AND MASSES AS SEEN BY CARMA AND ALMA

Patrick Sheehan, psheehan@ou.edu

University of Oklahoma, Norman, Oklahoma, United States

Class 0 I protostars are thought to represent early stages in the lifetime of protostellar disks, when they are still embedded in their natal envelope. As such, they provide an opportunity to study the initial conditions of protostellar disks, before any significant disk evolution or planet formation has occurred. We have conducted a survey of Class I protostars, initially with CARMA but now continuing with ALMA, to study the structure of their disks and measure their masses. We fit detailed radiative transfer models to our sample and find that Class I disks have similar structure to Class II disks, including several Class I disks with gaps, cavities, and other interesting features. Our measurements show that Class I disks are, on average, more massive than the older Class II disks. As such, Class I disks may be a better representation of the initial masses present in protostellar disks. These samples are, however, still small, so we have begun an effort to model all 330 Class 0 I protostars from the Herschel Orion Protostar Survey that were observed with ALMA as part of the VANDAM Survey. When completed, this study will produce a comprehensive picture of the youngest protostellar disks. We will finish by presenting early results from this effort.

B1.3-0007-18 CHARACTERIZING THE YOUNGEST DISKS USING CHEMICAL TRACERS.

Merel Van ’t Hoff, vthoff@strw.leidenuniv.nl Leiden Observatory, Leiden, Netherlands John Tobin, jjtobin@ou.edu

University of Oklahoma, Norman, Oklahoma, United States Ewine Van Dishoeck, ewine@strw.leidenuniv.nl

Leiden University, Leiden, Netherlands Daniel Harsono, harsono@strw.leidenuniv.nl Netherlands

Jes Kristian Jørgensen, jeskj@nbi.ku.dk University of Copenhagen, Copenhagen, Denmark

Disks around young stars are the birthplace of planets. The first steps of planet formation, that is, grain growth and maybe even the formation of larger bodies, already occur when the disk is still deeply embedded in its natal envelope. Thus, these young disks, rather than the more evolved protoplanetary disks, likely provide the initial conditions for planet formation. However, the physical and chemical structure of embedded disks is poorly characterized. We therefore aim to analyze the temperature profile of these youngest disks. The temperature is a critical unknown, since it directly influences the volatile composition of the planet-forming material. Reversing this argument means that certain molecules are good tracers of the disk temperature. An example is N2D+, which can only be abundant when CO is frozen out (T < 20 K). The non-detection of N2D+ in L1527, together with analysis of the optically thick 13CO and C18O emission, suggests that this embedded disk is likely warm enough to prevent CO freeze-out. These results are in contrast with more evolved protoplanetary disk observations that show large cold (T < 20 K) gas reservoirs in the outer disk. Higher temperature regions (> 100 K) can be probed with complex organic molecules such as methanol, because their volatility is expected to be similar to that of water. This means that methanol ice evaporates around the water snowline. Our ALMA observations toward the V883 Ori disk therefore provide a way to validate the water snowline location that Cieza et al. (2016) postulated based on the continuum optical depth. Finally, the high spatial resolution and large frequency coverage of the PILS survey toward IRAS 16293 allows us to probe the temperature structure at different radii using multiple H2CO lines. These measurements provide the first observational constraints on the temperature in embedded disks, allowing us to test model predictions that they are warmer than their more evolved counterparts.

B1.3-0008-18 CO DESTRUCTION IN PROTO-PLANETARY DISK MIDPLANES

Arthur Bosman, bosman@strw.leidenuniv.nl Leiden Observatory, Leiden, Netherlands Catherine Walsh, cwalsh@strw.leidenuniv.nl Leiden Observatory, Leiden, Netherlands Ewine Van Dishoeck, ewine@strw.leidenuniv.nl Leiden University, Leiden, Netherlands

CO has long been thought to be the best mass tracer for proto-planetary disks as it can be easily detected with ALMA in many disks. However, the inferred gas masses from CO in recent ALMA observations seem to be inconsistent with their inferred dust masses, with inferred gasto-dust ratios between 0.1 and 10, rather than the canonical value of 100. Moreover, those few disks that have Herschel HD detections have gas masses inferred from HD that can be orders of magnitude higher than those inferred from CO. This suggests that at least one additional mechanism, next to freeze-out and photodissociation, is removing CO from the gas-phase. One suggestion is that the bulk of the CO is chemically processed, and the carbon sequestered into other less volatile species such as, CO2, CH3OH and CH4, in the dense, shielded midplane regions of the disk.

We have studied this option by carrying out a parameter exploration with our gas-grain chemical code. We investigated the CO abundance evolution over a range of conditions representative of disk mid-planes. The impact of the assumed chemical parameters, especially the efficiency of tunnelling and diffusion was also studied. A reduction of the total CO abundance by a factor of 10-50 is found at high densities between 15 and 30 K on timescales of 3 Myr assuming an ionisation rate of 10−17 s−1. Main reactions are identified. Varying the tunnelling barrier and the diffusion to binding energy ratio shows that the order of magnitude destruction of CO is robust between 20 and 30 K, but that there is a very strong dependence on the tunnelling efficiency of H below 20 K.

The finding that CO is efficiently destroyed between 20 and 30 K on a 3 Myr timescale is encouraging since most of the 13CO and C18O emission is expected to come from parts of the disk with temperatures within this range.

B1.3-0009-18 EXPLORING DCO+ AS A TRACER OF DUST EVOLUTION IN PLANETFORMING DISKS

Vachail Salinas, vachail@gmail.com Kagoshima University, Kagoshima-shi, Japan

M.R. Hogerheijde, michiel@strw.leidenuniv.nl Leiden University, Leiden, Netherlands

Nadia Murillo, nmurillo@strw.leidenuniv.nl Leiden University, Leiden, Netherlands

In planet-forming disks, deuterated species like DCO+ often show up in rings. Two chemical formation routes contribute: cold deuteration at temperatures below 30 K and warm deuteration at temperatures up to 80 K. In this work we reproduce the DCO+ emission in the disk around HD163296 using a simple 2D chemical model for the formation of DCO+ through the cold deuteration channel and a parametric treatment of the warm deuteration channel. We use data from ALMA in band 6 to obtain a resolved spectral imaging data cube of the DCO+ J=3- 2 line in HD163296 with a synthesized beam of 0.″53× 0.″42. The observed DCO+ emission is reproduced by a model with cold deuteration producing abundances up to 1.6e11. Warm deuteration, at a constant abundance of 3.2e12, becomes fully effective below 32 K and tapers off at higher temperatures, reproducing the lack of DCO+ inside 90 AU. Throughout the DCO+ emitting zone a CO abundance of 2e107 is found, with 99% of it frozen out below 19 K. At radii where both cold and warm deuteration are active, warm deuteration contributes up to 20% of DCO+, consistent with detailed chemical models. The decrease of DCO+ at large radii is attributed to a temperature inversion at 250 AU, which raises temperatures above values where cold deuteration operates. This return of the DCO+ layer to the midplane reproduces the local DCO+ emission maximum at 260 AU. We can use the morphology of DCO+ emission to trace the temperature substructures of disks produced by dust evolution processes. Outer disk temperature inversions, expected when grains decouple from the gas and drift inward, can lead to secondary maxima in DCO+ emission and a reduction of its radial extent. This can appear as an outer emission 'ring', and can be used to identify a second CO desorption front.

B1.3-0010-18 A SURVEY OF CH3CN AND HC3N IN PROTOPLANETARY DISKS

Jennifer Bergner, jennifer.bergner@cfa.harvard.edu

Harvard-Smithsonian Center for Astrophysics, Cambridge, Massachusetts, United States Viviana Guzman, viviana.guzman@alma.cl

Joint ALMA observatory, Santiago, Chile Karin Oberg, koberg@cfa.harvard.edu

Harvard-Smithsonian Center for Astrophysics, Cambridge, Massachusetts (USA), Cambridge, Massachusetts, United States

Ryan Loomis, rloomis@cfa.harvard.edu

Harvard-Smithsonian Center for Astrophysics, Cambridge, Massachusetts (USA), Cambridge, Massachusetts, United States

Jamila Pegues, jamila.pegues@cfa.harvard.edu

Harvard-Smithsonian Center for Astrophysics, Cambridge, Massachusetts (USA), Cambridge, Massachusetts, United States

The organic content of protoplanetary disks sets the initial compositions of planets and comets, thereby influencing the subsequent chemistry that is possible in nascent planetary systems. The complex nitrile-bearing species CH3CN and HC3N are, along with CH3OH, the only large organic molecules detected towards protoplanetary disks to date and therefore provide crucial constraints on the growth of organic complexity in disks. We present observations of CH3CN and HC3N towards the disks around the T Tauri stars AS 209, IM Lup, LkCa 15, and V4046 Sgr, as well as the Herbig Ae stars MWC 480 and HD 163296. In this sample, HC3N and CH3CN are detected towards five and three disks respectively. For disks with multiple detections, we constrain the emission origin of these complex nitriles using the rotational diagram method to obtain emission temperatures. We also explore connections between the observed nitrile emission strength and the physical environment of the disk. The relative abundances of different nitrile molecules are consistent in protostars, disks, and comets, demonstrating a robust nitrile chemistry at play in different circumstellar environments. In contrast, nitrile abundances relative to oxygen-bearing molecules appear systematically higher in disks compared to protostars and comets; the origin of this distinct, nitrile-rich organic chemistry in disks is at present not fully resolved, pointing to a need to explore other potential chemical pathways in disk models.

B1.3-0011-18 RESOLVED OBSERVATIONS OF 12C/13C AND 14N/15N IN PROTOPLANETARY DISKS

Viviana Guzman, viviana.guzman@alma.cl Joint ALMA observatory, Santiago, Chile

Isotopic ratios are commonly used to trace the origin of Solar System bodies. This is a fundamental but still highly debated topic. It is still unclear whether most of the organics are inherited from the protosolar nebula or if they are the result of an active chemistry in the protoplanetary disk phase.

Disk-averaged 15N enrichments that are similar to comets have been observed in disks, assuming a standard isotopic ratio 12C/13C= 70. However, spatially resolved observations of N isotopic ratios are needed to elucidate the origin of these 15N enrichments, and ultimately the origins of organics, across the Solar System: a constant 14N/15N ratio across disks would favor a scenario where disks inherit their organics from the natal cloud, while a gradient would strongly suggest that the chemistry is modified during the disk phase.

I will present high-angular resolution (0.2” = 15 au) ALMA observations of the HCN isotopologues in a protoplanetary disk. We derive the radial dependence of both the 12C/13C and 14N/15N isotopic ratios within the planet and comet forming region. I will discuss how these results compare with observed values in the ISM and in Solar System bodies, and how we can disentangle between the inheritance and disk chemical processing scenarios.

B1.3-0012-18 COMETS AND THEIR RELATIONSHIP TO THE EARLY SOLAR SYSTEM: INSIGHTS FROM SPACE MISSIONS AND EARTH-BASED OBSERVATIONS

Karen Meech, meech@ifa.hawaii.edu

University of Hawaii, Honolulu, Hawaii, United States

Comets and small primitive bodies were witness to the solar system's formative processes. During the earliest epochs of our solar system's formation, temperature gradients led to a variety of compositional and isotopic chemical gradients within the protoplanetary disk. This disk chemistry left it's chemical fingerprints on the planetesimals that are preserved as today's comets. A goal of comet studies has been to use the chemistry of comet ices understand the disk chemistry and formation location of comets. The story is incomplete, however, without considering the dynamical movement of these small icy bodies as the giant planets formed. A legacy of several decades of dedicated surveys to characterize the orbits, chemistry and physical properties of comets has resulted in a picture of comets that is quite different from the initial models developed in the 1950s. Today there are three cometary reservoirs: the Oort cloud, the Kuiper belt and scattered disk, and the main asteroid belt. Our definition of what distinguishes a comet form an asteroid is blurring, and there is likely a continuum of compositions between volatile rich and volatile poor. There is increasing evidence that in contrast to the distinct dynamical reservoirs we see today that comet formation regions strongly overlapped in the protoplanetary disk [1].

Comet missions have shown that there was wide-scale migration of disk material and comets incorporated dust from a variety of temperature regimes. Some of the refractory comet dust component experienced high temperatures near the sun, while in other cases there was evidence of aqueous alteration. In contrast, results from missions, in particular from the Rosetta mission have shown that the volatile component is likely primordial, possibly preserving signatures from the interstellar cloud. Comet nuclei are now known to be very low-density highly porous bodies, with very low thermal inertia, which likely contributes to the preservation of primordial material. In contrast comet sizes suggest that they have undergone collisional evolution.

Both groundand space-mission data have shown that comets are not chemically homogeneous and that comets show different chemical taxonomies that are not correlated with their dynamical class. Isotopic information is known for a subset of these comets, however a detailed comparison between disk chemical models and solar system dynamical models will need to be made before the data can be interpreted in terms of formation location and delivery of volatiles to the terrestrial planets. Recent dynamical models are reproducing key characteristics of today's solar system; some of these require significant giant planet migration, while others do not. A key difference between these two classes of models is that the former models expel rocky material from the inner solar system into the Oort cloud while the latter do not [2]. This talk will present our understanding of comets and their relation to the early solar system and protoplanetary disk, and discuss how newly discovered objects may contribute to our understanding of the planet formation process in other solar systems [3].

This material is based upon work supported by the National Aeronautics and Space Administration through the NASA Astrobiology Institute under Cooperative Agreement No. NNA09DA77A issued through the Office of Space Science, and by grants from the National Science Foundation, AST 1413736 and AST-1617015.

B1.3-0013-18 THE COMPOSITION OF COMETS - 30 YEARS OF INVESTIGATIONS

Rita Schulz, rschulz@rssd.esa.int

ESA-ESTEC/RSSD, Noordwijk, Netherlands Jochen Kissel, cometkissel@kabelbw.de

Max Planck Institut für Sonnensystemforschung, Göttingen, Germany Johan Silen, johan.silen@fmi.fi

FMI, Helsinki, Finland

The study of comets is important for understanding the origin of our solar system and as such ultimately for identifying the prerequisites for the development of life. As comets are considered remnants of the early solar system formation and spent most of their lifetime at temperatures below 50 K, their chemical composition, particularly in view to organic compounds, is very important for understanding whether the complex organics, from which life might have developed, were formed from simpler molecules on the surface of the primitive Earth or were supplied as ready by impacting comets. The latter would mean that such complex molecules were already present 4.6 billion years ago. Also the intimate mixture between minerals and organic molecules is an essential aspect for the origin of life. Different grain surfaces provide different catalytic properties, and can locally lead to a decrease of entropy on the expense of the entropy elsewhere in the closed system of multigrain dust, once it is in water.

The first major breakthrough in identifying the organic composition of a comet nucleus dates back to 1986, when three spacecraft (VEGA 1, 2 and Giotto) passed through the inner coma of comet Halley and obtained in-situ measurements of its gas and dust composition. A number of small organic molecules, known to be present in the interstellar medium were detected in the gas coma, and the presence of organic macromolecules was discovered in the comet dust. About 10 years later (1996-1997) the apparition of the extraordinary bright comet Hale-Bopp in combination with the availability of new sophisticated observing facilities at sub-mm wavelengths, led to a quantum leap in our understanding of the evolution of the gas coma composition as a function of heliocentric distance. In 2006, after another decade, the Stardust mission returned a sample of dust particles collected in the coma of comet Wild-2 which permitted the detailed analysis of the returned material in laboratories available on the Earth; and in 2016, again about 10 years later, the Rosetta mission concluded its 2-year rendezvous-mission with comet Churyumov-Gerasimenko. In these 30 years of comet compositional investigations important progress was made in identifying the composition and chemistry of comets. An overview will be given of the most important milestones with special emphasis to organic material.

B1.3-0014-18 THE INVENTORY OF PREBIOTIC BUILDING BLOCKS AROUND A YOUNG, SUN-LIKE PROTOSTAR

Niels Ligterink, nielsligterink@gmail.com Leiden Observatory, Leiden, Netherlands Hannah Calcutt, calcutt@nbi.ku.dk

Small molecules such as methanimine (CH2NH), methylamine (CH3NH2), hydroxylamine (NH2OH) and methyl isocyanate (CH3NCO) belong to a select group of so-called prebiotic molecules that are thought to be at the basis of amino-acid and peptide-bond formation. On Earth, amino- acids are important building blocks of life, which through peptide bonds link with each other to form proteins. Recent ALMA observations have shown for the first time that CH2NH and CH3NCO are present around the low-mass, sun-like, protostar IRAS 16293-2422, showing that prebiotic building blocks could already have been present at the earliest formational stages of our own Solar System. [1][2]

This work is conducted as part of the protostellar interferometric line survey, a broad band ALMA survey of the protostellar binary IRAS 16293-2422. The detections of CH2NH and CH3NCO rotational transitions are presented and integrated emission maps show their presence at Solar System scales (60 AU) around the protostar. Supporting solid-state laboratory data shows that CH3NCO has its origin in the ice mantles of interstellar dust grains. Non-detections of NH2OH and CH3NH2 are used to constrain chemical pathways to interstellar amino-acid formation. Specifically, the abundance comparison of CH3NH2 between this low-mass protostar and the galactic centre source Sgr B2 shows that CH3NH2 is depleted by

at least 1-2 orders of magnitude in IRAS 16293-2422. This shows that around low-mass protostars CH2NH might be a more relevant precursor to amino-acid formation than CH3NH2.

Organic molecules are the building blocks of life and this is why the search for amino acids and their complex organic precursors at different stages of star and planet formation is one of the exciting topics in modern astronomy. Understanding how, when and where organics (simple as well as complex including potentially prebiotic molecules) are formed is one of the most important questions for Astrochemistry/Astrobiology. Complex organics have been detected in prestellar cores, protostars, and protoplanetary disks. Can a part of the organic content observed in these regions be preserved during the protostellar stages and incorporated into asteroids and comets, that can deliver it to planetary embryos through impacts? By looking at the cometary compositions, observations of solar-type protostars can help to address this critical question.

In this context, here we will present our observations towards the solar-type protostar IRAS 16293-2422 in the 3mm band of the IRAM 30m telescope along with existing ALMA observations. We will also describe how the chemo-dynamical simulations using the state-of-the-art gas-grain-bulk chemical-kinetic model can help us to understand the chemical composition of comet 67P observed by Rosetta.

For the first time, we will also shed light on to the possibility of protostellar inheritance of glycine (king of the ROSETTA Zoo) on to the comet 67P.

B1.3-0016-18 HOST ICES FOR VOLATILE SPECIES IN SOLAR SYSTEM PLANETESIMALS: THE CASE FOR CLATHRATES

Jonathan Lunine, jlunine@astro.cornell.edu

Cornell University, Ithaca, New York, United States Olivier Mousis, olivier.mousis@lam.fr

Laboratoire d'Astrophysique de Marseille, Marseille, France

The identity of the host material for volatile species present in comets, KBO's, icy moons and giant planet atmospheres is a key question in tying conditions in the outer solar system to the composition of these observable bodies. Planetesimals may contain crystalline water ice and/or amorphous water ice as host material, within which volatiles may be trapped, or the volatiles may condense out directly as ices. These processes depend on conditions within the protoplanetary disk and the history of the grains as they fall into, and then move within, the disk itself. Beginning with data from Comet Halley in 1986, and culminating with the observations of Comet 67/P Churyumov-Gerasimenko, comets have proved to be key in constraining the phases within which volatiles are trapped. Measurements of abundances of small species of similar volatility (Ar, N2, CO) provide a basis for testing different trapping patterns, and suggest clathrate hydrate as the preferred carrier phase (Mousis et al. Ap.J 819, L33, 2016). Subsequent analyses of other species such as O2 support this inference. Furthermore, returning to the Halley data-now three decades old-suggests consistency with the clathrate hypothesis but with an elevated C/O ratio in the gaseous disk.

B1.3-0017-18 BINDING ENERGY A KEY TO DEFINING INTERSTELLAR VOLATILE SPECIES

Icy grain mantles are the main repository of the complex organic molecule (COM) in the interstellar medium (ISM). Such icy mantles constitute the main reservoir of volatiles in clouds, protostellar envelopes, comets, and protoplanetary disks. Ices form by a condensation of atoms and molecules from the gas-phase and subsequent grain surface chemistry. Hydrogenation reactions initiate the complexity of interstellar grain mantle in molecular clouds (10 K). Since the chemical composition of interstellar grain mantle is mostly dependent on adsorption energies (also known as binding energy) of the surface species, it is a key to study the formation of more complex molecules on interstellar grain surfaces. H2 is believed to be a precursor of the COM. Since hydrogen is widespread either in atomic or in molecular form, our aim in this work is to review the variation of the adsorption energies of H and H2 and other important elements e.g., C, N, O, S, and P depending on the nature of the adsorbents. Choice of absorbents was based on relative abundances of interstellar material. Dust particles in the interstellar medium are composed mainly of silica (SiO2), magnesium and iron silicates (e.g., olivine, forsterite), amorphous carbon or water ice. Benzene is employed as a carbonaceous material and for silicate grain, a simple cluster of silicon dioxide (silica) (SiO2)3 is used (Sil et al. 2017). Around dense cloud regions, water is the major constituent of a grain mantle, therefore, usage of binding energies with bare grains is immaterial. To mimic the water as the adsorbents, we use watercluster.The outcome of our calculations is implemented in a large gas-grain chemical model to predict the abundances of various complex interstellar species.

How life emerged on Earth is a long-standing mystery. Comets are the reservoirs of primitive material, amino acids, organic compounds etc. It is thought that heavy bombardment of these comets in the early Earth could lead to the synthesis of Earth's prebiotic inventory (Chyba 1990). The recent observation of organohalogens in protostar IRAS 16293 and comet found CH3Cl to CH3OH ratio is consistent between comets and the Interstellar Medium (Fayolle et al. 2017). We will use gas-grain chemical modeling to determine the abundance of some simple and complex molecule and check their consistency with cometary observations. Monte Carlo simulation will also be employed to study the chemical composition under Interstellar environments on the interstellar dust surface to mimic the cometary grain surface compositions.

B1.3-0019-18 FROM ORGANIC INTERSTELLAR MATERIAL OF DIFFUSE INTERSTELLAR BANDS TO COMET NUCLEI: SURVIVING THE ACCRETION PROCESS.

Jean-Loup Bertaux, jean-loup.bertaux@latmos.ipsl.fr LATMOS / UVSQ - IPSL - CNRS, Guyancourt, France Rosine Lallement, rosine.lallement@obspm.fr Observatoire de Paris Meudon, Meudon, France

The analysis of dust grains collected by Rosetta spacecraft from comet 67/P ChuryumovGerasimenko has shown that they are constituted of about the same amount of minerals and large organic molecules (in mass 45% organic, 55% mineral, Bardyn et al. 2017). We suggest that they are the same organic molecules that produce, in the Interstellar Medium (ISM), diffuse absorption features imprinted on stellar spectra (DIBs, Diffuse Interstellar Bands). The large molecules forming the DIBs are not yet identified, except for fullerene C60+, but are thought to constitute ". the largest reservoir of organic material in the Universe" (Snow, 2014). They were certainly present in the parcel of ISM which condensed into our proto-solar nebula. They were conserved during the formation of the solid comet nucleus, within the scenario established by Davidsson et al. (2016) based on many arguments collected by Rosetta: a hierarchical scenario of gentle accretion of small interstellar grains to the final size of the nucleus. We back up our suggestion from both qualitative and quantitative arguments. A statistical analysis of DIBs suggests that in the ISM, the ratio organic/mineral is at least RISM=0.32, to be compared to RC= 0.8 for the comet. On the other hand, the sounding of some interstellar nebulae show that, when the line-of-sight approaches the centre, the DIBs depths are levelling off while the dust extinction is still increasing, suggesting an accretion process for the DIB molecules. These organic molecules would agglomerate to form interstellar grains that will end up in the proto-solar nebula, then in comet nuclei. This conclusion implies that a comet return-sample mission would not need to be much cooled to keep the double interest for comets and for Interstellar Medium studies.

B1.3-0020-18 THE CHEMICAL STRUCTURE OF THE ASTEROID BELT

Benoit Carry, benoit.carry@oca.eu Observatoire de la Côte d'Azur, Nice, France

The asteroid main belt between Mars and Jupiter holds evidences from the early Solar System history. Built from the originally thin and stratified accretion disk, it has been scrambled by planetary migrations, resulting in a dynamical excitement and radial mixing of compositions.

Since the 1970s, spectral surveys have characterized the surface compositions of the largest members first, then of smaller bodies, slowly progressing through the size distribution. These surveys led to major discoveries, including the succession of dominating compositional classes along heliocentric distances, and the presence of interlopers in this over-arching structure.

In the 2000s, these results have sustained the emergence of the current paradigm of Solar System formation in which planets migrated from their formation locations to their current orbits (the Nice model). Since then, the Sloan Digital Sky Survey and the NASA WISE mission have observed over a hundred thousands of asteroids in the visible and mid-infrared, characterizing their surface composition and providing their diameter. Simultaneously, our knowledge on asteroid density presented a tenfold increase.

This dataset allowed to push the description of asteroid compositions to smaller sizes and to study the distribution of material in the main belt by mass, rather than by numbers. The resulting picture go back over the previous view, and the few interlopers seem to be rule. The large scale structure discovered in the 1980s seen on the largest bodies holds, but mixing increases at smaller sizes. This detailed picture supports the main results from recent dynamical models of planetary migration and radial mixing of smaller bodies, albeit several observed structures remain yet to be explained: numerous primitive D-type in the inner belt, apparently missing mantle counterpart (A-types) to the crustal and iron core-like (Vand M-types) material.

In this talk, observational evidences from past decade will be reviewed, current picture of the compositional distribution of material in the main belt presented; open questions, inherited from past spectral surveys, summarized; and prospectives drawn.

B1.3-0021-18 LINKING THE NITROGEN ISOTOPIC COMPOSITION OF STAR-FORMING REGIONS WITH COMET 67P

Susanne Wampfler, susanne.wampfler@csh.unibe.ch University of Bern, Bern, Switzerland

Jes Kristian Jørgensen, jeskj@nbi.ku.dk University of Copenhagen, Copenhagen, Denmark Hannah Calcutt, calcutt@nbi.ku.dk

University of Copenhagen, Copenhagen, Denmark Audrey Coutens, audrey.coutens@u-bordeaux.fr Laboratoire d'Astrophysique de Bordeaux, Pessac, France Kathrin Altwegg, altwegg@space.unibe.ch

University of Bern, Bern, Switzerland Martin Rubin, martin.rubin@space.unibe.ch University of Bern, Bern, Switzerland

There are large variations in the stable isotope composition of the volatile elements hydrogen, nitrogen, and oxygen among the solar system bodies. The solar system solids are typically enriched in the rare heavy isotopes (D, 15N, 17O, 18O) compared to the Sun and Jupiter. To understand the origin of these isotopic anomalies, a cross-disciplinary link between the fields of astronomy, cosmochemistry, and solar system science is indispensable. However, establishing such as link is not straightforward, as astronomical observations mainly target the gas in starforming regions, whereas the most pristine solar system materials are present in the form of meteorites and cometary ices.

The ratio of the two stable nitrogen isotopes, 14N/15N, is a promising tool for linking results across the fields, as the nitrogen isotopic composition can be measured in star-forming regions and solar system bodies. The 14N/15N ratio should also be less prone to secondary alteration than the deuterium-to-hydrogen ratio.

In this contribution, we will present spatially resolved measurements of the 14N/15N ratio around embedded protostars from IRAM observations and the Protostellar Interferometric Line Survey (PILS) with ALMA. First results on the nitrogen isotopic composition of comet 67P/Churyumov-Gerasimenko by Rosetta-ROSINA will also be presented, and we will explain how we are trying to link these data sets to gain insights into the origin of nitrogen in our solar system and beyond.

B1.3-0022-18 CHEMICAL EVOLUTION OF COMPLEX ORGANICS IN ICES FROM INTERSTELLAR ICE TO COMETS

Daniel Paardekooper, daniel.m.paardekooper@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Murthy Gudipati, murthy.s.gudipati@gmail.com

Jet Propulsion Laboratory, California Institute of Technology/NASA, Pasadena, United States Bryana Henderson, bryana.l.henderson@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology/NASA, Pasadena, United States

Comets contain a wealth of information, as they preserve the earliest record of material from the formation of our solar system. Recently, after a 10 year journey, Rosetta visited the comet 67P/Churyumov-Gerasimenko. This mission unveiled the presence of significant organic material including the amino acid glycine.1 Although we cannot yet directly compare cometary ice to interstellar ice, this detection does support the hypothesis about the origin of life on Earth, e.g., that complex organic molecules may have been delivered from space.

In the Ice Spectroscopy Laboratory at NASA's Jet Propulsion Laboratory, we are in the process of upgrading the existing two-color Laser Ablation Ionization Mass Spectrometer system to enable spectroscopy of specific mass-filtered radiation products.2,3 This high vacuum system has a cryostat, enabling substrate temperatures down to 5 Kelvin. On top of this substrate, we can deposit an astrochemically-relevant mixture,. This ice can subsequently be processed using high-energy electrons, resembling the cosmic rays present in the interstellar medium. Radicals will be created in this ice, which can subsequently react and form complex organic molecules. We have previously demonstrated that we can directly study these radiation products at low temperature, using IR laser desorption combined with multi photon ionization mass spectrometry.

To enhance the existing capabilities of the system, we will incorporate a Quadruple Mass Filter; this allows us to spectroscopically study individual complex organic species (each with a specific mass over charge, m/z). With ion optics, a selected molecular ion will be guided toward a second cold substrate for re-deposition, where it can be subsequently studied using spectroscopic means. This powerful combination of mass spectrometry and spectroscopy will enable us to not only (1) better identify individual mass signals generated by radiation experiments, but to also (2) obtain clear spectral profiles of these products (which may be reactive and/or difficult to isolate by other means). The ultimate goal of this system is to better understand the low-temperature radiation processing of astrophysical ices, and to bridge our understanding of interstellar ices and cometary bodies.

Acknowledgements: This work has been carried out at Jet Propulsion Laboratory, California Institute of Technology under a contract with the National Aeronautics and Space Administration, and funded by JPL's R&TD Program and NASA Solar System Workings Program. DMP thanks NASA Postdoctoral Program (NPP) Fellowship.

B1.3-0023-18 NEW INTERSTELLAR DETECTIONS TO TEST AND REFINE ASTROCHEMICAL MODELS

Brett McGuire, bmcguire@nrao.edu

National Radio Astronomy Observatory, Charlottesville, Virginia, United States

We present the detections of three new oxygen-bearing molecules in the ISM: HC5O, HC7O, and methoxymethanol (CH3OCH2OH) that are found at the earliest (TMC-1: HC5O and HC7O) and latest (NGC 6334I: CH3OCH2OH) stages of star formation. TMC-1 is a cold, dense dark cloud at the stage just before star formation begins; it represents the t=0 chemical inventory, an inventory that is processed as soon as stars turn on. Observations at early stages offer the ability to benchmark our astrochemical models under relatively quiescent conditions. Conversely, NGC 6334I is an active, massive hot core region with extreme chemical and physical conditions that have processed this early inventory into that which will be incorporated into a forming solar system. We will discuss our results, including additionally the surprising first detection of the aromatic benzonitrile (c-C6H5CN) molecule in TMC-1, in these contexts, and examine the laboratory and observational studies that can address these issues.

B1.3-0024-18 PRIMITIVE LITHOLOGIES IN PRIMITIVE CARBONACEOUS CHONDRITE.

Akira Tsuchiyama, atsuchi@kueps.kyoto-u.ac.jp

Graduate School of Science, Kyoto University, Kyoto, Japan

Chondritic-porous interplanetary dust particles (CP IDPs) composed of amorphous silicates (GEMS: glass with embedded metal and sulfide), organics and silicate mineral grains at subμm scales are believed to be of cometary origins and represent samples of the building blocks of the solar system (e.g., [1]). Less aqueously-altered carbonaceous chondrites (CCs) have finegrained matrix of amorphous silicate (GEMS-like material), silicate mineral grains and organics and called primitive CCs. However, most of them are more or less oxidized (absence of metal) and aqueously altered (presence of hydrous minerals) (e.g., [2]). We found more primitive lithologies in two primitive CCs; Acfer 094 (C ungrouped) and MIL 090657 (CR2.7).

By using X-ray nanotomography, an ultra-porous lithology (UPL) having large porosity comparable with CP IDP was found in a matrix of Acfer 094 [3]. UPL is composed of GEMS-like materials, where hydrous layer silicate and metal are absent, silicate minerals and organics at sub-μm scales. The isotopic compositions are solar. After this founding, we found many UPLs 10 μm in typical size using SEM. Distinct UPL-matrix boundary without deformed texture suggests the presence of ice in void space for preserving UPLs during accretion with matrix.

Less porous lithology having GEMS-like materials with metal as well as sulfide and organics were found in a matrix of MIL 090657 [4,5]. This lithology is recognized only in microtomed sections. By using X-ray nanotomoraphy, similar lithology with slight aqueous alteration and others with relatively high aqueous alteration were found. The Texture of lithology boundary suggests that the primitive lithology was poorly lithified during their accretion.

The two primitive lithologies have different features with each other and also different from CP-IDPs. A primitive lithology in Paris (CM) [6] has different features as well. Nanoparticles similar to GEMS were formed by condensation experiments in the system Mg-Si-Fe-S-O, where a variety of mineralogy were formed in different redox conditions [7], suggesting that GEMS and GEMS-like materials were formed by condensation probably in different locations of the primitive solar nebula, and CP IDPs and the primitive lithologies in CCs may represent samples of the building blocks of the solar system in different locations.

Vincenzo Della Corte, v.dellacorte@gmail.com IAPS/INAF, Roma, Italy

Alessandra Rotundi, rotundi@uniparthenope.it University Parthenope of Naples, Naples, Italy

Recent high-resolution ALMA observations of protoplanetary disks (e.g. Isella et al. 2016, PRL, 117; ALMA Partnership et al. 2015, ApJ Lett. 808:L3,10pp) triggered interest on studying solid bodies in discs at different scales. The dynamics of small (from sub-micron grains up to solid bodies of sizes of hundreds of meters) dust particles is governed by the interaction of the gas with the gravity of the star in the disk. Consequently, the dust dynamics are subject to the vertical settlement of dust particles (see e.g. Armitage, P., Lect. Notes, 2017, arXiv:astro ph/0701485v6).

In the case of planetesimals (tens of kilometers in size) the interaction is governed mainly by gravity. Turrini et al. 2018 (AA, submitted, arXiv:1802.04361) investigated the dynamical and collisional response of the planetesimal population to the formation of HD163296's three giant planets. The resulting high impact velocities increase the collisional dust production and release gas species, like H_2O, due to the ice sublimation during impacts. Such high impact velocities would transform the gas flow into supersonic and could lead to transition from the Epstein regime to the continuum Stokes regime.

Here, we focus on applying of our code, developed for dynamics of non-spherical particles in cometary environment (Ivanovski et al. 2017, Icarus 282, 333-350), to the dynamics of secondgeneration dust collisionally produced in HD163296. We study: 1) the vertical settlement of the high speed dust and 2) its motion before the Epstein-to-Stokes regime transition occurs. We present results on how the dust non-sphericity affects the timescales of vertical settling of small dust, what are the dust rotational frequencies and a mechanism of accumulation of non-spherical dust particles in the disk gaps.

B1.3-0026-18 CHONDRULE FORMATION THROUGH COLLISIONS OF ROCKY AND ICY PLANETESIMALS

Sin-iti Sirono, sirono@eps.nagoya-u.ac.jp Nagoya University, Nagoya, Japan

Chondrule formation is one of the most important issues to be solved in planetary science. Although many models have been proposed, a consensus has not been reached. Heating by 26Al causes internal melting of rocky planetesimal. When such plantesimals collide, silicate melt can splash out from inside and may lead to formation of chondrules (e.g. Asphaug et al. 2011, EPSL 308 369, Sanders and Scott 2012, MAPS 47 2170). However, the size of a droplet should be much larger than the chondrule size in this model. Here I propose a new model based on collisions between a melting rocky planetesimal formed inside the snow line and a planetesimal formed outside the snow line. I determined a range of water content which is suitable for chondrule formation. Collision simulation is conducted to determine the efficiency of chondrule formation using iSALE hydrocode. If the inside of rocky planetesimal is totally melted, the total volume of chondrule is larger than that of a projectile object. This would be the origin of chondrules in ordinary chondrites. On the other hand, collisions involving cool rocky object leads to less efficiency of chondrule formation. Chondrules in carbonaceous chondrite can be formed in this process.

B1.3-0027-18 EARLY ACCRETION OF CHONDRULE DUST RIMS

Augusto Carballido, augusto_carballido@baylor.edu Baylor University, Austin, Texas, United States Lorin Matthews, lorin_matthews@baylor.edu

Center for Astrophysics, Space Physics, and Engineering Research (CASPER), Baylor University, Waco, Texas, United States

Truell Hyde, truell_hyde@baylor.edu

Center for Astrophysics, Space Physics, and Engineering Research (CASPER), Baylor University, Waco, Texas, United States

Chuchu Xiang, chuchu_xiang@baylor.edu Baylor University, Waco, Texas, United States

Fine-grained dust rims (FGRs) surrounding chondrules could have acted as the “glue” that allowed chondrules to stick and form centimeter-sized agglomerates. The porous structure of FGRs would have allowed inter-chondrule collisional energy to dissipate. Eventually, FGRs would have been compacted by these collisions.

We performed molecular dynamics simulations of FGR accretion to elucidate the initial structure of FGRs (i.e., before compaction) under different solar nebula conditions at a heliocentric radius of 1 AU. The disk model employed was the minimum-mass solar nebula. Our coagulation code takes into account the physics of collisions between micron-sized dust and submillimetersized chondrules. Both types of solids are assumed to be spherical. The relative velocities between dust and chondrules were taken to be due to Brownian motion and turbulence. The latter contribution was parameterized by the dimensionless turbulent viscosity α number of accretion disk theory. The collisional outcomes that we modeled are sticking, restructuring and bouncing. For computational expediency, we restricted dust particles to accumulate on a small circular patch on the chondrule surface.

Our simulations used α values of 10−k, k=1,. ,6. Dust grains had radii between 0.5 and 10 microns, distributed as a power law with exponent -3.5. We also varied the chondrule radius from 500 microns to 1000 microns, in 100 micron increments. In some cases, we modeled accretion of dust aggregates (cluster aggregation, CA), in addition to accretion of dust monomers (particle aggregation, PA). Rims were built to a total thickness of up to 400 microns. The time required to accumulate the rim was tracked for the duration of the simulations, which modeled up to 100 years of evolution.

For PA, we find that the porosity of FGRs is typically very high (> 60%), and that it increases with distance from the chondrule surface. The porosity radial profile of FGRs is qualitatively similar among different α’s and chondrule radii. This profile has a relatively small slope within 120 microns of the chondrule surface, with porosities between 55% and 70%. The slope increases markedly at a distance between 120 and 250 microns. As FGR thickness increases with time, the mean porosity of FGRs decreases from about 85% to between 66% and 70%,

depending on the chondrule radius.

The radial porosity profiles of FGRs formed by CA are qualitatively and quantitatively different from those formed by PA. The former accretion mode produces FGRs that are more porous than those obtained by PA by 30%, at least within 250 microns of the chondrule surface. The CA porosity profiles are flatter than the PA profiles.

Future work will need to take into account fragmentation of FGRs, non-sphericity of grains and chondrules, and the effect of electrical charges on the surfaces of both dust grains and chondrules.

B1.3-0028-18 DUST AND GAS IN DEBRIS DISKS AROUND NEARBY STARS

A. Meredith Hughes, amhughes@wesleyan.edu

Wesleyan University, Middletown, Connecticut, United States

Debris disks are signposts of mature planetary systems, with dust generated by collisions bodies that have grown to at least the size of Pluto-like planetesimals. While the origin of dust in most debris disks is reasonably well understood, the origin of gas in some systems is less clear. I will review our current understanding of the origin and nature of gas in debris disks, including whether the gas is primarily second-generation in nature like the dust, or whether it may be a remnant of the protoplanetary disk in some systems. I will also discuss recent high-resolution ALMA observations that allow us to dynamically measure the total mass inventory of the nearby debris disk around AU Mic, by resolving its vertical structure at millimeter wavelengths for the first time. Resolved observations at two widely separated radio frequencies (ALMA Band 6 and Band 9) also allow us to probe the strengths of bodies in the collisional cascade for the first time outside our Solar System.

B1.3-0029-18 ACHONDRITE METEORITES - INSIGHTS INTO SOLAR SYSTEM AND PLANETARY PROCESSES FROM 'OLD' AND 'YOUNG' ROCKS

Caroline Smith, caroline.smith@nhm.ac.uk

The Natural History Museum, London, United Kingdom

As of February 2018 there are approximately 57400 officially classified meteorites [1]. Of these approximately 4000 are classified as achondritic meteorites [1], based on their chemical, mineralogical and textural features. The classification system for the achondrite meteorites is complex and, in some cases remains contentious, with different characteristics seemingly contradicting the models of formation and evolution and the traditionally understood genetic links between different types of meteorite. Recent advances in isotope cosmochemistry, owing to improvements in both instrumentation and sample processing techniques, have helped to solve some outstanding issues but have also raised new questions [e.g. 2,3]. Despite this complexity, the non-chondritic meteorite samples represent a highly diverse set of Solar System materials and provide a wealth of information in the chemical and physical evolution of the early Solar System e.g. first few millions of years and, in the case of martian and lunar meteorites subsequent planetary processes.

Primitive achondrites: Primitive achondrites are made up of the stony meteorite acapulcoites, brachinites, lodranites, winonaites, ureilites and brachinites and also the iron meteorite IAB-complex and IIEs [4]. It is generally understood that the primitive achondrite meteorites experienced at least some partial melting or formed from material that was molten but had not experienced large-scale differentiation (i.e. segregation of metal from silicate) processes, thus they retain 'primitive' chemical signatures such as chondritic O isotope signatures [4]. Primitive achondrites provide information on the chemical and physical processes occurring early in the Solar System during planetesimal formation and prior to magma ocean formation.

Achondrites: Achondrites comprise both stony meteorites and stony-iron meteorites. The majority of the achondrites (angrites, aubrites, HED clan (howardite, eucrite, diogenite), pallasites and mesosiderites) are derived from asteroidal parent bodies, whereas the Martian and lunar meteorites and from 'planetary' bodies i.e. the planet Mars and the Moon. The asteroidal achondrites show evidence of igneous textures i.e. they formed from molten precursor material and chemical signatures indicative of derivation from a differentiated source. The stony-iron pallasites show complex textures and show some chemical affinities with the IIIAB irons [4], although other evidence, such as the cooling rates of metal indicates a genetic link is unlikely [5]. The traditional view of pallasite formation was that these samples represented the core-mantle boundary of a differentiated proto-planet(s) [e.g. 6], however more recent studies suggest that the pallasites may have formed by impact processes during a 'hit and run' collision [5]. Lunar meteorites provide additional insights as to the formation and evolution of Earth's moon given that they show more extensive variation than the Moon rocks collected during the Apollo missions. Martian meteorites are of great value given they are the only samples of Mars available to study in laboratories on Earth and thus provide some 'ground-truth' to compare with data generated from robotic remote sensing and lander missions. Indeed, the first conclusive evidence of liquid water on Mars was found during the study of the Martian meteorite Nakhla [7].

Interplanetary and interstellar dust particles (IDP and ISD) continually bombard the Earth. They ablate in the atmosphere, and their trajectories change due to drag forces by the time ground based optical and/or radar observations could fully characterize them. These particles carry valuable information about their parent bodies that can now be fully harvested by in situ dust measurements, using newly developed instrumentation. Placing a dust instrument onboard a near-Earth spacecraft will revolutionize our understanding of the composition of interstellar and interplanetary dust, contributing to our fundamental understanding of the evolution of our solar system, and will improve our dust hazard models for the safety of crewed and robotic missions to Mars and other destinations.

This talk will summarize the capabilities of a new in situ dust instrument capable of measuring the mass, charge, composition, and velocity vector of impacting dust particles. By deriving the orbital elements of dust particles their source regions can be identified. We will summarize the scientific rationales for a mission concept to carry a dust impact ionization mass spectrometer instrument onboard a near Earth spacecraft. The setup will enable future missions to explore the diversity of the chemical makeup of a broad range of bodies in our solar system and beyond, offering a powerful approach to testing the genetic relationships between small body reservoirs.

Prior to the Dawn mission, it was already known from telescopic observations that Vesta and Ceres, the two most massive bodies in the main belt, had divergent histories. Vesta's surface was very similar to basaltic achondrite meteorites [1], and Ceres' had affinity to primitive carbonaceous chondrites [2, 3]. Ceres mass and size provided a density of about 2.1 g/cm3, indicating a significant water content (25% by mass), and thermodynamic modeling [4, 5] showed heating, ice melting and silicate hydrothermal alteration with mass differentiation. Vesta was known to be much denser (3.46 g/cm3), suggesting a dry and hot history [6]. Prior to the Nice [7] and Grand Tack [8] models, Ceres and Vesta were thought to have formed in the same part of the protoplanetary disk near their current location [9], and their differences were ascribed to a delay in the formation of Ceres with respect to Vesta. The Dawn mission's exploration of Vesta and Ceres [10] has advanced our knowledge of their internal evolution and surface geology and composition, which elucidates their early histories and adds constraints on early solar system processes. These bodies offer remarkable examples where differentiation state can help constrain accretional environments. Dawn confirmed that Vesta experienced extensive silicate melting and differentiation, resulting from a hot, dry evolution [11]. On the other hand, Ceres exhibits a much milder thermal history, resulting in only partial differentiation and retention of volatiles [12-15]. This contrast can be primarily attributed to the abundance of water in Ceres that helped moderate internal temperature via latent heat and hydrothermal circulation [5, 16]. It has been suggested that Vesta and Ceres accreted from similar chondritic feedstocks but at different times, i.e., with different short-lived radioisotope budgets [4, 9]. Abundance of Al-26 could lead to rapid devolatilization of volatiles in Vesta, accreted earlier, while Ceres could preserve the bulk of its volatiles. However, it seems likely that the starting composition of Vesta and Ceres was very different, especially in terms of ice abundance. The remarkable discovery of ammoniated clays at the surface of Ceres [17] is a primary clue. Multiple models have been suggested to explain the origin of volatiles in the asteroid belt, and several distinct episodes of volatile migration have been suggested. The first one is that planetesimals in the 100-meter size range migrated from the outer Solar system via gas drag and could gently accrete with growing asteroids in the main belt [18]. However, migration of planetesimals across the gap opened by Jupiter in the solar nebula likely lead to de-volatilization and loss of most of the ammonia [19]. An alternative is that larger planetesimals (1-10s km) migrated following destabilization of feeding zones by the growing giant planets [20]. While this may have favored preservation of volatiles, the accretion of that material at velocities of 10s km/sec with growing asteroids is not well understood. Ceres' formation in, and subsequent migration from the Kuiper Belt [21] is challenged by dynamical and geophysical considerations [22]. The Grand Tack model or similar models tracking early planetary growth and migration may provide the best compromise, where Ceres came from the region between the giant planets [8]. Recent accretion models support the idea that planetesimals that large could form between Jupiter and Neptune [23].

The Dawn spacecraft orbited Vesta (2011-2012), is now orbiting Ceres (2015-2018), and has provided the first detailed evaluation of large planetary building blocks that reside in the asteroid belt. Analyses of these protoplanets involve integrating data from Dawn instruments to assess mineralogy and morphology in geologic context, quantify topography globally at high spatial resolution, and document global elemental composition, all coupled with coherent Doppler tracking that enables assessment of internal mass distribution from gravity measurements. These two protoplanets are quite dissimilar: Vesta (near 2.4 AU) exhibits affinities to the terrestrial planets as an anhydrous silicate body that differentiated early into a rocky crust, mantle, and core whereas Ceres (near 2.8 AU) exhibits affinities more associated with an 'ocean world' and represents an ice-rich partially-differentiated body. Although both bodies exhibit an extensive subsequent cratering history across their surfaces, they each capture different aspects of early Solar System history. The average surface of Vesta is relatively bright, reflecting its pyroxene-rich product of differentiation, whereas that of Ceres is quite dark, reflecting a regolith containing pervasive Fe and C opaque compounds. The mineralogy of Vesta

is now directly tied to Howardite-Eucrite-Diogenite achondrite meteorites (HEDs) in patterns on the surface associated with major impact events that excavated primary Vesta lithologies and mixed and redistributed them globally. Minor amounts of foreign materials that were delivered later contaminate the surface and exhibit carbonaceous chondrite affinities, including hydrous components. Such exogenic materials are identified and mapped in spatial context. In contrast, Ceres exhibits a globally dark aqueously altered surface mineralogy including ammoniated components. Small exposures of water-ice are detected at a few recent craters, while sub-surface ice in regolith pores increases toward the poles. Local areas enriched in sodium-carbonate are identified and mapped, including the prominent relatively recent and very bright deposits in Occator crater. Localized exposures of aliphatic organics have been mapped across an elongate 200 km region in the northern hemisphere. We explore how the very distinct compositional and geologic properties of these protoplanets, the two most massive bodies found in the asteroid belt, result from differences in their starting materials, location, and evolution during the subsequent 4.5 Ga.

B1.3-0033-18 THE CARBON CONTINUUM IN THE SOLAR SYSTEM

Amanda Hendrix, arh@psi.edu

Planetary Science Institute, Tucson, Arizona, United States Faith Vilas, fvilas@psi.edu

Planetary Science Institute, Tucson, Arizona, United States

Carbonaceous species evolve from hydrocarbons and organics to amorphous and glassy carbons to graphites with increasing levels of thermal processing and irradiation. Because of this evolution, a “carbon continuum” is present throughout the solar system, with overall less-processed organics more present in the outer solar system and overall more-processed carbonized materials in the inner solar system. Spectral signatures of carbonaceous species - in the ultraviolet as well as at infrared wavelengths - mark the amount of processing experienced by a solar system object’s surface.

With exposure and processing (thermal, irradiation), carbons and organics tend to lose their hydrogen component, ultimately leading to carbonization and graphitization. In the outer solar system, complex organics can exhibit diagnostic spectral features in the UV and infrared (e.g. at Pluto, Iapetus, comets 67P and Halley, outer main belt asteroid Themis and at dwarf planet Ceres). With more maturity, organics are expected to evolve from aliphatic (linear molecular chains) to aromatic (molecular rings). On this continuum, diagnostic features are expected to appear, especially in the UV (<300 nm). As processing of carbon species occurs and H is lost, a UV absorption feature at 220 nm forms. As more H is lost, the UV absorption narrows and shifts toward longer wavelengths, and is accompanied by an increasing brightness toward shorter wavelengths, the FUV rise, such as is seen at Ceres (Hendrix et al., 2016). The more evolved carbonaceous surfaces in the inner solar system are more likely to display evidence of graphite or graphitized carbon and exhibit a stronger UV absorption feature and associated far-UV rise.

We present spectra of the diagnostic spectral shapes and examples from throughout the solar system.

Association and segregation of volatiles and refractories are among the most important processes in the scenarios of formation and evolution of planets. In this scenario, the H2O molecule plays a unique role because its abundance and unique properties. Also, the H2O molecule interacts with the electromagnetic field over most of the spectrum, making it possible to identify and characterize water -mostly its solid formon planetary surfaces using different and complementary remote-sensing techniques. Because of the complexity of the interactions between light and the particulate layer (regolith) that covers most planetary objects in the Solar System, the physical models necessary for the quantitative inversion of remote-sensing data must be thoroughly tested to assess the accuracy of the retrieved values of various properties. This is particularly critical in the optical domain where a multitude of physical and chemical parameters influence the reflectance of the surface. Laboratory experiments with macroscopic analogues that reproduce part of the complexity of natural surfaces, but are nevertheless wellcharacterized quantitatively, are key for the assessment of the qualities and limitations of models. Libraries of reflectance data collected with series of well-characterized samples can also be used for direct comparisons with spacecraft data when model cannot be used. Working with well-characterized icy samples to be used as references is particularly complicated as the samples tend to be prone to fast metamorphism and caution must be taken at all times to keep them pristine. The Laboratory for Outflow Studies of Sublimating icy materials (LOSSy) has been developed for this purpose at the University of Bern since 2010 [1,2]. We have built machines and developed protocols to produce various types of icy analogues in reproducible ways. This includes intimate mixtures of ice and dust, grains of ice with dust embedded into the ice or frost grown onto a dust substrate [3,4]. In addition to H2O ice, we have also started experimenting with CO2 ice. In our laboratory, we measure the reflectance properties of these samples as a function of wavelength (spectra) and illumination and measurement geometry (Bidirectional Reflectance Distribution Function, BRDF). We have recently complemented our instrumentation with polarization-sensitive detectors to add this property to our photometric characterizations [5]. Through collaborations, we characterize our samples using other techniques over various spectral domains [6]. We have recently started distributing the spectro-photometric data through online databases [7]. We will present different examples of our recent and current investigations that are relevant for comets, Mars polar regions, the permanently shadowed polar craters of Mercury or the surfaces of the icy satellites in the outer Solar System.

B1.3-0035-18 GRAVITATIONAL INSTABILITY AS A PLANET-FORMING MECHANISM

Duncan Forgan, dhf3@st-andrews.ac.uk

University of St Andrews, St Andrews, United Kingdom

The fragmentation of self-gravitating discs into giant planets and substellar objects, until recently, has been largely a theoretical discussion. The last ten years have seen twin revolutions in both our capability to observe very young protostellar systems, and in our understanding of how multiple physical processes combine to shape disc fragments into a whole zoo of objects.

I will review our current state of progress in the gravitational instability mechanism for planet formation, from fragmentation itself, through the multiphysics process of "tidal downsizing" towards a final population of observable objects. It will be clear by the end of my review that much remains to be understood, especially the deep connections between gravitational instability and core accretion models of planet formation.

B1.3-0037-18 PROBABILITY FOR CLOSE LOOK AT INTERSTELLAR OBJECTS

Dusan Marceta, dmarceta@matf.bg.ac.rs Matematicki fakultet u Beogradu, Belgrade, Serbia Miljan Kolcic, www.miljan@gmail.com Matematicki fakultet u Beogradu, Belgrade, Serbia

Detailed study of interstellar objects is of crucial importance for understanding the connection between planetary systems formation and its interstellar surrounding. Recent discovery of the interstellar visitor Oumuamua (1I/2017 U1), by using Pan-STARRS survey, confirms previous speculations that our solar systems is populated by this transient object. These assumptions are based on the simulations of planetary systems dynamics and evolution which suggest that the early migration of giant planets ejected huge majority of original planetesimals into the interstellar space. They also give the assessment of their number density and velocity and absolute magnitude distributions in the solar neighborhood. The effective discovery of these objects gives an exclusive opportunity for the exploration of their composition and interstellar weathering in order to connect them with primordial planetesimals. In this research we analyze the probability of discovering of these objects by current and near-future surveys (such as ZTF and LSST) by applying novel techniques for their orbit determination in order to overcome their covering by tremendous number of solar system object detectable with increasing sensitivity of the surveys. We also give the qualitative analysis of the dependence of this probability on the orbital characteristics of the interstellar objects.

B1.3-0038-18 THE FEASIBILITY AND BENEFITS OF IN SITU EXPLORATION OF ‘OUMUAMUALIKE OBJECTS

Darryl Seligman, darryl.seligman@yale.edu

Yale University, New Haven, Connecticut, United States Gregory Laughlin, greg.laughlin@yale.edu

Yale University, New Haven, Connecticut, United States

A rapid accumulation of observations and interpretation have followed in the wake of 1I ‘Oumuamua’s passage through the inner Solar System. We outline the consequences that this first detection of an interstellar asteroid implies for the planet-forming process, and we assess the near-term prospects for detecting and observing (both remotely and in situ) future Solar System visitors of this type. Drawing on detailed heat-transfer calculations that take both ‘Oumuamua’s unusual shape and its chaotic tumbling into account, we affirm that the lack of a detectable coma in deep images of the object very likely arises from the presence of a radiation-modified coating of high molecular weight material (rather than a refractory bulk composition). Assuming that ‘Oumuamua is a typical representative of a larger population with a kinematic distribution similar to Population I stars in the local galactic neighborhood, we calculate expected arrival rates, impact parameters and velocities of similar objects and assess their prospects for detection using operational and forthcoming facilities. Using ‘Oumuamua as a proof-of-concept, we assess the prospects for missions that intercept ISOs using conventional chemical propulsion. Using a “launch on detection” paradigm, we estimate wait times of order a year between favorable mission opportunities with the detection capabilities of the Large-Scale Synoptic Survey Telescope (LSST), a figure that will be refined as the population of interstellar asteroids becomes observationally better constrained.

B1.3-0039-18 PLANET-FORMING GIANT IMPACTS: MACHINE LEARNING AND OTHER NEW IDEAS

Erik Asphaug, asphaug@lpl.arizona.edu

University of Arizona, Tucson, Arizona, United States

Bombardment by large projectiles played a key role in the formation of the inner planets through accumulation of rocky planetesimals. Our group uses Smooth Particle Hydrodynamics (SPH) to model giant impacts on planetary bodies such as the Moon, Mercury and Mars. As of today, our dataset is composed of over 1,500 simulations spanning a wide range of parameters (composition, size, mass ratio, impact angle, impact velocity). Each SPH outcome is a complex N-D state (consolidated planets, clumps, unconsolidated ejecta, and their characteristics including thermodynamic states, etc.) that requires detailed analysis.

In this regard, state-of-the-art machine learning techniques allow for several advantages: 1) they can streamline the generation of data sets to most efficiently explore regions of interest in a large parameter space; and 2) they can perform accurate mappings of initial conditions and endstates, with associated probabilities, taking into account a high-dimensional parameter space. This is in contrast to human operators that are often limited to a mostly 2-D understanding of the data. Modern machine learning schemes take advantage of this big data problem to spot new and sometimes unexpected correlations.

In this pilot study, we trained, tested and validated an algorithm able to map strictly the pre-impact conditions to the accretion efficiency (defined as the fraction of the projectile mass Mp. acquired by the target Mt). The adopted scheme is supervised: the machine learns the correlation between input and output using labelled data: xi; yi, where xi is an array of four input parameters (predictors): Mt (mass of the target), Mp. (mass of the impactor), q (impact angle) and the ratio between the impact velocity and the escape velocity; and yi is the corresponding response.

Results of that supervised classification exercise will be presented. Our pilot study has shown the potentialities of machine learning in: 1) processing large planetary formation datasets without a heavy involvement/bias from the user; 2) identifying "strange" or interesting regions in the parameter space requiring further study; 3) providing a statistical description to phase boundaries as opposed to the hardline boundaries of traditional scaling laws. One long- term scientific goal is to obtain systematic guidance to solutions of complex problems such as Earth-Moon system formation and Mercury formation that may exist on phase boundaries in outcomes of giant impacts.

B1.3-0040-18 SUPER-EARTHS COMPOSITION: SIGNATURES OF PLANET FORMATION

Diana Valencia, valencia@astro.utoronto.ca University of Toronto, Toronto, Canada

The composition of a planet reflects the primordial composition of the proto-planetary disk, location of formation, as well as post-processing mechanisms (such as giant impacts and atmospheric escape) that can alter the final inventory of a planet. I will focus on the results from composition constraints on low-mass exoplanets (super-Earths and mini-neptunes) and the information they provide on how they formed. In particular for the presumably rocky planets, we see a variety in the Fe/Si ratio that needs to be explained. From looking at primordial composition, to alteration through impact collisions I will present constraints on formation scenarios.

B1.3-0042-18 FORMATION OF PLANETARY ENVELOPES AND ATMOSPHERES: ROLE OF VAPORIZED ICY MATERIAL

Masahiro Ikoma, ikoma@eps.s.u-tokyo.ac.jp The University of Tokyo, Tokyo, Japan

Planetary envelopes and atmospheres are a final product of complex planet formation pro- cess and, thus, their final mass and composition depend on the properties and evolution of protoplanetary disc gas, initial solid materials, and central stars. Indeed, a diversity of volatilerich planets have been identified in the Solar System and beyond. Conventional ideas about the formation of planetary envelopes and atmospheres are gravitational capture of hydrogendominated disc gas and degassing of heavier volatiles from solid planetesimals and protoplanets. Recent planet formation theories, however, suggest that small solid particles such as pebbles and collisional fragments of planetesimals make a great contribution to planetary accretion. Such small particles are subject to gas drag and evaporation, which cause a significant change in the composition of accumulating atmospheres and protoplanetary discs. In this presentation, I will talk about current theoretical understanding of the accumulation processes of planetary envelopes and atmospheres with a focus on the effects of vaporized icy material.

In numerical simulations for terrestrial planet formation one usually traces the orbital evolution of numerous protoplanetary embryos over a timespan up to 100 Myrs. When collisional fragmentation is excluded, two embryos merge completely once their mutual distance becomes smaller than a pre-defined collision threshold. It is well known that this assumption is a weak point of such studies which needs to be improved. A more sophisticated model will consider fragmentation in different collision outcome regimes (see Leinhardt and Stewart, 2012).

In this study, we suggest a more realistic formation scenario that includes SPH (Smooth Particle Hydrodynamics) simulations of colliding embryos in the N-body computations. Since the SPH simulations provide the necessary information about volatile and material loss during impact this N-body–SPH combination yields a more realistic result for the growth of bodies and the water transport via collisions on terrestrial planets in the habitable zone.

We show the results for collisions of Moon and Mars sized objects moving in the habitable zone of a sun-like star (i.e. between 0.9 and 1.7 au) perturbed by a Jupiter-mass planet at 3 au and a secondary star at distances of 25/50/75/100 au. Besides the comparison of the different binary-star–planet configurations we also provide a study for a similar planetary system orbiting a single star. In this context, we show the mass-loss during collision depending on the impact velocity and angle. This might modify the result of perfect merging-based N-body simulations of terrestrial planet formation.

B1.3-0044-18 THE BULK COMPOSITION OF EXTRA-SOLAR PLANETESIMALS

Boris Gaensicke, boris.gaensicke@warwick.ac.uk University of Warwick, Coventry, United Kingdom

We know over 3000 extra-solar planets, and the past few years have seen a rapid expansion of the parameter space to wider ranges in host star and planet mass, as well as larger orbital separations. Consequently, the architectures of the known planetary systems are becoming increasingly diverse, and so does the entire field of exo-planets.

One fundamental question, "what are those other worlds made out of "?, can not be easily answered by the study of planets orbiting main-sequence stars, as radial velocity and transit surveys only provide a measurement of the bulk densities of planets, and internal compositions are model-dependent.

The key to answering the above question draws on a method well-established in planetary science: measuring the abundances of the building blocks of planets, and their fragments. We know more about the composition of the terrestrial planets in the Solar system from abundance studies of meteorites than from surface samples collected by astronauts and robots. Throughout the last decade, it has been demonstrated that the bulk composition of exo-planetary bodies can be accurately measured, in total analogy to Solar-system meteorite studies, from the spectroscopic analysis of white dwarfs accreting debris from tidally disrupted planetesimals. I will review the recent progress in this research field, highlighting the significant variety of disrupted parent bodies, which include evidence for unprocessed chondritic asteroids, differentiated cores, and even water-rich planetesimals and discussing the implications for planet formation models.

B1.3-0046-18 OBSERVATIONAL CONSTRAINTS ON THE BULK COMPOSITION OF EXTRASOLAR PLANETESIMALS

Jay Farihi, j.farihi@ucl.ac.uk

University College London, London, United Kingdom

There is a vast observational gulf between the characterization of interstellar and protoplanetary disk materials, and their eventual incorporation into planetary bodies. Yet many key scientific questions require detailed information of planet compositions, which for extrasolar systems are poorly constrained by transit and radial velocity observations that yield planet radius and mass.

Fortunately, it is now clear that the bulk compositions of large planetesimals can be obtained via observations of white dwarf debris disks and atmospheric pollution by heavy elements. These systems thus provide a critical empirical link between the protoplanetary disk stage and fully formed planets, in a way that is analogous to meteoritic studies in the solar system.

I will present the current state-of-the-art in polluted white dwarf observations, including recent results from the Hubble Space Telescope. The data collected to date provide compelling evidence for distinctly terrestrial-like compositions, and chemical differentiation within large parent bodies. Intriguingly, there is now indirect evidence for water-rich (but otherwise rocky) planetesimals that may represent the building blocks of habitable exoplanets.

B1.3-0047-18 HOW IS THE DISRUPTED PLANETESIMAL AT THE PULSATING WHITE DWARF G29-38 ACCRETED?

Odette Toloza, o.f.c.toloza@warwick.ac.uk Warwick University, Coventry, United Kingdom Boris Gaensicke, boris.gaensicke@warwick.ac.uk University of Warwick, Coventry, United Kingdom Detlev Koester, koester@astrophysik.uni-kiel.de University of Kiel, Kiel, Germany

J. J. Hermes, jjhermes@unc.edu

North Carolina State University, Chapel, North Carolina, United States

G29-38 was the first white dwarf found to have an infrared excess, interpreted as a dusty debris disc that formed from the tidal disruption of a planetesimal. The ongoing accretion from this debris disc explains the metals detected in the white dwarf atmosphere of G29-38. The analysis of the photospheric contamination provides a direct measurement of the bulk composition of the disrupted planetesimal, which is thought to be a blend of a chondritic object with some refractory-rich material. The discovery of G29-38 opened up a new research field in exploring the compositional make-up of exo-planetesimals. However, the geometry and the process of the accretion from the debris disc onto the white dwarf are not yet clearly understood, in particular the distribution of the metals across the white dwarf surface. The syphon model suggests the flow of the particles originates in a corona above the disc formed by evaporation of the disc. In this scenario the accretion of the metals would result in a homogeneous distribution all over the white dwarf surface, and so far, all abundance studies of debris-polluted white dwarfs assumed that this is the case. In contrast, accretion via a boundary layer or an accretion belt would result in the deposition of metals in an equatorial belt, and hence in a inhomogeneous distribution of metals, which would affect the interpretation of the abundance analyses. G29-38 displays large amplitude variability due to non-radial pulsations.The non-radial pulsations with periods between simeq110–1250,s offer a unique opportunity to diagnose any inhomogeneity of the metals across the white dwarf surface using the pulsations as a spotlight: As a consequence of the pulsations, localised areas on the white dwarf surface are heated by a few thousand degrees, outshining the flux emitted from the unheated regions. Therefore, the ultraviolet spectroscopy is largely dominated by the flux from these heated regions. I have been analysing fast highresolution ultraviolet spectroscopy obtained with the Cosmic Origins spectrograph mounted on the Hubble Space Telescope, extracting the spectra from individual pulses. Modelling the spectral absorption features of silicon and carbon in these spectra using a state-of-the art atmosphere code, I find that the distribution of metals across the white dwarf surface does not show large variations, arguing against an accretion geometry limited to an equatorial belt.

B1.3-0049-18 FORMATION OF SATELLITE SYSTEMS OF SMALL BODIES AND THE EMBRYOS OF THE MOON AND THE EARTH

Sergei I. Ipatov, siipatov@hotmail.com

Vernadsky Institute of Geochemistry and Analytical Chemistry, Russian Academy of Sciences, Moscow, Russia

Ipatov showed [1] that the angular velocities of condensations used in [2] as initial data for computer simulations of compression of rarefied condensations leading to the formation of satellite systems of trans-Neptunian objects could be obtained at collisions of condensations. Such considered model of the formation explains well the observed dependencies of the orbital elements and masses of the components of binary trans-Neptunian objects [3]. The initial angular momenta of the condensations were not sufficient for the formation of satellite systems of small bodies. The angular momentum of the condensation used by E.M. Galimov and

A.M. Krivtsov [4] in their computer simulations of compression of the condensation leading to the formation of embryos of the Earth and the Moon could be obtained at a collision of two condensations. I showed that the angular momentum of the present Earth-Moon system could be acquired at a collision of two rarefied condensations with a total mass not smaller than 0.1ME, where ME is the mass of the Earth. The mass of the condensation that was a parent for the embryos of the Earth and the Moon could be relatively small (0.02ME or even less), if we take into account the growth of the angular momentum of the embryos at the time when they accumulated solid planetesimals. If, as it is considered in [4], initial embryos of the Earth and the Moon were almost iron free, the initial mass of the Moon embryo could be less by only a factor of 1.3 than its present mass if it accumulated planetesimals of the same composition as the Earth. In the case of small relative velocities of planetesimals, the effective radius of an embryo is proportional to the square of the radius of the considered embryo. For such a model, for the growth of the mass of the Moon embryo by a factor of 1.3, the mass of the Earth embryo grew by less than a factor of 3. Besides direct collisions with planetesimals, the Moon embryo could also grow by accumulation of almost iron-free material ejected from the Earth embryo at many impacts of planetesimals with the Earth embryo. The work was supported in part by the grant of Russian Foundation for Basic Research № 17-02-00507 (formation of satellite systems of small bodies) and by the grant of Russian Science Foundation № 17-17-01279 (formation of the Earth-Moon system). B1.3-0050-18 MIGRATION OF BODIES FROM BEYOND JUPITER'S ORBIT TO THE EARTH AND THE MOON

Sergei I. Ipatov, siipatov@hotmail.com

Vernadsky Institute of Geochemistry and Analytical Chemistry, Russian Academy of Sciences, Moscow, Russia

Mikhail Ya. Marov, marovmail@yandex.ru Russian Academy of Science, Russia

Our studies of migration of planetesimals from the feeding zone of Jupiter and Saturn to forming terrestrial planets were based on computer simulations of the orbital evolution of planetesimals under the gravitational influence of planets. In series JN, all planets were considered in present orbits with present masses, and in series JS, Uranus and Neptune were excluded. In series JN01 and JS01 masses of planets in orbits of the terrestrial planets were by a factor of 10 smaller than the present masses of the planets. In some series of runs, orbits of the giant planets were located initially more close to each other than for the present planets. Initial eccentricities and inclinations of planetesimals were 0.3 and 0.15 rad, respectively. Their initial semi-major axes were between 4.5 and 12 AU in runs with present giant planets. For runs with closer initial orbits of the giant planets the upper boundary of the disk of planetesimals was extended to 20

or 23 AU. The obtained results show that the ratio of the fraction of the planetesimals collided with the Earth was about $2\times10-6$, and similar fraction was about $4\times10-7$ for the mass of the

Earth embryo equal to 0.1 of the Earth mass. We concluded that during the growth of the mass of the Earth embryo up to a half of the present mass of the Earth, the amount of planetesimals (or water) delivered to the embryo from the feeding zone of Jupiter and Saturn could be about 0.3 of all planetesimals (water) delivered to the Earth from this zone. The ratio of the mass of planetesimals (and water) delivered from beyond Jupiter's orbit to a planet to the mass of the planet for the Earth was smaller by a factor of 2 or 3 than that for Mars, and was about the same as that for Venus. For Mercury this ratio typically was not smaller than for the Earth. Based on our runs of migration of planetesimals from the feeding zone of Jupiter and Saturn and of migration of Jupiter-crossing objects, we calculated probabilities of collisions of such planetesimals and objects with the Moon. Such probabilities were typically smaller than probabilities of collisions with the Earth by a factor of 16 or 17. The probabilities of collisions of objects that came from beyond Jupiter's orbit with the Moon and with the Moon embryo with mass smaller by a factor of 10 than that of the Moon differed usually by about a factor of 4.7. The similar ratio for the Earth and the Earth embryo with mass smaller by a factor of 10 than that of the Earth was usually about 5.5-5.8. Based on the above results, we can conclude that the amount of the matter (water and volatiles including) delivered to the Moon from outside of the Jupiter's orbit could be about 20 times smaller than that consumed by the Earth. The work was supported by the grant of Russian Science Foundation N 17-17-01279 (migration to the Moon) and by the Program of Fundamental Studies of the Presidium of RAS

№ 17 (migration to the terrestrial planets).

B1.3-0051-18 INTERSTELLAR ICES, PROTOSTELLAR DISKS AND COMETARY COMPOSITIONS

Comets are the end product of a variety of processes, including chemical and dynamical evolution in the interstellar medium and in the protoplanetary disk. The “mixing ratios” between observed species (CH4/C2H2/C2H6/HCN/NH3/CO/H2CO/CH3OH/H2O, etc) vary substantially among the comets sampled to date. However, the identification of distinct taxonomic classes has been challenging, and the cosmogonic significance of the observations has remained elusive.

We present preliminary results of a study into the links between comet composition and the ices formed in interstellar clouds and in protostellar disks. We compare the predicted ice compositions from chemical models with the observations of individual comets to establish whether particular patterns of relative mixing ratios are associated with a particular phase of evolution and/or physical conditions. We explore whether the range of cometary abundances can be formed in the interstellar medium, and how processing in the protostellar disk can change ice compositions from their interstellar values.

B1.3-0052-18 ACCRETION OF CENTIMETER TO METER SIZE SOLIDS ON PLANETARY CORES

Gennaro D'Angelo, gennaro@lanl.gov

Los Alamos National Laboratory, Los Alamos, New Mexico, United States

The growth of a planetary core out of a swarm of km-size (and larger) planetesimals has been studied extensively over the past five decades. Much less attention has been devoted to the accretion of smaller, 1-1000 cm size particles, during the gaseous phase of a protoplanetary disk. Over the past few years, it has been pointed out that, thanks to their greater radial mobility and accretion efficiency, these small solids may provide growth timescales far shorter than those resulting from the accretion of planetesimals. Since the dynamics of small solids can be intimately coupled to that of the gas, via aerodynamic drag, the accretion rates are bound to depend on the thermodynamical state of the gas. Series of numerical experiments are presented here, which take into account the gas-particle dynamics and quantify the accretion efficiency as a function of particle size and core mass, Mc. These experiments target both lowmass cores (embryos), Mc M⊕, and large core masses, 3M⊕ Mc 20M⊕ at various orbital distances. In the low-mass case, the calculations are based on a simplified gas thermodynamics and assume that the embryos bare no bound envelope. In the high-mass case, gas fields are instead modeled by means of high-resolution radiation-hydrodynamic calculations that include the formation of a hydrogen/helium envelope as well as the thermodynamics of the particles. Implications of the accretion efficiencies are discussed and predictions are made about the core growth timescales, neglecting vaporization of the solids in the cores' gaseous envelopes.

B1.3-0053-18 DUST EVOLUTION IN PROTOPLANETARY DISKS WITH A PAIR OF PLANETS IN ORBITAL RESONANCE

Francesco Marzari, francesco.marzari@pd.infn.it Department of Physics, University of Padova, Padova, Italy Francesco Marzari, francesco.marzari@pd.infn.it Department of Physics, University of Padova, Padova, Italy Gennaro D'Angelo, gennaro@lanl.gov

Los Alamos National Laboratory, Los Alamos, New Mexico, United States

A significant fraction of extra-solar multi-planet systems are populated by planet pairs whose orbits are in, or in proximity of, mean-motion resonances. The 2:1 and 3:2 ratios are particularly common. A pair of giant planets orbiting in a 2:1 or 3:2 resonance and still embedded in a gaseous disk may undergo various regimes of migration, driven by the disk's tidal torques. These include coupled inward and outward migration. Here we concentrate on a pair of planets orbiting in proximity of the 2:1 resonance and study how they affect the evolution of dust in the surrounding of their orbits. By means of 2D and 3D hydrodynamic simulations that include the evolution of both gas and dust, we calculate the distributions of particles in the size range from 0.01 to 10 mm. Disk properties dictate the orbital evolution of the planets, including eccentricity excitation, which can impose distinctive features in the dust distributions. Under appropriate disk conditions, peculiar dust features, such as large cavities, could be connected to the migration history of the planets. We discuss dust configurations that may deliver information on the planets' orbital evolution.

B1.3-0054-18 PROMOTION OF SPACE WEATHERING WITH SULFUR

Sho Sasaki, sasakisho@ess.sci.osaka-u.ac.jp Osaka University, Toyonaka, Japan

Hirokazu Tanaka, h.tanaka@astroboy-jp.com Osaka University, Toyonaka, Japan

Mizuki Okazaki, mizuki1213.zoo@gmail.com Osaka University, Toyonaka, Japan Takahiro Hiroi, takihiroi@gmail.com

Brown University, United States

Akira Tsuchiyama, atsuchi@kueps.kyoto-u.ac.jp

Graduate School of Science, Kyoto University, Kyoto, Japan

Space weathering is proposed as the main process that should control the change of brightness and color of the surface regolith of airless silicate bodies: optical darkening, reddening and weakening of absorption bands. Formation of nanophase iron particles is the cause of the optical property changes of the space weathering. A small S-type asteroid Itokawa, which was observed by HAYABUSA spacecraft has weakly weathered LL5/6 spectrum, which was confirmed by detailed analyses of returned samples. The returned samples contain not only nanophase iron but also nanophase FeS (and MgS) particles play some role in space weathering. In the present study, we conducted laboratory simulation experiments using nano-second pulse laser irradiation simulating high-speed micrometeorite impacts, and found that additional FeS (45-75µm, 10wt%) as well as additional Fe should promote optical change compatible with space weathering, especially darkening of infrared spectra of olivine. We observed laser-irradiated sample by TEM. The amorphous layer about 200 nm thickness is formed around an olivine particle. Abundant nano particles are observed both at the bottom and the surface of the amorphous layer. On the basis of lattice parameters, we confirmed nano Fe particles but we did not find nano FeS particles. There is possibility that additional FeS promoted production of nanophase iron particles, which would have enhanced the space weathering effect. We also tried preliminary experiments with addition of pure sulfur particles (45-75µm, 10wt%) instead of FeS particles. We observed small change of reflectance after pulse laser irradiation which is less significant compared with the case of additional FeS. We have started very preliminary experiments using FeS2, which may enhance the spectral darkening and reddening as FeS.

B1.3-0055-18 ALMA OBSERVATIONS OF OXYGEN-BEARING COMPLEX ORGANIC MOLECULES TOWARDS THE LOW-MASS PROTOSTELLAR BINARY IRAS 16293–2422

Sebastien Manigand, sebastien@nbi.ku.dk University of Copenhagen, Copenhagen, Denmark Jes Kristian Jørgensen, jeskj@nbi.ku.dk University of Copenhagen, Copenhagen, Denmark Hannah Calcutt, calcutt@nbi.ku.dk

University of Copenhagen, Copenhagen, Denmark

Many questions remain concerning the formation of complex organic molecules and their presence in the inner region of solar-type protostars. The nearby low-mass Class 0 protostellar binary IRAS 16293–2422 (IRAS16293 hereafter) is an excellent object to study these species on solar system scales. The Atacama Large Millimeter/submillimeter Array (ALMA) provides the high angular and spectral resolution as well as the sensitivity needed to study the physical and chemical structure of such protostars in unprecedented detail.

We use observations from the Protostellar Interferometric Line Survey (PILS; Jørgensen et al. 2016), an unbiased line survey of IRAS16293 using ALMA, to analyse oxygen-bearing complex organic molecules in both IRAS16293A and IRAS16293B. A comparative analysis of the two sources reveals differences in abundances for some of the species and their isotopologues. For example, formaldehyde (H2CO), glycolaldehyde (CH2OHCHO) and ethylene glycol (CH2OH)2 are more than one order of magnitude more abundant towards the A source compared to the B source measured relative to methanol. In contrast, methyl formate (CH3OCHO), ethanol (C2H5OH) and dimethyl ether (CH3OCH3) show similar abundances towards the two components. This selective differentiation suggests that CH2OHCHO, (CH2OH)2 and CH3OCHO are formed on the grain surface via reactions involving H2CO and CH3OH photodissociation products, such as HCO, CH3O and CH2OH (Chuang et al. 2016). In addition, the high sensitivity of the ALMA observations enabled many deuterated species to be detected, including doubly-deuterated methyl formate (CHD2OCHO) for the first time in the ISM (Manigand et al. 2018, subm.). The D/H ratio of CHD2OCHO and CH2DOCHO were found to be extremely enhanced compared to the canonical value 2 10−5, with CHD2OCHO D/H ratio 2–3 times higher than CH2DOCHO D/H ratio. The supplementary information brought by these isotopologues confirms that methyl formate forms through grain surface reactions and suggests that the deuteration enhancement is driven by H-D abstraction substitution processes on the grain.

This study emphases the importance of high angular resolution and high sensitivity observations, for example, provided by ALMA, to separate the close components of protostellar multiple systems and detect less abundant isotopologues.

B1.3-0056-18 STATISTICS OF METEOROIDS FROM THE OUTER REGIONS OF THE SOLAR SYSTEM IN THE EARTH'S ATMOSPHERE

Svitlana Kolomiyets, s.kolomiyets@gmail.com

Kharkiv National University of Radio and Electronics, Kharkiv, Ukraine

In connection with the huge number of discoveries of distant cosmic objects behind the orbit of the Neptune (Sedna, Eris, etc.) and beyond the Solar system (exoplanets, 'Omuamua), including those discovered as a result of space flights, astronomers increasingly pay attention to the problems of cosmogony of planetary systems. The aforementioned discoveries have led to the emergence of new classifications of space objects (planetary and non-planetary type) and a change in the previous ones. Even the Pluto was deprived of the status of the ninth major planet of the Solar system. Previously, before the above discoveries about the structure of the most distant regions of the outer solar system, it was possible to obtain some experimental information only from the analysis of the orbital motion of long-period comets, which are not often observed, since they are only visible at sufficiently close distances from the Sun. And before, and now millions of meteoroids invade the Earth atmosphere every second. Dimensions of meteoroids are often insignificant by space standards. According to the proposed new terminology in meteor astronomy: a meteoroid is a solid natural object about 30 micrometers to 1 meter in size. At the same time, these tiny space objects are full members of the respected family of small bodies of the Solar System, and this family has been significantly enlarged due to the aforementioned discoveries. In this contribution, we presented the results of an analysis of the parameters of meteoroids that invaded the Earth atmosphere from the outer solar system. The database of 159,320 orbits of meteoroids of the Kharkiv National University of Radio Electronics (NURE MBD) is used. The research is based on the previously discovered fact that the aphelion of meteor orbits from the NURE MBD can reach 2,000 UA (KolomiyetsVoloshchuk, 2015). References Kolomiyets, S.V., Voloshchuk, Yu.I. 2015. The aphelion distribution of the Near Earth meteoroid orbits with larger eccentricities. The XXIX IAU GA, Honolulu, Hawaii. Abstract ID 2232974

B1.3-0057-18 HIGH PRIORITY DECADAL SURVEY SCIENCE FROM ORBIT AT VENUS

Suzanne Smrekar, ssmrekar@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Darby Dyar, mdyar@mtholyoke.edu

Mount Holyoke College, South Hadley, Massachusetts, United States Scott Hensley, shensley@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Jorn Helbert, joern.helbert@dlr.de DLR, Berlin, Berlin, Germany

Magellan, NASA's last mission to Venus, was the last mission aimed at studying the surface and interior of Venus. Launched 29 years ago, Magellan produced a better global altimetry dataset than was available for the Earth at the time, with a footprint size of 12-25 km. Global radar imaging was acquired at 125 m pixels. Magellan enabled numerous scientific breakthroughs, such as 1) Venus' relatively young surface age, comparable to Earth's, 2) the absence of plate tectonics but the presence of possible subduction, 3) an Earth-like number of 'hotspots' like Hawaii, 4) large plateaus that may be analogs of Earth's continents, and 5) thousands of volcanoes, as well as largeand small-scale mantle upwellings. These discoveries in turn have led to key questions about how Earth's twin (in terms of size, density, heat producing elements) evolved so differently. Why doesn't Venus have plate tectonics? How active is it today? ESA's Venus Express mission demonstrated the ability to see the surface of Venus from orbit in narrow windows in the CO2 atmosphere around 1 m (Helbert et al. 2018; Mueller et al., 2018), showing that orbital compositional mapping is possible. Venus Express also provided evidence for both recent volcanism (Smrekar et al., 2010) and for possible felsic crust in the highland plateaus (Gilmore et al., 2015). The case for exploring the surface of Venus from orbit has never been stronger: 1) New Earth-sized exoplanets are constantly being discovered. Understanding how Earth and Venus evolved along completely different evolutionary paths is essential to predicting habitability on such bodies. Earth developed the plate tectonic system that helps provide a clement, stable atmosphere while Venus' CO2 is largely in the atmosphere rather than locked away in rocks, as on Earth. How did this happen? 2) All other terrestrial planets (Mars, Mercury, and Earth plus Earth's Moon) have been investigated with high resolution topography, imaging and spectroscopy, yielding spectacular advances in our understanding of these planets, and in comparative planetology. The relatively poor resolution of Magellan image and altimetry data, and a lack of global, multichannel compositional data, means that Venus is effectively unexplored by comparison to its terrestrial planetary neighbors. 3) Current radar technology has

little in common with that flown on Magellan. Using onboard data processing, it is now possible to obtain geodetically controlled topography with 250 m (horz)

× 5 m (vert) resolution - 2 orders of magnitude better than Magellan. These data are critically important for a planet where high resolution visual imaging is not possible from orbit. Much of Venus (40%) is mapped as 'featureless plains' due to a lack of dielectric contrast, making radar imaging from Magellan of little value; modern imaging is possible at a scale of 15 m. Such an order of magnitude resolution improvement is likely to reveal entirely new processes. The first interferometric mapping of active deformation beyond Earth would reveal what processes are currently shaping the planet today. By optimizing a spectrometer to take advantage of the five available atmospheric windows, it is possible to provide global composition, mineralogy, surface-atmosphere interactions, and search for recent and active volcanism. Additionally, such a spectrometer would search for near surface water vapor from volcanoes, and map winds in both polar vortices effectively simultaneously. 4) As with orbital instrumentation, geochemical and other instrumentation for Venus landers has advanced well beyond what the Soviets did in the 1970s. Global reconnaissance will enable landing site characterization for safety and optimal science return. 5) This technology is ready to fly, and addresses a long list of NASA's Planetary Decadal Survey questions. NASA review panels have repeatedly rated proposed Venus missions as fully selectable, providing cost effective, ground breaking new science, with highly dependable technology. 6) Now is the time to return to Venus and resolve the unanswered question of how Earth-like planets do, and do not, become habitable. This research was partially conducted at the Jet Propulsion Laboratory, California Institute of Technology, under contract with the National Aeronautics and Space Administration.

B1.3-0058-18 THE FOOTPRINT OF COMETARY DUST ANALOGS IN THE LAB - LOWVELOCITY IMPACTS AND COMPARISON WITH ROSETTA DATA

Lucas Ellerbroek, ellerbroek@uva.nl

University of Amsterdam, Amsterdam, Netherlands

Comets are the most pristine elements of the solar system preserved to this day. The structure of cometary dust is a tracer of early growth processes in the formation of planetesimals. Measurements by the Rosetta spacecraft show that the dust in the coma of comet 67P/ChuryumovGerasimenko has a granular structure at size scales from sub-m up to several hundreds of m, indicating hierarchical growth took place across these size scales. However, the dust particles studied are a product of a collision within the instrument, which should be taken into account when interpreting the spacecraft data. We present the results of two series of laboratory experiments that simulate the collection of particles in the Rosetta instruments on the collection surfaces of COSIMA and MIDAS, instruments onboard the Rosetta spacecraft. We launched dust analogs (aggregates of pure SiO2, both polyand monodispersed) spanning a parameter range in tensile strength (1-10 kPa), size (10-500 m), and impact velocity (0.5-6 m/s). The resulting deposits on the target surface were subsequently imaged with the COSIMA and MIDAS flight spares. We found that velocity is a key driver in determining the appearance of deposits. At low velocities (< 2 m/s), particles either stick to the target plate, or bounce off, leaving a shallow footprint of monomers. At velocities > 2 m/s, particles fragment upon collision, transferring up to 50 per cent of their mass in a rubble-pile-like deposit on the target plate. The morphologies of the deposits are qualitatively similar to those found by the COSIMA and MIDAS instruments. The amount of mass transferred increases with the impact velocity, and decreases with tensile strength. Extrapolating these trends to the Rosetta data implies that more than half of the dust is lost in the spacecraft.

B1.3-0059-18 PLANET HUNTING WITH MOLECULAR EMISSION

Ilsedore Cleeves, ilse.cleeves@cfa.harvard.edu

Harvard-Smithsonian Center for Astrophysics, Cambridge, Massachusetts (USA), Cambridge, Massachusetts, United States

In the early phases of planet formation, young gas-giants still embedded in their parent disks are luminous, (1-10) x 10−4L sun, both during the accretion phase and immediately after (within a few M yr). U si mass protoplanet. Furthermore, the relevant chemical processes (freeze out and thermal desorption) are r mass planets in the T W Hya protoplanetary disk, where fine scale ringed structure was recently discovered w type, low mass stars.

B1.3-0060-18 COLLISIONAL GENERATION OF DUST IN CIRCUMSTELLAR DISKS DUE TO THE FORMATION OF GIANT PLANETS

Diego Turrini, diego.turrini@iaps.inaf.it INAF - IAPS Rome, Rome, Italy Francesco Marzari, marzari@pd.infn.it University of Padova, Padova, Italy

Danae Polychroni, danae.polychroni@iaps.inaf.it Universidad de Atacama, Copiapo, Chile Leonardo Testi, ltesti@eso.org

INAF/Osservatorio Astrofisico di Arcetri, Firenze, Italy

The amount of dust detected in circumstellar disks is expected to steadily decrease with age due to the growth from µm sized particles to planetesimals and planets. We show that this trend can be suddenly halted or reversed when the fast formation of giant planets triggers a period of dynamical excitation of nearby leftover planetesimals. Their dynamical excitation by the planetary perturbations should lead to a significant collisional dust production, rejuvenating the grain population of the disk in the µm size range. We focus on the HD 163296's circumstellar disk, observed by ALMA and thought to host three potential giant planets, as a dynamical test bench for the formation of second-generation dust. We use N-body simulations together with statistical methods to estimate the dynamical and collisional response of a putative planetesimal swarm populating the HD 163296's disk to the formation of the three giant planets. We also take advantage of impact experiments and scaling laws to assess the outcome of the collisions among the planetesimals. Our results show that the formation of HD 163296's giant planets should be followed by a global phase of dynamical excitation of the planetesimals inhabiting the circumstellar disk. This dynamical excitation will produce a violent collisional environment across the disk that might still be active today. The high impact velocities associated can cause a tenfold-to-hundredfold increase in the dust production by impacts, increasing the dust-to-gas ratio of the disk. This mechanism may be a common evolutionary process in circumstellar discs that host forming giant planets and a possible explanation of why also relatively old discs still have a significant dust population in spite of the coagulation and accretion processes. In addition to dust rejuvenation, the excited velocities of the planetesimals could result in the release of transient, non-equilibrium gas species like H_2O due to ice sublimation during impacts and, being supersonic with respect to the gas, could also produce bow shocks in the gas, possibly causing a broadening of its emission lines.

B1.3-0061-18 THE CHEMICAL CONNECTION BETWEEN 67P/C-G AND IRAS 16293-2422

Maria Drozdovskaya, maria.drozdovskaya@csh.unibe.ch University of Bern, Bern, Switzerland

The chemical evolution of protoplanetary disk materials begins in the earliest prestellar phase of star formation. Under the dark, cold conditions of cores the initial icy mantles of grains are built up. Already at this point, grain-surface chemistry starts to set the composition of these icy layers. Once collapse is initiated, the central protostars can boost chemical processing of the ices by serving as a source of additional UV photons, thereby enhancing photochemistry in both phases, and by heating the dust grains, which allows higher mobility of radicals in the solid phase. Regionally, the heating is sufficient to thermally desorb the ice mantles entirely. In such regions, the chemistry is set via gas-phase reactions. Protoplanetary disks are built up from the collapsing core materials, which are exposed to variable intensities of UV irradiation and heating. The build up of complex organic molecules initiates in the prestellar phase and continues across the subsequent evolutionary stages. I will highlight the chemical connection across various stages of evolution by presenting the latest observational constraints. For this purpose, the results from the ALMA-PILS survey on the infant Solar System analogue IRAS16293-2422 will be presented in the context of in situ measurements made by the Rosetta mission on comet 67P/Churyumov-Gerasimenko. Such comparative studies shed light on the earliest physicochemical conditions for our infant Solar System and give hints on the uniqueness of the ingredients to life.

B1.3-0062-18 EVIDENCE FOR AN EXTRASOLAR TROJAN ASTEROID POPULATION FROM KEPLER PHASE CURVE STACKING

Daniel Angerhausen, daniel.angerhausen@gmail.com University of Bern, Bern, Switzerland

We present the results of a statistical search for exo-trojans in the Kepler Data Set. By superstacking 4000 Kepler planets with a total of 90000 full orbital curves, searching for an average Trojan transit dip in the Langrange points, we find an upper limit to the average Trojan transiting area (per planet) that corresponds to one body of radius 460 km with 2 confidence. We find a significant Trojan-like signal in a sub-sample for planets with more and/or larger Trojans for periods >60 days. Our tentative results can and should be checked with improved data from future missions like PLATO 2.0, and can guide planetary formation theories.

B2.1-0001-18 REFERENCE FRAMES, GEODETIC OBSERVATIONS, AND ESSENTIAL GEODETIC VARIABLES

Richard Gross, richard.gross@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Terrestrial reference frames are determined from station position measurements that are also used to characterize the deformation of the Earth's surface. Understanding the shape of the Earth and how it changes in space and time is one of the three pillars of geodesy. So, the position of geodetic observing stations can be considered to be an Essential Geodetic Variable. Essential Geodetic Variables (EGVs) are observed variables that are crucial (essential) to characterizing the geodetic properties of the Earth and that are key to sustainable geodetic observations. Examples of EGVs might be the positions of reference objects (ground stations, radio sources), Earth orientation parameters, groundand space-based gravity measurements, etc. Once a list of EGVs has been determined, requirements can be assigned to them. Examples of requirements might be accuracy, spatial and temporal resolution, latency, etc. These requirements on the EGVs can then be used to assign requirements to EGV-dependent products like the terrestrial reference frame. The EGV requirements can also be used to derive requirements on the systems that are used to observe the EGVs, helping to lead to a more sustainable geodetic observing system for reference frame determination and numerous other scientific and societal applications.

B2.1-0002-18 ITRF: THREE DECADES OF RESEARCH AND DEVELOPMENT, CURRENT STATUS AND FUTURE PLANS

Zuheir Altamimi, zuheir.altamimi@ign.fr

Institut National de l'Information Géographique et Forestière, Laboratoire LAREG, Paris Cedex 13, France

Institut National de l'Information Géographique et Forestière, Paris Cedex 13, France

On the occasion of the thirtieth anniversary of the International Earth Rotation and Reference Systems Service (IERS), this paper reviews the progress that has been made in the development of the International Terrestrial Reference Frame (ITRF). A particular focus will be devoted to

(1) the frame definition (origin, scale, orientation and their time evolution) and how it is maintained over time, (2) technique systematic errors and their impact on the frame definition,

(3) the possible ways of dealing with station non-linear motions, and (4) the level of agreement between techniques at co-location sites. Improvements planned for the future ITRF releases will be outlined taking into account user needs in both operational geodesy and Earth science applications.

B2.1-0003-18 COMPARISON OF THE SEASONAL DISPLACEMENT PARAMETERS ESTIMATED IN THE ITRF2014 PROCESSING, WHAT CAN WE LEARN?

Institut National de l'Information Géographique et Forestière, Paris, France

In the ITRF2014 computation process, annual and semi-annual periodic coordinate variations have been simultaneously estimated with reference positions and velocities at each geodetic station. Those parameters were conventionally estimated in distinct reference frames for each space geodetic technique (GNSS, DORIS, SLR and VLBI) and so could not be compared. We have developed a combination procedure which allows a rigorous comparison of seasonal displacements estimated by different geodetic techniques. The level of agreement and the sources of discrepancies of seasonal parameters estimated by different techniques at co-location sites will be rigorously evaluated in both horizontal and vertical components. In addition, we model and supplement the elastic deformation induced by surface loading derived from the Gravity and Recovery Climate Experiment (GRACE) and the thermoelastic deformation of the ground to assess the quality of the combined seasonal parameters.

B2.1-0004-18 SYSTEMATIC EFFECTS ON THE REFERENCE FRAMES QUANTIFIED BY VLBI

Harald Schuh, schuh@gfz-potsdam.de

GFZ German Research Centre for Geosciences, Potsdam, Germany

Currently three global terrestrial reference frames (TRF) are available: the ITRF2014, the DTRF2014, and the JTRF2014. Although these frames are based on identical input data, the mathematical models applied and thus some coordinates significantly differ. ICRF3 (International Celestial Reference Frame 3), the next CRF (celestial reference frame) is very close to be presented by the corresponding IAU (International Astronomical Union) WG to the IAU General Assembly for acceptance. In the sense of IUGG (International Union of Geodesy and Geophysics) Resolution No. 3 (2011) which advocates the consistent determination of CRF, TRF, and EOP (Earth Orientation Parameters), one of the main tasks will be to make sure that the two reference frames, TRF and CRF, are consistent. VLBI (very long baseline interferometry) is the key space geodetic technique for this purpose. In this presentation, we will investigate state-of-the-art models in VLBI analysis vs. the analysis configuration specified through the IERS (International Earth Rotation and Reference Systems Service) Conventions 2010 and the Convention updates. We will apply several different a priori data sets as well as geophysical and astronomical models, such as geophysical loading deformation, neutral-atmosphere propagation delays, and a priori catalogs from which the NNT/NNR constraints are realized and we will quantify their impact on the reference system realization. The systematic effects found will be in the focus of our work, for example the choice of the mean terrestrial pole for the pole tide loading model. The science-driven quality criteria defined by IAG (International Association of Geodesy) and its GGOS (Global Geodetic Observing System) will be used to judge whether the size of the identified effects is significant or can be neglected.

B2.1-0005-18 EVALUATION OF THE INTERNATIONAL TERRESTRIAL REFERENCE SYSTEM 2014 REALIZATIONS BY PRECISE ORBIT DETERMINATION OF SLR SATELLITES

Deutsches Geodätisches Forschungsinstitut, Technische Munich, Germany

An International Terrestrial Reference System realization is a basis for precise monitoring global change phenomena, such as tectonic motion and deformations, postglacial rebound, global and regional sea level change, Earth's rotation, precise positioning applications on and near the Earth's surface, precise orbit determination (POD) and other applications. Three new ITRS realizations have been released recently. They are ITRF2014, DTRF2014 and JTRF2014. We present some results of the evaluation of these ITRS realizations for POD of 10 high and low Earth orbiting geodetic satellites using satellite laser ranging observations (SLR) over a total time span from 1993.0 to 2017.0. We show the impact of these new ITRS realizations on the root-mean-square (RMS) and mean fits of observations, weekly and pass-wise estimated mean station-specific range biases, RMS and mean of single-satellite sea surface height crossover differences using these realizations, as compared to the previous ITRS realization for SLR stations - SLRF2008.

B2.1-0006-18 ERRORS IN SLR-DERIVED TRF ORIGIN CAUSED BY DEFICIENCIES IN ORBIT AND ATMOSPHERIC DELAY MODELING

Krzysztof Sośnica, krzysztof.sosnica@igig.up.wroc.pl

Wroclaw University of Environmental and Life Sciences, Wroclaw, Poland Mateusz Drożdżewski, mateusz.drozdzewski@igig.up.wroc.pl

Wroclaw University of Environmental and Life Sciences, Wroclaw, Poland

Satellite Laser Ranging (SLR) is the space geodetic technique that is used for the definition of the Terrestrial Reference Frame (TRF) origin and along with Very Long Baseline Interferometry (VLBI) for the definition of the TRF scale. SLR is the only geodetic technique that employs optical (laser) wavelengths instead of microwave observations. In the microwave-based observations, the non-hydrostatic delay of the troposphere strongly influences the ray paths of the microwave signal. SLR observations are about 70 times less vulnerable to the non-hydrostatic delay, however, the impact of the hydrostatic delay in SLR is comparable to that affecting microwave observations.

Today, the standard SLR solutions do not employ any corrections due to the horizontal gradients of the troposphere delay. This leads to an assumption that the atmosphere is fully symmetrical above the SLR stations. All other techniques take into account the horizontal gradients into their solutions which may cause inconsistencies, because the SLR-derived TRF origin is common for all techniques. In this contribution we show that the SLR solutions are sensitive to the assymetricity of the troposphere above the stations by estimating horizontal gradients of the troposphere delay using SLR observations to LAGEOS-1/2. We also assess the impact of employing a priori horizontal gradients based on numerical weather models on SLR-derived products, such as geocenter motion, the scale and Earth rotation parameters. The neglect of the horizontal gradients in SLR causes a systematic shift in the TRF origin up to about 0.4 mm with the variations up to 1.0 mm. We also address the issue of the Blue-Sky systematic effect on the SLR solutions that is caused by the fact that SLR observations are collected only in the cloudless conditions which are typically associated with high air pressure values. The Blue-Sky effect affects not the estimated station coordinates introducing a vertical shift of about 1.4 mm, but also the scale of TRF. Finally, we address the issue of correlations between empirical LAGEOS orbit parameters used to absorb the direct solar radiation pressure and the estimated geocenter coordinates and how to avoid these correlations.

B2.1-0007-18 GEOCENTER MOTION FROM SLR OBSERVATIONS

Minkang Cheng, cheng@csr.utexas.edu

Center for Space Research, U. of Texas at Austin, Austin, Texas, United States

The Earth's center of mass (CM) is defined in the satellite orbit dynamics as the center of mass of the entire Earth system, including the solid earth, oceans, cryosphere and atmosphere. Variations of the vector from CM to the origin of the ITRF are defined as geocenter motion. Although number of 'geocenter motion' from different techniques were proposed, only Satellite Laser Ranging (SLR) can provide accurate and unambiguous range measurements to direct measure the geocenter motion (with centimeter level accuracy of precise satellite orbits), which is an important component for the realization of the Terrestrial Reference System and geoinformation applications. An accurate station laser ranging bias for SLR network is required for precise satellite orbit determination. This paper presents recent estimate of geocenter motion determined from analysis of multiple geodetic satellites of SLR data over the period from 1993 to present as a part of solution of lower degree (5x5) gravity field as well as the laser ranging bias of SLR network based on ITRF2014. Estimates of the ranging bias of SLR network and uncertainty will be presented as well.

B2.1-0008-18 THE ESTIMATION AND PREDICTION OF GEOCENTER MOTION BASED ON GNSS/SLR WEEKLY SOLUTIONS

Chunmei Zhao, 24471766@qq.com

Chinese Academy of Surveying and Mapping, Beijing, China
Tianming Ma, 837766251@qq.com

Chinese Academy of Surveying and Mapping, Beijing, China

The development of satellite space geodesy technology makes the establishment of global terrestrial reference frame based on the Earth's center of mass become reality. Precise and stable terrestrial reference frame is the foundation of the Earth science research, while determination and analysis of the position of the Earth's center of mass and its change is an important part to build high precision terrestrial reference frame. Firstly, based on GNSS weekly solutions provided by IGS, the geocenter motion (GM) time series between 2001 and 2016 are obtained by means of net translation method. Then the trend term and periodic term of GM are derived using singular spectrum analysis method. It is shown that the GM mainly presents seasonal variation and the dominant factor is annual variation with amplitudes about 4.12mm, 4.68mm, 9.51mm in the direction of X, Y and Z respectively. In order to provide real-time GM, BP neural network method is tested and the predicted values of GM of year 2017 are gotten. It is found that the prediction accuracy can reach 0.82mm, 0.91mm and 1.01mm in the direction of X, Y and Z respectively. Finally, GM estimation and prediction results with higher precision are obtained through co-location surveying and adding strong constraint observation between GNSS and SLR reference point of the co-location.

B2.1-0009-18 EVALUATION OF IMPROVEMENTS TO PRECISE ORBIT DETERMINATION AND DORIS GEOPHYSICAL PRODUCTS USING THE RESULTS OF JASON2/T2L2

Collecte Localisation Satellites, Ramonville Saint-Agne, France

Space geodesy applications currently demand better accuracy and better long-term stability, including the terrestrial reference frame and the Precise Orbit Determination (POD) of Earth observation satellites. This is why the Global Geodetic Observing System (GGOS) recommend both an accuracy of 1 mm and a stability of 0.1 mm/y for geodetic networks.

The Doppler Orbitography Radiopositioning Integrated on Satellite (DORIS) is a tracking technique based on an one way ground to space Doppler link. DORIS shows a robust capability in terms of data coverage and availability, due to a wide and well-distributed ground network. However, DORIS residuals remain in the range of 0.35 0.45 mm·s1, due to systematics errors (e.g. instabilities of the on-board clock to radiations encountered in space, DORIS time biases.), which limits the positioning of the beacons, especially for those located in the vicinity of the South Atlantic Anomaly (SAA).

The Time Transfer by Laser Link (T2L2) experiment carried on-board the Jason-2 satellite is a unique opportunity to read the on-board oscillator and extract frequency bias data at a level of a few parts in 1013. In addition to the frequency bias residuals deduced from the Medium Ephemeris Orbit (MOE) data, the CARMEN-2 experiment measuring particles flux, internal data (e.g. current, temperature of the DORIS receiver) and an analytical representation of environment-induced signals (e.g. radiation), we built a deterministic frequency model, reducing the DORIS residuals to a level of 0.8 × 1012 (0.24 mm·s1) over several years (20082017).

In this paper, we evaluate the impact of our new model for the on-board clock on geophysical products, such as beacon positioning, Earth Orientation Parameters (EOP) and precise orbit determination for Jason-2.

B2.1-0010-18 SCALE (IN)CONSISTENCY IN DORIS SOLUTIONS

Petr Stepanek, petr.stepanek@pecny.cz

Research Institute of Geodesy,Topography and Cartogrphy, Ondrejov, Czech Republic Vratislav Filler, vratislav.filler@pecny.cz

Research Institute of Geodesy,Topography and Cartogrphy, Ondrejov, Czech Republic

We analyzed the scale of the DORIS (Doppler Orbitography and Radiopositioning Integrated by Satellite) solutions w.r.t. DPOD (ITRF) 2014 with the main goal to explain the scale inconsistencies and to find the optimal DORIS solution reaching low-biased and consistent scale time series possibly participating in the future scale definition of global reference frames. Our analysis profited from 5 different strategies based only on GOP Analysis center solution, using DORIS Doppler exchange format data 2.2 from period 2011.0 - 2017.0. A difference in the sequence of the solutions directly corresponded to one of the changes in the solution settings: data elevation dependent weighting, application of data validity indicators, application of phase center - reference point correction and correction of the inaccurate a priori vector centre of mass - phase centre specifically for satellite Hy-2A. Our analysis examined scale inconsistency issues in 2011/2012 and in 2015. 2011/2012 scale increment is explained as a result of the concurrence of Hy-2A dismodeling and change in the provider data validity standards for Cryosat-2 and Jason-2. The scale increment in 2015 is explained as the effect of change in the standards for phase center - reference center corrections for Saral, Jason-2 and Cryosat-2. Moreover, we found a significant reduction of scale bias and scale variation applying data downweighting. We demonstrate that the optimal solution eventuates in a consistent scale time series with the offset w.r.t. DPOD 2014 under 10 mm and weekly scale variations under 2 mm.

B2.1-0011-18 CO-LOCATION OF SPACE GEODETIC TECHNIQUES USING A CLOSURE IN TIME AND A MULTI-TECHNIQUE REFERENCE TARGET

Federal Agency for Cartography and Geodesy, Bad Koetzting, Germany

The realization of a unique global terrestrial reference frame relies on the links between the different space geodetic techniques (VLBI, SLR, GNSS and DORIS). The classical approach in space geodesy is to treat individual systems separately and combine their measurements using co-located sites, where 3D-discrepancies are monitored on a regular basis using geometrical and physical dimensions of the instrumentations. However frequently repeated surveys have not provided evidence for large variable movements of reference points. Therefore, we have proposed a new calibration concept, which investigates instrumental system delays and incorporates system delays into local ties. This concept is based on a coherent time and frequency distribution system which enables to create a signal calibration loop starting in a common clock signal propagating through a multi-technique ground target, free space and the space geodetic technique itself. In this way we overcome the problem that local tie surveys monitor only distances between the geometric reference points of the instruments but not between the electronic reference points. Multi-technique ground targets use the same signal originating from a common clock and the known respective path delay for tying the instruments to a single point of reference on the observatory. The talk outlines the closure measurement concept with first results derived at Geodetic Observatory Wettzell to provide both, intraand intertechnique comparisons and delay control through the installed multi-technique ground target.

B2.1-0012-18 OBSERVATIONS OF THE APOD SATELLITE WITH THE AUSCOPE VLBI NETWORK

Andreas Hellerschmied, andreas.hellerschmied@geo.tuwien.ac.at Technische Universität Wien, Vienna, Austria

Johannes Böhm, johannes.boehm@tuwien.ac.at Technische Universität Wien, Vienna, Austria Lucia McCallum, lucia.mccallum@utas.edu.au University of Tasmania, Hobart, Australia Jamie McCallum, jamie.mccallum@utas.edu.au University of Tasmania, Hobart, Australia

Jing Sun, sunjing@nao.cas.cn China

Jianfeng Cao, jfcao@foxmail.com China

The Chinese APOD (Atmospheric density detection and Precise Orbit Determination) satellite, launched in September 2015, is the first LEO (Low Earth Orbit) satellite co-locating three spacegeodetic techniques including VLBI. Being equipped with a dual-frequency GNSS receiver, an SLR retro-reflector and a VLBI beacon transmitting DOR tones in the S and X band it can be considered as a first prototype of a geodetic co-location satellite in space. With the focus on VLBI observations we present a series of experiments carried out by the AuScope geodetic VLBI array in November 2016. These experiments represent first observations of a LEO satellite by VLBI radio telescopes with the goal of deriving baseline delays as common in the geodetic VLBI. We describe all steps integrated in the established process chain: the experiment design and scheduling, the antenna control and satellite tracking scheme, the correlation, and derivation of baseline delays. To stay as close as possible to the operational analysis scheme for geodetic VLBI sessions we widely adopted the use of standard software such as DiFX for correlation and the Haystack Observatory Post-Processing System (HOPS). In the subsequent analysis of the derived delay in the Vienna VLBI and Satellite Software (VieVS) we find delay residuals in the range of a few ns. VieVS provides options to estimate a variety of geodetic parameters based on such data. These presented experiments represent the first end-to-end realizations of VLBI observations of a tie satellite on a LEO orbit, and are a valuable resource for future more sophisticated space tie satellite missions in the style of E-GRASP/Eratosthenes.

B2.1-0013-18 COMPARING AND CONTRASTING CURRENT APPROACHES TO DETERMINING TERRESTRIAL REFERENCE FRAMES

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Xiaoping Wu, xiaoping.wu@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

The three IERS ITRS Combination Centers, IGN-LAREG, DGFI-TUM, and JPL-CALTECH, take three very different approaches to determining terrestrial reference frames.

IGN and DGFI both adopt a parametric representation of the frame. On the one hand, IGN individually stacks single technique space-geodetic inputs in order to determine a set of station position offsets and velocities and subsequently combine them together along with Earth Orientation Parameters and local ties.

On the other, DGFI combines frames based on the accumulation of normal equations from the four space-geodetic inputs. After stacking normal equations, they invert for linear piecewise station positions and EOPs.

JPL takes a sequential estimation approach using a Kalman filter wherein the frame is represented by a time series of station positions. These different estimation approaches and different representations of the frame have their advantages and disadvantages. For example, parameterizing the station motion leads to convenient models that can be easily evaluated at any epoch, both in the past and in the future. But the parameterized approach suffers from the inability to capture station motion that is not included in the model. On the other hand, while the time series approach allows arbitrary station motion to be captured, evaluating the position of the station at an arbitrary epoch, either in the past or in the future, is more complicated because the time series must be interpolated to the epoch of interest.

In this talk, the different approaches that are currently used to determine terrestrial reference frames will be reviewed and their advantages and disadvantages discussed.

B2.1-0014-18 DETERMINATION OF KALMAN FILTER TRF SOLUTIONS BASED ON WHITE NOISE STATION COORDINATE BEHAVIOR

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Kalman filtering has become an established technique for the creation of terrestrial reference frame (TRF) solutions, and has been successfully used in the determination of JTRF2014, the most recent ITRS realization by Jet Propulsion Laboratory. So far, the station coordinates have typically been modeled as random walk processes. Advantages of random walks are, for example, that they are computationally efficient and easy to implement in a Kalman filter environment. Furthermore, they guarantee a certain short-term stability of the station coordinate time series, since the coordinates of one epoch directly depend on those from the previous epoch.

However, time series of station coordinates from different space-geodetic techniques as well as non-tidal loading displacements, which are often associated with the non-linear part of coordinate variations, indicate a different stochastic behavior. Most often, the appropriate stochastic model would be white noise.

For this reason, we have implemented the option to use white noise as the process noise type for station coordinates, realized by including an additional parameter per coordinate component in the state vector of the Kalman filter (in addition to offset, velocity, and seasonal signals). Based on data from very long baseline interferometry (VLBI), we will compare the performance of white noise Kalman filter solutions with conventional solutions based on random walk processes. In particular, we will investigate their agreement with existing VLBI coordinate time series, as well as their capability of accurately predicting future station coordinates.

B2.1-0015-18 A SIMULATION STUDY TO INVESTIGATE REFERENCE FRAME STABILITY

Terrestrial reference frame origin stability is critically important to monitoring sea level change through altimetry satellite orbit and crustal motion determinations. Accurate measurements of translational motion between the center-of-mass of the Earth system and the geodetic network can also provide a stronger signal to infer degree-1 spherical harmonic components of Earth's surface mass variations with GRACE and other data. However, complications of GIA, plate motions, uncertainty of terrestrial reference frame origin, certain modeling concepts, and nonlinear motions have so far prevented translational signatures to be used in the determination of geocenter velocities. Also, the current ITRF frame has a net rotation of more than 1 mm/yr from a geodesy-based no-net-rotation plate motion model. We investigate the origin and orientation stability issues by a progressively realistic simulation study. First, synthetic geodetic data are generated from real world geodetic networks with realistic plate motion, GIA, surface loading, geocenter motion signals. These with or without noises generated using full covariance matrices of real geodetic input SINEX files are then passed to several TRF realization procedures to investigate their effects on TRF stability and possible systematic errors.

We found that geology-based plate motion model and apparent rotation due to geocenter motion likely included in the no-net-rotation constraint can both contribute to the net TRF frame rotation with the right order of magnitude. Fortunately, as long as plate motions are freely estimated along with other signals in post-TRF procedures, the origin and translational signals are not negatively impacted. Still, the use of a geodesy based no-net-rotation plate motion model and a no-pure-net-rotation constraint are recommended for future TRF realizations. Results

and challenges of studying other effects on reference frame origin and orientation stability such as those due to non-linear and accelerating surface load variations will be discussed.

B2.1-0016-18 POSTER HIGHLIGHTS SESSION

Geoffrey Blewitt, gblewitt@unr.edu

University of Nevada, Reno, Reno, Nevada, United States

This oral presentation slot is set aside for 2-minute oral summaries from each poster presenter. In the interest of time, presenters can display no more than a two slides, which must be submitted in advance before the conference by email to gblewitt@unr.edu.

B2.1-0017-18 THE IMPACT OF ATMOSPHERIC AND HYDROSPHERIC SURFACE LOADING DEFORMATION ON GLOBAL STATION NETWORKS

Time-dependent mass variations of near-surface geophysical fluids in the atmosphere, the oceans and the continental hydrosphere lead to significant and systematic load-induced deformations of the Earth's crust. Based on station coordinate time series it is possible to assess the impact of time-dependent mass variations on the Earth's surface geometry and, thus, to assess the impact of uncorrected deformations on station positions and terrestrial reference frame parameters. Model-based deformation products publicly available at http://isdc.gfzpotsdam.de/esmdata/loading contain vertical and horizontal crust deformations imposed by surface loading of geophysical fluids in atmosphere, oceans and the continental hydrosphere with a spatial resolution of 0.5° and a temporal sampling of down to 3 hours (Dill and Dobslaw, 2013).

More than 10 years of GNSS and VLBI observations from more than 300 GNSS stations and nearly 40 VLBI stations were reprocessed in order to quantify the impact of surface deformations on station positions. In the first part of this contribution, we discuss the impact of surface loadings on the local and regional scale based on the GNSS stations processed in PPP mode. Here the focus is especially on areas known for large annual surface deformations. The second part concentrates on the impact of surface loading deformations on the terrestrial reference frame. Based on transformation parameters between GNSS as well as VLBI network solutions corrected for different sets of loading deformations we discuss the effect of geophysical fluids on the terrestrial reference frame.

Dill, R. and H. Dobslaw (2013), Numerical simulations of global-scale high-resolution hydrological crustal deformations, J. Geophys. Res., 118 (9), 5008-5017, doi:10.1002/jgrb.50353.

B2.1-0018-18 COMPARING NON-LINEAR GEOCENTER MOTION DERIVED FROM GNSS AND SLR OBSERVATIONS CORRECTED FOR LOADING AND THERMOELASTIC DEFORMATION

Seasonal mass redistribution of continental water, atmospheric pressure, and non-tidal oceanic loading deforms the Earth, inducing horizontal and vertical surface displacements of a few mm and a few cm respectively. In addition, long wavelength annual temperature variations induce a thermoelastic deformation field, with vertical surface displacements of a few mm. The longest wavelength component of both effects, their spherical harmonic degree-1 component, not only deforms the solid Earth, but also induces geocenter motion between the Center-of-Mass of the total Earth system (CM) and the Center-of-Figure (CF) of the solid Earth surface.

SLR and GNSS station position time series used to retrieve geocenter motion are strongly affected by the deformation induced by surface loading and thermoelastic effect. We propose to evaluate the impact of both effects on geocenter motion estimates by correcting the station position time series using physical loading and thermoelastic deformation models. On the one hand, we model surface displacements induced by variations in continental water, atmospheric pressure, and non-tidal oceanic loading, derived from the Gravity and Recovery Climate Experiment (GRACE) for spherical harmonic degrees

two and higher. On the other hand, we model the thermoelastic deformation as the response of a realistic Earth rheological model to land surface temperature variations (NOAA).

We compare non-linear geocenter motion derived separately from SLR (using the network shift approach) and GNSS (using a the degree-1 deformation approach) and discuss the relative impact of loading and thermoelastic effects on each both estimates.

B2.1-0019-18 STOCHASTIC MODELING OF NON-TIDAL GROUND DEFORMATION USING GRACE DATA FOR TERRESTRIAL REFERENCE FRAME ESTIMATION

In recent realizations of terrestrial reference frame (TRF), such as ITRF2014 and JTRF2014, non-tidal ground deformation parameters are co-estimated to improve the accuracy of the frame estimate. The traditional linear motion model for TRF is enhanced by additional ground motion models including post-seismic displacements as well as annual, semi-annual, and random ground deformations due to atmospheric, oceanic, and ground water storage loading. Although such motions are often regionally correlated, the ground deformation models used so far for TRF realizations are formulated to be strictly local in space. We are investigating application of the GRACE data to improve the TRF stochastic models (used in JTRF2014) by determining spatial

statistics of the deformation of the Earth's surface caused by mass loading. A potential target of improvement is the non-uniform distribution of the geodetic observation sites, which can introduce biases in estimated TRFs. We compare the GRACE observation-derived spatial statistics to ones derived from numerical models of atmospheric, oceanic, and ground-water loading as well as ones from GNSS observation network.

B2.1-0020-18 GOING BEYOND REFERENCE FRAMES TO IMPROVE THEM: THE EXAMPLE OF HORIZONTAL DEFORMATION INDUCED BY GLACIAL ISOSTATIC ADJUSTMENT

Geoffrey Blewitt, gblewitt@unr.edu

University of Nevada, Reno, Reno, Nevada, United States Corné Kreemer, kreemer@unr.edu

University of Nevada, Reno, Reno, Nevada, United States William Hammond, whammond@unr.edu

University of Nevada, Reno, Reno, Nevada, United States

A common theme in scientific technique development is the need to go beyond that technique to obtain independent validation and evidence that can lead to further improvements. For example, the early days of GPS technique development was validated and facilitated by having ground truth from VLBI and SLR. A similar lesson can be applied to reference frames. The analogy would be to use measures of Earth surface deformation that are sufficiently insensitive to reference frame such that they can be used to improve geodynamic models that feedback into the definition of the reference system, thus ultimately improving the next generation of reference frames. Here, we illustrate this with the example of glacial isostatic adjustment (GIA) models that can disagree significantly in predictions of contemporary surface velocities, even at plate-scale distances. Thus, by the definition of geodesy, this can be considered a first-order problem. One problem with using station velocities to assess GIA models is that they are reference frame dependent, and so are affected both by rotation and translation rates. Ensuring that the modeled and observed station velocities are in the same reference frame is not trivial, particularly with regard to the rotation of the horizontal velocity field in the presence of plate tectonics and more localized processes that also affect the velocity field. To mitigate this problem, we use GPS velocities to create a robust image of the horizontal strain rate tensor. This can then be decomposed into reference-frame-insensitive scalar fields such as dilitation rate and shear magnitude rate. Here we use a new robust strain rate estimation method (MELD– Median Estimation of Local Deformation) applied to 3,271 GPS velocities in North America that were estimated using a robust algorithm MIDAS (Median Interannual Difference Adjusted for Skewness). The resulting images of strain rate are robust to anomalies localized in time or space, while respecting the inherent spatial resolution of the network. Despite the inherent high resolution of this method when applied to dense networks, our results show ultra-low strain rates with plate-scale coherence in intraplate North America, thus providing a coherent image of GIA, superimposed by more localized processes such as delta subsidence and ground fluid extraction. Our key finding is that the area underneath the Laurentide ice sheet is undergoing extension, surrounded by a semi-annular belt of contraction of up to 4 nanostrains (parts per billion) per year. Such observed long wavelength characteristics

of the ultra-low strain rate field in intraplate regions can therefore be used to provide robust constraints on viable GIA models, with the prospect of eventually contributing to an improved reference system and future realizations of the reference frame, including plate-fixed reference frames.

B2.1-0021-18 MONITORING OF PERMANENT GNSS NETWORKS USED FOR ACCESSING THE TERRESTRIAL REFERENCE FRAME

Carine Bruyninx, c.bruyninx@oma.be

Royal Observatory of Belgium, Brussels, Belgium Juliette Legrand, j.legrand@oma.be

Royal Observatory of Belgium, Brussels, Belgium Andras Fabian, a.fabian(at)oma.be

Royal Observatory of Belgium, Brussels, Belgium Eric Pottiaux, e.pottiaux@oma.be

Royal Observatory of Belgium, Brussels, Belgium

Scientific GNSS networks likes the ones operated by the International GNSS Service (IGS) and the EUREF Permanent Network (EPN) are continuously evolving, e.g. the number of stations increases, new satellite constellations are tracked, observation data and metadata formats change, and the importance of real-time data provision increases. Both the IGS and EPN are based on voluntary contributions. More than 130 agencies all over Europe contribute to the EPN. Although guidelines (based on IGS guidelines) exist within the EPN for data quality and data flow, equipment changes, or maintenance of metadata, different institutes use different practices and there is no formal guarantee that EPN stations are operated following the EPN guidelines. This explains the need for the extensive central monitoring of the EPN performed by its Central Bureau (http://epncb.eu).

To deal with the evolving GNSS landscape, the EPN Central Bureau (CB) revisited its monitoring procedures and interface with users and data providers. The frontend of the web site (http://www.epncb.eu) was completely redesigned and the majority of the backend software was rewritten. We will outline the philosophy behind the upgraded

GNSS data quality, availability and latency checks,

Monitoring of real-time data streams,

Position time series,

Management of individual receiver antenna calibrations,

System for the 'Management and distribution of GNSS Metadata for Multiple networks' (M3G).

We will illustrate the effectiveness of these monitoring procedures by focusing on the Galileo and real-time capability of the EPN.

The EPN CB monitoring and metadata maintenance procedures use standardized inputs and can therefore be applied to any

large-scale permanent GNSS network maintained by several contributors. Although often taken for granted, these procedures enhance the reliability of GNSS data for providing access to the terrestrial reference frame.

B2.1-0022-18 QUALITY ASSESSMENT OF THE EPN MULTI-YEAR POSITION AND VELOCITY SOLUTION

Juliette Legrand, juliette.legrand@oma.be Royal Observatory of Belgium, Uccle, Belgium Carine Bruyninx, c.bruyninx@oma.be

Royal Observatory of Belgium, Brussels, Belgium

The primary purpose of the EUREF Permanent Network (EPN) is to provide access to the European Terrestrial Reference System 89 (ETRS89) which is the standard precise GNSS coordinate system throughout Europe. To maintain the ETRS89, EUREF provides multi-year coordinates/velocities of the EPN stations in the latest ITRS/ETRS89 realization, also called the 'EPN multi-year solution'. The coordinates/velocities of the EPN multi-year solution are regularly updated (each 15 weeks) and are used as the reference coordinates/velocities for densifying the IGS14 realization of the ITRS in Europe. It is the core product of EUREF, the IAG (International Association of Geodesy) Reference Frame sub-commission for Europe. Starting with the release of IGS14 (January 2017), the EPN multi-year position and velocity solution is replaced by a new version based on the daily solutions instead of weekly solutions and on EPNrepro2 and routine solutions. The EPN multi-year position and velocity solution is computed with the CATREF software (Altamimi et al., 2007). The positions and velocities are expressed in IGS14 reference solution using minimal constraints on a selection of IGS14 reference stations. During the stacking, discontinuities are introduced to account for jumps in the position time series. In addition, this solution incorporates the ITRF2014 post-seismic deformation models. The EPN stations are categorized into Class A and Class B stations. Class A stations represent stations whose multi-year positions and velocities are reliable enough to be used as reference station for densification projects. The criteria for distinguishing between Class A and Class B stations have been recently revisited. They take into account the length of the available observation span and the "station quality". In order to assess the quality of the stations, the sensitivity of the velocity and its error estimation with respect to time correlated noise, used software, and tracking performance of the station has been investigated.

B2.1-0023-18 TOWARDS NEXT GENERATION REFERENCE FRAMES IN EUROPE

Markku Poutanen, markku.poutanen@nls.fi

Finnish Geospatial Research Institute, National Land Survey of Finland, Masala, Finland EUREF GB

Zuheir Altamimi, Elmar Brockmann, Carine Bruyninx, Alessandro Caporali, Rolf Dach, Jan Dousa, Rui Fernandes, Ambrus Kenyeres, Juliette Legrand, Martin Lidberg, Tomasz Liwosz, Rosa Pacione, Martina Sacher, Wolfgang Söhne, Gunter Stangl, Joao Torres, Christof Völksen

The IAG Sub-commission 1.3a EUREF merges efforts of National Mapping and Cadastral Agencies (NMCA), Universities and research institutes to define, realize and maintain the European Terrestrial Reference System 1989 (ETRS89) and the European Vertical Reference System (EVRS) for scientific and practical purposes in Europe. Technical development, new applications and increased accuracy of observations are setting new demands for the practical realizations of the reference systems. The release of the global International Terrestrial Reference Frame ITRF2014 raised also the question on future and needs on renewal of the realization of the European Terrestrial Reference System.

It is foreseeable an emerging mass market for precise positioning based on centimetre level positioning services worldwide without any regional or national reference frames. There will be also precise point positioning (PPP) service from Galileo and other provides. These worldwide services will most likely use ITRF in current epoch.

Crustal deformations and movements deteriorate the accuracy of static reference frames with time (like the currently used European realizations ETRF2000 or ETRF2014) as distortions are increasing. Monitoring the deformation with EUREF permanent GNSS Network (EPN) and research within EUREF working groups are necessity for the future, but these alone do not answer the question of future reference frames. We have to solve the European-wide question of national static reference frames.

There are many countries that have invested a lot in their national realizations of ETRS89 which are even fixed in their legislation and they will use the current frame effectively for many years to come. Additionally, the Directive 2007/2/EC of the European Parliament and of the Council of Infrastructure for Spatial Information in the European Community (INSPIRE) requires that the European Terrestrial Reference System 1989 shall be used, and for elevations, i.e. gravity-related heights, the European Vertical Reference System shall be the system.

Instead of a static reference frame, one can use semi-kinematic or kinematic approaches where either the transformation from global to the national reference frame or the coordinates of the benchmarks realizing the reference frame are time-dependent. For some years to come we may have a two frame approach where ETRS89 and ITRF will be used together, depending on the application. Using European-wide 3D deformation models, and dense network of permanent GNSS stations, we may link these together (semi-kinematic approach). However, shifting fully to an ITRF kinematic frame will pose problems both on the practical level and in national and European legislation. On the gravity related global heights we do not yet have a similar approach, which will take even longer time to get adopted. However, a need to be prepared on EUREF level is more urgent than ever and it should be discussed within the European geodetic community to find the best solution for the future both for scientific and practical use.

B2.1-0024-18 IMPROVING INFRASTRUCTURE AND STANDARDS TO MAXIMISE THE BENEFITS OF POSITIONING TECHNOLOGY IN AUSTRALIA

Nicholas Brown, nicholas.brown@ga.gov.au Geoscience Australia, Canberra, Australia John Dawson, john.dawson@ga.gov.au Geoscience Australia, Canberra, Australia

Sub decimetre accurate positioning in mobile devices from Global Navigation Satellite Systems (GNSS) with corrections from satellite or internet communications is expected within the coming decade. This will provide an expanding user base with positioning, navigation and timing information in a global reference frame such as ITRF. In recognition of this, Australia has recently updated its national datum to the Geocentric Datum of Australia 2020 (GDA2020); a static datum based on a continental scale adjustment of approximately two million measurements to rigorously propagate coordinates and uncertainties to 250,000 survey marks across Australia. This is the first update since the Geocentric Datum of Australia 1994 (GDA94) and reduces the offset between the national datum and ITRF2014 from 1.6 m to 0.2 m at present.

A static datum however, cannot meet the requirements of some current and future positioning applications which require real-time, high precision positioning aligned to a global reference frame such as the intelligent transport sector (e.g. autonomous vehicles and mining) and location based services (e.g. asset management, emergency services). To meet user demands, Australia plans to introduce a time-dependent reference frame in 2020 known as the Australian Terrestrial Reference Frame (ATRF). This reference frame will be an accurate and densely realised geodetic framework based on continuous observation and analysis of GNSS data and provide the Australian community with traceable, high-precision coordinates, closely aligned to ITRF and capable of meeting the most demanding positioning requirements. There will be very close alignment between ATRF and ITRF; in fact Australian sites contributed to ITRF will be a subset of reference sites constrained in ATRF.

The development of GDA2020 and the future ATRF are enabled in large part due to the design and construction of world class geodetic infrastructure. Over the past two decades Australia increased the number of high-quality GNSS Continuously Operational Reference Station (CORS) sites (geodetic antennas mounted on pillars attached to bedrock) from eight to 120. When plate tectonic motion is removed from the time series of these sites, the residuals are typically less than one millimetre. This reflects both the stability of the Australian continent and the quality of the infrastructure.

The geodetic community are increasing called upon to provide greater volumes of, and higher accuracy data and products to support a broad and expanding spectrum of government, industry, science and societal applications. To achieve this there is a need to combine the high quality infrastructure, data and analysis with high quality, autonomous, machine-to-machine communication based on international standards to abstract the lay user from the complexities of geodesy. In response, Australia and New Zealand are leading the development of geodetic standards (GeodesyML) in collaboration with the IGS Data Center Working Group. The vision in Australia is to use standards such as GeodesyML to better connect users with data and information to enable industry, scientists and the public to capitalise on this positioning technology and maximise its benefit.

B2.1-0025-18 REGIONAL REFERENCE FRAMES FOR NORTH AMERICA: CURRENT STATUS AND FUTURE PLANS OF REGIONAL SUB-COMMISSION SC1.3C

Michael Craymer, michael.craymer@canada.ca Natural Resources Canada, Ottawa, Canada Daniel Roman, dan.roman@noaa.gov

NOAA National Geodetic Survey, Silver Spring, Wyoming, United States

In collaboration with the IAG community, its service organizations and the national geodetic organizations of North America, the IAG Regional Sub-commission SC1.3c (Regional Reference Frames for North America) provides international focus, cooperation and coordination for issues involving the geodetic reference frames and control networks of North America. These issues include the establishment, maintenance, future evolution and inter-relation of reference frames throughout the continent, and the specification of consistent standards and guidelines. In order to realize these objectives the Sub-commission has been organized into three working groups dealing with (1) the densification of the ITRF and IGS reference frames in North America (NAREF), (2) the definition of new geocentric, ITRF-based plate-fixed reference frames to replace the existing non-geocentric NAD83 in North America, the Caribbean, and U.S. territories on the Pacific and Mariana plates, and (3) the maintenance of the relationship between NAD83 and global reference frames. Over the past few years there has been much preparation for major activities that are just now beginning. We report on these activities and the future plans of the working groups. In particular, we highlight work towards the implementation of the new plate-fixed references frames to replace NAD83 in 2022, including the reprocessing of all continuously operation reference stations and cumulative solutions with velocities. Other important efforts include the updating of NAD83 and transformations with respect to ITRF2014.

B2.1-0026-18 NAD83(CSRS) VERSION 7: AN UPDATED REALIZATION OF NAD83 FOR CANADA

Michael Craymer, michael.craymer@canada.ca Natural Resources Canada, Ottawa, Canada Remi Ferland, remi.ferland@canada.ca Natural Resources Canada, Ottawa, Canada Earl Lapelle, earl.lapelle@canada.ca

Natural Resources Canada, Ottawa, Canada Mieczyslaw Piraszewski, mike.piraszewski@canada.ca Natural Resources Canada, Ottawa, Canada Catherine Robin, catherine.robin@canada.ca

Natural Resources Canada, Ottawa, Canada Yanlai Zhao, yanlai.zhao@canada.ca Natural Resources Canada, Ottawa, Canada

The North American Datum of 1983 (NAD83) is the geometric reference frame of the Canadian Spatial Reference System (CSRS) and has been adopted by the federal and provincial agencies for georeferencing in Canada. In collaboration with the U.S., NAD83 was redefined in 1998 as a seven-parameter similarity (Helmert) transformation from ITRF96. Referred to as NAD83(CSRS), the frame was kept aligned with the North American tectonic plate using the NNR-NUVEL-1A plate motion model. NAD83(CSRS) has since been updated to later realizations of ITRF using the transformations between ITRFs published by the IERS and identified by version numbers. In order to account for crustal motions within the NAD83(CSRS) frame, a crustal velocity model based solely on GPS velocities was introduced with version 5 (based on ITRF2005) and updated in version 6 (based on ITRF2008). The velocity model, represented by an interpolation grid, enables coordinates to be propagated to different reference epochs, including those of the realizations of NAD83(CSRS). These velocity models were unreliable in the northern territories where GPS coverage was sparse. A new NAD83(CSRS) version 7 has recently been published based on a transformation from ITRF2014 and a reprocessing of all continuous and high accuracy repeated GPS campaign surveys in Canada, bordering areas of the U.S. and all of Greenland. A set of approximately 80 global IGS stations used for alignment to IGS14. To overcome the weakness of the previous GPS-only velocity models, a new model was created based on a novel integration of GIA models with the new GPS velocity field. In addition to providing a more precise regional reference frame for geospatial positioning throughout all of Canada, the new NAD83(CSRS) version 7 is capable of providing more accurate predictions of crustal velocities for propagating coordinates to different reference epochs and for supporting geoscience studies such as natural hazards related to earthquakes and relative sea level rise.

B2.1-0027-18 THE IMPACT OF INDEPENDENT GNSS GEOCENTER AND SCALE INFORMATION ON FOUR-TECHNIQUE REFERENCE FRAMES

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Xiaoping Wu, xiaoping.wu@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

GNSS geocenter and scale information has typically been excluded from terrestrial reference frame combinations because current IGS combinations have been aligned with ITRF by application of rotational and translational constraints and adjustment of antenna offsets. Haines et al. (JGR, 2015) have computed alternate GNSS solutions with independent geocenter and scale information. We can now investigate the use of GNSS geocenter and scale information in the context of a four-technique reference frame. JPL's new GipsyX software will be used to compute linear reference frames based on traditional IDS, IGS, ILRS, and IVS inputs and then the IGS combinations will be replaced by Haines GNSS solutions. These frames will be compared to assess the viability of GNSS geocenter and scale information.

B2.1-0028-18 INTER-SATELLITE LINKS WITHIN FUTURE GNSS CONSTELLATIONS AND THEIR IMPACT ON THE TRF-DEFINING PARAMETERS

Susanne Glaser, susanne.glaser@gfz-potsdam.de

GFZ German Research Centre for Geosciences, Potsdam, Germany Grzegorz Michalak, michalak@gfz-potsdam.de GeoForschungsZentrum Potsdam, Wessling, Germany

Rolf Koenig, koenigr@gfz-potsdam.de

Deutsches GeoForschungsZentrum, GFZ, Wessling, Germany Hans Neumayer, neumayer@gfz-potsdam.de GeoForschungsZentrum Potsdam, Wessling, Germany Benjamin Männel, benjamin.maennel@gfz-potsdam.de

GFZ German Research Centre for Geosciences, Potsdam, Germany Harald Schuh, schuh@gfz-potsdam.de

GFZ German Research Centre for Geosciences, Potsdam, Germany

The four main space geodetic techniques, namely Doppler Orbitography and Radiopositioning Integrated by Satellite (DORIS), Global Navigation Satellite Systems (GNSS), Satellite Laser Ranging (SLR), and Very Long Baseline Interferometry (VLBI), are currently combined to determine global terrestrial reference frames (TRF). The origin of the TRF is realized by SLR only and the scale by SLR and VLBI. DORIS and GNSS do not contribute to the realization of the origin and scale mostly due to persisting systematic effects. Since the Global Geodetic Observing System (GGOS) requirements of 1mm accuracy and 1mm/decade long-term stability are not met by current TRFs, it seems worth to investigate the potential of future GNSS constellations using innovative optical ranging and time transfer technology. Within the joint project ADVANTAGE (Advanced Technology for Navigation and Geodesy) by the German Aerospace Center (DLR) and the GFZ German Research Centre for Geosciences, simulations of a future satellite constellation connected by two-way optical links are carried out to investigate potential improvements in the TRF-defining parameters. The chosen ADVANTAGE constellation consists of 24 Middle Earth Orbit (MEO) navigation satellites and 4 Low Earth Orbit (LEO) satellites. We evaluate the impact of highly precise clocks and inter-satellite ranging on the TRF in terms of origin, scale and orientation. We also assess the effect of systematic modeling errors like solar radiation pressure, antenna phase center offsets, and others.

The International Laser Ranging Service (ILRS) has completed a full re-analysis of the modernera data (1993 to present), based on an improved modeling of the data and a novel approach that ensures the results are free of systematic errors in the underlying data. Over the past three years, since the completion of the last ITRF (2014), the ILRS Analysis Standing Committee (ASC), devoted almost entirely its efforts to develop, evaluate and implement the new approach. Initially with the execution of a Pilot Project (PP) that demonstrated the robust estimation of persistent systematic errors at the millimeter level, and now, with the production of essentially an improved version of the ILRS contribution to ITRF, using the new approach. The improved results for the TRF attributes were reflected in the resulting new time series of the TRF origin and scale. The ILRS ASC is now using the new approach in the development of its operational products and we are using this as a tool to monitor station performance and to extend the history of systematics at each station, to be used with each re-analysis for all future ITRF model developments. The new operational products form a seamless extension of the re-analysis series, providing a continuous product based on our best knowledge of the ground system behavior and performance, without any dependence whatsoever on a priori knowledge of systematic errors. The presentation will demonstrate the level of improvement with respect to the previous ILRS product series.

B2.1-0030-18 SLR TARGET CONSTELLATION FOR AN IMPROVED FUTURE ITRF

Erricos C. Pavlis, epavlis@umbc.edu

University of Maryland Baltimore County, Baltimore, Maryland, United States Magdalena Kuzmicz-Cieslak, magdak@umbc.edu

Joint Center for Earth Systems Technology, University of Maryland, Baltimore, Maryland, United States

Keith Evans, evans@umbc.edu

Joint Center for Earth Systems Technology, University of Maryland, Baltimore, Maryland, United States

The International Terrestrial Reference Frame (ITRF) is the prime contribution of the Global Geodetic Observing System-GGOS, to the Global Earth Observation System of Systems (GEOSS) by the organization itself, as well as a product of the International Association of Geodesy-IAG Services that contribute to its development. To meet the stringent requirements imposed by the user community, GGOS set strict goals for the accuracy and stability for the ITRF: definition of its origin at 1 mm or better, temporal stability of 0.1 mm/y, and similar numbers for its scale and orientation components. None of the IAG positioning techniques can achieve this goal alone. The main reason is the non-observability of certain TRF attributes from each technique. Another reason is the poor state of the ground segment and/or limitations of the space segment. The ground segment of all four space geodetic techniques is now under renovation and upgrade. The SLR network in particular, has already more than a dozen new systems operating in kHz repetion rates, as expected for next-generation systems. In the case of the space segment, the unavailability of suitable SLR targets in a more frequent daily schedule results in lower accuracy and resolution for some of the SLR products. The small number of satellite targets used in ITRF development at present has been a driving force behind several attempts to launch better-designed targets in various configurations. The first successful mission was ASI's LARES (LAser RElativity Satellite), launched by ESA in February 2012. This new cannonball target added to the existing two LAGEOS' and two ETALON satellites will certainly contribute to the next ITRF model. Furthermore, ASI has recently approved the launch (provided again by ESA) of a second LARES-type satellite-LARES-2, in the very near future (late 2019). However, it is already possible to increase the number of the available targets, even if not as optimal in design as the cannonball satellites may be, by including all or some of the GNSS spacecraft that carry Laser Retroreflector Arrays-LRAs. With the planned outfitting of current and future GNSS constellations with LRAs, there is an opportunity to dramatically improve the sky-coverage, the chances that a SLR station has a target to track at any time, and the geometry of available data over each station per day. In the case of future launches, with careful designs and a calibration of the LRA location with respect to the radiometric phase center and the center of gravity of the s/c, these targets can become a very significant contribution in the development of the future ITRF realizations, imposing a strong tie between the two techniques in space. With the number of such targets reaching well over one hundred over the next decade, we will soon need to define minimum requirements and a concept of operations in order to avoid undue burdening of the SLR network and a waste of resources. Our current effort is to evaluate at first the contribution of LARES and subsequently that of LARES-2, with the next additions coming from existent in-orbit missions like Starlette, and in a final stage the addition of selected GNSS targets. We plan to eventually examine the utility of bringing the two techniques together in orbit and the tangible benefits that we expect to reap on the ground in realizing the ITRF. We will present here initial results of specific targets' combination studies aimed at achieving the GGOS accuracy goals.

B2.1-0031-18 ICRF-3: AN OVERVIEW OF THE PROPOSED NEXT GENERATION MULTIWAVELENGTH ICRF

Christopher Jacobs, chris.jacobs@jpl.nasa.gov

NASA Jet Propulsion Lab / California Institute of Technology, Pasadena, California, United States

The ICRF-3 proposal to the 2018 IAU General assembly improves the precision, spatial coverage, and frequency coverage relative to the current standard, the ICRF-2 (Ma et al, 2009).

This paper will discuss all three frequencies (8, 24, 32 GHz) of the proposed ICRF-3 highlighting their strengths and weaknesses. Inter-comparisons will be used to estimate true accuracy of the frame. Comparisons of radio-based VLBI frames to the optical Gaia DR2 frame will provide a complementary assessment from an independent wavelength and technique. We will close with prospects for future development of the ICRF.

B2.1-0032-18 WHERE - A NEW SOFTWARE FOR GEODETIC ANALYSIS

Geir Arne Hjelle, geir.arne.hjelle@kartverket.no Norwegian Mapping Authority, Hønefoss, Norway Ann-Silje Kirkvik, ann-silje.kirkvik@kartverket.no Norwegian Mapping Authority, Hønefoss, Norway Ingrid Fausk, ingrid.fausk@kartverket.no Norwegian Mapping Authority, Hønefoss, Norway Michael Dähnn, michael.daehnn@kartverket.no Norwegian Mapping Authority, Hønefoss, Norway

The Norwegian Mapping Authority (Kartverket) is an associated analysis center within the IVS. We are currently developing Where, a new software for geodetic analysis. Where is built on our experiences with the Geosat software, and will be able to analyse geodetic data from the VLBI, SLR, and GNSS techniques. At the moment we are preparing to contribute VLBI analyses to IVS. We plan to make the Where-software available to the community.

This presentation will show some of the current capabilities of Where, including benchmarks against other software packages. Where supports parameter estimation using Kalman filters, and a comparison to the classical methods will be shown.

B2.1-0033-18 THE ISO GEODETIC REGISTRY AND RELATED STANDARDS

Michael Craymer, michael.craymer@canada.ca Natural Resources Canada, Ottawa, Canada Larry Hothem, ldhothem@gmail.com

US Geological Survey, Bethesda, Maryland, United States

The International Standards Organization Technical Committee 211 (ISO/TC 211) on Geographic Information/Geomatics has taken responsibility for establishing the ISO Geodetic Registry, a registry of international geodetic reference systems and transformations. A principal use of the Registry is in defining the various reference frames and transformations used for applications in the geosciences, such as for satellite orbital coordinates and geographical information systems software. The data contained in the registry are the parameters defining geodetic reference systems and adopted transformations between them and need to be validated by official sources. The ISO Geodetic Registry has been defined in accordance with the new ISO International Standard (IS) 19127 (Geodetic register). This standard defines the data elements required, as well as the rules for its maintenance, in compliance with IS 19135 (Procedures for item registration) and the recently updated IS 19111 (Referencing by coordinates) that describes the elements necessary to fully define reference systems. As specified in IS 19135, the ISO Geodetic Registry consists of an online information system or database with a user interface and web services for access, a Registry Manager hosting the Registry and taking care of its daily operations, and a Control Body that approves the content of the Registry. The Norwegian Mapping Authority is serving as the initial Registry Manager and has funded and hosted the registry management software. The Control Body consists of geodetic experts nominated by the TC 211 member and liaison organizations with its chair and vice-chair appointed by the IAG. After significant delay, the ISO Geodetic Registry was made publically available earlier this year, populated with an initial set of most global and regional reference frames and their associated transformations. Further population of the Registry continues and geodetic agencies are encouraged to submit their own reference frames and transformations. We describe the parameters required to be entered for such reference frames and transformations as well as the status of recent revisions to the defining standards IS 19111 and IS 19127.

B2.1-0034-18 TIME EVOLUTION OF THE SIRGAS REFERENCE FRAME

Laura Sanchez, lm.sanchez@tum.de

Technische Universitaet Muenchen, Munich, Germany

Sistema de Referencia Geocentrico para Las Americas (SIRGAS)

(1) Deutsches Geodätisches Forschungsinstitut, Technische Universität München, Munich, Germany (2) Universidad del Zulia, Maracaibo, Venezuela (3) Argentinean - German Geodetic Observatory, La Plata, Argentina (4) Consejo Nacional de Investigaciones Científicas y Técnicas, Argentina (5) Universidad Nacional de La Plata, La Plata, Argentina (6) Instituto Brasileiro de Geografia e Estatistica, Rio de Janeiro, Brazil, (7) Gabriel Gaytan, Instituto Nacional de Estadística y Geografía, Aguascalientes, Mexico, (8) Hernan Guagni, Instituto Geográfico Nacional, Buenos Aires, Argentina, (9) Universidad Nacional de Cuyo, Mendoza, Argentina (10) Universidad Juan A. Maza, Mendoza, Argentina (11) Agencia Nacional Minera, Bogota, Colombia (12) Instituto Geográfico Militar, Quito, Ecuador, (13) Universidad Nacional, Heredia, Costa Rica (14) Instituto Geográfico Militar, Santiago de Chile, Chile (15) Instituto Geográfico Agustín Codazzi, Bogota, Colombia (16) Servicio Geográfico Militar, Montevideo, Uruguay

Studying, understanding, and modelling geophysical phenomena, such as global change and geodynamics, require geodetic reference frames with (1) an order of accuracy higher than the magnitude of the effects we want to study, (2) consistency and reliability worldwide, and (3) a long-term stability. The definition, realisation and maintenance of the ITRS are oriented to guarantee a globally unified geometric reference frame (i.e., the ITRF) with reliability at the mm-level. The densification of the global ITRF in Latin America and The Caribbean is given by SIRGAS (Sistema de Referencia Geocentrico para Las Americas), primary objective of which is to provide the most precise coordinates in the region. At present, SIRGAS is the backbone for all regional projects based on the generation, use, and analysis of geo-referenced data at national as well as at international level. Besides providing the reference for a wide range of scientific applications such as the monitoring of Earth's crust deformations, vertical movements, sea level variations, atmospheric studies, etc., SIRGAS is also the platform for practical applications such as engineering projects, digital administration of geographical data, geospatial data infrastructures, etc. However, the reliability of SIRGAS as reference frame is being affected by the frequent occurrence of seismic events deforming the geometry of the network and by the omission of non-lineal station movements including systematic errors in epoch coordinates. In this context, this presentation summarises the main challenges faced currently

by SIRGAS: (1) A high-resolution monitoring of the reference frame deformation by means of more reference stations and improved analysis standards; (2) Co-seismic deformation models for the transformation of station positions between preand post-seismic frame realisations;

(3) Reliable modelling of non-lineal station movements in the reference frame computation to improve the estimation of epoch coordinates.

B2.1-0035-18 MASS AND MOTION TERMS OF ATMOSPHERIC AND OCEANIC ANGULAR MOMENTUM AND THEIR IMPACT ON GEODETIC HYDROLOGICAL EXCITATIONS

Jolanta Nastula, nastula@cbk.waw.pl

Space Research Centre of the Polish Academy of Sciences, Warsaw, Poland Małgorzata Wińska, m.winska@il.pw.edu.pl

Warsaw University of Technology, Poland, Warsaw, Poland Justyna Śliwińska, jsliwinska@cbk.waw.pl

Space Research Centre of the Polish Academy of Sciences, Warsaw, Poland

The Earth's rotation is not constant over the time and these changes are observed both in terms of rotation speed and the orientation of the rotation axis. The determination of the Earth's rotation parameters is a very important challenge in present-day geodesy since they are the elements of the transformation matrix between celestial and terrestrial reference frames.

Here, we would like to focus on the changes in the orientation of the Earth's rotational axis in relation to the terrestrial reference frame known as the polar motion. The main conductor of non-tidal changes in the pole's coordinates is the time-depend variability of mass distribution in the geophysical surficial fluids: atmosphere, oceans and land hydrosphere.

The main method to determine the influence of the atmosphere and ocean on polar motion excitation is a computation of so-called Atmospheric Angular Momentum (AAM) and Oceanic Angular Momentum (OAM) functions. Nevertheless, the mass terms related to the air and ocean bottom pressure as well as motion terms reconnected with wind speed and ocean currents, vary from one model to another.

The choice of combination of atmospheric and oceanic models is essential for designation the hydrological signal in observed polar motion excitation provided by geodetic techniques (socalled geodetic residuals - GAO). This contribution is calculated as a difference between geodetic excitation (Geodetic Angular Momentum - GAM) and the sum of AAM and OAM. The discrepancies between observed polar motion variations and geophysical contributions appear more likely to be caused by the errors of the atmospheric, in particular of the motion term, and oceanic models.

Here, we would like to present the consistency of full polar motion excitation provided by geodetic measurements (GAM) with geophysical excitations that are the sum of AAM (pressure + wind) and OAM (bottom pressure + currents) contributions. To do this, we use several models of atmosphere and oceans. For determination of AAM we use the following models: NCEP/NCAR reanalysis model provided by the Sub-bureau for the Atmosphere of the Global

Geophysical Fluid Centre (GGFC), Effective Atmospheric Angular Momentum (EAAM) obtained from GeoForschungsZentrum (GFZ) and Atmospheric Angular Momentum (EAAM) obtained from the analysis of the European Centre for Medium-Range Weather Forecasts (ECMWF). Oceanic Angular Momentum is calculated here with the use of: ECCO kf079 and ECCO kf080 ocean models provided by Jet Propulsion Laboratory (JPL) as well as effective angular momentum functions (EAMF) of the ocean calculated from Max Planck Institute Ocean Model (MPIOM). An additional data set for our analyses are the time series of sea-level angular momentum function (SLAM) that reflect the impact of sea level mass balance and are provided by the GFZ.

In this study, we present the comparable analysis of mass and motion terms of Atmospheric and Oceanic Angular Momentum in terms of decadal, seasonal, and short term oscillations. The comparison of prograde and retrograde annual and semiannual oscillations is also included. These analyses could let us indicate, which components of different AAM and OAM models cause the biggest errors in the geodetic budget.

B2.1-0036-18 IMPROVING THE ACCURACY OF INTER-TECHNIQUE TIES AT CORE GEODETIC SITES THROUGH ESTIMATION STRATEGIES THAT EXPLOIT ATMOSPHERIC STRUCTURE

Local ties between reference points of geodetic instruments at colocation sites are one of the limiting error sources in establishing a robust multi-technique terrestrial reference frame (TRF) suitable for geophysical applications having stringent accuracy requirements, such as global sealevel change. Generally, disagreement between local ties and space geodetic solutions is significantly larger than the formal uncertainties of the local surveys. We are investigating approaches that could improve the accuracy of relative positions obtained from geodetic techniques and their ties, and hence of TRF combinations. These approaches use external constraints based on local atmospheric structure at core geodetic sites where multi-techniques are co-located. This method considers known stochastic (i.e., turbulent) structure as well as systematic (e.g., fronts, gradients) atmospheric structure. The challenge is to add information to the geodetic solution based on our knowledge of atmospheric structure without biasing the estimates of the intersite vectors. We will present results from preliminary tests wherein atmospheric structure is used to enhance the strength of geodetic solutions and combinations.

The infrastructure of the Global Geodetic Observing System in Poland (GGOS-PL) is currently being extended in order to fulfill the goals of the EPOS-PL by providing the reliable geodetic reference frames. The project EPOS-PL, European Plate Observing System for Poland, was launched in January 2017 with the main objective of observing surface land deformations and seismicity affecting inhabitants, environment, infrastructure and buildings in two mining regions of Upper Silesia, south Poland. These regions are subjected to present or former intensive coal exploitation activities. EPOS-PL engages scientists and industry experts from various fields: geophysics, seismology, geodesy, mining, geology, geomagnetism, and gravimetry with a common goal of providing comprehensive and complementary information on the effects and possible causes of surface land deformations. EPOS-PL is founded by the National Centre for Research and Development in the Smart Growth Operational Programme 2014-2020.

The new GGOS-PL infrastructure includes multi-GNSS permanent stations, radiometers, tidal gravimeters, seismometers, and ground reflectors for synthetic aperture radar (SAR) observations. In total, eight new GNSS receivers will be installed; four of which will serve as reference receivers installed in stable areas and another four receivers in the area, where surface displacements are expected. The receivers will have the capability of tracking multi-GNSS signals which included six GNSS and RNSS systems: GPS, Galileo, GLONASS, BeiDou, SBAS, and QZSS with the possibility of 20Hz to 50Hz data recording.

The high-rate GNSS data shall be compared with seismic records for the integrated near realtime seismic wave detection. The seismic records will be confronted with signals recorded by tidal gravimeters. Two GNSS receivers will be supported by radiometers for integrated GNSS troposphere modelling. One reference GNSS receiver will additionally be supported with an external frequency standard realized by an atomic clock for future experiments with the clock parameter stability in multi-GNSS real-time Precise Point Positioning solutions. Finally, the surface mass displacements in long and medium timescales will be determined using SAR technique data and validated using results from multi-GNSS permanent stations. This paper will outline the concept of the integrated geophysical and geodetic monitoring of surface deformations and geodynamic processes as well as first results from the project.

Precise knowledge of the terrestrial reference frame is essential in order to meet numerous existing and future science requirements for the study of the effects of, for example, tectonic motions, climate change, and sea-level rise. With the aim of improving space and time references on Earth, and the realization of a terrestrial reference frame accurate to 1 mm and a long-term stability of 1 mm in 10 years set by the Global Geodetic Observing System (GGOS), satellite missions have been proposed providing co-location in space, e.g., GRASP (Geodetic Reference Antenna in Space) to NASA and E-GRASP/Eratosthenes to ESA. Our VLBI group at the GFZ Potsdam has performed numerical simulations of observations of different satellites proposed to be equipped with a very long baseline interferometry (VLBI) transmitter, including GRASP, E-GRASP, and Galileo sub-constellation, in order to investigate how well the VLBI frame can be linked to the satellite frames under various observation scenarios. In addition to a simulation of standard VLBI observables, we also investigate the contribution to the solution of time of flight (TOF) information transmitted by the satellite VLBI frequency transmitters and received by the VLBI stations. Our simulations show that VLBI observations can meet the 1 mm and 1 mm/decade frame requirements as long as the observing VLBI network contains a large number of stations, many weeks per year are allocated to observing the spacecraft, and the VLBI and spacecraft techniques are independently able to reach the GGOS accuracy goals for their own frames.

B2.1-0039-18 EARTH ORIENTATION PARAMETERS ESTIMATED FROM K-BAND VLBA MEASUREMENTS

DLR - German Aerospace Center, Bonn, Germany

The Earth Orientation Parameters (EOP) which connect the Terrestrial and Celestial Reference Frame are regularly estimated by Very Long Baseline Interferometry (VLBI). The UT1-UTC and nutation components of EOP can only be measured using the VLBI technique. Until now, published VLBI estimates of EOP were based solely on observations from the S/X frequency band. For the first time, we present VLBI estimates of EOP from an observing frequency independent of the traditional SX-band using Very Long Baseline Array (VLBA) measurements at K-band (24 GHz, 1.2 cm). By June 2018, we will have about 1.5 years of regular VLBA experiments conducted with telescopes located in U.S. territory. We investigate the potential of K-band VLBI to produce more accurate EOP because of its reduced source structure effects relative to SX-band. We will compare our K-band EOP S/X VLBA results and the IERS C04 data.

Acknowledgements: We acknowledge our respective sponsors: Austrian Science Fund (FWF, T697-N29), SARAO/HartRAO is a facility of the National Research Foundation (NRF) of South Africa, and the U.S. government for portions of this research. We gratefully acknowledge the grant of observing time on the VLBA under the USNO time allocation.

B2.1-0040-18 CONSISTENT REALIZATION OF CRF, TRF, AND EOP

The International Celestial Reference Frame (ICRF) and the International Terrestrial Reference Frame (ITRF) are the realizations of the International Celestial Reference System (ICRS) and the International Terrestrial Reference System (ITRS), respectively. The Earth orientation parameters (EOP) are the parameters linking these two frames, and they are common parameters between the space geodetic techniques whose observations are used to estimate the ICRF and ITRF. Both realizations have been computed separately based on different data sets and by fixing parameters corresponding to the other frame, respectively. This causes inconsistencies between the frames themselves but also between the EOP series resulting from the two computations even though they should be the same. To gain consistency between the two reference frames, a common adjustment is performed. This implies the usage of identical input data, a consistent parameterization and that no parameters are fixed. The realizations benefit in many ways: consistency of the frames and EOP is reached, poorly estimated parameters of one technique could be strengthened by information from the other techniques and consequently the quasar coordinates are improved. In this study, we simultaneously estimate the celestial and terrestrial reference frames together with the full set of EOP based on homogeneously processed GNSS, VLBI, and SLR data over a time period of 11 years (2005.0-2016.0). We present the impact of various combination setups for the EOP and for the local tie handling and discuss the benefits of a simultaneous estimation.

B2.1-0041-18 GEO-REFERENCING SYSTEM INDEPENDENT FROM GNSS SYSTEMS.

Eduardo Perez Macho, edu_point@hotmail.com

Universidade Presbiteriana Mackenzie/CRAAM, SÃO PAULO, Brazil

A new system's geo-referencing from space is entirely free from any GNSS (GPS or equivalent) systems. The system addresses to various strategic and economic applications such as in remote clock synchronism, aircraft and balloon navigation, missile and smart bombs tracking, satellite orbital determination and remote target geo-positioning. The new geometry concept corresponds to an "inverted GPS" configuration, utilizing four ground-based reference stations, synchronized in time, installed at well known geodesic coordinates and a repeater in space, carried by an aircraft, balloon, satellite, etc. Signal transmitted by one of the reference bases is retransmitted by the transponder, received back by the four bases, producing four ranging measurements which are corrected for the time delays undergone in every retransmission. A minimization function was derived to compare the repeater's positions referred to at least two groups of three reference bases, to correct for the signal transit time at the repeater and propagation delays, and consequently to provide the accurate repeater position for each time interaction. Once the repeater's coordinates are known, the other determinations and applications become straightforward. The system solving algorithm and process performance has been demonstrated by simulations adopting a practical example with the transponder carried by an aircraft moving over bases and a target on the ground. Effects produced by reference clock synchronism uncertainties at the four bases on the measurements are reviewed.

B2.1-0042-18 VERY LONG ARC TIMING COEFFICIENT AND SOLAR LUNAR PLANETARY EPHEMERIS FILES AND APPLICATIONS

Zachary Folcik, zjfolcik@mit.edu

Massachusetts Institute of Technology Lincoln Laboratory, Lexington, Massachusetts, United States

Paul Cefola, paulcefo@buffalo.edu Massachusetts, United States

Previously the Timing Coefficient (TCoeff) and the Solar Lunar Planetary (SLP) ephemeris file function-alities of the TRAMP program were ported to the Linux platform. We used the Linux TRAMP program to generate binary TCoeff and SLP files that allow the GTDS orbit propagation and orbit determination pro-grams to generate results that closely match GTDS results generated with TCoeff and SLP files received from the NASA Flight Dynamics Facility (FDF). The design of the Timing Coefficient file was updated to support arcs that are hundreds of years in length and associated software modifications to the TRAMP and GTDS programs were made. We demonstrated the extended format TCoeff and SLP files for an 110-year GPS orbit using both GTDS numerical integration and semi-analytical orbit propagator programs. These 110-year files employ the JPL DE 200 ephemeris file. The DE 200 file is referred to the dynamical equator and equinox of 2000. In the current work, we further extend the GTDS TCoeff and SLP files to cover the interval from 1973 to 2169: a total of 196 years. The 1973 start date is dictated by the availability of the time difference, polar motion, and EOP data in the modern format from the US. Naval Observatory. The 2169 end date is the end of the DE200 file. Subsequent JPL files such as DE 405 or later provide data referred to the International Celestial Reference Frame (ICRF). The ICRF files, while allowing even longer orbit propagation intervals, will require implementation of compatible integration coordinate systems in GTDS. We use exploratory data analysis techniques to develop statistical models for the errors in the TCoeff and SLP file representations for the A.1-UT1 time difference, the polar motion parameters, and the rotation matrix data. The Cumulative Distribution Function (CDF) plots are important to this analysis. A goal is to connect the statistical errors in the EOP representations with the deterministic errors observed in the orbit propagation results. Long arc orbital evolution using the 196-year files is investigated for several test cases: 1. GPS

2. EGP/Ajisai (modified to be near critical inclination) 3. High eccentricity test cases 4.

WT1190F Near Earth Asteroid case

B2.1-0043-18 METHOD RESEARCH AND ACCURACY ANALYSIS ON THE INTRA-TECHNIQUE COMBINATION FROM SPACE GEODETIC TECHNIQUES

Xiaoya Wang, wxy@shao.ac.cn

Shanghai Astronomical Observatory, Chinese Academy of Sciences, Shanghai, China Bing He, hebing@shao.ac.cn

Shanghai Astronomical Observatory, Chinese Academy of Sciences, Shanghai, China

Precisely determined Terrestrial Reference Frame and the Earth Orientation Parameters independently in China has become the urgent needs in the precise orbit determination ,navigation, the exploration of deep space, the realization and application of the high-precision geodetic datum. Before the inter-technique combination of the space geodesy techniques, it needs to finish the intra-technique combination of different solutions from different analysis centers. Method researches on the intra-technique combination of weekly or 24-h session-wise solutions from various analysis centers for SLRhas been done. We described the intra-technique combination methods of ILRS. It mainly includes: the models of the intra-combinations, the realization of the datum definition or datum-free of the intra-combined TRF, the re-weighting of the solutions from the different analysis centers. Thenthe precision of the stations' coordinates and the EOP of the time series of the intra-technique solutions from ILRSwas estimated and the long-term characteristic of the datum definition of the underlying TRF was analyzed. From the perspective of datum definition, the translation of SLR intra-combined SINEX series w.r.t the ITRF2014 are of the longest time-span and has no significant bias of drift. While, the series of the GPS intra-combined weekly solutions have the smallest scatters in the translation w.r.t. the ITRF2014 but has drifts in Xand Y-translation and jumps in Z-translation, similar as the DORIS intra-combined solutions. From the perspective of the stations' precision, the distinguishment of the core and non-core stations is of great importance. Moreover, due to the good global distribution of GPS stations the EOP from GPS is more accurate than that from other techniques.

B2.1-0044-18 DENSE ITRF2014/IGS14 VELOCITIES FIELD OF POLAND BASED ON GNSS COMMERCIAL NETWORKS

Grzegorz Nykiel, grzegorz.nykiel@pg.edu.pl Gdansk University of Technology, Gdansk, Poland Mariusz Figurski, mariusz.figurski@pg.edu.pl Gdansk University of Technology, Gdansk, Poland

Coordinates velocities are becoming an important improvement of the accuracy of reference frame realization in Europe. Increase number of global navigation satellite system (GNSS) stations, and availability of long-term observations, caused that coordinates time series can be used to determine dense fields of velocities which should be an enhancement to the classical coordinates for all mapping agencies. In Poland there has been a sharp increase of the number of stations belonging to private companies since 2013. Currently, their number is almost 400. Most of stations are quipped with multi-GNSS receivers which allow the acquisition of observations from GPS, Galileo, GLONASS, and BDS satellites. Such high number of stations may be an alternative source of coordinates velocities which can be used for multiple task, such as dense velocities field determination, better realization of European reference frame in regional area, or local strain determination. The importance of having a dense velocities field is very clearly visible in such countries as Italy, Greece, or in Scandinavia region, where high movement of tectonic plate can be seen. However, even in relative stable part of Euroasian plate, the local stresses may occur. In this presentation we determine dense velocities field in Poland in global reference frame (ITRF2014/IGS14). We used daily GPS/GLONASS observations, from 1735 to 1982 GPS week, from almost 400 stations belonging to private companies. Our calculations were made using Bernese GNSS Software ver. 5.2 in relative (double differencing) and precise point positioning (PPP) mode. We present comprehensive analysis which relate to verification of availability and quality of observations, and identification of network errors and its impact on coordinates and velocities. All of these activities were aimed to determine velocities on the accuracy below ±0.3 mm/year. We also show analysis of accuracy and quality of obtained velocities field.

SPACE STUDIES OF THE EARTH-MOON SYSTEM, PLANETS, AND SMALL BODIES OF THE SOLAR SYSTEM (B)

LUNAR SCIENCE AND EXPLORATION (B3.1)

B3.1-0001-18 INTRODUCTION TO LUNAR SCIENCE AND EXPLORATION

Bernard H. Foing, bernard.foing@esa.int ESA/ESTEC, Noordwijk, Netherlands

This session will address:

Recent lunar results: geochemistry, geophysics in the context of open planetary science and exploration

Synthesis of results from SMART-1, Kaguya, Chang'e 1, 2 and 3, Chandrayaan-1, LCROSS, LADEE, Lunar Reconnaissance Orbiter and, Artemis and GRAIL

Goals and Status of missions under preparation: orbiters, Luna-Glob, Google Lunar X Prize, Luna Resurs polar lander, SLIM, Chandrayaan2, Chang'E 4 and 5, Lunar Resource Prospector, Future landers, Lunar sample return missions

Precursor missions, instruments and investigations for landers, rovers, sample return, and human cis-lunar activities and human lunar surface sorties

Preparation for International Lunar Decade: databases, instruments, missions, terrestrial field campaigns, support studies

ILEWG and Global Exploration roadmaps towards a global robotic/human Moon village

Strategic Knowledge Gaps, and key science Goals relevant to Lunar Global Exploration

Lunar science and exploration are developing further with new and exciting missions being developed by China, the US, Japan, India, Russia, Korea and Europe, and with new stakeholders.

Space exploration builds on international collaboration. COSPAR and its ILEWG International Lunar Exploration Working Group (created in 1994) have fostered collaboration between lunar missions.

A flotilla of lunar orbiters has flown in the last international lunar decade (SMART-1, Kaguya, Chang'E 1 and 2, Chandrayaan-1, LCROSS, LRO, GRAIL, LADEE). Chinese Chang'E 3 lander and Yutu rover. Upcoming other landers from 2018 (GLXP, Chang'E 4 and 5, SLIM, Luna, LRP) will constitute a Robotic Village on the Moon.

B3.1-0002-18 SYNTHESIS OF RESULTS & PROSPECTS FROM LRO MISSION

John Keller, john.keller@nasa.gov

Goddard Space Flight Center, Greenbelt, Maryland, United States
Noah Petro, noah.e.petro@nasa.gov

NASA Goddard Space Flight Center/Solar System Exploration Division, Greenbelt, MD, Maryland, United States

Since entering lunar orbit on June 23, 2009, the Lunar Reconnaissance Orbiter (LRO) has made comprehensive measurements of the Moon and its environment. The seven LRO instruments use a variety remote sensing techniques to obtain a unique set of observations. These measurements provide new information regarding the physical properties of the lunar surface, the lunar environment, and the location of volatiles and other resources. Scientific interpretation of these observations improves our understanding of the geologic history of the Moon, its current state, and what its history can tell us about the evolution of the solar system. Scientific results from LRO observations overturned existing paradigms and deepened our appreciation of the complex nature of our nearest neighbor. LRO has been in orbit for nine years, in that time it has been a witness and leader of a remarkable era of lunar science where a paradigm shift is taking place from the view of the Moon as a static planet to one with active processes on multiple scales. With ample fuel to remain in orbit (for up to eight more years) and a healthy suite of instruments and spacecraft systems, LRO is ready to continue uncovering and addressing key planetary science questions. In addition, LRO will support key exploration goals of NASA as well as assist in the planning and targeting of future missions to the Moon by governmental space agencies and commercial endeavors. In this presentation we will discuss recent results and describe the LRO created resources available to the community for planning lunar missions.

B3.1-0003-18 SYNTHESIS OF RESULTS FROM GRAIL MISSION

Maria T. Zuber, zuber@mit.edu

Massachusetts Institute of Technology, Cambridge, Massachusetts, United States David E Smith, smithde@mit.edu

Massachusetts Institute of Technology, Cambridge, Massachusetts, United States

The GRAIL Discovery mission was launched to the Moon on 10 September 2011 with the primary objective to map the lunar gravity field with unprecedented accuracy and resolution. The mission consisted of twin spacecraft inserted into lunar polar orbit on 31 December 2011 and 1 January 2012. GRAIL had two primary science objectives: (1) determine the structure of the lunar interior, from crust to core; and (2) advance understanding of the thermal evolution of the Moon. The fundamental measurement was spacecraft-to-spacecraft tracking of the velocity changes between the two spacecraft, from which models of the lunar gravity field were developed in spherical harmonic degree and order. By the end of the mission, the resolution of the field was degree and order 1800, with an effective global surface resolution of 3 - 5 km. The GRAIL lunar gravity field revealed features not previously resolved, including tectonic structures, volcanic landforms and intrusions, basin rings, crater central peaks, and abundant simple craters. From degrees 80 through 600, over 98% of the gravitational signature is associated with topography, a result that reflects the preservation of crater relief in highly fractured and homogenized crust. The remaining 1-2% represents fine details of subsurface structure not previously resolved. In addition to making scientific discoveries the GRAIL gravity models enabled significant improvement in the determination of spacecraft in lunar orbit, including the orbit of the Lunar Reconnaissance Orbiter, which was obtaining accurate topography of the Moon and was used in the interpretation of the gravity data.

B3.1-0004-18 CUBESATS TO THE MOON

Pamela Clark, pamela.e.clark@jpl.nasa.gov JPL, Pasadena, California, United States

Overview: Cubesats, first successfully launched into Earth orbit just over a decade ago, are about to be launched into deep space. A disruptive technology initially made possible by advances in consumer electronics, cubesats (named by Bob Twiggs for the 10-centimeter cube size (1U) of the very first one) are spacecraft that combine several desirable attributes: compactness, rapid development, low cost, standardization of deployers, buses and interfaces, and a 'test by flying' risk posture not unlike that of the early space program. In fact, the very first cubesats designed with the goal of obtaining scientific data from another body will head for the Moon, after being deployed from the second stage of the NASA heavy lift launch vehicle (SLS) in 2019. Three of them will enter lunar orbit with the goal of increasing our knowledge of lunar volatiles, acting as the first de facto deep space cubesat cluster. Three in-ternational participants will also be deployed at that time: the ESA Equuleus radiation monitor, and JAXA Omotenashi impactor and ArgoMoon camera. Overcoming Challenges: Cubesats operating in deep space face challenges Earth-orbiting cubesats do not. Earth-orbiting cubesats required minimal resources and few active control systems: once deployed in an acceptable orbit (without the need for propulsion), they can utilize the Earth's magnetic or gravitational fields for attitude con-trol, GPS for navigation, and a simple UHF system (and prevalent ground stations) for communication. Deep space cubesats will be required to have the full functionality, and active control systems, of any spacecraft operating in deep space. MARCo, the 2018 demonstration of dual communication system at Mars, and the 13 diverse cubesats being deployed from SLS the following year, are effectively 'prototypes' for deep space cubesats. These are 6U cu-besats, larger than their typical Earth-orbiting counterparts (3U) to accommodate additional needs. Many of them will utilize the JPl Iris X-band radio and the DSN for communiciation, navigation, and tracking. Bandwidth is a limited resource and a variety of strategies are used to manage it. All of the cubesats have small propulsion units, adequate to get them into lunar orbit in the cases where that is needed (up to 1.5 km/sec DeltaV). Thermal engineer-ing has turned out to be a major challenge for those in orbit around the Moon, and much of the new work in cubesat design is going on in this area, as well as in the development of micro-cryocoolers, more compact versions of re-quired instruments and more capable micro-propulsion systems. Architectures and Roles: The cubesat technology attributes are particularly suitable for demonstrating and qualifying new technologies and new systems, and for multi-platform concepts. The first spatially and temporally distributed networks, created based on the cubesat paradigm, could study the dynamics of lunar and planetary envi-ronments in situ for less than the cost of a flagship mission. Such concepts have already been proposed. On the other hand, getting individual cubesats to remote targets with their own low impulse propulsion systems is time consuming and a major driver for the design and resource utilization. Using a 'carrier' to deliver a small swarm to a target and provide communication and tracking support would be ideal. Current science missions and measurements: Four of the cubesat missions to be deployed at the Moon have instruments for lunar surface/regolith measurements. Lunar Ice Cube, with its 1-4 micron broadband IR spectrometer, and LunIR, with its thermal IR spectrometer, were selected by the NASA HEOMD NextSTEP program to demonstrate a cubesat-scale instrument capable of addressing NASA HEOMD Strategic Knowledge Gaps related to lunar volatile distribution (abundance, location, and transportation physics of water ice), as well as, for Lunar Ice Cube, to demonstrate cubesat propulsion, via the Busek BIT 3 RF Ion engine. Lunar Flashlight was selected by HEOMD Advanced Exploration Systems to confirm the presence of surface ice at the lunar poles, utilizing an active source (laser), and looking for absorption features in the returning signal indicating the presence of surface ice. Lu-naHMap was selected for NASA SMD SIMPLEx program to characterize ice at or below the surface at the poles with a compact neutron spectrometer. In addition, the BIRCHES instrument on Lunar Ice Cube will provide the first demonstration of a microcryocooler (AIM/IRIS) in deep space. Although not originally required, all will be delivering science data to the Planetary Data System, the first formal archiving effort for cubesats. The future: As I write this abstract, interest in deep space cubesats escalates. The final reports of approximately 20 NASA-sponsored (PSDS3) studies for deep space cubesat/smallsat mission concepts, most involving 12U cu-besats, are about to be completed. These include 5 lunar mission concepts: BOLAS, MiLUV, Innovative Strategies for Lunar Surface Exploration CUBEx and WATER. NASA is about to release the SIMPLEX 2/SALMON 3 AO, creating ongoing opportunities for proposing cubesat/smallsat missions as 'rides' on government space program or private sector vehicles become available. Finally, several private sector contenders already have partnerships with NASA to provide transportation to the lunar surface or lunar orbit for small payloads before the end of the decade.

The Lunar Meteoroid Impact Observer (LUMIO) is a CubeSat mission to observe, quantify, and characterise the meteoroid impacts by detecting their flashes on the lunar farside. This complements the knowledge gathered by Earth-based observations of the lunar nearside, thus synthesising a global information on the lunar meteoroid environment.

The mission utilises a CubeSat that carries the LUMIO-Cam, an optical instrument capable of detecting light flashes in the visible spectrum. On-board data processing is implemented to minimise data downlink, while still retaining relevant scientific data: only those images containing flashes are stored.

The mission implements a sophisticated orbit design: LUMIO is placed on a halo orbit about Earth-Moon L2 where permanent full-disk observation of the lunar farside is made. This prevents having background noise due to Earthshine, and thus permits obtaining high-quality scientific products. Repetitive operations are foreseen, the orbit being in near 2:1 resonance with the Moon orbit. Innovative full-disk optical autonomous navigation is proposed, and its performances are assessed and quantified.

The spacecraft is a 12U form-factor CubeSat, with <22 kg mass. Novel on-board micropropulsion system for orbital control, de-tumbling, and RW desaturation is used. Steady solar power generation is achieved with solar array drive assembly and eclipse-free orbit. Accurate pointing is performed by using reaction wheels, IMU, start trackers, and fine sun sensors. Communication with the Lunar Orbiter is done in UHF band. Advanced thermal coating and resistance heater for thermal control, as well as lightweight structure with radiation shielding are considered.

LUMIO is one of the two winner of ESA's LUCE (Lunar CubeSat for Exploration) SysNova competition, and as such it is being considered by ESA for implementation in the near future.

B3.1-0006-18 VMMO LUNAR VOLATILE AND MINERALOGY MAPPING 12U CUBESAT

Roman Kruzelecky, roman.kruzelecky@mpbc.ca MPB Communications Inc., Pointe Claire, Canada

VMMO is a low-cost 12U Cubesat that is being designed for operation in a low-eccentricity lunar frozen orbit to enable both new science and supporting technology demonstration. It comprises two payloads; the LVMM Lunar Volatile and Mineralogy Mapper and the CLAIRE Compact LunAr Ionising Radiation Environment. The supporting 12U Cubesat bus accomodates dual ion and cold-gas propulsion, UHF communications to the potential SSTL Lunar Communications Pathfinder Orbiter, as well as direct to Earth X-band and optical communications, on board data processing and a suite of altitude and pointing sensors for semiautonomous navigation and mission operations. VMMO addresses the need for understanding the lunar near-surface distribution of relevant in-situ useable resources, such as ilmenite (FeTiO3), and volatiles, such as water/ice. This data is critical for the planning of future potential manned missions and sustained bases on the lunar surface. The compact LVMM is a multi-wavelength Chemical Lidar (<6.1 kg) using 3W fiber lasers emitting at 532 nm and 1560 nm for stand- off mapping of the lunar ice distribution using the active laser illumination, with a focus on the permanently-shadowed craters in the lunar south pole and detection of frosting during the lunar night. This combination of spectral measurement channels can provide very sensitive discrimination of water/ice in various Mare and Highland regolith. The associated fiber-laser technology has heritage in the ongoing MPBC Fiber Sensor Demonstrator flying on ESA's Proba-2 spacecraft. LVMM can also be used in a low-power passive mode to map the lunar mineralogy and ilmenite in-situ resource distribution during the lunar day using the surfacereflected solar illumination. This configuration includes a 280 nm UV channel to enhance the ilmenite discrimination. The CLAIRE payload (0.5 kg) is designed to provide a minimum impact, highly miniaturized radiation environment and effect monitor, suitable for CubeSat operation in cis-lunar space. The payload draws on heritage from the MuREM and RM payloads, flown on the UK's TDS-1 spacecraft launched in 2014. The payload includes PIN-diode sensors to measure ionizing particle fluxes (protons and heavy-ions) and to record the resulting linear energy transfer (LET) energy-deposition spectra. It also includes solid-state RADFET dosimeters, to measure accumulated ionizing dose, and dose-rate diode detectors, designed to respond to a Coronal Mass Ejection (CME) or Solar Particle Event (SPE). The CLAIRE payload also includes an electronic component test board, capable of measuring SEEs and TID effects in a selected set of candidate electronics. Thus, direct correlations can be drawn between effects and the real measured environment. This will assist the TRL advancemnet of critical

COTS components (FPGAs, RAM, A/Ds) for beyond-LEO space applications. This paper provides an overview of the ongoing VMMO mission development and some of the supporting relevant lab predevelopment.

Acknowledgements

The authors would like to acknowledge the European Space Agency for enabling this mission concept study through the ESA LUCE Cubesat SysNova Challenge program.

B3.1-0007-18 POLAR REGIONS ON THE MOON AS LOCATIONS FOR FUTURE OUTPOSTS

Anton Sanin, sanin@mx.iki.rssi.ru

Results of lunar polar surface analysis, focused on searching for the best potential outpost locations for the future robotic and manned scientific and exploration missions, are presented. Data from LEND [1], LOLA [2], Diviner [3] and LROC [4] instruments are taken into account. The method of spatial analysis initially developed for Luna-25 landing site selection [5] was used to identify possible location candidates, and multi-parameter prioritization was performed to determine the best of them. Several location candidates are described in details, with the main characteristics of their environment presented.

It has long been thought that the Moon was dry upon its formation and therefore devoid of native water. Recent observations suggest that water from external sources may be extensive on the lunar surface. Here, we report the first detection of signatures of near-surface water released into the lunar exosphere using observations collected by the Neutral Mass Spectrometer onboard the Lunar Atmosphere and Dust Environment Explorer spacecraft during its 8 monthlong mission. The water signatures were measured as 736 distinct episodic, short-lived signal increases above the instrument background level of 5 cm^{-3}. The most intense event was recorded with a magnitude of 600 cm^{-3}. An analytical description of the behavior of the instrument when subjected to exospheric water reveals that these fluctuations in instrument background capture variations of the underlying source of water released into the exosphere. Our study shows that the intensity and frequency of these water events are correlated with the Moon's encounter with known intense meteoroid streams. These fluctuations carry information on both the nature of the meteoroids that triggered the water release into the exosphere and the nature of the reservoir that was sequestering the water beforehand. In order to shed light on the nature of the water reservoir, we use a Monte Carlo model to simulate the evolution of released water produced by the impact of meteoroids on the surface of the Moon. The model shows that the signatures detected by the NMS instrument are commensurate in size and distribution with vapors released from shallow depths in the lunar soil by impacts that occurred at various distances from the spacecraft. Using this model, information about water concentrations in the lunar soil and its variation with depth were inferred by comparing the distribution of the intensity of the observed water events against the distribution that would result from a given impactor flux distribution.

B3.1-0011-18 NASA'S MOON TREK: EXTENDING CAPABILITIES FOR LUNAR MAPPING AND MODELING

Brian Day, brian.h.day@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States Emily Law, emily.law@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States

NASA's Moon Trek (https://moontrek.jpl.nasa.gov) is the successor to and replacement for NASA's Lunar Mapping and Modeling Portal (LMMP). Released in 2017, Moon Trek features a new interface with improved ways to access, visualize, and analyze data. Moon Trek provides a web-based Portal and a suite of interactive visualization and analysis tools to enable mission planners, lunar scientists, and engineers to access mapped lunar data products from past and current lunar missions. This presentation will provide an overview of the uses and capabilities of NASA's Moon Trek online mapping and modeling portal, and describe recent enhancements to the portal. Moon Trek provides a suite of interactive tools that incorporate observations from past and current lunar missions, creating a comprehensive lunar research Web portal. The online Web portal allows anyone with access to a computer to search through and view a vast number of lunar images and other digital products. The portal provides easy-to-use tools for browsing, data layering and feature search, including de-tailed information on the source of each assembled data product and links to NASA's Planetary Data System. Interactive maps, include the ability to overlay a growing range of data sets including topography, mineralogy, abundance of elements and geology. Originally designed for mission planning, Moon Trek also addresses the lunar science community, the lunar commercial community, education and out-reach, and anyone else interested in accessing or utilizing lunar data. Its visualization and analysis tools allow users to measure the diameters, heights and depths of surface features, perform analyses such as lighting and local hazard assessments including slope, surface roughness and crater/boulder distribution. Moon Trek features a generalized suite of tools facilitating a wide range of activities including the planning, design, development, test and operations associated with lunar sortie missions; robotic (and potentially crewed) operations on the surface; planning tasks in the areas of landing site evaluation and selection; design and placement of landers and other stationary assets; design of rovers and other mobile assets; developing terrain-relative navigation (TRN) capabilities; deorbit/impact site visualization; and assessment and planning of science traverses. Significant advantages are afforded by Moon Trek's features facilitating collaboration among members of distributed teams. Team members can share visualizations and add new data to be shared either with the entire Moon Trek community or only with members of their own team. Sharing of multi-layered visualizations is made easy with the ability to create and send URL-encoded visualization links. Moon Trek is also a powerful tool for education and outreach, as is exemplified by its being designated as key supporting infrastructure for NASA Science Mission Directorate's STEM Activation Initiative, and its serving of data to a growing community of digital planetariums. Developed at NASA's Jet Propulsion Laboratory (JPL) and managed as a project of NASA's Solar System Exploration Research Virtual Institute (SSERVI) at NASA Ames Research Center, Moon Trek is a browser-based web portal. There is nothing additional to buy or install. New tools have been added to facilitate traverse path planning, surface potential analysis, and laser retroreflector studies. A new pipeline to the PDS is facilitating the creation of NAC mosaics and NAC stereo pair DEMs. The Moon Trek interface provides enhanced 3D visualization and navigation. Standard keyboard controls allow the user to maneuver a first-person visualization of "flying" across the surface of the Moon. User-specified bounding boxes can be used to generate STL and/or OBJ files to create physical models of surface features with 3D printers. This interface has become the standard across all of the existing and upcoming Trek products including the portals for Mars, Phobos, Vesta, Titan and more.

B3.1-0012-18 TRANSFORMATIVE LUNAR SCIENCE

Carle Pieters, carle_pieters@brown.edu

Brown University, Providence, Rhode Island, United States Robin Canup, robin@boulder.swri.edu

Southwest Research Institute, Boulder, Colorado, United States David Kring, kring@lpi.usra.edu

USRA - Lunar and Planetary Institute, Houston, Texas, United States James Head, james_head@brown.edu

Brown University, Providence, Rhode Island, United States David R. Scott, david_scott@brown.edu

Brown University, Providence, Rhode Island, United States

The foundation of Apollo and Luna programs implemented 50 years ago combined with more recent results from the renaissance of international lunar exploration over the last 15 years has provided humanity a deeper and more intimate view of the Moon. It has also opened enormous opportunity for accomplishing Transformative Lunar Science (TLS) which are the next major breakthroughs in understanding the origin and early habitability of our Earth-Moon system as well as fundamental constraints on events that control the evolution of our Solar System. A few examples of TLS topics include: a) Establish the period of early giant planet migration and its effects in our Solar System, b) Provide an absolute chronology for Solar System events over 4 billion years, c) Understand and utilize the recently recognized water cycle of the Moon and other airless bodies, d) Characterize the Moon's interior to reveal how this differentiated cousin of Earth formed and evolved, e) Use the accessible vantage from the lunar farside to view the universe, f) Evaluate the extended record of space weather and fundamental processes of plasma interactions with surfaces. As human/robotic partnerships are developed further for space exploration, the next era of significant lunar exploration is a broad international undertaking, including commercial involvement. An enabling element for such Transformative Lunar Science is joint development of a stable infrastructure for efficient integrated activities.

B3.1-0013-18 THE FUTURE OF LUNAR SCIENCE AT NASA

Sarah Noble, sarah.noble-1@nasa.gov

NASA Headquarters, Washington, District of Columbia, United States

The future is bright for lunar science. In the last decade, enormous advances have been made in our understanding of the Moon, enabled by several successful orbital missions (LRO, LADEE, GRAIL, Chandrayaan-1, Kaguya, ARTIMIS), as well as continued efforts with samples and through laboratory studies and modeling. This work has answered some of our questions, and given us some new questions, but most of all, has allowed us to better refine our lunar science goals and placed us in a strong position to take maximum advantage of the next era of lunar exploration. While there is still room for additional progress to be made from orbital missions, the advancement of many of our science goals now requires landed missions. In parallel to our science efforts, a number of commercial companies, spurred on in part by the Google Lunar X-Prize, have been working towards developing lunar lander capabilities. These capabilities, along with international partnerships, opens up a new trade space of opportunities for lunar science and we are well poised to take advantage. NASA is creating a new Lunar Discovery and Exploration program that will develop instruments and other payloads for missions to the lunar surface. In partnership with industry, the international community, and other NASA organizations, science will lead the way as the agency prepares for a sustained program of lunar exploration.

B3.1-0014-18 RESOURCE PROSPECTOR: EVALUATING THE ISRU POTENTIAL OF THE LUNAR POLES

Richard Elphic, richard.c.elphic@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States Anthony Colaprete, anthony.colaprete-1@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States Daniel Andrews, daniel.r.andrews@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States

Resource Prospector (RP) is a lunar volatiles prospecting mission currently in development for potential flight as early as CY2022. The mission includes a rover-borne payload that (1) can locate surface and near-subsurface volatiles, (2) excavate and analyze samples of the volatilebearing regolith, and (3) demonstrate the form, extractability and usefulness of the materials. The primary mission goal for RP is to evaluate the In-Situ Resource Utilization (ISRU) potential of the lunar poles.

Mission Goals: While it is now understood that lunar water and other volatiles have a much greater extent of distribution, possible forms, and concentrations than previously believed, to fully understand how viable these volatiles are as a resource to support human exploration of the solar system, the distribution and form needs to be understood at a "human" scale. That is, the "ore body" must be better understood at the scales it would be worked before it can be evaluated as a potential architectural element within any evolvable lunar or Mars campaign. To this end the primary mission goals for RP are to: (1) Provide enough information to allow for the next step: e.g., targeted survey, excavation and pilot processing plant demonstration; (2) Provide ground truth for models and orbital data sets, including: temperatures at small scales, subsurface temperatures and regolith densities; surface hydration; hazards (rocks and slopes).

(3) Correlate surface environments and volatiles with orbital data sets to allow for better prediction of resource potential using orbital data sets. (4) Address key hypotheses regarding polar volatile sources and sinks, retention and distribution, key to developing economic models and identifying excavation sites.

To address the viability/economics of lunar ISRU the volatile distribution (concentration, including lateral and vertical extent and variability), volatile form (H2, OH, H2O, CO2, ice vs bound, etc.), and accessibility, including overburden, soil mechanics, and trafficability, must be understood. To this end RP will assess the hydrogen and water distribution across several relevant environments that can be extended to a more regional and global assessment. Currently these environments are defined by their thermal character: (a) Dry: Temperatures in the top meter expected to be too warm for ice to be stable; (b) Deep: Ice expected to be stable between 50-100 cm of the surface; (c) Shallow: Ice expected to be stable within 50 cm of surface; (d) Surface: Ice expected to be stable at the surface (i.e., within a Permanently Shadowed Region, PSR).

Real-time Prospecting and Combined Instrument Measurements: Given the relatively short planned duration of this lunar mission, prospecting for sites of interest needs to occur in near real-time. The two prospecting instruments are the Neutron Spectrometer System (NSS) and the NIR Volatile Spectrometer System (NIRVSS). NSS will be used to sense waterequivalent hydrogen at concentrations as low as 0.5 wt% to a depth of approximately 80-100 cm. This instrument is the principle instrument for identifying buried hydrogen-bearing materials. NIRVSS, which includes its own calibrated light source, radiometer (for thermal correction and surface temperature measurements) and multicolor context camera, will look at surface reflectance for signatures of bound H2O/OH and general mineralogy. Once an area of interest is identified by the prospecting instruments the option to map the area in more detail (an Area of Interest activity) and/or sub-surface extraction via drilling is considered. The RP drill, The Regolith and Ice Drill for Exploration of New Terrain (TRIDENT), is an auger which can sample from discrete depths using "biting" flutes, deep flutes with shallow pitch which hold material as the drill is extracted. As the drill is extracted a brush can deposit cuttings from the biting flutes to the surface in view of NIRVSS for a "quick assay" of the materials for water or other volatiles. If this quick assay shows indications of water or other volatiles, a regolith sample may be extracted for processing. Processing of the sample is performed by the Water

Analysis by Volatile Extraction system (WAVE). WAVE consists of a sealed oven to heat the sample first to 150°C, pause, then to 450°C. Any gases evolved from the sample are analyzed by a Gas Chromatograph/Mass Spectrometer system. This talk will provide an overview of the RP mission with an emphasis on mission goals and measurements, and will provide an update as to its current status.

B3.1-0015-18 THE DUST ENVIRONMENT OF THE MOON

Mihaly Horanyi, horanyi@colorado.edu

University of Colorado, Boulder, Boulder, Colorado, United States Jamey Szalay, jszalay@princeton.edu

Princeton University, Princeton, New Jersey, United States Xu Wang, xu.wang@colorado.edu

University of Colorado, Boulder, Colorado, United States

The Moon, as all other airless bodies in the solar system, is continually bombarded by interplanetary dust particles, and is also immersed in the solar wind plasma flow and UV radiation. There are several controversial observations from the Apollo era that can now be revisited due to new spacecraft data, and recent dedicated laboratory experiments. Hypervelocity dust impacts generate secondary dust ejecta particles, neutral and ionized gases, sustaining the recently discovered, permanently present dust cloud engulfing the moon, and contributing to the production of the dilute lunar atmosphere and ionosphere. UV and plasma exposure results in the electrostatic charging of the lunar regolith, that can lead to the mobilization, transport, and large-scale redistribution of the lunar fines. We focus on the recent results of in situ observations, as well as the latest laboratory results, a combination which resulted in a much improved understanding of the lunar dust environment.

This talk will summarize the LADEE/LDEX results identifying the permanently present and intermittently enhanced lunar dust ejecta cloud that is sustained by the continual bombardment by interplanetary dust particles originating form the sporadic background population, as well as the meteoroid streams. The measurements indicate no electrostatically lofted high-altitude dust density enhancements over the terminator regions, as was anticipated due to possible dust charging and strong electric fields in this region. However, there is strong supporting evidence for efficient dust mobilization and transport near the surface, due to electrostatic effects a process that is likely to be responsible to be responsible for the observed dust ponding on asteroids, and its full effect is yet to be investigated for the lunar surface.

B3.1-0016-18 HIGHLIGHTS OF SCIENCE AND EXPLORATION ACTIVITIES AT THE SSERVI TREX NODE

Amanda Hendrix, arh@psi.edu

Planetary Science Institute, Tucson, Arizona, United States The TREX Team

Jean Paul Allain, Maria Banks, Amy Barr-Mlinar, Roy Christoffersen, Mark Cintala, Roger Clark, Ryan Clegg Watkins, Ed Cloutis, Deborah Domingue, Darby Dyar, Rebecca Ghent, Amara Graps, Jennifer Grier, Jorn Helbert, Gregory Holsclaw, Henry Hsieh, Andrea Jones, Melissa Lane, Jian-Yang Li, Eldar Noe Dobrea, Mikki Osterloo, Noah Petro, Thomas Prettyman, Lynnae Quick, Edgard Rivera-Valentin, Daniel Wolf Savin, Norbert Schorghofer, Karen Stockstill-Cahill, Faith Vilas, David Wettergreen, Charles Wood, Shawn Wright

The Toolbox for Research and Exploration (TREX) is a NASA SSERVI (Solar System Exploration Research Virtual Institute) node. TREX (trex.psi.edu) aims to decrease risk to future missions, specifically to the Moon, the Martian moons, and near-Earth asteroids, by improving mission success and assuring the safety of astronauts, their instruments, and spacecraft. TREX studies focus on characteristics of the fine grains that cover the surfaces of these target bodies their spectral characteristics and the potential resources (such as H2O) they may harbor. TREX also places an emphasis on ultraviolet measurements, in addition to visible and nearand mid-infrared studies, for thorough compositional analyses.

TREX studies are grouped into four Themes: lab studies, Moon studies, small bodies studies, and field work. The tasks and products of each Theme within TREX are connected. The Laboratory Studies Theme's products are inputs to the photometric and spectral studies of the Small Bodies and Moon Themes. The laboratory data will be used to validate models and as direct inputs for modeling spacecraft observations of surfaces. The models and lab data are inputs to the Field Studies Theme for use in creating autonomous decision-making software packages.

The TREX spectral library focuses on fine-grained (<10 micron) planetary materials measured over ultraviolet, visible/near-infrared, and mid-infrared (UV-VNIR-MIR) wavelengths under environmental conditions that mimic the surfaces of the airless targets (in vacuum, when possible, and at various temperatures). This library will be invaluable in interpreting spacecraft data (e.g. for the Moon and small bodies Themes) and will be made available to the larger community as well. Furthermore, the spectral library will be ingested into software used in autonomous sample selection in the TREX fieldwork. The lab measurements include a range of pure terrestrial minerals (including 6 samples previously measured in other SSERVI labs, for cross-correlations), lunar samples and meteorites, along with mineral mixtures and ice-mineral mixtures. A goal of performing measurements in a suite of labs is to harness both unique and overlapping capabilities to derive a robust set of cross-calibrated laboratory spectra. TREX labs are at PSI (Tucson), Univ. Colorado, Univ. Winnipeg, DLR, NASA/JSC, Univ. Illinois and Mount Holyoke.

The Moon is a primary focus of TREX studies, as the only Solar System body humans have visited, and a likely future human destination. TREX lunar investigations combine the lab measurements acquired under lunar conditions with lunar spacecraft data and modeling techniques to characterize particle size, mineralogy, thermal attributes, space weathering effects, and correlations with geologic features. The overarching goals of the lunar studies are to expand our understanding of the Moon scientifically and as a target for future human and robotic exploration, and to address ISRU and future instrument development needs. The TREX Small Bodies Theme delves into several topics, including photometry, spectral modeling, laboratory simulations of space weathering processes relevant to asteroids, the assembly of an asteroid regolith database, the dichotomy between nuclear and reflectance spectroscopy, and the dynamical evolution of asteroids and the implications for the retention of volatiles.

TREX field work focuses on improving science yield by delegating mission planning, data collection, analysis, and decision-making to an automated robotic explorer. The objectives of our field investigations are to test the accuracy of our autonomous selection software and UV field spectrometer, and to compare the science yield of current robotic exploration strategies with that of the semi-autonomous robotic exploration system. Fieldwork will be performed at small body analog sites containing fine-grained materials analogous to those expected on asteroids and the Moon. Two locations have been chosen: the Palouse glacial loess site in Washington and the phyllosilicate-bearing Hopi Volcanic Field in Arizona. Multiple instruments will be used during the field campaigns, including three spectrometers (UV, VNIR, FTIR), a gamma ray / neutron spectrometer with active interrogation (GNS), and a Raman spectrometer. These data (UV, XRD, GNS, and VNIR) will be the inputs for our Tetracorder autonomous decision making. The mineral and elemental data will provide a complete picture of the physical and chemical mineralogy of the surface.

TREX is based at the Planetary Science Institute. Roughly two-thirds of TREX scientists are with PSI, distributed at locations across the country and Europe, with co-investigators and collaborators at NASA/GSFC, NASA/JSC, Columbia Univ., Carnegie Mellon, LPI, Univ. Colorado, Univ. Winnipeg, Univ. Illinois, DLR and Smithsonian Institution: TREX thus represents a truly virtual team.

B3.1-0017-18 NARROWBAND ION CYCLOTRON WAVES IN THE EARTH'S MAGNETOTAIL OBSERVED BY MOON-ORBITING ARTEMIS SPACECRAFT

Peter Chi, pchi@igpp.ucla.edu

University of California, Los Angeles, Los Angeles, California, United States Hanying Wei, hwei@igpp.ucla.edu

Institute of Geophysics and Planetary Physics, University of California, Los Angeles, California, United States

William Farrell, william.m.farrell@nasa.gov

NASA/Goddard Space Flight Center, Planetary Magnetospheres Laboratory, Code 695, Solar Systems Exploration Division, Greenbelt, Maryland, United States

Jasper Halekas, jasper-halekas@uiowa.edu University of Iowa, Iowa City, Iowa, United States

Analysis based on Apollo surface magnetometer data has shown that narrowband ion cyclotron waves are often observed on the lunar surface when the Moon is in the Earth's magnetotail. The proposed generation mechanisms of these narrowband waves still require further confirmation by observations. This paper presents results based on ARTEMIS field and particle observations near the Moon and when the Moon is in the magnetotail. We find that the characteristics of narrowband waves near the ion cyclotron frequencies can be divided into three types: (1) Left-handed polarized waves in the plasma sheet; (2) Left-handed polarized waves outside the plasma sheet; (3) Right-handed polarized waves in the plasma sheet boundary layer. In Type 1 wave events, the ion velocity distribution shows a clear depletion in the direction toward the Moon, indicating that the Moon absorbs most ions traveling to it. The resulting temperature anisotropy is subject to ion cyclotron wave growth. In Type 2 events, the observed ion velocity distribution does not present a clear temperature anisotropy. Although spacecraft measurements of ions cannot confirm the mechanism of wave generation, it is possible that waves are generated elsewhere and propagate to the spacecraft. Type 3 waves are not evident in the Apollo surface magnetometer data examined in our previous study, but they resemble the right-handed waves observed by ISEE 3 and Geotail spacecraft in the distant magnetotail. These waves are generated through a resonant interaction with the ion beam in the plasma sheet boundary layer. This paper also discussed WHAMP analysis of wave excitation, the possible role of pickup ions in generating Type 2 waves, and the comparison with recent results of narrowband ion cyclotron waves based on Kaguya and Geotail observations.

B3.1-0018-18 FUTURE LOW-COST LUNAR AND PLANETARY MISSIONS ENABLED BY COMMERCIAL SPACE COMPANIES

Alain Berinstain, alainberinstain@moonexpress.com

Moon Express Inc., Cape Canaveral, Florida, United States Robert Richards, bob@moonexpress.com

Moon Express Inc., Cape Canaveral, United States Bernard H. Foing, bernard.foing@esa.int ESA/ESTEC, Noordwijk, Netherlands

Introduction: Science missions to the Moon need not be seen as rare and expensive opportunities. Affordable, repeated access to lunar orbit and/or the lunar surface is being made possible by innovations by commercial space companies. Moon Express' vision is to open the lunar frontier with turn-key payload, data and services for missions to the Moon for a wide range of customers globally, including governments, NGO's, commercial enterprises, universities, and consumers. Like the Earth, the Moon has been enriched with vast resources through billions of years of bombardment by asteroids and comets. Unlike the Earth, these resources are largely on or near the lunar surface, and therefore relatively accessible. Moon Express is blazing a trail to the Moon to seek and harvest these resources to support a new space renaissance, where economic trade between countries will eventually become trade between worlds. All Moon Express expeditions will prospect for materials on the Moon as candidates for economic development and in-situ resource utilization.

One of the greatest practical space discoveries of our generation is the presence of vast quantities of water on the Moon. Water not only supports life but its constituents, hydrogen and oxygen, are energetic and clean rocket fuel. The discovery of water on the Moon is a game changer, not just for the economic viability of lunar resources, but for the economics of humans reaching Mars and other deep space destinations. Water is the oil of the solar system, and the Moon can become a gas station in the sky to fuel human space exploration, development and settlement of the solar system. Moon Express will begin prospecting for water resources on the Moon with its very first expedition.

The MX family of spacecraft: Moon Express has developed a family of flexible, scalable robotic explorers that can reach the Moon and other solar system destinations from Earth orbit. The MX spacecraft architecture supports multiple applications, including delivery of scientific and commercial payloads to the Moon at low cost using a rideshare model, or charter science or commercial expeditions to distant worlds.

The MX robotic explorer spacecraft are optimized for launch on existing and emergent rocket systems. The payload masses quoted below assume no launcher constraints. MX-1: A single stage spacecraft capable of delivering up to 30kg to the lunar surface. MX-2: A dual-stage spacecraft that doubles the capability of the MX-1 and can reach the moons of Mars. MX-5: A cis-lunar workhorse spacecraft that can deliver up to 150kg to lunar orbit or 50kg to the surface. MX-9: A lunar prospector/harvester that can deliver up to 500kg to the lunar surface, including an embedded MX-1R spacecraft that can launch from the lunar surface and return lunar samples to Earth. The MX spacecraft architecture supports multiple applications, including delivery of scientific and commercial payloads to the Moon at low cost using a rideshare model, or charter science expeditions to distant worlds. Designed for Scout Class exploration capabilities starting from low Earth orbit, MX-1 delivers flexibility and performance to revolutionize access to the Moon and cis-lunar space.

Dual stage flexibility drives more payload to the lunar surface or extends the reach to deep space. Compatible with existing and emergent launch vehicles, the MX-2 delivers Scout Class possibilities for exploration and commerce at low cost.

Designed as a workhorse that can deliver 150kg to low lunar orbit from low Earth orbit, with a range of configurations to support lunar landing and cis-lunar operations, the MX-5 can also be outfitted with MX-1 or MX-2 staged systems that can bring the entire solar system within reach. Available in orbiter, lander, deep space probe and sample return configurations.

Designed for Frontier Class exploration capabilities, MX-9 will support robust lunar sample return operations. Like it's MX-5 little brother, the MX-9 can also be outfitted with MX-1 or MX-2 staged systems that can deliver over 10kms V and extend its reach to span the solar system, and beyond.

Currently-Planned Lunar Missions: Our first expedition will utilize our MX-1E robotic explorer to deliver a diverse manifest of scientific and commercial payloads to the lunar surface. Our customers for this mission include the International Lunar Observatory Association, the University of Maryland, The National Laboratories of Frascati, Celestis and Google. Following our initial "Lunar Scout" expedition next year, we will offer payload accommodations on future voyages, planned at the rate of one per year. But we can also scale up and increase the frequency of our lunar flights to meet market demand and opportunity. Our second expedition in 2020, "Lunar Out-post", will enable the first commercial presence and exploration of the lunar South Pole. It may in fact be the first-ever soft-landing at a lunar pole. The primary goals of this mission are to set up the first lunar research outpost at a "peak of eternal light", prospect for water and useful minerals, and accommodate a variety of research instruments for our expedition partners. Our third expedition, "Harvest Moon", will take place by 2021 and includes the first commercial sample return, beginning our business phase of lunar resource prospecting and harvesting. The samples brought back will be the only privately obtained lunar materials on Earth, and will be used to benefit science as well as commercial purposes.

Collapsing the cost of lunar missions: The paradigm of what it takes to fly a lunar mission has begun to shift. Launch costs are rapidly decreasing with emerging commercial launch providers.

Commercial operators can reduce the cost of orbiters and landers by re-using designs and by innovating in ways that national space agencies are not mandated to do.

Although the current architectures for Moon Express missions involve going from Low Earth Orbit directly to Lunar orbit, then Lunar surface, or to other destinations in the solar system, integrating the MX family spacecraft into an architecture that involves the Deep Space Gateway presents new and exciting opportunities for science and for cis-lunar operations in general.

Mission concepts that assume that the DSG is available as a hub of operations in Lunar orbit can enable much larger landed masses on the lunar surface and/or continuous shuttle service for assets on the surface or for returned samples to DSG. The Deep Space Gateway can also be a starting point for repeat robotic science and exploration missions to Mars or its moons, or to other solar system destinations. One could imagine scenarios in which refuelling of MX spacecraft could occur at DSG.

Moon Express has been able to collapse the cost of Lunar missions, and the incorporation of DSG into mission scenarios enable even lower mission costs with a workhorse for small payloads to and from the surface of the Moon, and from the Deep Space Gateway itself.

B3.1-0019-18 ALPHA PARTICLE X-RAY SPECTROMETER ONBOARD CHANDRAYAAN2 ROVER

M. Shanmugam, shansm@prl.res.in

Alpha Particle X-ray Spectrometer (APXS) is a well proven instrument for quantitative elemental analysis of the planetary surface through in-situ measurements. This technique involves measurement of X-ray fluorescence by irradiating the lunar surface with Alpha particles and X-rays using radioactive sources. The proposed landing site for Chandrayaan-2 lander is in the high latitude region in the southern hemisphere, which provides the first opportunity to explore the lunar surface with in-situ measurements. The objective of the APXS experiment is to analyze several soil/rock samples along the rover path. The plan is to image the Moon samples to be measured using navigation and imaging cameras onboard rover and traverse the rover towards the sample to carry out the fluorescence measurement. APXS uses Cm-244 radioactive alpha source which emits both Alphas and X-rays. The energy of alpha particle is 5.8 MeV and the energy of X-rays are 14.3 keV and 18.4 keV. It is well known that the PIXE is dominant for low Z elements while XRF is more prominent for high Z elements, allowing the determination of elements from Na to Br, spanning the energy range of 0.9 to 25 keV, for the K X-rays. We use six alpha sources, each with activity of 5 mCi (total activity of 30 mCi). The

Flight Model (FM) of the APXS payload has been completed and tested for various instrument parameters. The design details and the performance of the APXS instrument will be presented in the conference.

B3.1-0020-18 OLIVINE RICH EXPOSURES IN THE GRIMLADI BASIN ON THE NEARSIDE OF THE MOON: IMPLICATIONS FOR LUNAR ENDOGENIC PROCESSES

Rajesh V.J, rajeshvj@iist.ac.in

Indian Institute of Space Science and Technology, Trivandrum, India Thesniya P. M., thesniyathesni91@gmail.com

Indian Institute of Space Sciences and Technology, Trivandrum, India

Lunar magma ocean hypothesis suggests that the Moon was completely molten immediately after its accretion. As the magma ocean crystallized, anorthosite and cumulate pile of denser mafic minerals were formed as products of differentiated magma. Olivine is the primary mafic mineral crystallized in the early stages of magma evolution and represents a significant component of the lunar mantle. Detection of olivine on the lunar surface indicates the exposures of such deep seated materials. The deep seated rocks and minerals provide information on lunar interior. We investigated the Grimaldi basin (50S, 680W, on the western limb of the lunar nearside region and Pre-Nectarian in age) for the distribution and geological context of olivine exposures in the basin. This basin has been selected as it is located in the region where the crust is relatively thin. Crustally thinner regions on Moon are potential areas for the exploration of dense mafic mineral assemblages. Pure anorthosite on the peak ring, noritic anorthosite, anorthosotic norite and few occurences of gabbro have been previously reported in the basin using telescopic spectral measurements (Spudis et al., 1195, Geophys. Res. Lett., v. 22:3055-3058). Hyperspectral images from HySI and M3 (Moon Mineralogy Mapper) and high resolution panchromatic images from TMC and LROC have been utilized for the mineralogical and morphological analyses. Olivine with diagnostic triplet absorption bands at 0.85µm, 1.05µm and 1.25µm in NIR spectra have been identified at 68 locations within the basin; several of them are new areas of discovery. The olivine rich exposures have mostly been found to be occurring on the walls (locally on slumped walls) and rims of the fresh impact craters located on the concentric inner rings of the multi-ring impact basin while few occurrences are located on the sloped area of peaks within the basin. Orthopyroxene rich materials have also been exposed in association with olivine rich exposures. At two locations, olivine is associated with crystalline plagioclase on the crater wall indicating a crustal unit of pure anorthosite. Fe-Mg spinel has been detected in mature surfaces of outer facies of Havelius formation in the basin as well as on the sloped wall of impact craters and peaks. Fe-Mg spinel has also been found to be coexisting with the olivine rich sites on the crater walls. In addition to the olivine dominating spectra, olivine bearing Mare basalts as well as olivine rich localized pyroclastic deposits are also present in the basin. However, spectra from these areas exhibit a mixture of olivine and pyroxene, defined by the absorption features near 2µm in association with the 1µm band. The spectra of olivine exposed in peak ring craters don't exhibit the 2m band corresponding to the presence of Fe2+ in M2 site. Therefore, it can be inferred that olivine exposures concentrated in the peak ring craters of the basin represent deep seated material. The peak rings of the basin is believed to be formed by the upliftment of deep seated materials due to elastic rebound followed by the impact event. Subsequent impact cratering on the peak rings would have exposed these deep seated suites of rocks comprising olivine rich materials. Spectral modelling of the HySI and M3 data to determine the abundance and Mg no. of olivine would be done in future. These aspects undoubtedly will address the possible sources and origin of olivine and the nature of endogenic processes operated in the basin.

B3.1-0021-18 APPLYING MODERN ANALYTICAL TECHNIQUES TO THE APOLLO SAMPLES: A POTENTIAL MODEL FOR FUTURE SAMPLE RETURN MISSIONS

NASA Johnson Space Center, Houston, Texas, United States

Background: From 1969-1972 the Apollo missions collected 382 kg of lunar samples from six distinct locations on the Moon. Studies of the Apollo sample suite have shaped our understanding of the formation and early evolution of the Earth-Moon system, and have had important implications for studies of the other terrestrial planets (e.g., through the calibration of the crater counting record). Despite nearly 50 years of research on Apollo samples, scientists are still developing new theories about the origin and evolution of the Moon. In order to resolve these questions, scientists need access to new lunar samples, particularly new plutonic samples. Although no new large plutonic samples (i.e., hand-samples) remain to be discovered in the Apollo sample collection, there are many large polymict breccias in the Apollo collection containing relatively large (1 cm or larger) previously identified plutonic clasts, as well as a large number of unclassified lithic clasts. In addition, new, previously unidentified plutonic clasts are potentially discoverable within these breccias. The question becomes how to non-destructively locate and identify new lithic clasts of interest while minimizing the contamination and physical degradation of the samples. Results: The solution to the identification of new clasts within the Apollo samples while still keeping the samples pristine is micro-computed X-ray tomography (micro-XCT). The technique uses high energy X-rays (typically 180-320 kV) to make 3-dimensional images of a sample. These images highlight materials with different X-ray attenuation values, which are determined by the density and composition of the materials. Thus, lithic clast materials can be differentiated from the breccia matrix, and different types of lithic clasts can often be differentiated from each other [1-3]. The scans can also be used to estimate the volume and mass of clasts, which is useful in determining which studies they are most suited for. The high-energy nature of the x-rays allow for scanning of relatively large samples (up to 15 cm) while triply bagged in Teflon containing a dry-nitrogen atmosphere. This protects the samples from potential contamination. Once the XCT-scans have identified the location and approximate composition of the lithic clasts within the polymict breccia sample, this information can then be used to more precisely cut the samples into slabs, exposing the clasts of interest for sampling and further study. Although micro-XCT provides x-ray attenuation data for a sample, it does not give direct compositional or mineralogical information (although making reasonable assumptions and using standards during analysis allows for good estimations). Micro X-ray fluorescence (micro-XRF) uses a focused (25 micron) high energy (up to 50 kV) X-ray beam to produce semi-quantitative compositional maps of relatively flat surfaces. These maps can be used to better characterize clasts identified in micro-CT data, or to identify clasts that are compositional or textural outliers. Another technique, scanning laser-Raman analyses of cut slabs of breccias, has the potential to give direct mineralogical information that can be co-registered with the compositional data from the micro-XRF scans. Neither micro-XRF nor laser-Raman scanning can be easily done on samples contained in Teflon bags, but both scanning laser Raman and micro-XRF could be adapted to work in a standard nitrogen glove box. Future Missions: The original Apollo sample preliminary examination teams (PET) used binocular microscopy as they made their initial descriptions and observations of the samples. This was in part due to the technology available at the time, and in part, an effort to keep the samples as pristine as possible. Subsequent missions have used progressively more sophisticated techniques for PET, e.g., FTIR for Genesis or EDAX and laser-Raman for Hayabusa. Future sample return missions like OSIRIS-REx or South-Pole Aitken sample return are likely to incorporate micro-XCT, micro-XRF, and other sophisticated techniques into their PET analysis. B3.1-0022-18 TAPPING INTO THE LUNAR VOLATILE CYCLE WITH A SAMPLE RETURN MISSION TO THE SCHRODINGER BASIN

David Kring, kring@lpi.usra.edu

USRA - Lunar and Planetary Institute, Houston, Texas, United States
Katharine Robinson, robinson@lpi.usra.edu

USRA - Lunar and Planetary Institute, Houston, Texas, United States

The detection of water and other volatile species in Apollo samples has provided a new tool for assessing the accretion of the Moon, processing of volatiles during the magmatic evolution of the lunar interior, venting at the surface, and deposition in near-surface ice caches that may be harvested to support a sustainable exploration program on the lunar surface. Analyses of Apollo 17 glasses, norites, and a troctolite, for example, indicate that those types of samples can be used to measure OH abundances and isotope compositions that are key signatures of volatile sources and subsequent processing. Deciphering a volatile cycle from those samples is difficult, however, because they may not be derived from the same system in a Moon with a heterogeneous distribution of volatiles. The crystalline rocks were delivered to the Apollo 17 site as ejecta and, thus, come from a site tens to perhaps more than a 1000 km from the pyroclastic glass.

To address that complexity and evaluate the volatile cycle from accretional delivery, through processing in the lunar interior, to venting at the surface, we ideally want a set of samples that taps into that system at different depths in the same location on the Moon. We also ideally want to probe the lunar farside, for which we do not yet have any data except from meteorites without a known provenance. The Schrödinger basin is a geologically perfect site to address those issues and has already been identified as a high-priority landing site for robotic sample return missions and human sample return missions. In the Schrödinger basin, one can collect material from an immense pyroclastic vent that may be the largest indigenous source of volatiles in the South Polar Region during the past 3.7 billion years. Lava flows were also emplaced on the basin floor of Schrödinger, forming deposits that may provide evidence of a less-volatile rich portion of magma ascent from the same mantle source region as the pyroclastic vent or, if a different age than the pyroclastic vent, potentially of a different mantle source depth. Samples that record volatile abundances at a variety of crustal depths above the mantle can be extracted from the peak-ring, which was uplifted from depths down to 30 km, and from clasts in polymict impact breccias on the basin floor that contain excavated material from depths down to 19 to 24 km. Collectively, a suite of samples involving pyroclastic material, peak-ring lithologies, impact breccias, and mare flows would probe volatile abundances in the lunar interior at several different depths as they were being processed and eventually vented at the surface. A key advantage of the Schrödinger landing site over other sites is that it provides probes of the volatile cycle at different depths in the same location. This is an essential element of any study of the volatile cycle, particularly if volatiles are heterogeneously distributed laterally within the lunar interior.

B3.1-0023-18 HIGHLIGHTS OF SCIENCE AND EXPLORATION ACTIVITIES AT THE SSERVI VORTICES NODE

Andrew Rivkin, andy.rivkin@jhuapl.edu JHU/APL, Laurel, Maryland, United States Rachel Klima, rachel.klima@jhuapl.edu JHU/APL, Laurel, Maryland, United States Jeffrey Plescia, jeffrey.plescia@jhuapl.edu JHU/APL, Laurel, Maryland, United States

The surface and near-surface of a planetary object is host to a wide variety of processes. It is the part of the body that interacts with impacts, solar and galactic energy to create or destroy volatiles, it is the part that we see with remote sensing instruments, and the part that will be sampled and tested by robots and astronauts. The Volatiles, Regolith and Thermal Investigations Consortium for Exploration and Science (VORTICES), a Solar System Exploration Virtual Institute (SSERVI) team headquartered at the Johns Hopkins University Applied Physics Laboratory, focuses on the entire volatile-regolith system occurring on small bodies and on the Moon. The team focuses on the sources, sinks and transport mechanism of volatiles (e.g., H2O, OH); the regolith and its properties and how it acts as a transport medium and storage reservoir; and how volatile and solar resources facilitate planetary exploration. At the time of selection, VORTICES had team members at 12 different institutions across the United States and its territories, at the current writing personnel movements have reduced that number to 10 institutions.

The work done by VORTICES team members involves interlocking themes considering the entire regolith-volatile system of the Moon and small bodies in the context of science and exploration. These themes are: 1) Volatiles in the Solar System: Sources, Processes, and Sinks: Understand how and where volatiles (e.g., OH and H2O) form, how they interact physically and/or chemically with regolith, how they are transported across and within the regolith, and their ultimate fate - be it sequestration in a cold trap or loss from the body. 2) Regolith: Origin and Evolution on Airless Bodies: Understand how regoliths are formed and evolve, and how those formation and evolution processes vary across the inner solar system. 3) Resources: Identification and Exploitation: Understand how volatile and solar illumination resources are distributed and how they enable robotic and human exploration.

In 2017, the group expanded modeling efforts of the thermal properties of the regolith, penetration of protons into the regolith and thermal fatigue of rocks and regolith generation. A new laboratory facility to examine how proton bombardment of regolith particles (solar wind bombardment of a surface) influences their ability to store and transport OH has been developed. This complements existing facilities that simulates micrometeorite impact to understand space weathering and the influence of micrometeor impact on ability to store and transport volatiles. The recent work builds upon work supported by VORTICES in the first three years of the institute, some highlights of which include: identification of lunar polar wander via regolith hydrogen signatures by Siegler et al., simulation of regolith creation by thermal stresses and calculation of the characteristic particle size created (El Mir, Ramesh et al.), modeling of impact gardening and its effect on lunar ice retention and burial (Hurley et al.), laboratory simulations of space weathering on carbonaceous asteroids (Kaluna, Gillis-Davis et al.), modifying an asteroidal shape/thermal modeling code to include additional features derived from Diviner thermal models (Magri, Hayne et al.), and measuring the desorption of water from lunar samples to understand the stability of surficial lunar water and the origin of the diurnal cycle seen from several spacecraft (Orlando, Hibbitts et al.).

We will provide an overview of the work done by VORTICES, including collaborations with other SSERVI teams.

Presently, KPLO (The Korea Pathfinder Lunar Orbiter)'s Gamma-Ray Spectrometer (KGRS) is being developed for an engineering model. The scheduled final KGRS development will be completed no later than mid-2019. The KPLO weighs approximately 550 kg and it will be launched in late 2020 by Falcon 9 rocket. The KPLO Gamma-Ray Spectrometer system is a compact low-weight instrument for the chemical analysis of lunar surface materials within a gamma-ray energy range from 10s keV to 10 MeV. The KGRS will collect low energy gamma-ray signals by either X-ray fluorescence or by natural radioactive decay in the low energy regions of spectrum and higher-energy gamma rays due to either neutron capture or inelastic scatter. The GRS system will determine the elemental compositions of the near surface of the Moon for investigation of the lunar geology and resources. The main LaBr3 detector of KGRS is surrounded by an anti-coincidence counting module of a boron-loaded plastic scintillator to reduce both low energy gamma-ray background from the spacecraft and housing materials and high energy gamma-ray background from cosmic rays. The main detector has high and low gain settings for gamma-ray energy ranges up to 3 and 10 MeV, respectively. One month of calibration and 11 months of a nominal mission period are planned with a minimum required GRS background measurement at anti-nadir direction. The planned altitude of KPLO in orbit is 100 ± 40 km, and KGRS data will be collected every 10 sec. The KGRS investigation will help to assess open questions related to the spatial distribution and origin of the elements on the lunar surface and will contribute to unraveling geological surface evolution and elemental distributions of potential lunar resources. This talk introduces the current development of KGRS and prospective scientific outcomes by KGRS data.

B3.1-0025-18 RADIO ASTRONOMY ON AND AROUND THE MOON

Heino Falcke, h.falcke@astro.ru.nl

Radboud Universiteit Nijmegen, Nijmegen, Netherlands Marc Klein Wolt, m.kleinwolt@astro.ru.nl

Radboud Universiteit Nijmegen, Nijmegen, Netherlands Jinsong Ping, jsping@bao.ac.cn

National Astronomical Observatories, CAS, Beijing, China

The exploration of remote places on other planets has now become a major goal in current space flight scenarios. On the other hand, astronomers have always sought the most remote and isolated sites to place their observatories and to make their most precise and most breath taking discoveries. Especially for radio astronomy, lunar exploration offers a complete new window to the universe. The polar region and the far-side of the moon are acknowledged as unique locations for a low-frequency radio telescope providing scientific data at wavelengths that cannot be obtained from the Earth nor from single satellites. Scientific areas to be covered range from radio surveys, to solar-system studies, exo-planet detection, and astroparticle physics. The key science area, however, is the detection and measurement of cosmological 21 cm hydrogen emission from the still unexplored dark ages of the universe. Developing a lunar radio facility can happen in steps and may involve small satellites, rover-based radio antennas, of freeflying constellations around the moon. A first such step could be the Netherlands-Chinese Long Wavelength Explorer (NCLE), which is supposed to be launched in 2018 as part of the ChangE'4 mission to the moon-earth L2 point.

B3.1-0026-18 DEVELOPMENT OF THE NETHERLANDS - CHINA LOW FREQUENCY EXPLORER (NCLE)

Linjie Chen, ljchen@nao.cas.cn

National Astronomical Observatories, CAS, Beijing, China Jinsong Ping, jsping@bao.ac.cn

National Astronomical Observatories, Chinese Academy of Sciences, Beijing, China Heino Falcke, h.falcke@astro.ru.nl

Radboud Universiteit Nijmegen, Nijmegen, Netherlands Marc Klein Wolt, m.kleinwolt@astro.ru.nl

Radboud Universiteit Nijmegen, Nijmegen, Netherlands

In radio astronomy, the very low frequency (VLF) range, below30 MHz, as one of the last remaining unexplored spectrum regions, plays an important role to understand comprehensively the physical processes of celestial sources by observing their emissions in the entire detectable EM spectrum. However, the artificial radio frequency interference (RFI), the cutoff frequency of the Earth's ionosphere, the AKR and QTN noise make it difficult or impossible to observe the sky VLF radio emissions with terrestrial telescopes. To open up this remaining spectral window virtually, a spaceborne telescope turns to be the only possibility.

Based on a space cooperation agreement signed between the Netherlands and China, a joint scientific team including Chinese researchers and Dutch researchers proposed a low-frequency scientific instrument, the Netherlands-China Low Frequency Explorer (NCLE). The NCLE will be hosted by the Chang'e 4 relay satellite, it will operates on an orbit at the Earth-Moon L2 point (around 64000 km behind the Moon), and serves as a reply between the Earth and a lander working on the far side of the Moon. The satellite is expected to be launched in 2018.

The NCLE will operate at the frequency band from 80 kHz to 80 MHz. It consists of three colocated, 5 m monopole antenna elements mounted on one side of the spacecraft body to receive the radio signals with three-dimension polarizations. These antennas are optimized to have a good sensitivity between 1 and 80 MHz where the priority science signals are expected. However, they are also able to extend down to the kHz regime with the decreasing sensitivity. The analogue signals sensed by the antennas are digitized by an ADC board, and then the data are processed in a Digital Receiver System (DRS) on which several dedicated science modes are implemented in a Field Programmable Gate Array (FPGA). These scientific modes perform such as fast Fourier transforms to create average radio spectra, triggering to capture a short segment of the digitized signal for transient radio events, and direction of arrival (DOA) finding with beam-forming or goniopolarimetry techniques. Raw time

traces can be stored for groundbased post processing and VLBI experiments. More detailed analysis will be done after the data are sent back to the Earth.

As described above, the man-made RFI is a big obstacle to observe the VLF radio sky on the Earth. Besides, for a space-based low frequency radio instrument, the RFI from the spacecraft itself should also be considered.

In this work, the development of NCLE project will be introduced and discussed including payload design, choices of the design, and RFI suppression, etc., some of them will be illustrated with the simulation and measurement results.

The NCLE scientific payload are mainly developed by the Radboud University, ASTRON, and Innovative Solutions in Space in Netherlands, in close collaboration with National Astronomical Observatories, CAS (NAOC), National Space Science Center, CAS (NSSC), and DFH Satellite CO.,Ltd in China.

B3.1-0027-18 THE CUBESAT LOW FREQUENCY EXPLORER (CLE) IN LUNAR ORBIT

In radio astronomy, as in astronomy in general, a wide range of frequencies is observed, as each spectral band offers a unique window to study astrophysical phenomena. At the low-frequency part of the radio spectrum, telescopes such as LOFAR, GMRT and the MWA provide windows to study for example cosmology, pulsars, and (extra)galactic phenomena. Observing at even lower frequencies is very interesting as well, but, due to the influence of the Earth's ionosphere this is not possible from Earth. Thus, the only option to observe the lowest frequencies is a telescope in space.

In 2009 the OLFAR radio telescope based on a swarm of (50+) nano-satellites in lunar orbit was proposed. In order to assess the status of current-day technologies for OLFAR, the CubeSat Low Frequency Explorer (CLE) mission concept and technology study was conducted. This was done in the context of the SysNova "LUnar Cubesats for Exploration (LUCE)" challenge of ESA's General Studies Programme (GSP). The CLE mission concept is aiming at conducting radio astronomy below 30 MHz. This CLE radio mission and technology analysis is helping to pave the way towards deploying a larger scale distributed low frequency radio telescope in space, in the coming decades.

The Sysnova mission scope includes a circular lunar orbit requirement of >500 km altitude, a total mass of <60 kg, and data communication to a Lunar Obiter in elliptical polar orbit. The CLE study looked into astronomical science to be conducted, and also looked into technical feasibility with associated Technology Readiness Levels (TRLs). It turned out that for CLE with current-day technologies an instantaneous bandwidth of 10 MHz and 4 satellites with maximum baselines of 10 km can be supported with roughly 15% observational duty cycle. Given radio instrument space heritage and recent developments such as the Chang'e 4 NCLE receiver, it should be technologically possible to develop CLE in the coming decade. For a larger scale system such as OLFAR with more than 50 satellites, it turns out that the inter-satellite and downlink communication bandwidth (and associated mass) are currently the main limiting factors. However, novel optical communication links and novel RF communication schemes are currently being developed, and this give a promising outlook.

B3.1-0028-18 A UNITY OF PURPOSE IN EXPLORATION AND SPACE SCIENCE: HIGHLIGHTS FROM THE SSERVI NESS TEAM

Jack Burns, jack.burns@colorado.edu

University of Colorado at Boulder, Boulder, Colorado, United States

The Network for Exploration and Space Science (NESS) is one of the new teams selected in 2017 to be part of NASA's Solar System Exploration Research Virtual Institute (SSERVI). NESS conducts multifaceted and multidisciplinary research in the space sciences, including the areas of astrophysics, heliophysics, and exoplanetary science, that are enabled through human and robotic exploration of the Moon. Our team focuses on low radio frequency observations of the Sun, exoplanet systems, and the early Universe using the unique radio-quiet of the lunar farside and collaborative tools for exploration. The design of wide bandwidth receivers, prototype antennas, and arrays of radio dipoles on the lunar farside to investigate Cosmic Dawn, Heliophysics, and Extrasolar space weather are core activities within NESS, as well as the continuous research of theoretical and observational aspects of these subjects. NESS is developing designs and operational techniques for teleoperation of rovers on the lunar surface facilitated by the planned Deep Space Gateway in cis-lunar orbit. New experiments, using rover + robotic arms and Virtual Reality simulations, are underway to guide the development of deployment strategies for low frequency antennas via telerobotics.

When the super sonic solar wind plasma from the Sun interacts with the Moon, an airless body without a global magnetic field, it creates a void behind the Moon in the downstream. This void, known as the lunar plasma wake, was conventionally thought to be almost devoid any plasma especially at distances close to the Moon (few hundered lunar radii downstream), until the recent lunar missions revealed a competely different scenario. It was found that solar wind can access the near wake region (100-200 km altitude on nightside) by processes that are kinetic in nature. The SARA (Sub-keV Atom Reflecting Analyzer) experiment onboard Chandrayaan-1 carried an ion-mass analyser namely SWIM (Solar Wind Monitor), and the observations brought out new mechanisms for wake refilling and better understanding of the characteristics of plasma populations in near wake. SWIM observations showed for the first time that protons access the near wake even under a special scenario of magnetic aligned flow where the interplanetary magnetic field (IMF) is aligned with the solar wind velocity so that none of the known mechanisms can explain such protons. These were found to be the solar wind protons from the tail of the velocity distribution. Such protons have gyro-radii larger than lunar radii so that they enter the near wake region directly even under magnetic aligned flow. A new population of suprathermal protons (sim1.5–3 times the solar wind energy) were observed around the Moon. These protons have large initial velocity (>100 km s–1) and originate from a high altitude source (>500 km above the dayside lunar surface). Discovery of these protons calls for a new source feeding the plasma environment around Moon, which is yet to be identified. Whereas in most of processes protons access the near wake region by travelling perpendicular to the IMF, wake refilling parallel to IMF also has been observed. Comparison of the observed protons (energy sim700 eV) with the 1-D analytical model of an electrostatic plasma expansion into a vacuum showed the observed velocity to be higher by a factor of 2 to 3 and the observed density to be lower by a factor of 2 to 25 than the model predictions. Thus, the simple analytical models cannot explain the observed ion dynamics along the magnetic field in the vicinity of the Moon. The analysis of the complete data set from SWIM in near wake region showed the presence of several proton populations with distinct velocity distributions coexisting in this region. Based on the characteristic velocity distribution functions and the backtracing model, most of these populations could be explained by known mechanisms although there are a few populations whose sources are yet to be found out. The observations have showed an additional mechanism which involves the transport of the solar wind that is scattered from the small scale magnetic fields on the Moon (lunar magnetic anomalies) on the dayside to the near wake region. The understanding of the plasma environment and the electrodynamics on the lunar nightside is still evolving. These observations not only throw light on this aspect but also on the possibility of the interaction of such plasma with the lunar surface. The interaction can modify the surface charging, and also cause sputtering from the nightside surface that contributes to lunar nightside exosphere. The recent observations of energetic neutral atoms emitted from the lunar nightside surface supports this. Further explorations of the Moon is required to have a comprehensive understanding of lunar plasma environment.

B3.1-0030-18 HIGHLIGHTS OF THE FRANCE SSERVI PARTNERSHIP

Patrick Pinet, patrick.pinet@irap.omp.eu IRAP/CNRS/Observatoire Midi-Pyrénées/UPS, Toulouse, France IRAP team

André,N; Calvet,M.; Chevrel,S.D.; Daydou,Y.H.; Forni,O.; Gasnault,O.; Genot,V.: Lasue,J.; Margerin,L.; Meslin,P.-Y.; Monnereau,M.; Toplis,M.

Overall context:

IRAP has become a SSERVI partner, with the official signing on May, 24th, 2016 of its affiliation, as the result of the submission of the proposal 'SSMMAC-France' (Space Studies of the Moon, Mercury, Asteroids and Comets in France).

A few science and future projects highlights:

Lunar Orbital Imaging Spectroscopy and Geology. Given the wealth of the dataset acquired by the imaging spectrometer M3 on board Chandrayaan-1 mission, advanced hyperspectral processing appears needed to explore the existing variability involving plagioclase and mafic crystal field absorptions, and better constrain the lunar crust lithology and cratering process. Laboratory data are used to improve the capability of MGM modeling to realistically model complex mafic mineralogies when considering rock slab surfaces with coarse textures, involving plagioclase and mafic crystal field absorptions. This strategy is tested on M3 spectra with the objective of documenting the petrology at Copernicus and Aristarchus craters through characterization of plagioclase and mafic crystal field absorptions, from exposed outcrops (e.g., central peaks, inner walls and rims).

Lunar Interior. Lunar seismic signals (Apollo data) are notably different from terrestrial seismic records: the energy rise at the onset of the signal is gradual, the S-wave arrival is difficult (or impossible) to detect, the maximum of energy is broad, and the energy decay in the coda is very slow. In 1974, Dainty et al. made the first attempt at modeling the scattering processes in the Moon using diffusion theory, and inferred a thickness of 25 km for the scattering layer. However, the modeling was limited to the planar case. Given the size of the Moon and the duration of seismic signals, spherical effects appear quite relevant. For the first time, stratification of scattering properties and spherical geometry are addressed. Using an advanced attenuation model, the depth of shallow moonquakes is determined by inversion based on the observed variation of the time of arrival of the maximum of energy with epicentral distance. They are found to originate from a depth of about 50 km ± 20 km, likely resulting from the failure of deep faults in the brittle part of the Moon.

Future lunar missions and instruments.

SELMA: IRAP is contributing to the SELMA (Surface, Environment, and Lunar Magnetic Anomalies) mission proposal submitted in response to ESA Cosmic Vision AO for M5 mission

Opportunity. SELMA is a mission to study how the Moon environment and surface interact. It focuses on the origin of water on the Moon, on how the “volatile cycles” and the lunar minimagnetospheres work, on the influence of dust on the lunar environment and surface. SELMA uses a unique combination of remote sensing via UV, IR, and energetic neutral atoms and local measurements of plasma, fields, waves, exospheric gasses, and dust. It will also conduct an impact experiment to investigate volatile content in the soil of the permanently shadowed area of the Shackleton crater. The spacecraft will carry an impact probe to sound the Reiner-Gamma mini-magnetosphere and its interaction with the lunar regolith from the SELMA orbit down to the surface.

DORN: Since the early stages of the lunar exploration, radon-222 and its progeny have been identified as key tracers of the present-day lunar seismic and venting activity. Long-term monitoring of the radon cycle on the surface of the Moon would thus provide valuable ground truth for orbital measurements and would help address several key issues related to the transport of lunar volatiles and dust, including the study of the transport of gases through the lunar regolith, cycles in the lunar exosphere, monitoring of the venting activity and identification of active outgassing spots. A prototype for an in situ instrument called DORN aimed at measuring both radon and polonium atoms around the lander, and the subsurface flux of radon at the landing site is being developed at IRAP.

LIBS: Since 2012, LIBS (Laser-induced Breakdown Spectroscopy) has been successfully used under low atmospheric pressure for exploring the geology of Mars at Gale Crater with ChemCam instrument onboard Curiosity. Laboratory studies have also demonstrated that LIBS can give accurate and precise results under vacuum conditions. Its potential for rapid and accurate in situ elemental analysis of lunar materials and characterization of resources is currently under study.

Small bodies plasma physics. IRAP is also deeply involved in ROSETTA and Dawn data analysis and interpretation, as well as in planetary plasma activities related to CDPP (Plasma Physics Data Center).

B3.1-0031-18 RADON-222 AND POLONIUM-210: TRACERS FOR VOLATILE TRANSPORT ON LUNAR SURFACE

Debabrata Banerjee, deba@prl.res.in

Physical Research Laboratory, Ahmedabad, India

D. K. Panda, pdipak@prl.res.in

Physical Research Laboratory, Ahmedabad, India

S. K. Goyal, goyal@prl.res.in

Physical Research Laboratory, Ahmedabad, India

Samples returned from the moon have established that widespread lunar volcanism ceased around 3.2 Ga, and only impact craters reshaped the lunar surface over the last billion years. However, morphological and spectral evidence suggests recent outgassing activity at Ina structure, close to one of the regions where high 210Po alpha activity has been previously observed. Further, 222Rn (half life = 3.8 days) produced in decay chain of 238U, can be expected to be released from the upper layers of the hot sunlit side of the lunar surface by thermal diffusion and be trapped in the permanently shadowed regions of the moon and other cold traps in the polar regions. The mean free path of a radon atom's random walk is not determined by collisions with other gas molecules in the extreme lunar vacuum, but rather from collisions with soil grain surfaces. Subsequently, 222Rn decays to 210Pb, and a thin layer of 210Pb and 210Po is expected in the permanently shadowed regions of the lunar surface. We propose to develop an alpha particle spectrometer for a lunar lander/rover mission using ion-implanted silicon detectors for measuring signals from alpha particles produced by the decay of 222Rn (5.490 MeV) and 210Po (5.304 MeV) at permanently shadowed regions of the lunar surface. Alpha spectrometers on Surveyor landers and Apollo orbiters measured 222Rn and 210Po in lunar rocks and soils and suggest temporal and spatial variability in their concentrations. Several models have been proposed for transport of radon from the lunar interior to the lunar surface and then across the terminator to the colder regions. Permanently shadowed regions near lunar poles should have high concentrations of 222Rn, 210 Po and an alpha particle spectrometer and a cooled HPGe gamma ray spectrometer (for 210Pb measurements using 46.5 keV gamma line) on a future lunar lander/rover mission should be able to determine their concentrations and help us understand the transport and deposition of volatiles on the lunar surface.

B3.1-0032-18 LUNAR SIMULANT IN LOW TEMPERATURE VACUUM TESTING FOR OUTGASSING CHARACTERISATION

Michèle Roberta Lavagna, michelle.lavagna@polimi.it Politecnico di Milano, Milano, Italy

Nowadays interest towards ice in space is increasing. One of the reason why stays in the great importance icy the volatiles elements play in the exobiology and pre-biotic components potential existence. The ESA Juice mission towards the Jupiter icy Moons, in preparation for flying in 2022 is just an example, as well as the on going, proposed and future missions focusing on asteroids with samples return. More nearby in time, the first incoming challenge is represented by the lunar 27 ESA-Roscosmos mission, supposed to land n the Moon south Pole to collect and analyze in situ icy volatiles. Icy volatiles sampling in vacuum is quite a tough operation: icy gases immediately sublimate as soon either the pressure decreases - because of the extraction - or the temperature increase - because of the friction provoked by the mechanical energy injected in the soil to crack it and collect the specimen. The risk is, therefore, to penetrate the soil, collect subsurface samples supposed to have the volatiles content required to run scientific analysis and to release to the instruments soil with no volatiles at all inside, because of the occurred sublimation in vacuum. Currently, no validated model exists on sublimation phenomenon for gases trapped in a soil composite while in vacuum. Therefore experimental tests would be beneficial to characterize it and tune both the tool to sample and the operations to run while sampling the icy planetary soil. At Politecnico di Milano-Aerospace Science Technology Dept. the design and setup of a dedicate experimental facility to assess the gasses and icy volatiles sublimation phenomenon in vacuum is under development. A vacuum chamber, equipped with soil inside - either dry or wet - which correctly reproduces the polar Moon conditions is a challenge also in the setting up activities: soil is prepared in air at sea temperature, therefore, even the dry soil traps air molecules which contribute to the sublimation as soon as the soil undergoes a vacuum creation procedure; the amount of gases coming from trapped air has to be distinguished from gases being part of the simulated icy volatiles purposely inserted in the soil to run the scientific test. Previous tests, performed at Glenn Research Center, have identified how lunar soil simulants, inserted in a thermal vacuum chamber, increase the time needed to reach the target pressure because of the gas load, coming from the simulant, provoked by the air trapped between the soil particles, and the water vapor absorbed by the simulant when exposed to atmospheric conditions. Therefore, to correctly support the design of a planetary icy soil sampler the terrestrial infrastructure must firstly quantify the gas load produced by the soil during the chamber pressure decreases and provoked by the trapped air; then it must be equipped to monitor and measure the gas load, in vacuum, provoked by the tool-soil energy exchange. The NU-LHT-2M is here used as Moon highlands simulant. A scaled experimental set up, made up of a soil chamber and a vacuum chamber, connected by a pressure regulated line has been realized. The two chambers scheme allowed characterizing and

controlling the experienced soil sputtering and boiling as soon as the pressure starts decreasing. This is a critical phenomenon to be avoided to keep the soil characteristics known and as desired to correctly simulate the planetary soil during any functional testing of tools interacting with the soil itself (e.g. drilling, sampling, impacting, etc). The adopted two chambers scheme is required to keep the experiment completely independent from a classical TVAC internal chamber with suffer from any particle which can enter the pump line, jeopardizing the complete plant because of pump failure; the system can be easily cooled down just inserting the whole in a freezing plant, decoupling the vacuum creation from the temperature regulation process. A 10-5 bar pressure conditions can be obtained; The lunar simulant NU-LHT-2M has been prepared setting up a compaction procedure based on a layered vibrations campaign to reproduce at the best the lunar soil bulk density. The experimental campaign run so far revealed the significant air content in the compacted soil while getting to the correct vacuum level in the soil chamber, confirming the need of a standardized procedure to prepare the soil in vacuum to be not only chemically but also physically representative of the planetary soil as soon as any technological or scientific experiment involving interaction with low temperature, maybe icy, soil in vacuum is conducted. The facility design, implementation and calibration will be critically discussed and presented, together with the results of the tests which led to the soil behavior characterization (dry and wet) and to the soil preparation procedures definition.

B3.1-0033-18 METEOROID BOMBARDMENT AND IMPACT GARDENING IN THE LUNAR POLAR REGIONS

Jamey Szalay, jszalay@princeton.edu

Princeton University, Princeton, New Jersey, United States Petr Pokorny, ppokorn2@uwo.ca

University of Western Ontario, London, Canada Mihaly Horanyi, horanyi@colorado.edu

University of Colorado, Boulder, Boulder, Colorado, United States

The Moon is continually bombarded by interplanetary meteoroids. While meteoroids turn into shooting stars at Earth due to our thick atmosphere, airless surfaces like the Moon's are completely exposed to meteoroid impacts. The surface of the Moon is covered with a layer of loose rocky material, including fine dust particles. This regolith has been formed, and remains continually reworked, by the intermittent impacts of comets asteroids, and the continual bombardment by meteoroids. Each meteoroid impact produces orders of magnitude more ejecta mass compared to the primary impactor mass, most of which is bound and returns to reblanket the lunar surface.

Water is thought to be continually delivered to the Moon through geological timescales by water-bearing comets asteroids and produced continuously in situ by the impacts of solar wind protons of oxygen-rich minerals exposed on the surface. Meteoroids are an unlikely source of water due to their long UV exposure in the inner solar system, but their high-speed impacts can mobilize secondary ejecta dust particles, atoms and molecules. Other surface processes that can lead to mobilization, transport and loss of water molecules and other volatiles include solar heating, photochemical processes, and solar wind sputtering. However, since these drivers are minimized at high latitudes, particularly in Permanently Shadowed Regions (PSRs), dust impacts are an important driver governing the evolution of volatiles in these regions.

The meteoroid environment at the lunar polar regions has been difficult to constrain, given the paucity of available data. However, recent Earth-based observational and modeling efforts have revealed a persistent, high speed and high inclination source of meteoroids at 1 au that continually bombard the lunar polar regions. In-situ ejecta measurements were made at the Moon by the Lunar Dust Experiment (LDEX) onboard the Lunar Atmosphere and Dust Environment Explorer mission. LDEX observations enabled a detailed understanding of the structure of the impact generated, permanently present lunar ejecta cloud and subsequent gardening rates near the lunar equatorial plane. Here, we extend those equatorial measurements to the lunar polar regions using advanced models of meteoroid impactors at the Moon to constrain the associated impact gardening rates.

B3.1-0034-18 A TENTATIVE PLAN OF CHINA TO ESTABLISH A LUNAR RESEARCH STATION IN THE NEXT TEN YEARS

Yongliao Zou, ylzou@nao.cas.cn

upChina successfully implemented the missions of Chang'E-1 in 2007, Chang'E-2 in 2010 and Chang'E-3 in 2013 respectively, and Chang'E-4 will be launched in 2018 to achieve landing and inspection on the far side of the Moon. And later, Chang'E-5 will be launched in 2019, with an attempt to collect lunar samples and return them to the Earth. On this basis, through years of study and discussion, Chinese scientists have proposed a preliminary plan for establishing a lunar research station on the lunar South Pole by implementing 3-4 missions between 2021 and 2030. The first mission is designed to carry out geological investigations on the landing site and the detection of water ice in the permanently shadow crater. The main scientific task of the second mission is to collect lunar rock and soil samples and return them to the Earth for further analysis. The third mission is focused on the test of insite utilization of lunar resources on the Moon.

B3.1-0035-18 TOWARDS THE INTERNATIONAL LUNAR DECADE

Vidvuds Beldavs, vid.beldavs@fotonika-lv.eu University of Latvia, Riga, Latvia International Lunar Decade

Vidvuds Beldavs, David Dunlop, Jim Crisafulli, Bernard Foing

In November, 2014 an international group gathered in Hawaii at the conference "Next Giant Leap: Leveraging Lunar Assets for Sustainable Pathways to Space" issue the International Lunar Decade (ILD) Declaration. The central premises of ILD are: 1. The inspiration for ILD is the International Geophysical Year 1957-8 that marked the first global effort to understand the Earth. ILD is proposed as framework for international cooperation towards permanent presence of humankind on the Moon and beyond. Initially proposed by COSPAR to start on the 50th anniversary of IGY in 2007, global conditions were not favorable. Now, with many countries planning missions to the Moon the decade of 2020-2030 would be appropriate to work towards the strategic goal of making possible permanent presence on the Moon. 2. Economic use of lunar resources is a precondition for sustainable research and commercial activities on the Moon. There is speculation about lunar water and asteroid resources, but no business case for use of space resources has so far been offered. Markets for space resources do not exist. Technologies to mine and process space resources need to be developed. Even the legal right to use space resources within existing space law is uncertain. Recent developments suggest that a business case for lunar resources can emerge over the next few years. Lunar regolith includes significant basalt content from which basalt fibre could potentially be produced by melting regolith at about 1500C with concentrated solar energy. Uses could include thermal barrier shields as well as impact shielding for spacecraft and structural and body parts of spacecraft and rovers and haulers on the lunar or Martian surface thereby generating major savings in lunar and planetary exploration. Space Solar Power is another development where technical designs promise electrical costs competitive with other alternatives with zero CO2 emissions. An early application with commercial potential could be a Lunar Power Utility that could lower costs and speed up lunar development. Lunar water is another promising resource. Low cost launch from the lunar surface is key to realizing the economic potential of lunar resources. Additionally, the issue of rights to use lunar resources, particularly as commercial products, remains to be addressed.

Moon Village provides a structure to link between exploration and research and commercial developments into a mutually augmenting whole. Moon Village is a bottom-up, open, evolutionary concept for development on the Moon and in cislunar space by an international community including scientific research, business and cultural interests, as well as space agencies and international organizations. Moon Village, however, does not address the policies required to enable use of lunar resources or to engage the global research community, the UN, and other international organizations such as the International Science Council, which coordinated the IGY. Moon Village and other

developments can benefit from the framework for strategically directed international cooperation from 2020 to 2030 provided by the ILD to: develop internationally accepted policies for use of space resources, foster innovation and the development of enabling technologies and infrastructure aimed at driving down the costs of activities in cislunar space and on the Moon, and facilitate the creation of markets for space resources. Adoption of the ILD framework by UN COPUOS, COSPAR, International Science Council, ILEWG, ISECG and other forums for international cooperation in outer space can lead to greater progress in the 2020-2030 period for all participants individually and jointly through initiatives such as Moon Village and the Deep Space Gateway. The ILD framework can also provide mutually agreed to strategic direction to meet UN Sustainable Development Goals through lunar exploration and development. The use of lunar and asteroid resources can create economic activities that do not damage the environment while expanding wealth and opportunities for people on Earth.

B3.1-0036-18 FLASH ORAL PRESENTATION OF POSTERS (2 MINUTES /POSTERS)

Bernard H. Foing, bernard.foing@esa.int ESA/ESTEC, Noordwijk, Netherlands

Flash oral presentation of posters (2 minutes /posters)

Lunar science and exploration are having a renaissance with as many as twelve missions (and 18 vehicles) sent to Moon during the last "International Lunar decade". This session is aimed at discussing new progress in lunar science from recent missions, latest science results, newer insight into our understanding of Moon, modelling and synthesis of different scientific data, future missions, and science questions. It will include inv ited, contributed, and poster papers. Papers on new lunar mission concepts, instrumentation for the future missions, the upcoming lunar decade of landers and lunar robotic village, and preparations for human lunar exploration are also welcome in this session. COSPAR-18-B3.1 will also be ICEUM13A, part of the 13th International Conference on Exploration and Utilisation of the Moon from the ILEWG ICEUM series started in 1994.

The chemical analysis of lunar samples collected in the regolith or rocks is of primary importance to assess their content in volatile species. These volatiles could reveal, for instance, part of the nature of: materials delivered to Earth from exogenous sources, minerals present in the Lunar regolith and surface rocks, and Lunar indigenous organic material. These are key information to improve our knowledge on the origin and evolution of the Moon, but also on important processes for the prebiotic chemistry that took place on Earth. Even if the accuracy and sensitivity of the analytical instrumentation used in the laboratory are very high to characterise the chemical content of samples brought from the Moon, the journey of these samples in space, as well as their transportation to the Earth environment, could change the nature in the volatile content of the samples (e.g. loss of chemical species, possible chemical reactions or contaminations). For these reasons, in situ chemical analysis, in addition to provide direct information on the chemical composition of the Lunar regolith, could be of precious help for the interpreting the results obtained in the laboratory, and their transposition to the Moon surface environment. This is the reason why our team proposes an instrumentation to characterize in situ the content of volatiles in the lunar soil and rocks. This instrumentation is part of the Luna Resurs payload. This space probe should land near the lunar South pole, thus giving for the first time the opportunity to characterise this region which is thought to be rich in volatiles from remote sensing, whereas the previous lunar missions were all constrained to land near the equator. Our instrumentation is based on pyrolysis coupled with gas chromatography and mass spectrometry. It has the capability to: extract volatile materials (either condensed or present in the minerals) from the solid samples; separate the volatile and analyze their structure for identification and quantification; and analyze isotopic ratios in a certain extent. With this aim, the instrument is composed of: i. a pyrolyser capable to heat the samples up to about 1000°C; ii. a gas chromatograph devoted to separate and detect the volatile species released from the samples. The chromatograph includes two analytical channels, one devoted to separate the noble gases and the most volatile molecules, and one devoted to analyse very volatile organic molecules;

iii. a time of flight mass spectrometer for the structural identification of the molecules. This instrumentation should allow the identification of inorganic volatile molecules and small organic molecules (up to about benzene). This communication aims at presenting this instrumentation of the Luna Resurs space probe, and results obtained from calibration of individual parts and qualification model that give an overview of the analytical performances of this instrument.

B3.1-0038-18 LUNAR ICE LOCATION EXPLORATION

The main objective is to show a detailed trade study on the potential water deposit locations for future exploration missions. Large quantities of resources are required to enable any crewed exploration missions to successfully explore and live away from earth. The basic need of any crewed mission is water, and the idea of extracted it from celestial bodies or utilization of water from in-situ locations could potentially increase the performance and reduce the cost of exploration missions is highly considered today. Also, water is a combination of Hydrogen and oxygen molecules which can be further used to serve as propellants for the propulsion system. NASA plans to establish systems in the cis-lunar space, therefore Moon is an excellent potential location for the collection of in-situ resources. Several Lunar probes such as INDIA's Chandrayaan, NASA's Lunar Prospector, Japan's Kaguya have shown evidence of water on the lunar surface.Water is likely to be in the deep impact craters and polar regions.

This paper investigates the locations of the highest concentration of water, comparison of these target locations for future missions, and a brief discussion on solar heating's impact on these locations. After analyzing all the requirements necessary for the water exploration landing site such as zone of direct radio communication, density of water ice, Circular Polarization Ratios from the Mini SAR observations, degree of illumination and many other factors, our research concludes that The Peary Crater (88.5°N, 30°E) located in the Northern Polar Region is the best suitable location for finding water on the moon. The crater floor of peary is permanently a shadowed region(northern rim of Peary crater, Peary B and Peary W experience permanent shadow, as cold as -248°C) whereas it also has areas along its rim that are permanently illuminated by the Sun that can be further used as a crucial solar energy source for the exploration rover. Peary is a location in constant sunlight still near the suspected stores of water ice.

B3.1-0039-18 POSSIBLE LANDING SITES NEAR THE NORTH POLE OF THE MOON

Ekaterina Feoktistova, hrulis@yandex.ru

Sternberg Astronomical Institute Lomonosov Moskow State University, Moscow, Russia Svetlana Pugacheva, sve-pugacheva@yandex.ru

Moscow State University, Sternberg Astronomical Institute, Moscow, Russia Vladislav Shevchenko, vladislav_shevch@mail.ru

Sternberg Astronomical Institute Lomonosov Moskow State University, Moscow, Russia

Currently, a number of areas in the southern polar region of the Moon have been selected as the proposed landing sites for the future mission of the Luna-25. When choosing potential landing sites, one of the criteria was the enhanced abundance of hydrogen at a given location. The enhanced abundance of hydrogen in the polar regions of the Moon is generally attributed to the presence in these regions of deposits of volatile compounds, in particular water ice. Also, the proposed landing sites must meet certain criteria: 1. the dimensions of the landing ellipse should be 15 × 30 km, with the semi-major axis of this ellipse should be located in the direction of the meridian. 2. the surface slopes at the landing site must not exceed 7º. 3. illumination at the landing sites should be maximum. The increased hydrogen content in the regolith in the northern polar region of the Moon was detected by the neutron spectrometer of the probe Lunar Prospector (LP). More accurate information about this phenomenon was obtained by the LRO probe. According to the data of the neutron spec-trometer LEND onboard LRO probe in the region of the north pole of the Moon, three regions are distin-guished in which the hydrogen content is signifi-cantly higher than in the surrounding terrain. These areas are located near the craters of Peary, Nansen F and Rozhdestvenskiy U. Siegler et al., (2016) analyzed in their work the features of the motion of the Moon and showed that more than 3 billion years ago the north pole of the Moon was located in the crater of the Rozhdestvenskiy U (84,9° N, 152° E). During this period, the south pole was located in the r of Kabeo crater (85,5 ° S, 45 ° W), where sig-nificant deposits of a number of volatile compounds were discovered. So, it can be expected that the excess hydrogen found in this region can be associ-ated with the deposition of volatile compounds. simi-lar to those found in the southern polar region. In this paper, we have studied the area of the Rozhdestvensky U crater in order to search for pos-sible landing sites for future lunar missions in the area. We used the data of the DEM altimeter LOLA onboard LRO probe for the study of the relief in the area of Rozhdestvenskiy U crater. We calculated the slopes and aspects of the surface in a given re-gion using the method of. Using the obtained results, we investigated the illumination conditions and the thermal regime on the surface and in the sub-surface layer of the regolith in this region. As a result, we have identified a number of areas that meet the criteria of landing sites.

B3.1-0040-18 MOON-SOLAR WIND INTERACTION AND CORRESPONDING WAVE PHENOMENA

Andrei Sadovski, asadovsk@rssi.ru

Space Research Institute (IKI), Russian Academy of Sciences, Moscow, Russia Alexander Skalsky, skalsky@iki.rssi.ru

Space Research Institute (IKI), Russian Academy of Sciences; Moscow Institute of Physics and Technology, Moscow, Russia

The latest observation revealed that the significant deflected proton fluxes exist over magnetic anomalies at lunar surface and these observations gave possibility to imply that the magnetic anomalies may act as magnetosphere-like obstacles (mini-magnetospheres). Such obstacles modify the upstream plasma and number of many models was developed to describe such formations. Also on the Wind spacecraft across the lunar wake number of different types of electric fluctuations were observed: langmuir waves, electrostatic modes above electron cyclotron frequency, whistlers. The investigations revealed emissions on plasma frequency and its first harmonic. Electron reflection at quasi-shock at leading edge of magnetic anomaly could drive the electric field oscillations. The generation mechanism is similar to that known for foreshock of planetary bow shock.In KAGUYA and Lunar Prospector missions the monochromatic whistlers near the Moon were observed as narrow band magnetic fluctuations with frequencies close to 1 Hz, and are mostly left-hand polarized in the spacecraft frame. We present the review of actual observations and different mechanisms of wave and magnetic disturbances generation in plasma environment around the Moon: in solar wind closely to the Moon, over the magnetic field anomalies at its surface, in the lunar wake and around its boundaries. The generating mechanisms, propagation and other characteristics of waves are presented. Particular attention is pointed on Electrostatic Solitary Waves (ESWs), monochromatic whistlers, large-amplitude monochromatic ULF waves and non-monochromatic whistler waves. However all these questions remain open and require further experimental confirmation as on the basis of already available data (the Kaguya and Chandrayaan missions) and data to be obtained in advanced scientific projects of the Moon's exploration (the project LunaResursOrbitalInyapparat).

B3.1-0041-18 RESTORED APOLLO MAGNETIC FIELD RECORDS

Peter Chi, pchi@igpp.ucla.edu

University of California, Los Angeles, Los Angeles, California, United States

Between 1969 and 1975, several Apollo missions measured the magnetic field at the Moon either on the lunar surface by the Apollo Lunar Surface Experiment Packages (Apollos 12, 15, and 16) or at low altitudes by orbiting sub-satellites (Apollos 15 and 16). As of today, these data still represent the only joint surface-space magnetic field observations in the lunar environment. For decades, Apollo's magnetic field data were stored on magnetic tapes in an obsolete data format. An effort has been made in recent years to restore these precious digital records. This poster summarizes the data restoration efforts to date and the new findings based on the restored Apollo magnetic field data.

B3.1-0042-18 A NEW POLAR COORDINATE EXPRESSION FOR MOON-BASED EARTH OBSERVATION IMAGES

Lu Zhang, zhanglu@radi.ac.cn

Institute of Remote Sensing and Digital Earth, Chinese Academy of Sciences, Beijing, China Guang Liu, liuguang@radi.ac.cn

Institute of Remote Sensing and Digital Earth, Chinese Academy of Sciences, Beijing, China

The moon, as the unique natural satellite of the earth, is an ideal earth observation platform for obtaining consistent and continuous global-scale earth observation images compared with observation from artificial satellites. As a result, the Moon-based earth observation (MEO) already has aroused many scholar's interests for its advantages in observing the large-scale geoscience phenomena chronically and continuously. However, it is difficult to build the coordinate mapping relationship between the MEO images coordinates and the geographical coordinates directly, due to the change ranges of sublunar point caused by variation relationship of the moon and the earth, the geometric distortion of MEO images caused by curvature of the earth, and so on.

In this paper, a polar coordinate expression (ρ,ϑ) on the projection surface related to the sublunar point is designed and used to express the MEO large scale hemisphere image, that is applied as a mid-coordinate between the original image coordinate and geographical coordinate. The MEO image with polar coordinate expression on the projection is similar to original acquiring image and it is easy to register them with less information lost and geometric deformation. In addition, an analytical relationship can be built easily between the proposed polar coordinate and the geographical coordinate. Therefore, the polar coordinate expression for MEO images can effectively deal with the geometric deformation caused by the varying sublunary point and the earth curvature, and improve the geometric correction accuracy.

The remote X-ray Fluorescence spectroscopy is a powerful technique to investigate the elemental abundances in the atmosphere-less planetary bodies. The experiment involves measuring spectra of fluorescent X-rays from lunar surface using a low energy X-ray detector onboard an orbiting satellite. Since the flux of fluorescent X-ray lines critically depend on the flux and spectrum of the incident solar X-rays, it is essential to have simultaneous and accurate measurement of X-ray from both planet and Sun. In the context of moon, this technique has been employed since early days of space exploration to determine elemental composition of lunar surface, however the elemental abundance measurements are available for only 15 % area of the lunar surface. Hence, it is planned to continue the remote X-ray fluorescence spectroscopy experiment on-board Chandrayaan-2 which includes both lunar X-ray observations and solar X-ray observations as two separate payloads. The lunar X-ray observations will be carried out by Chandra Large Area Soft x-ray Spectrometer (CLASS) experiment; whereas the solar X-ray observations will be carried out by a separate payload, Solar X-ray Monitor (abbreviated as XSM). The XSM will provide high energy resolution (3% @ 5.9 keV) and high cadence (at every second) measurement of the solar X-ray spectra, which will also be greatly helpful for independent solar studies. The Flight Model (FM) of the XSM payload has been completed and tested for various instrument parameters. The design details and the performance of the XSM instrument will be presented in the conference.

B3.1-0044-18 LUNAR CORE EFFECTS ON LOW-ALTITUDE MAGNETIC FIELD

Peter Chi, pchi@igpp.ucla.edu

University of California, Los Angeles, Los Angeles, California, United States

Magnetic sounding of the lunar interior can be carried out in at least two different ways. A popular approach is to measure the transfer function, which compares the magnetic field fluctuations on the lunar surface with those from external sources. An alternative approach is to use low-altitude magnetic field measurements to detect the induced magnetic moment due to a conducting core. The second approach requires only spacecraft measurements and has successfully been applied to the data from Apollo subsatellites, Lunar Prospector, and Kaguya for estimating the size of the lunar core.

This paper considers both theoretical and measurement aspects of the second approach of magnetic sounding. We perform 3-D finite-element calculations of the magnetic field, including the crustal magnetic fields and the core effects, to examine expected magnetic field at low altitudes. We also examine the feasibility of using ARTEMIS magnetic field measurements in the Earth's magnetotail to estimate the magnetic moment induced by the core. Since the start of its lunar orbit in 2011, ARTEMIS has been making many low-altitude passes to tens of km from the lunar surface, where the induced magnetic moment is observable. We find that measurements from the more distant probe can represent the external fluctuations, reducing the uncertainty in measuring the core-induced magnetic field at the close approach by the second probe.

B3.1-0045-18 SUBLIMATION RATE OF VOLATILES IN PURE AND MIXED ICES

Edith Fayolle, edith.c.fayolle@jpl.nasa.gov

NASA Jet Propulsion Lab / California Institute of Technology, Pasadena, California, United States

Volatile molecules are found in ices on Solar System bodies. For example, H2O, H2S, NH3, CO2, or CH4 have been detected and quantified in the Cabeus crater on the moon by LCROSS [1]. Some super-volatiles have even been detected, despite lukewarm surface temperatures at which they should not be in the condensed phase if they were pure. Current surface models that employ sublimation rate inputs to predict ice composition do not account for the existence of entrapment mechanisms by the more abundant water molecules [2]. Moreover, most sublimation rates applied to surfaces at cryogenic temperatures encountered in the Solar System are extrapolations based on vapor pressure measurements performed at higher temperatures.

Here we present measurements of the H2O and CO2 sublimation rates at cryogenic temperatures for pure ices and preliminary results for CO2 mixed with H2O. These measurements have been obtained by depositing ice films onto a gold coated electrode of a quartz crystal microbalance cooled at low temperature (T 10K) under ultra high vacuum. The ice is further warmed up and the rate at which molecules sublimate is measured by the microbalance for various temperatures. A mass spectrometer is employed in the case of mixtures to decompose the microbalance ice loss rates into species specific components.

Small temperature shifts due to phase changes are observed for pure ice sublimation (e.g. for amorphous vs crystalline H2O ice), which emphasizes the impact of the ice structure onto its thermodynamical parameters. In the case of volatiles mixed with H2O ice, a fraction of the volatiles stays trapped at high temperature until the H2O matrix desorbs. Preliminary results on entrapment parameterization as a function of the mixing ratio is presented. Such parameterization could be included in models to contribute to a better ice composition prediction as a function of surface temperature.

B3.1-0046-18 RELATIVE DYNAMICS IN NON-KEPLERIAN ORBITS FOR PROXIMITY OPERATIONS AT CISLUNAR OUTPOST

Michèle Roberta Lavagna, michelle.lavagna@polimi.it Politecnico di Milano, Milano, Italy

Andrea Colagrossi, andrea.colagrossi@polimi.it Politecnico di Milano, Milano, Italy

Lorenzo Bucci, lorenzo.bucci@polimi.it Politecnico di Milano, Milano, Italy

The near future sees a strong cislunar environment exploitation as a key element to develop and test several new enabling technologies to support more challenging science and exploration missions and the human presence beyond Earth. .The realisation of these forthcoming space programmes entails setting up space infrastructures in lunar vicinity, to be exploited as outposts for different manned and robotic activities. Moreover, risk mitigation, safety and robustness maximisation ask for a gradual robotized construction of those gateways to be ready to host the human presence. This milestone of near future future space roadmap opens interesting and multidisciplinary challenges from a space system engineering perspective. The knowledge of the spacecraft dynamics in cislunar space is well known thanks to studies about restricted Three-Body Problem (R3BP), which became relevant for engineering applications with the development of numerical computing capabilities. However, these studies are often focused on point mass dynamics and applied to find low-energy transfers between different locations in space. The paper presents results of the 6DOF spacecraft dynamics investigation in cislunar environment, with particular attention to the relative dynamics between approaching spacecrafts moving on non-Keplerian orbits; such dynamics understanding and precise modelling is fundamental to practically support forthcoming autonomous rendezvous and proximity operations for on orbit assembly in outer space. High-level 6DOF GNC strategies shall be settled, based on high fidelity dynamics modelling. The relative dynamics based on a Circular Restricted Three-Body Problem (CR3BP), on an Elliptic Restricted Three-Body Problem (ER3BP) and on a full Ephemeris model, including the presence of the Sun are critically compared to show the need for a high fidelity modelling whenever dealing with the relative guidance design in such domains. In particular, attention is focused on finding whether non-Keplerian orbits branches exist on which simplified models may still be valuable with respect to the accurate dynamical model. Sensitivity analyses are carried out to understand the effects that the features of the different modelling approaches separately have on the relative dynamics (e.g. influence of the Sun, influence of the eccentricity of the Earth-Moon orbit, influence of the out-of-plane force components). Analyses are presented according to the non-Keplerian orbits classes evaluated as the most suitable for a cislunar space station location: NRHO, Halo and DRO. Finally, the best modelling approach to study relative dynamics in cislunar space is highlighted and use case scenario is discussed.

Evidence of discoveries involved with lunar water (e.g., polar ice and OH−/H2O) have been observed in recent years. The dynamic H2O loss and rehydration cycle over a lunar day

indicated solar wind hydrogen should be an important source of lunar surface water. In this study, we investigate the influence of the Earth's magnetosphere in the formation of the lunar surface hydration. Based on Moon Mineralogy Mapper (M3) data onboard Chandrayaan-1, we perform a statistical study of the lunar hydration distribution at high latitude regions. The lunar surface OH−/H2O abundance increases with latitude toward the polar regions, which is consistent with previous studies. When the Moon entry into the Earth's magnetosphere, the lunar surface hydration can also be formed and the magnitudes are of the same order inside/outside magnetotail. We will discuss the physical mechanism in this work.

B3.1-0048-18 STRUCTURAL MEMBERS PRODUCED FROM UNREFINED LUNAR REGOLITH SIMULANT

Stephen Indyk, sjindyk@honeybeerobotics.com

Honeybee Robotics, Washington, District of Columbia, United States Haym Benaroya, benaroya@soe.rutgers.edu

New Jersey, United States

Introduction: The potential of utilizing lunar rego-lith as the raw material for manufacturing structural members is very appealing for future exploration of the Moon [1,2]. Future lunar missions will depend on in-situ resource utilization (ISRU) for structural components. Manufacturing structural components directly from unrefined lunar regolith would have the advantage of needing less specialized material processing equipment in comparison with refining the lunar regolith for its raw elements. Sintering lunar regolith has been proposed as a structural material by previous researchers but has not been evaluated for its elastic material properties. Sintering can be a highly variable process and only with the material constants can a structure be designed from this material.

Background: Sintering of actual lunar regolith has been accomplished by Taylor and Meek using mi-crowaves. However, there is not enough lunar regolith available for destructive testing to accurately quantify the mechanical material properties of sintered regolith. Lunar simulant substituted for lunar regolith in exper-iments then becomes the commonplace. The lunar simulant JSC-1A has become the standard for re-searchers in the topic of structural ISRU. Through a geothermic reaction produced by the inclusion of addi-tives, JSC-1A has been used to fabricate bricks for constructing a voissoir dome as performed by Faierson et al. [4]. In addition, Balla et. al. [5] has utilized JSC-1A, filtered for particle size, as the base material in a selective laser sintering (SLS) machine to prove the simulants additive manufacturing potential. As a proof of concept, fabrication of small solid cylinders was performed and the parameters for the SLS machine were evaluated. Focusing on developing an optimal method of sintering lunar simulant, Allen, et al. [6] compared the fabrication of bricks with two unrefined simulants, JSC-1and MLS-1.

Test Results and Data Analysis: Two batches of sintered lunar regolith simulant, JSC-1A samples with porosities 1.44% and 11.78% underwent compression testing. Analysis of the data sets were evaluated based on the comparative material density. Compressive strength compared to the shows two clear classes of material quality. The average compressive strengths of the 1.44% porosity material were 219 MPa, and 85 MPa for the 11.78% porosity material. Material properties were evaluated from the load vs. deflection data acquired. Stress, strain, modulus of elasticity, toughness, the compression strength, bulk modulus. By comparing these values with other ISRU derived structural mate-rials, sintered lunar regolith is expected to be one of the strongest material derived from lunar sources.

Russian Lunar orbiter mission Luna-26 (Luna-Resource-1 Orbiter) will have onboard 160 kg of science instrumentation to probe lunar surface and subsurface with radio waves, infrared, neutron and gamma ray emissions as well as exosphere, with UV remote sensing and full-set in-situ plasma package. The core experiment is lunar stereo-camera, which will provide images with 3-6 m resolution. The orbit scenario includes one year with near-circular orbit 60-80 km and later, which requires periodic correction maneuvers and later more permanent orbit with initial height of 140 km.Expected launch date is 2022. We present information on instrument package and mission planning

B3.1-0050-18 THE MOON ANTIPARTICLE ASTROPHYSICS STUDY

Sergey Voronov, savoronov@mephi.ru

National Research Nuclear University "MEPhI", Moscow, Russia

The study of cosmic ray antiparticle fluxes and the search for antimatter in space as well as the question of the nature of "dark" matter is today one of the highest priority tasks of astrophysics which will undoubtedly continue to be actual for the next decades. In the PAMELA and AMS02 satellite experiments the energy spectra of positrons and antiprotons were measured and the upper limits of the existence of antihelium nuclei were found. However these experiments have already reached the limit on particle energy measurement. To continue the search and study of antimatter in the Universe instruments with a large aperture (also mass) and a long observation time (more than 10 years) are required. The main part of such type instrument is superconducting magnet requiring rather low temperatures. Detectors of AMC-02 and PAMELA type could be installed on the Moon. They could have a much larger aperture and a superconducting magnet at the base part of spectrometer. They will measure antiparticle fluxes up to extremely high energies with unprecedented statistics. Measurements on the Moon have a number of indisputable advantages. Small magnetic field of Moon magnetosphere and the absence of the atmosphere allow to simplify obtaining of the scientific results. The experimental setup can use large area detectors. The constant temperature at a depth of 1 meter under the surface is about -35°C that helps to cool the superconducting magnet. Furthermore there are craters (including at the south pole) where the temperature is constant -150°C and even -240°C. In this case the possibility of maintenance since long-term measurements and replacement of the failed unit of the scientific instrumentation could be preview.

Choices made today, decides our tomorrow. When human are cursive to become multi-planetary species, the exploration of the planets with proper resources are crucial. The paper deals with study of available technology ready to use for the space mission to determine the quantity and mapping of one of very fundamental need for human survival, i.e. water on various planets and moon. The study deals with the selection of the available technology and instruments, on basis of efficiency, power required and cost-effectiveness. The paper also deals with the study and implementation of the instruments used in various space mission like Gamma ray Spectrometer which was used in Lunar Prospector and ODESSY mission and its trade study with neutron spectrometer and LCROSS on the basis of the power, size and efficiency ratios. Devolving an algorithm of mapping of the planet in terms of the water density. Hence determining the locations of the rich hydrogen and water content which can be a potential site of water and hydrogen extraction. The design of the equipment discussed in paper is based on the moon but could be implemented on any planet with minimal changes. The paper is an eye opener for the establishment of the humans on the different planets. It discusses about the equipment which can detect the water from the maximum altitude of 100kms above lunar surface. It demonstrate the difference of the different mapping that can be done using different equipment and hence help to select the best suitable and efficient equipment.

B3.1-0052-18 MOON GALLERY: AN EDUCATIONAL PROGRAM TO BUILD STRATEGIES FOR IMPLEMENTING AN INTERNATIONAL ART GALLERY ON THE MOON.

Alexander Zaklynsky, azaklynsky@gmail.com Netherlands

Bernard H. Foing, bernard.foing@esa.int ESA/ESTEC, Noordwijk, Netherlands Anna Sitnikova, annesitnikova@gmail.com studio anna sitnikova, The Hague, Netherlands

Introduction - A short History of Art on the Moon:

The Moon Museum is a small ceramic wafer three-quarters of an inch by half an inch in size. The artists with works in the "museum" are Robert Rauschenberg, David Novros, John Chamberlain, Claes Oldenburg, Forrest Myers and Andy Warhol.

https://en.wikipedia.org/wiki/Moon_M useum

Fallen Astronaut: 8.5 cm aluminium sculpture by Paul Van Hoeydonck.

https://en.wikipedia.org/wiki/Fallen_Astronaut

A Gallery on the Moon project: Concept:

An international collaborative art work and Moon village promotion structure.

A crowd sourced online gallery of images created by an international group of participants.

A 10 by 10 cm patch of Lunar Rover exterior paneling is one intended venue for this Gallery.

A robust online presence, promotion structure and dissemination of information/teaching materials related to the program along with the potential of realising an art work on the moon.

Format:

A 10 x 10 cm square can be split into 100 cels of 1 cm x 1 cm. It can be split into even more equal sizes down to the pixel. A hi definition 10 x 10 cm printed image could have 1000 x 1000 pixels. That is 1 million pixels. The current initiative is to define and develop the aesthetic approach to this structure.

Digital Format:

Through an online interactive web platform individuals could input their designs into the grid.

Over a set time period and with multiple submissions from the public a variation of designs could be collected into an archive representing a broad spectrum of aesthetic approaches to a set of guidelines

Project outline/structure:

1] Research, concept development, collection of informative materials.

2] Design Implementation of website international call for artistic proposals/submissions. 3] Selection Process of submitted works and management of aesthetic organism online.

4] Potential implementation of gallery on the moon via ESA lunar rover or other craft destined for the moon.

Project Abstract:

The Moon Gallery is a proposal for defining and promoting the evolution of an aesthetic organism. The three main components of this project are research, collaboration and archive. The Research component is directed toward the development of context, informative materials and structure for the promotion of a call for artistic submissions. The Collaboration component is the implementation of the online creative tool and website designed for collecting submissions and showing a realtime evolution of the 'aesthetic organism'. The Archive component is both the dissemination of an online resource of images and artist proposals along with a possibly random selection of proposals fabricated into an actual material installation on the moon surface in the 10 x 10 cm grid format. What is an 'aesthetic organism'. A petri dish is good for growing bacteria cultures while a website is good at growing visual cultures. The 10 cm x 10 cm grid structure along with an online signup and submit image structure could develop a large amount of submissions over time with good promotion. Each section of the grid relates to both the biological concept of cells and the understanding of perspective. As the grid is filled with more and more input / imagery, the more it evolves. Over time an expanding stack of grids will create a 3d space of aesthetic intentions. What can we find out by such a construction of content. What is there to gain from studying the outcomes of such a visual social experiment? At the very least the intention of this endeavour is to raise awareness and interest in space and the moon village project along with attempting to develop a program which can have the potential to inspire new explorers of the imagination, perspective and space through a collaborative, interactive and evolving web project.

Additional Information - Current progress:

This Initiative of implementing a strategy for an International Art Gallery on the Moon is in a preliminary phase of sketching out ideas and methods while building a resource of information and developing a platform on the web for an international call to participate. In February 2018 Sitnikova and Zaklynsky have participated in meetings at Estec with MoonVillage Colleagues and have begun preparations for collaborations.

Sitnikova and Zaklynsky have initiated the residency with the MoonVillage project at Estec and will be working at Estec on a weekly basis for the next 6 months to year. We have tentatively scheduled presentations at The Royal Academy of Art and Willem De Konig Academy to engage younger artists into the project. We are in Planning stage for developing a series of presentations and Lectures at Pulchri Studio in Den Haag from May 19 to June 12, 2018. The Moon Gallery Project has been accepted into the 6th European Lunar Symposium in Toulouse, France. We have also begun a collaboration with the EuroMoonMars Team to develop a test launch of the general moon gallery project and to explore its physical implementation and interaction with moon villagers.

Connected to the research and conceptual development of this initiative we are producing a series of large scale 2 x 2 m paintings which utilise custom built drawing machines. These paintings will show a study of the grid format mentioned previously in various abstractions. We will also use these machines to plot the paths of satellites around the earth with via a collaboration with computer programmers at Estec. An Exhibition of this work along with a presentation on the initiatives development will be presented at Pulchri Studio in Den Haag on the 19th of May and run until June 12th, 2018. - http://pulchri.nl/

Launch Your Design With Cheops - ArtScience@ESA. http://blogs.esa.int/artscience/2017/11/02/launch-your-design-with-cheops/ Visual Material:

The below images and art work show an evolution in concepts of perspective and space. The invention of techniques to aid in the accurate reproduction of our landscape and environment led to philosophical advancements in concepts of our aesthetic and spiritual nature on one hand while on the other it led to the ability of our species to infer a map of the observable universe we exist in. Our perspective has taken us from the terrestrial to the celestial while solidifying the understanding of our place in between. The images aim to illustrate the evolution of our human perspective and our capacity for the exploration of the space within and around us.

Brunelleschi's mirror. Filippo Brunelleschi was one of the founding fathers of the Renaissance and is generally known for developing this technique for linear perspective in art.

Institute of Remote Sensing and Digital Earth, Chinese Academy of Sciences, Beijing, China

Currently most developing platforms are satellite, in contrast carry out systematic observations with moon based Earth observation platform is still a new concept. The Moon is the biggest satellite of our planet Earth, and it is the only natural satellite of the Earth, moreover it is the only place other than Earth, where humans could arrive and have arrived. Prior exploration mission orbiting or passing or landing the moon has showed the feasibility to observe the earth from the moon. Earth observation from the moon will give people different perspectives when observe the earth with sensors from the moon.

This research will discuss key issues of observation geometry of the moon-based sensor. We first designed a coordination system transformation conception from fixed seleno-centric coordinate systems to terrestrial coordinate systems, where the position, liberation and attitude of earth and moon will be obtained, and the position of the moon-base sensors is obtained by coordinate transformation. Based on these the main frame of the lunar based earth observation geometry simulation system is realized, and with the simulation system we analyzed the geometric features, overall coverage, and ground observation angle and observation time. We found that the on the moon the complete observation area (80 degrees north and south latitude, east longitude 80 degrees between the earth) have optimal space coverage, the earth target time coverage, angle of coverage; high latitudes of earth observation in this interval can be as much as possible to reduce the influence of pointing error. The aberration caused by the motion of the moon cannot be ignored. But the quadratic term of the aberration is one percent of the first item. The influence of the additional aberration caused by the relativistic effect is 10 of the negative eight power. It can be neglected in the application of lunar base to earth observation.

B3.1-0054-18 LINEAR AND NON-LINEAR WAVES NEAR THE SURFACE OF THE MOON

Tatiana Morozova, timoroz@yandex.ru

Space Research Institute (IKI), Russian Academy of Sciences, Moscow, Russia Sergey Popel, popel@iki.rssi.ru

Space Research Institute of RAS, Moscow, Russia Sergey Kopnin, serg_kopnin@mail.ru

Space Research Institute (IKI), Russian Academy of Sciences, Moscow, Russia

Linear and nonlinear waves in a dusty plasma over the lunar dayside are considered. It is shown that the relative motion of the solar wind with respect to the photoelectrons over the lunar surface leads to the excitation of high-frequency oscillations with frequencies in the range of Langmuir and electromagnetic waves. The dust acoustic wave excitation is possible in the vicinity of the lunar terminator. The parameters of the dust acoustic solitons in the dependence on the height over the lunar surface are determined. Solutions in the form of dust acoustic (DA) solitons corresponding to the parameters of the lunar dusty plasma system have been found [1]. In [1, 2] adiabatic trapping of electrons when considering the solitons has not been taken into account. However, DIA localized wave structures (in particular, solitons) can be accompanied by either positive or negative electrostatic potential, the positive being the potential well for electrons. The localized wave structure properties with taking into account the influence of the effect of adiabatic trapping are determined.

This work was supported in part by the Presidium of the Russian Academy of Sciences under Fundamental Research Program no. 28 (“Space: Research of Fundamental Processes and Their Interrelations”) as well as by the Russian Foundation for Basic Research (project no. 18-32- 00037).

B3.1-0055-18 LOW-HYBRID WAVE TURBULENCE IN THE INTERACTION REGION OF THE EARTH'S MAGNETOTAIL WITH DUSTY PLASMA NEAR THE MOON

Tatiana Morozova, timoroz@yandex.ru

Space Research Institute (IKI), Russian Academy of Sciences, Moscow, Russia Sergey Popel, popel@iki.rssi.ru

Space Research Institute of RAS, Moscow, Russia Yulia Izvekova, besedina_yn@mail.ru

Space Research Institute of RAS, Moscow, Russia

The lower-hybrid wave turbulence that take place under the interaction of the Earth's magnetosphere with dusty plasma near the lunar surface is considered. It is shown that the lower-hybrid waves can be excited due to the onset of linear hydrodynamic instability, which is caused by the relative motion of the magnetosphere and charged dust grains. The dynamics of the development of lower-hybrid wave turbulence is investigated. It is described in terms of strong turbulence theory, where the modulational interaction is important. The energy density of oscillations, the effective collision frequency, and the electric fields arising in the system are determined for lower-hybrid wave turbulence. The obtained effective collision frequency should be taken into consideration when deriving hydrodynamic equations for dusty plasma particles with allowance for turbulent plasma heating.

This work was supported in part by the Presidium of the Russian Academy of Sciences under Fundamental Research Program no. 28 ("Space: Research of Fundamental Processes and Their Interrelations") as well as by the Russian Foundation for Basic Research (project no. 18-32- 00037).

The Active Particle-induced X-ray Spectrometer (APXS) is one of the payloads on board the Yutu rover of Chang'E-3 mission. During the operation on the Moon, two in-situ measurements of the lunar regolith were conducted in the northern (19.51W, 44.12N) of Mare Imbrium.The abundance of major (Mg, Al, Si, K, Ca, Ti, Fe) and mirror (S, Cr, Sr, Y, Zr, Nb) element was achieved using the fundamental parameter method based on ground calibration of geochemistry reference samples. The results show that the regolith around the landing site contains abundant Fe, medium Ti and relatively high Al.

University of Petroleum & Energy Studies, 248007, India

The Human race is on it hastens to be a multi-planetary species and the primary destination would be the Moon for obvious reasons. While colonizing the Moon comes into the picture, many aspects have to be taken into account and the most important factor is the lunar dust. Studying the Lunar dust deals pivotal figure in finding a sustainable livelihood in the lunar surface. As of now, it is known that lunar dust is abrasive and clingy as well as it is the fine powder glass with magnetic behavior. These properties of lunar dust make it extremely hostile for life as well as dangerous for the life-supporting equipment because of clogging up. However, there are still some advantages such as the lunar soil can be easily microwaved into flat surfaces, meaning roads and landing/launching pads can easily be created for future missions. Therefore the main mission objective is to design, build and operate a dust analyzer package which mainly consists of two parts, a magnetometer, which will answer to the magnetic properties of the lunar dust, and a set of solar cells, which are used in determining how fast is the dust accumulation takes place in moon on a solar panel, by calculating the net current drop from the solar cells. The main reason for this experiment is that we need to get an idea about the possible effects of lunar dust in the future of energy production and the feasibility of electricity generation for a long-term from using solar power plants. Using the magnetic flux obtained reading we will develop a microwave sintering process that can be used for converting lunar dust into flat surfaces, which can be used to develop Infrastructure on the moon in future. Keywords: multi-planetary, lunar dust, magnetic, microwave, magnetometer, solar cells, energy, electricity, magnetic flux, microwave sintering, Infrastructure.

B3.1-0058-18 WATER MINING IN THE SPACE

Alexander V. Bagrov, abagrov@inasan.ru

Astronomical Institute of the Academy of Sciences, Moscow, Russia Vladislav Leonov, leonov@inasan.ru

Institute of Astronomy of the RAS, Moscow, Russia

Water appears the highly sought product in space. There is hope to find water ice under ever shadowed lunar polar regions. But even this hope will be proved, it does not mean that water mining on the Moon will be successful, because hardness of water ices at extremely low temperature is comparable with diamond hardness. As ever shadowed territories have lack of solar energy, the water mining on the Moon may become unreliable desire. At the same time our Solar System has a lot of water ice in its outer parts. All satellites of giant planets as well as all Kuiper Belt objects consist mainly of water ice. Comet nuclei contain water ice too, and they often have orbits with perihelion distance less then 1 a.u. Some of comets are on orbits that even cross the Earth orbit. Loosing volatiles and being decayed, they produce meteoroid streams. Among tiny refractory particles that burn in the Earth atmosphere when collide it, there are some larger fragments of dispersed parent comet nuclei. These “minicomets” blast in the Earth atmosphere from 10 to 20 times each year, so the total number of minicomets that cross Near-Earth space may be up to 40000 a year. If average diameter of minicomet poses to be 3 meters, it is about 15 m3 of snow or ices and contain at lest 10 ton of pure water. Earlier we proposed to use such mimicomets as kicking bodies to push away dangerous asteroids. It is not hard technical problem to deliver to a minicomet simple vapor rocket engine (“Gheron mahine”). This jet will use unlimited solar energy for heating of cometary material to high temperature an use it as propellant body. Just the same device may be used to capture minicomets in the vicinity of the Earth and to deliver them to Near-Earth orbits or even to the Moon surface. Rocket engines that use solar energy and material of captured bodies can be used many times in space. This allows water mining in space in any necessary amounts without supply from the Earth.

B3.1-0059-18 ORBIT DETERMINATION OF CE-5T1 IN EARTH-MOON L2 LIBRATION POINT ORBIT WITH GROUND TRACKING DATA

Yong Huang, yongh@shao.ac.cn

Shanghai Astronomical Observatory, Chinese Academy of Sciences, Shanghai, China Peijia Li, pjli@shao.ac.cn

Shanghai Astronomical Observatory, CAS, Shanghai, China Min Fan, fanmin@shao.ac.cn

Shanghai Astronomical Observatory, CAS, Shanghai, China

The CE-5T1 extended mission is the first of China to fly spacecraft in the Earth-Moon Lissajous regions. It stayed at the L2 region for about 40 days from Nov. 2017 to Jan. 2018

. The Shanghai Astronomical Observatory (SHAO) team utilizes the SODP (SHAO Orbit Determination Program), using a batch least squares method, to process range, Doppler and VLBI tracking measurements from ground stations. The tracking accuracy for range, Doppler, VLBI delay and rate are typically 1 m, 1 mm/s, 1 ns and 1 ps/s. The typical accuracies of orbit determination solutions are on the order of several hundred meters in position and 1 cm/s in velocity with 5-7 days tracking data. The combination of VLBI data with range/Doppler data can improve the orbit accuracy in the L2 region comparing with the range/Doppler data only. The technique and analysis method used can provide a baseline for future Earth-Moon libration point spacecraft mission, including CE-4 relay satellite in the L2 region.

B3.1-0060-18 PROTECTED ANTIPODE CIRCLE (PAC) ON THE MOON FARSIDE AND AWAY FROM THE MOON VILLAGE

Claudio Maccone, clmaccon@libero.it

International Academy of Astronautics, Torino, Italy

The Moon Farside is the only place in space, and not too far from the Earth, where radio transmissions and noises produced by Humanity on Earth may not reach since the spherical body of the Moon blocks them, acting like a shield. Thus, protecting the Moon Farside from all kinds of non-scientific future exploitations (e.g. real estate, industry and military) has long been a concern for many far-sighted space scientists as well as for several IAA Academicians.

We started facing this problem in the 1990s, when the French radio astronomer Jean Heidmann (1923-2000) of the Paris Meudon Observatory first promoted an IAA Cosmic Study about which areas of the Moon Farside should be reserved for scientific uses only. But Heidmann passed away on July 3, 2000, and his work had to be continued by others. This author took over his IAA Cosmic study and a paper describing both the scientific and legal aspects of the problem was published in 2008.

Later, on June 10, 2010, this author was the first scientist to present the case for the Moon Farside Protection at the United Nations Office of Outer Space Affairs in Vienna during a meeting of UN-COPUOS, the United Nations Committee on the Peaceful Uses of Outer Space. Unfortunately, the undeclared but quite real “current, new race to the Moon” complicates matters terribly. All the space-faring nations now keep their eyes on the Moon, and only the United Nations might have a sufficient authority to Protect the Farside and keep safe its unique “radio-noise free” environment.

But time is money, and the “Moon Settlers” may well reach the Moon before the United Nations come to agree about any official decision concerning the Farside Protection. Quite an urgent issue.

In this paper, we propose that the new “Moon Village” supported by the vision of the ESA Director General, Jan Woerner, be located outside the PAC (obviously not to interfere with the detection of radiation coming from space) but also south of the PAC, to be “close” to the South Pole as much as needed to benefit of water there.

It thus appears the best venue for the “Moon Village” would be on or around the 180 degree meridian and south to the -30 degree in latitude of the PAC, possibly much more south of that, almost at the South Pole, thus resolving Moon Village location issue.

B3.1-0061-18 GEOLOGICAL MAP OF LUNAR IMPACT BASINS

Jingwen Liu, liujw_gis@163.com

Institute of Geochemistry, Chinese Academy of Sciences, Guiyang, China Liu Jianzhong, liujianzhong@mail.gyig.ac.cn

Institute of Geochemistry, Chinese Academy of Sciences, Guiyang, China Lunar and Planetary Science Research Center, Institute of Geochemistry, CAS Li Zhang, Jin Ji, Juntao Wang

Abstract According to the requirements of 'Chinese 1:2.5 M Geologic Mapping of the Global Moon' project the whole impact basins were divided into five geological units which mainly identified by morphological characteristics and formation mechanism: central peak ring formation, basin rim formation, basin wall formation, basin floor formation, ejecta formation. It is much more normalized, unified and practical than others' work about mapping impact basins like some map in research articles and the American geological map in which every impact basin contains many geologic units with rock composition and geological age. Its attribute table contains basins' names, age, apparent diameter, apparent depth, each impact ring diameter, gravity anomaly, unit type, unit area. enditemize beginitemize

The whole lunar work was done in ArcGIS. Combining the formation theory of impact craters and interpretation results from LRO image, LOLA, M3 and IIM, the lunar impact crater whose diameter was greater than 200km and not have central peak was chosen as the impact basins. Then, 76 impact basins were interpreted out in our work. enditemize beginitemize

Key Words lunar impact basin; 200km; five geological units enditemize

Gregory Schmidt, gregory.k.schmidt@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States

The Solar System Exploration Research Virtual Institute (SSERVI) is a NASA research entity with scientific focus on celestial bodies of the Solar System that can be considered as intermediate steps in the roadmap for human exploration, namely the Moon, Near Earth Asteroids, the Martian moons Phobos and Deimos and their surrounding environments. The SSERVI central office is at NASA Ames Research Center and, as virtual institute, SSERVI funds investigators at a broad range of domestic institutions, bringing them together via virtual technology, along with international partners, that can be involved at different levels. In this frame, the "SSERVI Italian node" was established in September 2014, when the Istituto Nazionale di Fisica Nucleare (INFN) of the Italian Republic became an Affiliate partner, with the main research topic on retroreflectors for planetary exploration. The Italian partnership in SSERVI's international program evolved to the Associate level, when the NASA and Italian Space Agency (ASI) signed a dedicated Implementing Arrangement, during the Workshop held on 14th June 2017, at the Italian Embassy in Washington DC. Since then, ASI has taken the role of Italian Principal Investigator and coordinator of the national scientific community involved in Exploration scientific activities, with particular reference to the above mentioned target in the Solar System. The Associate Partnership has been based on the "Italian Proposal for the participation to the NASA SSERVI International Partners Program -Associate membership Application", issued by ASI in June 2016 and reviewed and accepted by NASA in the following months. The Proposal summarize the main research areas where the Italian scientific community, mainly composed by research institutes like INFN and Istituto Nazionale di Astrofisica (INAF) and national Universities, is active. This paper describes the premises and perspectives of the Italian partnership in the SSERVI International Program, based on common research interest, in order to promote joint scientific activities, in preparation of the collective challenge to bring humans to Lunar and Martian surfaces.

B3.1-0063-18 ORBIT DETERMINATION USING VARIOUS MEASUREMENTS FOR INTERPLANETARY MISSIONS

Peijia Li, pjli@shao.ac.cn

Shanghai Astronomical Observatory, CAS, Shanghai, China Yong Huang, yongh@shao.ac.cn

Shanghai Astronomical Observatory, Chinese Academy of Sciences, Shanghai, China Min Fan, fanmin@shao.ac.cn

Shanghai Astronomical Observatory, CAS, Shanghai, China

For the interplanetary navigation, the regime offers little dynamics thus requiring an extensive amount of time and tracking data to attain a solution. In order to increase the accuracy of the interplanetary orbit determination, it is necessary to use the S/C-based observations as well as the Earth-based data, such as the optical data taken by the onboard camera, the GNSS data and so on, which offered different information of the spacecraft (S/C) besides the line of sight direction. The results shown that the optical data taken by the onboard camera could improve the accuracy of the mars-transfer orbit determination by 1 magnitude. The measurement data of the GNSS receiver with high sensitivity on CE-5T1 spacecraft was also analyzed. The position error using GNSS single-difference pseudo range in the 1.5 hour arc is less than 109 m.

B3.1-0064-18 HOW TO IMPROVE THE QUALITY OF HXI IMAGING

Huang Yongyi, huangyy@pmo.ac.cn

Purple Mountain Observatory, Nanjing, China

The Hard X-ray Imager on board ASO-S(Advanced Space -based Solar observatory) is a fouriersynthesis-type imager for solar flare observations;it measures a set of spatially modulated photon counts with one hundred,idependent,bigrid modulation collimators and an image is reconstructed from these data using sophisticated image synthesis procedures,such as the Maximum Entropy Method(MEM) and PIXON.In order to ensure the quality of the image, we take measures from the following aspects: 1, Fully understand the impact of the shift between the top and the bottom grids through the simulation on the image and the corresponding correction effect; 2, Fully understand the impact of the twist between the top and the bottom grids through the simulation on the image and the corresponding correction effect ; 3, intends to use the MEM method to improve the quality of HXI on orbit data, The quality of HXI imaging can be guaranteed from the result of the simulation.

B3.1-0065-18 IS THE SPHEROIDAL APPROXIMATION OF THE MOON IMPORTANT FOR HIGH-RESOLUTION GLOBAL GRAVITATIONAL FIELD MODELLING?

Michal Sprlak, michal.sprlak@gmail.com

University of Newcastle, Australia, Callaghan, Australia Shin-Chan Han, shin-chan.han@newcastle.edu.au University of Newcastle, Australia, Callaghan, Australia Will Featherstone, w.featherstone@curtin.edu.au

Curtin University of Technology, Perth, Australia

Global gravitational field models for terrestrial planets and small bodies are usually developed in terms of a series of spherical harmonics. The corresponding expansions are strictly convergent only on or above the Brillouin sphere, i.e., the sphere enclosing all gravitating masses. However, when modelling gravitational fields of oblate or prolate planetary objects, the spheroidal approximation and the corresponding spheroidal harmonic expansion are more appropriate, particularly for high-degree gravitational models from Gravity Recovery And Interior Laboratory (GRAIL) and for precision navigation of satellites orbiting closely around the small bodies like OSIRIS-Rex. In this contribution, we consider a realistic spheroidal shape of the Moon and examine its consequences to the lunar global gravitational fields. The lunar Brillouin spheroid fits the shape of the Moon much better than the Brillouin sphere. In particular, the lunar Brillouin spheroid differs from the Brillouin sphere by 600 m at the poles, where improved gravitational models are expected from the spheroidal modelling and analysis. For the purposes of this study, we derive the spectral form of the Newton integral in the spheroidal approximation and develop an efficient computer algorithm for the global gravitational field modelling. Accuracy of the numerical algorithm is tested with known analytical solutions of the spheroidal gravitational potential. We next calculate spheroidal Bouguer gravity disturbances on the surface of the lunar Brillouin spheroid. The results are compared with those synthesised from spherical harmonics on the Brillouin sphere. The differences are investigated and quantified for different spectral bands and at different spatial regions to examine our new spheroidal gravitational models for the Moon.

B3.1-0066-18 MEMORANDUM IN OPPOSITION TO PROPOSAL TO WEAKEN THE MOON TREATY

Dennis O'Brien, dennisobrien@sharejerusalem.com

The Space Treaty Project, Ukiah, California, United States

Memorandum in Opposition to Proposal to Weaken the Moon Treaty (keywords: moon, treaty, law, commerce, chm)

by Dennis O'Brien The Space Treaty Project Abstract

In two recent articles in The Space Review, Vidvuds Beldavs of the University of Latvia argues that the Moon Treaty must be revised so that investors in a future space economy can achieve a sustainable return on their investments. Although creation of a sustainable economic model in outer space is essential for humanity's future there, his proposed revisions throw out the baby with the bathwater.

Mr. Beldavs' main concern, shared with many others, is that the declaration that outer space is the "common heritage of mankind" (CHM), made in both the Moon Treaty and the original Outer Space Treaty of 1967, precludes the establishment of property rights sufficient to establish and sustain a space economy

Mr. Beldavs' proposal:

"The moon and other cosmic bodies and their natural resources are the common heritage of mankind to explore and to use. While the moon is a subject of interest for mankind as whole this does imply that the moon and its resources are the property of mankind or that rents should be collected by an international authority for their use, which finds its expression in the provisions of this Agreement, in particular in paragraph 5 of this article." (change highlighted)

(Note: It appears that Mr. Beldavs intended to say, "this does not imply that the moon and its resources are the property of mankind or that rents should be collected. . ." Otherwise the paragraph and his entire argument do not make sense.)

The short answer to these concerns is that the international regime of laws will provide private enterprise the necessary legal rights and protections while ensuring that the benefits of commercialization are realized by all of humanity. But that legal structure and the agency that implements it must have the underlying legal and moral authority that the CHM and the Moon Treaty provide.

The real issue at this time is how such payments would be collected and distributed. A new agency, perhaps an Agency for International Development of Outer Space, could be created to receive such revenues and determine their best use, including distributing them to lessdeveloped countries. The structure, policies, and procedures of any such agency would need to be determined as part of the "international legal regime" created by

the parties to the action. But if the authority to collect revenues was specifically removed from the Treaty, then there would be no legal basis for such an agency and no incentive for the space-faring nations and companies to create a mechanism to share the economic benefits of space commerce with the rest of humanity. For all practical purposes, the Treaty would be dead.

Although some oppose such a regime of laws and regulations on a philosophical basis, most businesses want a legal regime that they can rely on to reduce the uncertainty that investors deplore.

The proposed solution is to allow the private ownership of property in outer space. But the right to economic benefits does not require private ownership. Such rights can be guaranteed by the leases, use permits, etc. provided by the international agency that is established by treaty. That is the kind of certainty that allows for rational economic decision-making.

Using the revenues created to assist developing countries is not just theoretical. It is already possible to fund a space mission that directly engages such countries. The United Nations recently announced an agreement with Sierra Nevada Corporation to use SNC's Dream Chaser reusable space plane to carry the experiments of dozens of countries to orbit and safely return them when their science is complete. Only the funding is needed, funding that could come from benefits of space commerce that other countries/companies are beginning to realize.

The weakening of the CHM in the Moon Treaty would destroy not only its legal authority for an international regime of laws, but also its moral authority to affect customary international law. Humanity would cede control of its own destiny to the unseen hand of economic forces and political power. This would be a far greater "loss of sovereignty" than any claimed by individual nations.

The proposed solution is not only harmful to humanity, but also to free enterprise. Businesses need the certainty that a legal regime provides to make rational economic decisions. Humanity needs the protections that a legal regime provides so that everyone will share the benefits realized from the exploration and use of outer space.

We are currently living in an age when war, violence, and neglect are weighing heavy on the human spirit. People are increasingly feeling out of control of their own lives and are losing hope for the future. Our mission, the mission of the Moon Treaty, is to restore that hope, to create that shining city on the hill that will light the way for all.

This is not the time to shy away from our responsibilities. There will be only one time when humanity leaves its home planet, one chance to establish a pattern that will ripple far into the future. Full implementation of the Moon Treaty will protect businesses, big and small, and will free up the creativity and innovation that have long been the hallmark of free enterprise. At the same time, it will ensure that all of humanity benefits from space exploration and commerce, that no one is left behind.

As Klaatu reminded us, the choice is ours.

B3.1-0067-18 HUNGARIAN TEAM PULI TOWARDS LUNAR SCIENCE AND EXPLORATION

Muhammad Shadab Khan, shadab_khan@msn.com IMT Mines Albi, Albi, France

Tibor Pacher, tibor.pacher@pulispace.com Puli Space Technologies, Budapest, Hungary

Moon, our nearest neighbor in space which ignited our efforts towards outer space exploration in the 1960s and that led to several manned and unmanned missions in quick span of time to explore it and search for the sources of life and environment on a outer space body, is presently again in the spotlight as we are preparing to go to Mars and beyond. It is believed that most likely before humans go to Mars, manned mission to Moon in the 21st century is most certain. Not only using Moon as a base camp or a stopover towards manned Mission to Mars but Moon has several mysteries hidden in it, which, if found and explored, can be utilized to help in establishing the human colonies on Moon. In this direction several organisations around the world are preparing towards future exploration of Moon using Landers, Rovers and Orbiter Missions. Puli Space Technologies is a Hungarian startup which was founded in the year 2010 to participate in the Google Lunar XPRIZE Competition. The GLXP's objective was to design, build and send a craft to Moon to take panoramic pictures of the Lunar surface and transmit it back to Earth. Team Puli developed a unique rover with its "whegs" (Pentagon shaped wheel+legs), designed in such a way that the whole Rover can flip 360 Degree and stand back to its normal position if the Rover is obstructed by any rock or similar object.The Puli Rover was succesfully tested in various field simulation missions in Morocco [1], Hawaii and Austria [2]. Puli Space Technologies continues its journey on to the Moon after the GLXP to become the first Hungarian organisation to reach to Moon

B3.1-0068-18 LUNAR LAVA TUBES: A POTENTIAL OPTION FOR FUTURE HUMAN HABITATION ON THE LUNAR SURFACE

Lucas Tombrowski, bookmuncher40@gmail.com Antarctic Institute of Canada, Calgary, Canada Austin Mardon, aamardon@yahoo.ca

Antarctic Institute of Canada, Edmonton, Canada

Introduction: For the past several years it has been suggested that the next manned mission to the Moon could make use of lunar lava tubes as habitable shelters and/or storage areas. The lava tubes on the moon would provide protection against cosmic radia-tion, micrometeriods, meteorites, and other natural hazards while also providing a habitable environment with relatively stable temperatures compared to the wildly fluctuating day/night temperatures on the Moon's surface.

Benefits: There are numerous potential benefits to building a manned lunar base inside a lava tube. Due to the more stable temperatures in the tube, space suits and base modules would not require as extensive of temperature regulation systems as on the surface of the moon. This would allow astronauts a greater de-gree of freedom of movement while inside the tube. Eliminating the need for bulky insulation also means a lunar base only requires pressurization, therefore im-proving the size and portability of base components (this is assuming that the risk of debris falling from the roof of the tube is negligible). The protection from cosmic radiation inside the tubes presents the possibil-ity of a long-term manned lunar mission without the need for as extensive of shielding from radiation. Lu-nar lava tubes may also provide the opportunity for mining operations and geological study from directly beneath the Moon's surface. Study of the tubes them-selves may provide clues as to how the Moon was formed.

Further Study: More information on the exact structure and location of lunar lava tubes is required. At the present moment, only observational evidence has been found to support the existence of lava tubes on the Moon. Unmanned missions using lunar rovers and/or probes must be conducted in advance of a manned mission in order to determine the suitability of a tube for human habitation. Research must also be conducted in order to determine safe and efficient methods of moving supplies, astronauts, and other equipment in and out of the tube. Due to a lower gravi-ty and absence of atmosphere, lunar lava tubes could be significantly larger than lava tubes on Earth.

Seismic Activity: The exact cause and intensity of seismic activity on the moon is currently unknown. Therefore, study on the seismology of the Moon must be conducted in order to measure the potential risk of a lava tube collapsing or debris falling from the ceiling of a tube. Methods for safely clearing the floor of a tube of debris, boulders, or other potential obstructions must also be looked into.

Power: Considering the scenario where the main base and living quarters are located inside of a lunar lava tube, options for power generation and storage would have to be examined. If the power is generated from outside the tube (e.g. solar panels), an appropriate power transfer system and backup system must be established inside the tube, or vice versa if power is generated inside the tube.

Conclusion: The usage of lunar lava tubes for human habitation and/or storage in future manned missions to the Moon is largely theoretical at this point in time. There are unquestionably great potential bene-fits to the concept, however a considerable amount of study and further unmanned missions to the Moon will be required before any conclusions regarding the via-bility of the tubes can be reached.

B3.1-0069-18 NEW CONSTRAINTS ON THE ESCAPE OF SODIUM AND POTASSIUM FROM THE MOON

Menelaos Sarantos, menelaos.sarantos-1@nasa.gov

Goddard Space Flight Center, Greenbelt, Maryland, United States Dona Kuruppuaratchi, kuruppud@my.erau.edu

Embry Riddle Aeronautical University, Daytona Beach, United States Edwin Mierkiewicz, mierkiee@erau.edu

Embry-Riddle Aeronautical University, Daytona Beach, United States

Recent measurements and models of the lunar alkali exosphere enable us to better understand the effect of the Sun on the escape of the Moon’s weak atmosphere. Sodium and potassium gases are important tracers of microphysical processes on the Moon because they can be easily observed from Earth as well as from lunar orbiters. Comparing exospheric transport models to recent high-resolution spectroscopic measurements from Earth, we may significantly constrain the velocity distribution of alkalis liberated from the lunar surface and the surface release processes. We find that a systematic increase in Doppler width towards full Moon phases is consistent with photon stimulated desorption with a high speed tail. Additionally, residual Doppler widths correlate to the solar wind flux measured by ARTEMIS, a finding that suggests non-negligible contributions by sputtering.

B3.1-0070-18 REGIONAL RECOVERY OF THE LUNAR GRAVITATIONAL FIELD BY INVERTING GRAIL LINE-OF-SIGHT GRAVITATION OBSERVABLES

Michal Sprlak, michal.sprlak@gmail.com

University of Newcastle, Australia, Callaghan, Australia Shin-Chan Han, shin-chan.han@newcastle.edu.au University of Newcastle, Australia, Callaghan, Australia Will Featherstone, w.featherstone@curtin.edu.au

Curtin University of Technology, Perth, Australia

The Gravity Recovery And Interior Laboratory (GRAIL) satellite mission mapped the global gravitational field of the Moon with unprecedented accuracy (several mGal) and resolution (12 km). The fundamental inter-satellite tracking data have been exploited for estimating various lunar global gravitational field models. However, such global models in terms of spherical harmonic coefficients make use of a constraint (also known as Kaula's rule). This may lead to undesirable smoothing over different regions. In this contribution, we discuss a new approach for high-resolution regional recovery of the lunar gravitational field by integral transforms. Firstly, we derive integral estimators relating the GRAIL line-of-sight gravitation to the disturbing potential and gravity disturbance on the lunar surface. The integral estimators are composed of two terms, i.e., the truncated integration and the effect of the distant zones. Secondly, we validate the accuracy of the integral estimators in a closed-loop simulation. We investigate the optimal parameters for the integration radius and the maximum degree/order of a priori gravitational field model. The numerical stability of our regional integral inversion is studied. Thirdly, we determine the disturbing potential and gravity disturbance at different regions of the lunar surface. We use GRAIL Level-1B and SPICE orbital data combined with a priori gravitational field model. Finally, our regional solutions are compared with other GRAIL global lunar gravitational field models.

B3.1-0071-18 LUNAR SETTLEMENT BASED ON ITS CRATERS' CHARACTERISTICS

Shahin Malek, ali72227@gmail.com

Islamic Azad University, Shiraz Branch, Shiraz, Iran Zahra Erfanian, dr.zahra.erfanian@gmail.com

Pardis Clinic, Shiraz, Iran

Moon has been one of most considered subjects of space research since 20th century. It is because of different reasons such as its close distance to earth, concerns about future climatic conditions of earth in order to have living camps on moon, and its potential characteristics for general and particular space researches. If we want to focus on living camps and conditions on the moon, we must consider various important factors such as water and other resources discoveries and conditions, air pressure, and low gravity of the moon. In this way, one of the potential and effective places on the moon could be the edge of lunar craters because of protections from rays and meteoroids, craters' inside-moon surface views, two sides access for discoveries, and lunar dust as main-protective local material. Also the craters itself as volcanic action or as meteoric impact, could be suitable places for any researches about lunar minerals. On the other hand, from physiological point of view, astronauts will use less energy and have less negative physiological impacts by the help of two sides slopes from the camp toward the crater's surface and toward the moon's surface.

B3.1-0072-18 RETURN TO THE MOON: FINDINGS FROM THE LUNAR SCIENCE FOR LANDED MISSIONS WORKSHOP

Sarah Valencia, sarahnvalencia@gmail.com

Goddard Space Flight Center, Greenbelt, Maryland, United States James Crowell, james.crowell@asu.edu

Arizona State University, Tempe, Arizona, United States Erica Jawin, erica_jawin@brown.edu

Brown University, Providence, Rhode Island, United States Ryan Watkins, rclegg-watkins@psi.edu

Planetary Science Institute, Saint Louis, Missouri, United States Clive Neal, cneal@nd.edu

University of Notre Dame, Notre Dame, Indiana, United States Gregory Schmidt, gregory.k.schmidt@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States

The Lunar Science for Landed Missions workshop was held at NASA Ames Research Center January 10-12, 2018. The meeting was attended by both lunar scientists and representatives from commercial companies, and was jointly sponsored and co-chaired by SSERVI and LEAG. The goals of the workshop were to produce a set of priority targets for near-term landed missions on the Moon, primarily, but not exclusively, from commercial exploration firms interested in pursuing science missions to the lunar surface, and to foster discussion between scientists and commercial companies about a path forward to meet current lunar science goals. Scientists were invited to submit abstracts detailing high-priority landing sites on the surface of the Moon to which landed lunar missions would fulfill community science goals. These contributed talks presented landing site options across the surface of the Moon that would meet scientific goals in a wide variety of areas, including cratering processes, age determinations, volatiles, volcanism, magnetism, geophysics, and astrophysics. Invited talks and panels from commercial attendees focused on new technologies to enable landed lunar missions and potential payloads of lunar landers. In addition, invited talks from international colleagues addressed space programs in Japan, and the European Space Agency. The workshop findings are presented in a summary report of prioritized landing sites on the lunar surface prepared for the NASA Science Mission Directorate. This talk will report on the findings (high-priority landing sites, overarching science themes) from the the workshop.

The contributed science talks centered around 5 overarching themes:

Impacts: Establish a precise impact chronology, and better understand impact processes

Volatiles: Understand the source, form, and concentration of lunar volatiles

Volcanism: Determine the origin and evolution of lunar volcanism through space and time

Geophysics/Tectonism: Constrain the interior structure and evolution of the Moon

Space Weathering/Astrophysics: Examine regolith formation and space weathering processes, including astrophysical and cosmological analyses

Each proposed landing site within these themes works to meet science goals laid out by the 2007 National Research Council's (NRC) Scientific Context for the Exploration of the Moon (SCEM) report, and the Vision and Voyages for Planetary Science Decadal Survey. Each landing site also meets exploration goals established through Strategic Knowledge Gaps (SKGs) determined by NASA's Human Spaceflight Architecture Team and two LEAG Specific Action Teams.

An emerging theme from the workshop was the need for advancements in technology in order to meet primary science goals. The necessary technological advancements included automated hazard avoidance, cryogenic sampling, caching, and transport, landers and rovers that can survive extreme cold and darkness, and permanent lunar infrastructure in the form of a communications relay. A dedicated communications relay is perhaps the most enabling of the above technologies, as over half of the landing sites discussed at the workshop have the potential for communication difficulties due to locations on the lunar limb or farside.

B3.1-0073-18 NEW DEVELOPMENTS IN X-RAY DIFFRACTION AND X-RAY FLUORENCE FOR LUNAR APPLICATIONS

David Blake, david.blake@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States Philippe Sarrazin, psarrazin@seti.org

SETI Institute, Mountain View, California, United States Thomas Bristow, thomas.f.bristow@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States Richard Walroth, richard.c.walroth@nasa.gov

Ames Research Center, NASA, Moffett Field, California, United States

Introduction: X-ray diffraction (XRD) is a general purpose technique used for definitive, quantitative mineralogical analysis. The MSL CheMin instrument, the first XRD instrument flown in space, established the quantitative mineralogy of the Mars soil [1], char-acterized the first habitable environment on another planet [2], and provided the first in-situ evidence of Martian silicic volcanism [3]. CheMin is now employed in the characterization of the depositional and diagenetic environments of lacustrine mudstones that comprise the lower strata of Mt. Sharp [4]. CheMin requires substantial sample preparation. Deployment of XRDs for smaller missions to the moon will require simpler sample preparation and decreased instrument size and complexity. Efforts in these direc-tions are underway.

XRD with Limited Sample Preparation: XTRA (Extraterrestrial Regolith Analyzer) is intended to analyze fines in as-delivered surface regolith, without sample preparation [6]. XTRA can be configured in transmission or reflection geometry using vibrated cells for as-delivered powders, allowing direct analysis of materials scooped at the surface.

XRD without Sample Preparation: Hybrid-XRD (HXRD) is a concept under development to analyze rocks or soils without sample preparation [7]. If the material is sufficiently fine-grained, a powder XRD pattern is obtained, similar to CheMin or XTRA. With coarsegrained crystals, the white bremsstrahlung radiation of the tube is diffracted into single crystal Laue patterns. Unlike typical Laue applications, HXRD analyzes the energy of each Laue spot, enabling the measurement of single crystal Bragg diffractions. Dedicated crystallographic software has been developed for identification of minerals responsible for the Laue patterns.

High resolution XRD: With CheMin and any of the previously described XRD concepts, instrument resolution suffers from the system miniaturization and is limited to about 0.3° 2. A planetary XRD based on Guinier geometry is under development to provide a compact high-resolution instrument. This design hinges on the use of a parafocusing geometry with a curved 2D detector to cover the angular range of interest. A substantial gain in resolution has been demonstrated with a basic proof-of-concept instrument. Both reflection and transmission geometries can be developed with the Guinier design and are being explored as part of a PICASSO funded project.

X-ray Fluorescence Imaging: MapX is a full-field XRF imager which employs a CCD detector operated in single photon counting mode. The number of electron hole pairs created by an incident photon is energy dependent, and by summing multiple frames it is possible to produce XRF spectra for each pixel of the CCD. The same technology is employed in the CheMin instrument on MSL, which provides qualitative bulk compositional information as well as spatially-resolved diffraction information for mineral identification. MapX combines this CCD with a micro-pore optic (MPO) which focuses X-rays 1:1 onto the CCD. The resulting instrument is capable of producing XRF maps with a resolution of 100 m. Data is currently being collected using two prototypes employing X-ray tube sources, MapX-II and MapX-III, which are at TRL3 and TRL4 respectively [8,9].

Development of High TRL Components: Rapid and cost-effective development of flight instruments requires the availability of mature technologies of the critical components. High TRL subsystems are being developed for future XRD and XRF instruments in collaboration with industry partners who can provide expertise in design and manufacturing of flight subsystems. Special full-frame and frame-transfer X-ray CCD detectors are being developed with e2V (UK); some detectors featuring internally cooled packages. Custom FPGA based electronics for low noise CCD operation with embedded data processing capabilities are under development with Baja Technology. Miniature microfocused X-ray tubes capable of operation

>10W are being developed by RTW of Germany with power supplies developed by Battel Engineering.

Deployment Opportunities: XRD and XRF instruments will be proposed for future lunar instrument opportunities. Instruments can be tailored to the specific mission constraints (robotic or human missions) and will be comprised of combinations of the features and flight hardware presented above.

Chang'E4, the next Chinese mission to the Moon, is planned to launch in December 2018 and to land on the far side of the Moon in the South Pole Aitken Basin. The mission consists of a lander, a rover, and a communication relay around the Earth-Moon L2 libration point. Here we describe the Lunar Lander Neutron Dosimetry experiment (LND) on the lander. It consists of a stack of 10 segmented Si solid-state detectors (SSDs) which forms a particle telescope to measure charged particles (electrons 150-500 keV, protons 12-30 MeV, and heavier nuclei 15-30 MeV/nuc). A special geometrical arrangement allows observations of fast neutrons (and g-rays) which are also important for dosimetry and cosmic-ray exposure of lunar soils. Thermal neutrons are measured using a very thin Gd conversion foil which is sandwiched between two SSDs. Thermal neutrons are sensitive to subsurface water and important to understand lunar surface mixing processes. Despite the aim of landing humans on the Moon in the not too distant future, radiation measurements in the vicinity of the Moon are remarkably scarce. Fairly recent measurements in lunar orbit were provided by the Radiation Dose Monitor (RADOM) on board Chandrayaan-1. The spacecraft reached its operational 100 km circular orbit on November 12, 2008. Measurements showed a dose rate of 0.23 mGy per day averaged over 3545 hours of measurement time (20/11/2008 to 18/5/2009). Newer measurements have been provided by the Cosmic Ray Telescope for the Effects of Radiation (CRaTER) instrument on board the Lunar Reconnaissance Orbiter (LRO). CRaTER measured a radiation exposure of about 0.22

0.27 mGy per day in its 50 km orbit. In comparison with these meager orbital data, there is a real dearth of data on the lunar surface. The current knowledge about the radiation environment on the surface of the Moon is based exclusively on calculations using radiation transport models with input parameters from models for the galactic cosmic ray spectra and for solar particle events. This is highly questionable, especially since we know that these models are fraught with uncertainties. Thus LND will provide the first active dosimetry measurements on the surface of the Moon. In this presentation we will discuss the science, implementation, and status of LND on China's Chang'E4 mission.

Because of the lack of atmosphere, small meteoroids impact the Moon surface at high speeds. The impacts release plumes of dust from the surface termed the secondary dust ejecta cloud. The Lunar Atmosphere and Dust Environment (LADEE) was a NASA satellite launched in 2013 with several scientific objectives, one of which was to measure and characterize this ejecta. LADEE showed several surprising temporal features of this cloud. We interpret recent observations of the secondary dust ejecta cloud around the Moon from the Lunar Dust Experiment (LDEX) on board the LADEE spacecraft with help from dynamical models of meteoroids. Results suggest that in order to match the spatial structure of observed ejecta profiles, the flux of meteoroids on the Moon must be primarily provided by short-period comets with an excess ratio of at least 1.3:1 compared to long-period comets. This ratio increases significantly if the dependence of the ejecta yield on impactor velocity is stronger than generally believed. The model accounts for the orbital geometry of LADEE and shows no indication of a large asymmetry in the meteoroid flux impacting from the Helion and Anti-Helion directions.

B3.1-0076-18 LUNAR ULTRAVIOLET COSMIC IMAGER (LUCI)- NEAR UV ASTRONOMICAL OBSERVATIONS FROM THE LUNAR SURFACE

Joice Mathew, joice@iiap.res.in

Indian Institute of Astrophysics, Bengaluru, India Joice Mathew, joice@iiap.res.in

Indian Institute of Astrophysics, Bengaluru, India

Observations from the Moon provide a unique opportunity to observe the sky from a stable platform far above the Earth atmosphere. This is especially relevant in the ultraviolet (UV) field. Hence we have explored the prospects for UV observations from the lunar surface, mainly the feasibility, scientific outcomes and possible configuration of UV telescopes. To realize this, we have been in collaboration with TeamIndus, (an entry to the Google Lunar X prize competition), to put a UV telescope (LUCI-Lunar Ultraviolet Cosmic Imager) on the Moon as a piggyback payload. LUCI is an all spherical near UV (passband:200 -300 nm) telescope with a field of view of 0.46° x 0.34°. LUCI will be mounted on the lunar lander as a transit telescope and will perform a survey of the available sky from the surface of the Moon. It has potential capability of delivering unique science - perform a survey of the available sky in the NUV domain from the surface of the Moon, with the aim to detect bright UV transients such as SNe, novae, TDE etc. The instrument has been assembled in the class 1000 clean room at the M.G.K Menon Laboratory for Space Sciences and is awaiting various environmental tests. Here we will describe the various science cases of LUCI and will also cover the design and development of the instrument. We will also briefly explain the assembly, integration, and calibration of LUCI.

B3.1-0077-18 MULTI-OBJECTIVE OPTIMIZATION FOR SPACECRAFT STATION KEEPING ON LIBRATION HALO ORBIT OF EARTH-MOON SYSTEM

Zhang Yechen, yexuan1008@qq.com

China Academy of Launch Vehicle Technology, Beijing, China Chen Xuan, yexuan1008@qq.com

China

There are five equilibrium points (three collinear libration points and two triangle libration points), called libration or Lagrangian points, in the Circular Restricted Three Body Problem (CRTBP) model. The existence of periodic halo orbits around such libration points has been known for many years and has been focus of much astronomical observation mission, research in celestial mechanics and deep space exploration. The important applications of libration point orbits have been paid more attentions from all over the world.The halo orbit around L2 point (a collinear libration point at the far-side of the moon) in Earth-Moon system can provide an approach to deal with the far-side communication problems of the moon, due to the same face of the moon always faces the earth. But the halo orbits around the L2 point are unstable, the necessary orbit station keeping operations are required for spacecraft in order to maintain around L2 libration point for a long time. In the past, many of strategies dealing with halo orbits station keeping have been researched. The Target strategy and the Floquet strategy are the most efficient solution for halo orbits station keeping problem. The divergence of unstable flow is restrained to realize orbit station keeping in Floquet strategy. The guidance law is designed for guide spacecraft close to target orbit in Target strategy. Although the fuel consumption in Floquet strategy is less than Target strategy, Target strategy has advantage in engineering implementation due to its common structure of spacecraft control systems. This paper adopts the time-variant LQR optimal control theory deal with the problem of Spacecraft Station Keeping on libration Halo Orbit of Earth-Moon System based on the Target strategy. Under the contradict objectives, fuel consumption and orbit maintaining precision, a multiobjective optimization method to design time-varying controller in the Halo orbit stabilization missions is proposed. Firstly, a time-varying controller, based on the linearization CRTBP model, is constructed. Then, the weighting matrix elements of the controller are optimized with multi-objective algorithm. Finally, numerical simulations are presented. A study case is optimized and the Pareto fronts of the optimization are obtained. The results show the trajectories of spacecraft are closed to the nominal orbit under the environment errors. The Pareto fronts show the trade-off between the fuel consumption and orbit maintaining, and prove the feasibility of this method. The method in this paper can be applied to other halo orbits station keeping problems in circular restricted three body systems, and have high value of engineering application and prospects.

B3.1-0081-18 STUDY OF SKID SLIDING SYSTEM TO TRAVEL ON LUNAR AND PLANETARY SURFACE

To improve the exploration efficiency of planetary landing missions, planetary surface exploration techniques including traveling on the surface of planets need to be studied. As a traveling technique, we propose a "skid sliding system", which uses skids and thruster forces to travel via skid sliding. In this study, we considered the application of this system to a small lander. The reason of this is that the skid sliding system can be configured to be light weight; it is advantageous for a small lander mission with severe weight constraints. To implement this system, we performed a numerical skid sliding simulation and a skid sliding experiment using a small lander model. To express skid sliding in the simulation, we developed a three-dimensional interaction force model for the forces between the skid and the soil via an experiment that measured the interaction force between a moving flat aluminum plate adjusted for attitude and soil type. This paper reports the skid sliding simulation using the interaction force model and the skid sliding experiment using the small lander model.

B3.1-0082-18 HOLMS, HETERODYNE OH LUNAR MINIATURIZED SPECTROMETER

Sona Hosseini, sona.hosseini@jpl.nasa.gov

There are many indications in recent lunar studies that water ice and other volatiles are present near the lunar poles. Temperatures of the lunar cold traps are low enough to prevent substantial sublimation losses over billion-year time scales. Understanding the source and the processes that affect the delivery of lunar volatiles is key to understanding the formation of the moon, and early volatiles in the inner solar system. It also has a great importance for lunar mining and possibly utilizing volatiles in future missions. Lunar remote sensing by orbital spacecraft, and the Lunar Crater Observation and Sensing Spacecraft (LCROSS) impact experiment provided compelling evidence for the existence of cold-trapped volatiles, but their abundance, composition, and distribution remain uncertain. This is, in part, because the most commonly used technique for remote sensing spectroscopic measurements is grating spectrometers. These instruments are broadband, but they have small fields of view (FOV) and relatively low throughput and have to be paired with large aperture telescopes for high spectral resolving power (R) applications.

Here, we demonstrate a lunar volatile remote sensing technology, by employing a Spatial Heterodyne Spectrometer (SHS) in an orbiter around Earth. SHS is a relatively novel candidate for high throughput spectroscopy in compact, low-mass, a low-power architecture using no or small aperture (D<10cm) telescope for UV to IR wavelengths. SHS provides integrated spectra at high R (R>50,000), over a wide FOV (FOV 40 arcmin) in compact designs in which it offers the ability to search for OH volatiles at 308nm. SHS can be implemented on ISS or a dedicated SmallSat that can sit at a GEO altitude and stare at lunar exosphere for the long duration of time that cannot be done from the ground or on big missions. SHS measurements will improve constraints on lunar volatile composition and could help identify possible origins, including comet and asteroid impacts, solar wind ion implantation, and outgassing of primordial volatiles from the lunar interior.

B3.1-0083-18 A POLITICAL HISTORY OF THE HUMAN MISSION TO MARS GOAL IN THE U.S.

Louis Friedman, louisdfriedman@gmail.com California, United States

Mars is the only other world we can reach that has the basic stuff of life - atmosphere and water. It beckons us both as a possible place with extinct or even extant life and also as the most likely place where humans could evolve as a multi-planet species. The literature of Earth is replete with stories containing the visions. Sending humans to Mars has been a goal of space exploration since before the space age. In the space age that goal has remained constant, but mostly implicit - never resulting in any flight development and only in the last Administration (Obama) was it a specific program objective. When first suggested by Wernher von Braun in 1948 he imagined it could be done in 1965 (17 years hence). 21 years later, in 1969, the same year as Apollo first Moon landing, von Braun published an updated and more detailed plan imagining launches beginning in 1981 (12 years hence). This led to the first political initiative for a human Mars mission goal for the American space program - a proposal to President Nixon. This paper reviews the political history of the humans to Mars mission goal in NASA. It does not review the technical history - the many mission studies conducted by and for NASA over the years. Many of these were wish fostering the thought, others were generated as part of program initiatives or budgetary proposals, and others were generated as intellectual exercises of what could be done if only. No attempt is made here to capture or review those technical studies; our focus is only on what has led to serious political consideration of the human Mars goal. Since that goal has in one way or another driven NASA in three of the last four Administrations we hope that it will offer guidance on how to proceed or not with its further consideration. Ironically, we will conclude that none of those three Administrations came close to a real political initiative and that the closest we ever come to a political decision for humans to Mars was in the Reagan Administration, even though they, themselves, didn't really consider it.

The table below summarizes the consideration of a human Mars mission goal in each of the space age Administrations.

President Proposal/Initiative Result Kennedy Apollo:Race Soviets to the Moon, No Mars Connection Success - Concluded Johnson Nixon Space Task Group's Mars Goal rejected Shuttle program Ford Carter No "high challenge" goal Reagan 1. Back to Back to the Moon

B4.1-0001-18 CURRENT MARS WEATHER AND CLIMATE.

Francois Forget, forget@lmd.jussieu.fr

CNRS Research Scientist (Chargé de recherche), Paris, France

Since Viking, we know that the present-day Mars climate is a complex system in which the atmospheric circulation is coupled with an atmospheric dust cycle (dust devils and dust storms), CO2 cycle (seasonal and perennial polar caps and clouds), water cycle (clouds, frost and glaciers) and even an active photochemistry. Twenty more years of observations by a fleet of modern spacecrafts (notably Mars Global Surveyor, Mars Express, Mars Reconnaissance Orbiter and MAVEN) interpreted with the help of numerical models have helped identify the physical processes at work and shown how much they are connected. However, these studies have also revealed new enigmas: what creates the detached layers of dust in the atmosphere? Can water vapor be strongly super-saturated in the middle atmosphere? Why global dust storms occur some years and not others? How clouds and dust evolve throughout the diurnal cycle? Can the sublimation of CO2 ice carve the surface and create gullies? Many questions remain. Furthermore, the Martian climate system has probably experienced large variations related to the oscillations in the parameters of the Martian orbit a few millions or even thousands of years ago, and we are just starting to understand what could have happened then and how these variations have shaped the observed Mars geology.

In my presentation, I will briefly review our current understanding of the Mars Climate system and highlight the most puzzling enigmas.

Interestingly several new space missions will soon provide unprecedented observations and most likely revolutionize our understanding of the Martian environment. We can cite in particular the ESA Exomars Trace Gas Orbiter (starting its science mission in spring 2018) which combines nadir observations at various local time with high precision solar occultations to monitor the vertical profiles of multiples species and aerosols. The Emirates Mars Mission will later (in 2021) complement these investigations by monitoring Mars meteorology throughout the diurnal cycle thanks to an innovative orbit, and several other missions from various countries (China, Japan, India) may also contribute to this international investigation on the mysteries of the Martian world.

B4.1-0002-18 THE MARS CLIMATE SOUNDER - SIX MARTIAN YEARS OF GLOBAL ATMOSPHERIC OBSERVATIONS

John Schofield, john.t.schofield@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States Armin Kleinboehl, armin.kleinboehl@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States David M. Kass, david.m.kass@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, United States Daniel McCleese, mccleese@gmail.com

Synoptic Science, Altadena, California, United States

The Mars Climate Sounder (MCS) on the Mars Reconnaissance Orbiter (MRO) spacecraft, began continuous observations of the surface and atmosphere of Mars on 24th September 2006 and has been operating successfully ever since, completing six Mars years of daily, global coverage on 6th January 2018.

MCS is a compact, limb sounding radiometer with 5 mid-infrared channels, 3 far-infrared channels, and one broadband 0.3-3.0µm albedo channel. All 9 spectral channels use uncooled, linear, thermopile detector arrays, consisting of 21 elements, to sample the atmosphere from

-10 to 90 km with 5km vertical resolution when pointed at the martian limb. Elevation and azimuth actuators direct the instrument fields-of-view over the entire downward hemisphere from the nadir oriented MRO spacecraft, allowing MCS to view Mars using nadir, off-nadir, and limb viewing geometries in all azimuth directions.

Surface temperature and atmospheric profiles of pressure, temperature, dust and water ice opacity are retrieved operationally from radiance profiles measured by the MCS infrared channels. Every day, atmospheric fields are sampled globally with a resolution of 5km in altitude, 4° in latitude and 27° in longitude at local times of both 3 am and 3 pm from the sunsynchronous, polar orbit of MRO. Early in the mission, measurements focused on the forward in-track limb, but these are now interspersed with off-track and cross-track limb measurements to broaden the coverage of local time, particularly at high latitudes. Retrieved atmospheric profiles are delivered to the Planetary Data System (PDS) every three months, and are publically available at: http://atmos.nmsu.edu/data_and_services/atmospheres_data/MARS/ atmosphere_temp_prof.html.

Although MCS operations are mature, there are still many improvements planned for the data set. In particular CO2 ice profiles will be retrieved, and dust and water ice profiles will be extended to higher opacities using radiance profiles from the far-infrared channels. Further improvements in aerosol profiles and columns will be realized by combining off-nadir and limb measurements, which has already been done operationally for temperature. Ultimately, assimilating the dataset into Mars general circulation models, will extract the maximum amount of information on atmospheric dynamics and the transport of dust and volatiles from the measurements.

The MCS climatological atmospheric data set is distinguished by the superior vertical resolution, radiometric sensitivity, and radiometric stability provided by limb sounding radiometry with linear thermopile arrays, combined with the daily global coverage, both day and night, provided by the MRO spacecraft for 6 Mars years. This has resolved the global structure of the atmospheric tides for the first time, and has revealed unexpected complexity in the vertical distribution of dust and water ice and their seasonal and inter-annual variation.

The pointing flexibility of the MCS instrument has allowed it to make coordinated observations with other MRO instruments and Mars missions. In particular, MCS has supported orbiter aerobraking and the Entry Descent and Landing (EDL) activities and surface operations of landers and rovers with both climatological and real-time data. Plans for MRO spacecraft operations extend to 2028 to provide relay services for future landed missions. MCS will continue its support for these missions, and extend the climatological data set, increasing its value for future missions to Mars by humans. At the time of writing MCS is healthy and appears capable of continuing operations well into the future.

B4.1-0003-18 A MARS ATMOSPHERIC CLIMATOLOGY SPANNING A MARTIAN DECADE

David Kass, dkass@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, PASADENA, California, United States

John Schofield, john.t.schofield@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Michael Smith, michael.d.smith@nasa.gov NASA/GSFC, Greenbelt, Maryland, United States

Over the last martian decade (almost 20 terrestrial years), orbiting spacecraft have acquired a global continuous set of temperature and aerosol observations of the lower atmosphere (surface to at least 40 km). The observations were acquired by MCS (on MRO), TES (on MGS) and THEMIS (on Odyssey). The measurements span Mars Years 24 though 33 (MY; MY 1 started in 1955) and are continuing into MY 34. The observations include sufficient overlap between the individual instruments to help validate the entire dataset. In addition to helping understand the atmosphere, the climate record will provide vital input for successfully designing and executing future human and robotic missions to Mars.

Here, we focus on the zonal mean daytime and nighttime temperatures at 50 Pa (25 km), which provide an excellent overview of the climate. The binned, zonal mean temperatures filter out the boundary layer and local weather phenomena, better revealing the background climate. Temperatures at 50 Pa are influenced by large scale dust activity that dominates the inter-annual variability. Likewise, they are influenced by the overall seasonal changes, including the change in distance to the sun as well as aerosols. To help understand the climate, we have used the 10 year record to create a median year for Mars.

The most obvious, and well known, feature in the climatology is the difference between the cool aphelion season and the warm perihelion season. In addition, the polar vortices are clearly defined at 50 Pa, revealing the extremely cold winter polar regions (where CO2 clouds form).

The aphelion season, northern spring and summer, is not only cloudy (water ice clouds), but is also quite repeatable from year to year. The coldest non-polar temperatures at 50 Pa are not at aphelion (nor the northern summer solstice), but are around Ls 40°. At this time, the atmosphere is rapidly transitioning from the equatorially symmetric two-cell Hadley circulation of the equinoctial season to the single, cross-equatorial, cell of the solstice season. The other three transitions of this kind are less obvious, but are also rapid (<15° of Ls) and visible in the dataset. During the aphelion season, inter-annual variability is generally limited to less than 5 K. While relatively uncommon, dust events affecting middle atmosphere temperatures occur during the season and result in larger differences (up to ~20 K of warming).

The perihelion season, southern spring and summer, shows much more inter-annual variability due to the occurrence of large-scale dust events. Many years have three regional-scale events in a generally repeatable pattern, but two years in the climatology show the impact of a global dust storm. Even in years with a repeatable pattern, there are noticeable differences, as well as subtle similarities. Despite the sometimes large variations in this season, by the beginning of the aphelion season, the climate returns to the median state.

With both MRO and Odyssey still returning data and TGO soon to start observing, we hope to continue the collection of this valuable atmospheric dataset into the next martian decade.

B4.1-0004-18 MAJOR DUST STORMS AND CHANGES IN ATMOSPHERIC CIRCULATION ON MARS

Huiqun Wang, hwang@cfa.harvard.edu

Smithsonian Astrophysical Observatory, Cambridge, Massachusetts, United States

Dust storms on Mars can sometimes grow into planetary scale and profoundly affect global atmospheric circulation. These major dust storms control the seasonality and inter-annual variability of the Martian dust cycle, and are of great concern for spacecraft missions. The atmospheric circulation at each development stage of a major dust storm appears to have its own special characteristics. The relationship between the development process of a major dust storm and the timing of change in the circulation is important for deciphering the mechanism involved. This relationship will be investigated for representative examples using dust storms observed in Mars Daily Global Maps (MDGM) and meteorological variables in Mars Analysis Correction Data Assimilation (MACDA) product. Special attention will be paid to large-scale eddies, such as, traveling waves, stationary waves, and thermal tides.

B4.1-0005-18 MODELING THE MARTIAN SEASONAL DUST CYCLE

R. John Wilson, robert.j.wilson@nasa.gov

NASA Ames Research Center, Moffett Field, New Jersey, United States Melinda Kahre, melinda.a.kahre@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States

An outstanding problem for simulating the present Mars climate is representing the spatial and temporal variability of aerosols and the feedbacks that connect dust raising and transport with the evolving atmospheric circulation. A particular challenge has been the inability of Mars global circulation models (MGCMs) to realistically simulate interannual variability, most notably in the occurrence of major dust storms. The threshold for dust lifting by resolved surface stresses plays a central role in the current parameterizations of dust lifting used in these simulations. In the results to be presented, the GFDL MGCM is run with fairly typical representations of convective ("dust devils") and wind stress lifting. A new type of negative feedback has been introduced to the model climate system by providing a finite surface dust reservoir and allowing the stress threshold for dust lifting is vary as a function of the surface dust depth. The simulated surface dust typically evolves toward a relatively statisticallystable distribution that reflects the seasonally-integrated effects of stress dust lifting. Dust is preferentially depleted in regions with unusually high stress but surfaces are never stripped clean. Thus the stress lifting scheme continues to allow dust to be raised in these regions, but on a more episodic basis that is dependent on the replenishment by local and remote dust lifting activity. This work provides support for the concept, first proposed in a pair of papers by A. Pankine and A. Ingersoll, that surface/atmosphere dust interactions are able to organize to yield aperiodic global dust storm activity.

B4.1-0006-18 ADDRESSING INTERANNUAL VARIABILITY OF MARTIAN GLOBAL DUST STORMS WITH ORBIT-SPIN COUPLING AND ACTIVE DUST LIFTING IN STUDIES WITH A MARS GENERAL CIRCULATION MODEL

Michael Mischna, michael.a.mischna@jpl.nasa.gov JPL, Pasadena, California, United States

James Shirley, james.h.shirley@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States Claire Newman, claire@aeolisresearch.com

Aeolis Research, Pasadena, California, United States Mark Richardson, mir@aeolisresearch.com

Aeolis Research, Pasadena, California, United States

The occurrence of global dust storms (GDS) in some Mars years and not in others is recognized as an outstanding unsolved problem of atmospheric physics. While GDS exhibit a clear seasonality as to when they occur (centered loosely around Mars' perihelion), no clear pattern exists among years in which GDS take place, and predicting their occurrence in any one Mars year remains a problem that is stubbornly unresolved. Attempts to address the underlying factors behind this interannual variability have generally focused on two complementary areas.

First, it has been suggested that the limited availability of dust in key regions on the martian surface may inhibit the growth and development of GDS, simply due to the absence of enough dust to loft into the atmosphere and trigger positive feedbacks which grow more regional dust activity into a global-scale event. Simulations that assume an infinite supply of surface dust show much more limited growth behavior (with respect to timing and source location) than do simulations that exhaust dust in key regions over time. These key regions are areas with peak surface stress lifting, from which dust is most readily lofted. As these regions are depleted of dust, secondary regions continue the process of injecting dust into the atmosphere. This increased distribution of lifting sites yields model results with greater interannual variability, and which coincide with observations of the origin of recent dust storms.

Second, it has been recently argued that year-to-year differences in the orbital angular momentum of Mars, and the coupling of this orbital angular momentum to Mars' rotational motion can yield small but cumulatively significant changes in the martian circulation that have heretofore been unrecognized. These changes come about from the effect of a time-varying 'coupling term acceleration' (CTA), based on the calculable Mars ephemerides, and which varies significantly in time and exhibits variable phasing with respect to Mars' annual insolation cycle. A strong correspondence between years in which the CTA act in such a way as to constructively enhance the overturning meridional circulation on Mars and years in which a GDS was observed has been identified.

Most recently, studies have been undertaken to combine these two processes in a Mars general circulation model (GCM), examining the feedback of enhanced dust lifting and the CTA on the growth and timing of GDS in prior Mars years. Together, they make up the first successful attempt at replicating the observed interannual variability of GDS on Mars, and provide an avenue for making viable predictions of future dust storms. Such predictions can impact launch considerations and surface operations of spacecraft at Mars. Here, we present the current status of this work and demonstrate results obtained for both prior and future Mars years.

B4.1-0007-18 TEN YEARS OF MESOSCALE AND MICROSCALE MODELING OF THE MARTIAN ATMOSPHERE AT LMD: FROM MARS EXPRESS TO INSIGHT

Aymeric Spiga, aymeric.spiga@sorbonne-universite.fr

Sorbonne Université, Laboratoire de Météorologie Dynamique (LMD), PARIS, France LMD / LATMOS / IPSL Mars Modeling Team

F. Forget, E. Millour et al. (LMD) A. Määttänen, F. Montmessin et al. (LATMOS)

Following the scientific activities of Mars Express, the LMD Martian Mesoscale Model was developed circa 2007 as an interface between an adapted version of the terrestrial WRF model and the physical parameterizations developed for the LMD Global Climate Model. Since its inception, the model has been applied to various topics of interest to understand the variability of the Martian atmosphere at spatial scales smaller than those resolved by GCMs. This includes: slope flows and their thermal impact, boundary-layer turbulence and dust devils (with Large-Eddy Simulations), gravity waves (notably their impact on the formation of CO2 clouds), polar meteorology and katabatic jumps, dust-induced convection in "rocket dust storms", ice-induced convection in "turbulent snowstorms". The simulations with the LMD Martian Mesoscale Model helped to interpret the results obtained from space missions in the last decade, contributing to an international community effort with Martian Mesoscale Models developed and used in other teams. The approach developed at LMD for Martian mesoscale modeling has also been recently transposed to Venus. The upcoming InSight mission to Mars opens new perspectives for mesoscale and microscale atmospheric science, where the use of small-scale simulations has proven useful to prepare the mission's observations and will be instrumental to interpret the unprecedented signals caught by the InSight instruments.

Above the well-mixed lower and middle atmospheres of Mars, above the homopause at 120 km, lies Mars' upper atmosphere, partially ionized and extending tenuously to many tens of thousands of kilometers out into space. Its structure and dynamics are complex, driven both from below by lower atmospheric conditions (temperature, density, waves) and from above by solar extreme ultraviolet photons and energy input from the solar wind in the form of charged particle precipitation and plasma waves. It is also the conduit through which all escaping atoms and molecules must pass on their way out to space. Building on the success of previous missions, the MAVEN mission is the first to focus exclusively on exploring the structure, composition, variability and dynamics of the Mars upper atmosphere and near-space environment. Here we review what MAVEN has taught us about the upper atmosphere, the processes which operate therein, how they affect water and CO2 escape from Mars, and how they vary with season and solar activity. We will also look forward to upcoming synergistic measurements from the ESA Trace Gas Orbiter and the Emirates Mars Mission, both of which will explore the connections between Mars' lower and upper atmosphere and escape.

Neutral escape of hydrogen and oxygen is the most important atmospheric escape mechanism currently at work at Mars. Pickup ions provide important insights into the exospheric density and escape rates of these neutrals. As they are escaping the planet, neutral hydrogen and oxygen atoms become ionized in the solar wind and are picked up by the solar wind electric and magnetic fields. Charged particle detectors onboard the Mars Atmosphere and Volatile EvolutioN (MAVEN) spacecraft can measure these pickup ions, acting as a probe for their source neutrals. By following the production and transport of pickup ions in the solar wind, the source positions of the measured pickup ions can be found and neutral densities at those positions derived by comparing the modeled pickup ion fluxes with the measured ones. Neutral escape rates can also be constrained using these model-data comparisons, since neutral escape rates are directly proportional to exospheric neutral densities. We use this pickup ion modeldata comparison technique to probe the exosphere of Mars by fitting to data different exospheric density profiles based on a variety of exobase distribution functions. This allows us to gain insights into the sources and structure of the Martian exosphere, constrain the 3D distribution of neutrals in the exosphere, and investigate the neutral escape variability at Mars.

B4.1-0010-18 INDIAN MARS AND VENUS MISSIONS: SCIENCE AND EXPLORATION

Syed A. Haider, haider@prl.res.in

Physical Research Laboratory, Ahmedabad, India

Mars and Venus have been the focus of explorations in recent decades by various space agencies. Several orbiters have provided a wealth information on the planet Mars and Venus, but have also posed some important questions for further exploration. Indian Chandrayaan-1 and Mars Orbiter Mission Mangalyaan-1 were explored to Moon and Mars in October, 2008 and September, 2013 for a focused study of Moon and Mars' environment respectively. ISRO is now planning to explore Mangalyaan-2 and Shukrayaan-1 in the orbits of Mars and Venus during 2022-2023. The science objectives of these missions are to investigate the atmosphere, ionosphere, surface geology, magnetic fields, and interplanetary dust in the environment of both planets. In this talk we will discuss in brief objectives and science of important Indian payloads viz. color Camera (MCC), Radio Occultation Experiment (ROX), Retarding Potential Analyzer (RPA), Langmuir Probe Electric Field Analyzer (LPEX), Magnetometer (MAG) and Mars Orbit Dust Experiment (MODEX).

B4.1-0011-18 ACTIVE MARTIAN SURFACE PROCESSES: A DYNAMIC WORLD

Colin Dundas, cdundas@usgs.gov

United States Geological Survey, Flagstaff, Arizona, United States

The surface of Mars has been known to change since the era of telescopic observation [1]. The advent of long-duration orbital missions with high-resolution imagers has enabled detection of many smaller-scale changes. This has demonstrated that current processes are not merely repainting the albedo, but are actively shaping the surface through both Earth-like processes and some that are unique to Mars.

Several planet-wide processes are now recognized. Aeolian processes account for the large-scale albedo changes [2] and have been studied in situ by landers, particularly Curiosity [3]. Perhaps the key recent discovery has been planet-wide dune and ripple migration [4]. New impacts up to decameters in diameter have also been found to occur globally [5].

Seasonal frost effects occur at middle and high latitudes and produce a variety of spots and fans, redistributing surface fines [6]. These are driven by basal sublimation of CO2, a uniquely Martian process [7]. The effects of this are not merely superficial: observations now confirm formation of new araneiform landforms [8] and annual modifications of the dunes of the north polar erg [9]. The south polar residual cap also has pits that expand every summer, but the net mass balance is uncertain [10].

A host of different slope processes are now also known and provide some of the most important puzzles in understanding modern Mars. Thousands of slope streaks may form every Mars year [11]. Blockfalls and powder avalanches occur regularly on the north polar layered deposits [12]. Boulders shift on creep slopes [13] and lobate slump features occur in Valles Marineris [14]. Perhaps the most important slope processes are those where liquid water has been suspected. New deposits in gullies were at first thought to indicate liquid water [15]. However, a decade of observation has demonstrated that activity correlates with seasonal frost, which is primarily CO2 [16, 17]. The activity includes major channel incision and new lobate deposits, which raises the possibility that gullies could form with no liquid water involvement. Recurring Slope Lineae (RSL) have many characteristics expected of present-day liquid flows [18]. However, new evidence demonstrates that they terminate on slopes that closely match the dynamic angle of repose for dry sand [19], suggesting that RSL are granular flows.

An axiom of geology is that the present is the key to the past, and understanding Martian surface changes is essential to an understanding of the planet. The long-baseline monitoring by a succession of orbiting spacecraft has been essential to the detection and initial characterization of these changes. This

presentation will summarize current activity and discuss the many unknowns about the processes and their effects, particularly the role of volatiles in gullies and RSL.

J.J. Wray, R. Ziethe

The Colour and Stereo Surface Imaging System (CaSSIS) is the imaging system onboard the joint-European Space Agency/ Roscosmos ExoMars Trace Gas Orbiter. The instrument provides colour and stereo imaging of Mars at 4.6 m/px from the nominal orbit 400 km above the surface of Mars. CaSSIS has been tested during the first capture orbits in November 2016 but has been switched-off during the aerobraking phase of the mission. The instrument was shown to be performing well with stereo pairs, colour composites and images of Phobos produced from two short 40 minute bursts of data. At the time of writing, preparations are being made to enter the prime mission in April 2018 when up to 36 individual images can be acquired per 2 hour orbit during high data rate periods. We will present the first results from this mission phase.

B4.1-0013-18 WATER IN THE GALE CRATER, AS OBSERVED BY DAN INSTRUMENT ONBOARD THE CURIOSITY ROVER

Recent results of DAN experiment are presented for estimations of water mass fraction in the soil of the Gale crater along the traverse of NASA Curiosity rover. They are based both on active and passive DAN measurements of the shallow subsurface gathered for the period from August 2012 till now. Local variations of water content are discussed in comparison with results of another instruments installed onboard of the Curiosity rover and the orbital missions.

B4.1-0014-18 INCREASING OUR UNDERSTANDING OF PERCHLORATE SALTS DURING THERMAL DECOMPOSITION AND THEIR IMPLICATIONS FOR LIFE DETECTION ON MARS

Samuel Royle, s.royle@imperial.ac.uk

Imperial College London, London, United Kingdom Wren Montgomery, w.montgomery@imperial.ac.uk Imperial College London, London, United Kingdom Elizabeth Oberlin, elizabeth.a.oberlin@jpl.nasa.gov JPL, Pasedena, California, United States

Imperial College London, London, United Kingdom

The search for life on Mars targets the detection of organic matter from extinct or extant organisms. The majority of life detection missions have used thermal extraction as a method to transfer organic matter to the mass spectrometry detectors. So far, however, no mission has conclusively detected anything other than CO, CO2 and simple organochlorine molecules. It has been suggested that it is the presence of oxidising minerals, such as perchlorate salts, which obfuscates organic detection. Thermal decomposition of perchlorate releases oxygen which promotes combustion of any organic carbon present - thus the majority of organic molecules are lost as CO and CO2.

We have performed studies on magnesium perchlorate, one of the main perchlorate parent salts proposed to be present within the Martian soil, to better understand its response to thermal decomposition in order to find a work around for this 'perchlorate problem'.

In one series of experiments, magnesium perchlorate hydrate was dehydrated to various extents. This revealed that the hydration state of this salt affects the temperature of O2 release just as much as cation chemistry, which has previously been attributed to the differing O2 responses between MSL drill sites. Consequently, incorrect identification of perchlorate species may occur if hydration state is not taken into account and a mixture of metastable hydration states may be mistaken for a mixture of perchlorate salts. Our findings are important for Mars as the hydration state of salts in the regolith may change throughout the Martian year due to large variations in humidity and temperature.

In a follow-on study we investigated the gas-phase breakdown products of magnesium perchlorate and organic matter during thermal decomposition to identify a minimum organic matter: perchlorate ratio in the samples that allows excess organic carbon

to survive combustion for detection in the GC-MS. Our data show that there needs to be a minimum of 5 times more organic carbon than perchlorate in analysed samples for incomplete combustion; although for a statistically significant detection this rises to around 9 times. Therefore the expected organic carbon and perchlorate content for average Martian regolith would preclude the detection of organic matter by thermal decomposition techniques. Locations on Mars with an increased concentration of organic carbon and/or a decreased concentration of perchlorate will need to be targeted to increase the chances of successful life detection. Because habitability is enhanced by the presence of liquid water and because perchlorate is a water-soluble salt, locations on Mars with evidence of past or recent liquid water are obvious high priority targets. This could explain the detection of chlorinated hydrocarbons in the lacustrine Sheepbed Mudstone deposit.

B4.1-0015-18 INVESTIGATION OF SUBSURFACE STRUCTURES IN LUNAE PLANUM, MARS, WITH MARSIS SUPER-FRAME FLASH MEMORY DATA.

Graziella Caprarelli, caprarelli@irsps.unich.it IRSPS, Pescara, Italy

Roberto Orosei, roberto.orosei@inaf.it

Istituto di Radioastronomia, Istituto Nazionale di Astrofisica, Bologna, Italy Andrea Cicchetti, andrea.cicchetti@iaps.inaf.it

IAPS/INAF and Università di Roma Tor Vergata, Roma, Italy Marco Mastrogiuseppe, marco.mastrogiuseppe@uniroma1.it Sapienza Univeristy of Rome, Rome, Italy

Marco Cartacci, marco.cartacci@ifsi-roma.inaf.it IAPS/INAF, Rome, Italy

Here we report the results of our ongoing study of Lunae Planum, a vast Martian plain centered at coordinates 294°E - 11°N, bounded by Echus Palus (west), Sacra Mensa and Kasei Valles

(north), Xanthe Terra (east), and the northernmost chasmata of Valles Marineris (south). Overall, Lunae Planum appears to be morphologically uninteresting when compared to other geological features in the region. The presence of wrinkle ridges, grabens and impact craters with fluidized ejecta however, indicates that Lunae Planum had a complex geological history, further evidence of which is likely buried under the surface. To obtain information about the nature of subsurface materials and the presence of subsurface structures, we have processed data from the Mars Advanced Radar for Subsurface and Ionosphere Sounding (MARSIS), which has been operating on board Mars Express (MEX) since 2005. Throughout the duration of its mission, the sounder acquired hundreds of orbits over the approximately 1,500,000 km^2 areal extent of Lunae Planum. We processed 36 orbits in standard mode, but found no obvious reflectors, which we interpreted to indicate that: (a) similar material, or materials with similar values of dielectric constant (ε), form Lunae Planum at all depths of penetration of the radar signal; and/or (b) porous lithologies compaction by overburden pressure affect the ε values [1]. From new super-frame (SF) data acquired during the period November 20-30, 2017, we observed time-delayed echoes in MEX-MARSIS orbits 17590, 17597, and 17604 radargrams. The absence of similar echoes in surface clutter simulations suggests the presence of a real subsurface reflector with a time delay of 11 µs along one of the SF tracts of orbit 17597. Assuming a putative value of $\varepsilon = 8$ (for basalt [2]), this would indicate a reflector at a depth of 580 m in this location. We continue to test this working hypothesis by: (a) conducting additional processing of the data;

examining the implications of the putative presence of reflectors at this depth in the area, within the known geological context. [1] Caprarelli et al. (2017) LPSC 48, 1720. [2] ElShafie

A., Heggy E. (2012) LPSC 43, 2790.

B4.1-0016-18 THE AMAZONIAN CLIMATE OF MARS: A COLD AND DRY SUMMARY

Ali Bramson, bramson@lpl.arizona.edu

University of Arizona, Tucson, Arizona, United States

The climate of the last 3 billion years of Mars' history, the "Amazonian," has been characterized by cold and dry conditions. During this time, atmospheric and surface conditions have been largely controlled by periodicities in orbital and rotational parameters analogous to Earth's Milankovitch cycles. The obliquity of the planet in particular has undergone large variations that affect the distribution of insolation and therefore volatile stability. Much progress has been made to inventory the current distribution of volatiles on Mars, including recent discoveries of extensive water ice deposits at mid-latitudes from radar and image data. However, outstanding questions remain as to the relationship between the current inventory and the previous climatic conditions in which these volatiles were emplaced and subsequently modified. I will present on the current understandings, as well as the outstanding questions, regarding the climate of the Amazonian, especially as it pertains to the role of volatiles. Included in this presentation will be a synthesis of the studies presented at the Mars Workshop on Amazonian and Present Day Climate [1] to be held June 18-22, 2018, as well as the progress and outstanding questions identified at the Sixth International Conference on Mars Polar Science and Exploration [2].

Neutron flux observed from the orbit is sensitive to hydrogen content in the planetary soil, up to 1m depth. Performing such measurements allows to build, with time, maps of hydrogen content in the surface of a celestial body. This technique was successfully used in the past, for example by HEND instrument onboard Mars Odyssey. Fine Resolution Epithermal Neutron Detector (FREND) is an instrument onboard the Trace Gas Orbiter (TGO) of the ExoMars mission and its main feature is the collimator that allows for neutron detectors' very narrow field of view up to 28 km radius spot. This will create new hydrogen deposition maps of a much higher spatial resolution than that of HEND, which produced maps with only 200 km radius pixel size. A finer resolution of hydrogen deposition maps would allow for selection of prospective landing sites and help understanding the geology of Mars better, cross-correlating neutron data with relief features. TGO arrived in the Martian orbit in October 2016 and finalized its aerobraking period in April 2018 that brought the mission to the final circular 400km altitue orbit. After short period of engineering commissioning, the Science Phase begins and we present here the first data acquired by the instrument, together with preliminary interpretations.

B4.1-0018-18 GROUND ICE RESOURCES OF THE PROTONILUS MENSAE

Sophia Casanova, s.casanova@student.unsw.edu.au University of New South Wales, Sydney, Australia

The Mid-Latitude Protonilus Mensae region on Mars is host to a number of distinctive land- forms that can be interpreted as evidence of the presence of water ice buried and preserved under the regolith. If existing at depths accessible by excavation equipment, these deposits may represent a significant water resource for future human missions to the red planet. In this work we discuss the geomorphological properties of these features and interpret them in the context of their formation, preservation, and age. We also discuss technological approaches for the potential utilisation of these deposits as a resource to support human operations, and present a review of the environmental and terrain conditions in which mining and exploration activities may likely be conducted.

B4.1-0019-18 HOW PLAUSIBLE IS AN ORBIT-DRIVEN WATER ICE CLOUD GREENHOUSE ON MARS?

Melinda Kahre, melinda.a.kahre@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States Robert M. Haberle, robert.m.haberle@nasa.gov

NASA Ames Research Center, Moffett Field, New Jersey, United States

Clouds in planetary atmospheres can either cool or warm the climate system. Clouds provide a negative forcing to the system by increasing the planetary albedo when they reside over relatively dark surfaces. Conversely, clouds provide a positive forcing to the system in the infrared, where they absorb radiation and emit a fraction of it back to the surface. The net effect on the climate system depends on the relative strength of these opposing effects, which depend on the cloud optical depths, altitudes, and particle sizes. In Earth's atmosphere, low clouds tend to cool the surface, while high clouds tend to warm the surface. A similar effect occurs in Mars' atmosphere-low clouds cool while high clouds warm. Water ice clouds in Mars' current atmosphere provide weak net annual warming of less than 1 Kelvin. However, recent climate modeling studies suggest that water ice clouds could have provided significant greenhouse warming during Mars' recent history. Even modestly increasing obliquity to 30° can produce water ice cloud greenhouse annual mean warming of 15 K. At 35° obliquity, the cloud-generated greenhouse warming can reach more than 25 K. If clouds warm Mars this significantly at moderate obliquity, the planet's climate could have been dominated by the effects of water ice clouds through much of its history. Given the potentially large effect of water ice clouds, it is important to critically evaluate how realistic these results are. The conditions necessary for a significant cloud greenhouse depend both on microphysical processes and on the characteristics of the general circulation and transport processes. We use a Mars global climate model, equipped with a state-of-the-art water ice cloud microphysics package, to isolate and investigate these processes to better understand the plausibility of a strong water ice cloud greenhouse in Mars' recent past.

B4.1-0020-18 MAPPING ANCIENT PERIGLACIAL LANDSCAPES ON MARS

Malmi Kiriwandalage, malmi.pasandi@gmail.com

Suffolk County Community College, Patchogue, New York, United States

My project is about searching for evidence of the nature of the Martian climate during the ancient past. In this work, I investigated the nature of an enigmatic terrain observed at 25 S latitude on Mars. Qualitatively, the terrain resembles a periglacial landscape, which is land that built up in a cold climate, often adjacent to a glacier or an ice-sheet, and was subjected to intense cycles of freezing and thawing. However, at the latitude where this terrain is found, ground ice is not stable in the present day. Thus, we hypothesized that this terrain could represent the remnants of an ancient icy climate in this region. To test the hypothesis, I performed a quantitative morphometric comparison of the landscape with known periglacial surfaces on Mars. I worked on three different HiRISE images (from NASA Reconnaissance Orbiter) in the southern hemisphere of Mars. The first and second images were located in area where the ground ice is not stable in the present day. The third image was located in area where the ground ice is stable at depth. With the help of ArcGIS and ArcMap, I was able to map the distinctive terrain patterns that were observed at relatively low latitudes where ground ice does not exist. And then I measured the size, orientation and clustering of a distinctive set of quasi-circular features that resemble pingos on the earth or as an inverted crater. Pingos also called hydro laccolith are small, elongate to circular, ice-cored mounds that can reach up to 70 m (230 ft.) in height and up to 600 m (2,000 ft.) in diameter. And inverted carter means a once-normal appearing impact crater that was filled in with sediment. The fill became indurated, or hardened, until it was more resistant to subsequent erosion than the surrounding material. At last, I compared those patterns with the present-day periglacial landscapes at higher latitudes on Martian surface. At the end of my research I was able to conclude that features in image 1 and 2 are similar in diameter to known periglacial features in image 3, supporting the hypothesis that the enigmatic terrain had a periglacial origin.

B4.1-0021-18 ISOTOPIC CONSTRAINTS ON MARTIAN CLIMATE SUGGESTED BY SAMPLE ANALYSIS AT MARS (SAM) MEASUREMENTS

Heather Franz, heather.b.franz@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States Paul Mahaffy, paul.r.mahaffy@nasa.gov

NASA/GSFC, Greenbelt, Maryland, United States Sushil K. Atreya, atreya@umich.edu

University of Michigan, Ann Arbor, Michigan, United States Chris Webster, chris.r.webster@jpl.nasa.gov

JPL, Pasadena, United States

Since arriving at Gale Crater in August 2012, the Sample Analysis at Mars (SAM) suite of Mars Science Laboratory's Curiosity rover has probed the isotopic composition of the martian atmosphere and of volatile compounds in surficial and near-surface deposits with its Quadrupole Mass Spectrometer (QMS) and Tunable Laser Spectrometer (TLS). The complementary capabilities of these two instruments provide an unprecedented ability to query multiple isotope systems in situ on Mars. Through a combination of direct-sampling and enrichment experiments, SAM has observed evidence for fractionation and ongoing loss to space in atmospheric isotope ratios of C, O, H, N, and Ar [1-5]. Significant fractionation of atmospheric Kr and Xe isotopes as measured by the QMS suggests a history of early hydrodynamic escape [6] overprinted by contributions from spallation and neutron capture [7]. These collective observations indicate substantial loss of Mars' initial atmosphere to space [8]. Isotopes of volatile elements preserved in minerals offer additional constraints on the history of atmospheric loss, the current atmospheric composition, and geochemical processes that have occurred within sedimentary deposits over time. The D/H ratio of hydroxyl groups in hydrated minerals, such as sulfates and phyllosilicates, released at high temperature through pyrolysis of drilled fines by SAM, may record the isotopic composition of water in more ancient times, providing constraints on the history of H loss to space [3]. In addition, ongoing SAM measurements of readily exchangeable water released from minerals at low temperature, which reflect the isotopic composition of the current atmosphere, suggest seasonal variability in D/H. Sulfur isotope ratios in reduced and oxidized mineral phases indicate a history of S fractionation by photochemistry in the martian atmosphere and hydrothermal processing in the subsurface [9]. Significant fractionation in Cl isotopes of HCl produced from processing of oxychlorine and chloride minerals during pyrolysis also suggests effects of atmospheric photochemistry or reduction of oxychlorine compounds at the surface [10]. Details regarding the history of atmospheric loss and the environment, on both global and local scales, at the time when lakes were present at Gale crater [11] are still poorly constrained. More in situ measurements are needed to expand our understanding of Mars' climate history.

B4.1-0022-18 THE LONGEST RECORD OF WATER ON MARS: RECENT RESULTS FROM MRO NEAR THE MARS-2020 LANDING SITE CANDIDATE NORTHEAST SYRTIS

Bethany Ehlmann, ehlmann@caltech.edu

California Institute of Technology, Pasadena, California, United States Eva Scheller, eschelle@caltech.edu

California Institute of Technology, Pasadena, California, United States Daven Quinn, dquinn@caltech.edu

California Institute of Technology, Pasadena, United States

The Mars-2020 rover mission is in the process of selecting a landing site for the first step in sample return. Recent new results from the Mars Reconnaissance Orbiter (MRO) provide new insights into the oldest and youngest materials accessible at one candidate landing site, highlighting the ability to interrogate, at the mesas of Northeast Syrtis, multiple igneous units spanning the Noachian and Hesperian, megabreccia and basement recording the effects of basinscale impacts, and multiple later episodes with water in groundwaters and surface waters – including lakes – in multiple phyllosilicate, carbonate, and sulfate deposits.

To review, prior work [1] showed the lowermost stratigraphic group to be a basement of phyllosilicate and low-calcium pyroxene rich units, disrupted by the Isidis basin impact, with diverse morphologies ranging from megabrecciated to layered to massive and with variable degrees of alteration. This was overlain unconformably by an olivine-enriched unit, variably altered to Mg-carbonate. In the southern part of the region, layered sulfates and lavas from Syrtis Major unconformably overlie the olivine-carbonate. The compositional stratigraphy has a characteristic geomorphology [2].

Recent new work on the basement unit [3,4] shows that Fe/Mg phyllosilicates are found in topographic highs within the landing ellipse with small patches of kaolinite while low-calcium pyroxene is restricted to topographic lows. The massive units with low-calcium pyroxene show no signs of aqueous alteration in CRISM data. Furthermore, distinct classes of megabreccia are identified including zones of layered, polymict, monomict, and single, dispersed megabreccia. The landing site has multiple distinct outcrops with megabreccia blocks, including both those dominated by Fe/Mg phyllosilicate and those dominated by low-calcium pyroxene in distinct 1- 100 m blocks. In the extended mission zone, one of the largest outcrops of layered megabreccia is found near the sulfates.

Recent new work [5] on the layered sulfates shows that they fill local topographic lows with sediments reaching 500 m thick. Shallow (<10deg) but non-zero dips and thinning of deposits embaying basement indicate the NE Syrtis sulfates were deposited subaqueously in deep sedimentary basins. Either these represent deposits from an ocean that filled Isidis or local confinement by an ice sheet, now removed. Subsequently, dewatering, creation of fractures, and mineralization created large veins of jarosite boxwork cross-cutting the sulfates. These were capped, eroded by fluvial valleys, and then the valleys were exploited by Syrtis Major lavas, filling in channels previously carved by waters. Aqueous activity continued even after these Hesperian lavas, carving channels on the surface of the lavas and depositing flat lying sediments and fan-deltas in local topographic lows indicative of a late generation of lakes in the late Hesperian or Amazonian.

Thus, recent data confirm the Northeast Syrtis mesas preserve the longest records of geological processes on Mars, including liquid water. Fe/Mg phyllosilicate-rich basement from the Early Noachian (or earlier) is preserved in megabreccia and the sulfate and fan-deltas in the extended mission sulfates near the Syrtis Major lavas record Amazonian surface waters in lake/ocean sediments, all available for in situ interrogation and sampling.

Space Applications Centre (ISRO), Ahmedabad, India

The chemical and spectral characterisation studies of hydrated secondary sulphate minerals, copiapite [Fe2+Fe3+4(SO4)6(OH)2 20H2O] and rozenite [Fe2+SO4 4H2O] in Southern India, can be considered as probable chemical analogue minerals of Mars. Copiapite and rozenite in Wayanad region in Kerala in South India are associated with gossan developed over sulphide-rich Banded Iron Formations (BIFs). Copiapite in Wayanad occurs as pale-yellow bloom over sulphide-rich rocks while white-coloured rozenite occurs as powdery encrustations. The formation of these minerals as encrustations on primary sulphide minerals (pyrrhotite and pyrite) indicates direct transformation of primary sulphide minerals to secondary sulphates by the processes of weathering and oxidation. The sulphide-rich BIFs hosting hydrated iron sulphate minerals in Wayanad region were identified and reported by Geological Survey of India (Praveen et al., 2013, Geological Survey of India Reports, Vol. ME/SR/KRL/2012/070, pp. 61-64 & Praveen and Sajinkumar K. S., 2017). We carried out hyperspectral analyses in visible-NIR-SWIR band, Thermal infrared emission spectroscopy (TIR), laser Raman and Fourier transform mid-infrared spectroscopy (FTIR) measurements and interpreted the absorption and emission bands and vibration modes in the lattice.

Copiapite shows the characteristic triple absorption feature around 2400 nm which is due to combinations of different bending and stretching modes of SO42−, H2O and OH−. In rozenite, only two absorption bands are observed around 2400 nm which characterises and helps in distinguishing the absorption features from that of copiapite. Copiapite also exhibits strong doublet peak around 1000 cm−1 region in Laser Raman spectrum which is due to symmetric stretching mode of sulphate. For rozenite, strong characteristic stretching vibration of sulphate molecules is observed at 993 cm−1. The continuum-removed spectra were quantitatively matched with reference spectra (RELAB and USGS databases) and MRO-CRISM data using different matching algorithms like Pearsonian Correlation Coefficient (PCC) metric

and Spectral Feature Fitting (SFF). We will discuss the ocurrence of copiapite in outflow channels in Mawrth Vallis, Mars (W.H. Farrand et al./Icarus 241 (2014) 346-357) and the implications of terrestrial occurrences of hydrated secondary sulphate to Mars. The genetic model of copiapite and rozenite occurrence in Wayanad will be compared with Martian occurrences outlining the importance of aqueous processes.

The above-mentioned instruments are considered as next-generation instruments for exploration of Mars. Laser Raman spectrometer is also included in near-future Mars missions (SHERLOC, MARS 2020, Exo-Mars Pasteur suite, 2020) and the results can be helpful in instrument calibration using mineral/chemical and site analogue and can aid in minerals and organic compounds detection. Copiapite-occurring analogue sites in terrestrial conditions include the Río Tinto (Iberian Pyritic Belt) and El Jaroso ravine, Sierra Almagrera, Spain, hosting microbial colonies with Methanogenic activities which is also precursor to complex organic compounds on earth. The abundance of water in these sites can give important hints to the aqueous processes on Mars. These hydrated sulphates are thermodynamically stable on Mars and may preserve the biogeochemical properties and gives an insight to environmental condition prevailed in geological history and evolution of Mars with possibility of different genesis mechanisms.

B4.1-0024-18 CLAY MINERAL BASED PALEOENVIRONMENTAL RECONSTRUCTION OF ANCIENT GALE CRATER LAKES, MARS

Thomas Bristow, thomas.f.bristow@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States

Mars Science Laboratory (MSL) has documented clay minerals in various drill samples as it traversed the floor of Gale crater and began its ascent of Mt. Sharp. The clay minerals provide important constraints on the syndepositional conditions within lakes that occupied the crater floor sim3.5 Ga. The most recent drill samples, named Marimba, Quela, and Sebina come from a succession of fluvio-lacustrine mudstones/siltstones/sandstones making up part of the Murray formation. Clay minerals constitute as much as 28 wt.% of these samples. A combination of CheMin X-ray diffraction, SAM evolved gas analysis, and APXS bulk chemical data indicate that clay minerals consist of a mixture of Al-rich dioctahedral and Mg-rich trioctahedral smectite. This contrasts with Fe-rich trioctahedral smectite (saponite) documented in lacustrine mudstones recovered from Yellowknife Bay (YKB), earlier in the mission.

YKB saponite is thought to have formed via isochemical aqueous alteration of detrital olivine close to the time of sediment deposition, under anoxic to poorly oxidizing conditions. Al-rich dioctahedral smectite and Mg-rich trioctahedral smectite are also thought to have formed close to the time of deposition. However, these clay mineral species indicate oxidizing conditions in which sediments were subject to an increased degree of element mobility and evaporative concentration. Observed changes in bulk mineralogy and sedimentary facies support the inferences from clay mineralogy. These observations include: 1) a transition from magnetite to hematite as the main Fe-oxide in sediments over the course of MSL's traverse, 2) increasing abundances of Ca-sulfates, 3) a reduction in the quantity of reactive mafic minerals, and, 4) mudcracked Murray formation mudstones - indicating episodic desiccation. These results broaden the spectrum of mineralogical facies documented by MSL. Together sedimentology and mineralogy indicate a long lasting, dynamic, fluvial-lacustrine system encompassing a range aqueous geochemical processes under varying redox conditions.

The sedimentary rock strata explored in Aeolis Palus and the lower slopes of Aeolis Mons using the Curiosity rover are interpreted to be a record of persistent fluvial, deltaic, and lacustrine environments. Fluvial and deltaic rocks of the Bradbury group are interpreted to interfinger with the recessive Murray formation exposed on lower Aeolis Mons (Mount Sharp). The environments are arranged into a progradational stacking pattern similar to lacustrine basins on Earth in which the accumulation of water and sediment exceeds loss from evaporation. The more than 250 vertical meters of Murray formation investigated using Curiosity consist mainly of finely laminated (0.5 to 2 mm) mudstones, with intercalated cross-stratified facies and sandstones higher in the succession. These rocks are interpreted as lacustrine with minor fluvial, lake margin, and possible aeolian intervals. Comparison with depositional rates in Earth's lacustrine settings suggests that lakes were present in Gale crater for millions of years.

Facies diagnostic of seasonal or perennial ice cover, or of ice within the sediment, have not been identified. Calculated chemical index of alteration (CIA) values are consistent with cold and drier conditions in the rocks of Aeolis Palus, with warmer and more humid conditions in the younger rocks of lower Aeolis Mons. Evidence of early and late diagenesis, e.g., concretions, mineral veins, crystal molds, and fracture-adjacent alteration haloes, implies that multiple generations of groundwater interacted with the sediments after deposition. The fractures and veins indicate continued interaction with subsurface fluids long after the sediments were lithified, providing an extended duration for potentially habitable conditions.

Crater counts indicate that Gale crater formed at about 3.8-3.6 Ga near the Noachian-Hesperian boundary and that deposition, burial, lithification, and exhumation of the lower section of the central mound occurred by 3.3-3.1 Ga. Together, these observations constrain the climate of early Hesperian equatorial Mars to conditions that permitted liquid water to be thermodynamically stable at the surface and in the subsurface at Gale crater, and that were sufficiently humid to reduce evaporative losses and to drive fluvial erosion, transport, and re-charging of the lakes with a hydrological cycle.

Isotopic measurements of atmospheric gases and of water evolved from Hesperian-age clay minerals support models of atmospheric loss in the early history of Mars. These measurements indicate that the planet's exchangeable water inventory had not yet decreased to its present value when the clay minerals formed.

B4.1-0026-18 WARMING EARLY MARS BY IMPACT DEGASSING OF REDUCED GREENHOUSE GASES

Robert M. Haberle, robert.m.haberle@nasa.gov

NASA Ames Research Center, Moffet Field, California, United States Kevin Zahnle, kevin.j.zahnle@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States Nadine G. Barlow, nadine.barlow@nau.edu

Northern Arizona University, Flagstaff, Arizona, United States

We suggest a new role for impacts on early Mars: the delivery of reduced greenhouse gases that can raise surface temperatures above freezing for geologically significant periods of time. Rainfall during these temporary warm epochs can erode the surface, alter basaltic rocks, and cut fluvial features thus providing at least a partial solution to the vexing faint young sun paradox. The mechanism operates as follows. Some of the kinetic energy of an impactor is converted to thermal energy when impacting the surface. This heats the materials it contains and the surrounding atmosphere. The fast thermochemical reactions that take place in the plume eventually cease as it rapidly cools and reactions are quenched. Gas equilibrium calculations suggest that for many impactor types (e.g., carbonaceous chondrites, comets, etc.) CO2, CO, and H2 are the dominant gases at typical quenching temperatures (1000-1500K), but CH4 can also be produced. If the impact takes place in a thick enough pre-existing CO2 atmosphere, collisions between the CO2, H2, and CH4 molecules introduce new infrared absorption bands that reduce the outgoing longwave radiation and strengthen the greenhouse effect. Surface temperatures then rise facilitating a hydrological cycle involving rainfall and runoff. The effect is temporary, however, since H2 escapes and CH4 is photo-chemically destroyed. Eventually (105 years) conditions return to "normal" until the next impact disturbs the system. The cumulative effect of multiple impacts depends on the impactor flux, size distribution, type, and delivery history, as well escape rates and photochemical sinks. A simple model we developed that includes these processes suggests that just the H2 alone produced from impact events is sufficient to elevate Mars surface temperatures above freezing for cumulative times between 105-107 years during the Noachian epoch depending on impactor type. Any CH4 added would lengthen these times. It is not clear if this mechanism can explain all of the water-related features on Noachian surfaces, but these results suggest it must have played some role since impacts did occur. Thus, a new line of research into the mystery of early Mars opens up.

B4.1-0027-18 EXPLORING GEOMORPHIC PROCESSES AND MARTIAN GALE CRATER TOPOGRAPHY USING CTX AND HIRISE EXPRESS IMAGE DATASET

Pavan Kumar, pawan2607@gmail.com Jamia Millia Islamia, New Delhi, India Meenu Rani, meenurani2607@gmail.com

G.B. Pant National Institute of Himalayan Environment & Sustainable Development, Almora, India

Spatially referenced topographic dataset Context Camera images acquired from Mars reconnaissance orbiter were used to explore geomorphic processes and topography of Gale Crater. A base map was prepared by mosaicking all images. This base map was utilized for preparing geomorphologic map of the crater. Surface map of the topography of the Crater was prepared using Mars Orbiter Laser Altimeter (MOLA) data. HiRISE images were used to enhance the identified geomorphic features. Results revealed the presence of both fluvial and aeolian processes and their respective associated landforms in the Crater. Depositional landforms such as alluvial fan, inverted channel and mound and erosional landform namely canyons produced by fluvial action were distinctly identified and mapped. Yardangs produced by erosional and ripple and dunes formed by the depositional work of wind were also identified in the Crater. The fluvial channels, inverted channels and fan shaped deposits further clued of ongoing aqueous activity. Sinuous ridges are most common features present on the floor of crater. Rock sand and silt in the crater were found to have been transported and deposited by flowing water on its floor. Presence of different sedimentary structures and valley revealed ancient sedimentary deposits due to water action. Erosional and depositional signs found in observation make the study a good comparison among other intra-crater fans and sedimentary land forms. Topographic data set Context Camera (CTX) and High Resolution Imaging Science Experiment (HiRISE) images can best be utilized for geomorphic and topographic mapping of the Mars planet.

Harvard University, Cambridge, California, United States

Abstract: A rocky planet, from deep interior to atmosphere has the potential to generate essential nutrients and redox gradients critical for the emergence and the evolution of life. I will present first results on two very different large-scale planetary processes that generate nutrients and redox gradients on Mars-within the deep interior and in shallow brinesacross time (from planet formation to modern day) and space (local resolution, global coverage).

We use time-dependent geodynamic models, capable of computing the 3D temperature profile - self-consistently accounting for serpentinization and radiolysis reactions as a function of subsurface temperature, pressure, and chemistry - throughout the last 4.5 billion years (based on [1]-[4]). Additionally, we couple a global climate model (the Mars Weather Research and Forecasting, MarsWRF). MarsWRF is a global model based on the terrestrial mesoscale WRF model (see [5]-[7]) and is a Mars-specific implementation of the PlanetWRF GCM [8], accounting for a changing climate with variable planet obliquity through time.

Geodynamic and climate models combined allow us to compute for Mars the 4D distribution (one dimension in time and 3D distribution in space) of 1) hydrogen-rich reducing subsurface environments, driven by serpentinization and radiolysis of water, and 2) oxygen-rich regions as a product of atmosphere-brine (e.g., perchlorate brines) interactions governed by climate and surface chemistry. We will show time-dependent spatial maps of such zones, suggesting a large potential for aerobic respiration on Mars today and in its recent geologic past (previous 20 Ma) varying with obliquity changes throughout time, as well as the potential for locally large modern-day hydrogen fluxes. These two examples provide insight into the emerging capabilities of modeling the Martian habitability in three spatial dimensions with increasing resolution and across time, from planet formation to today.

The NASA InSight (Interior Exploration using Seismic Investigations, Geodesy and Heat Transport) mission will land on Mars on November, 26th after a launch in May, 2018. The payload is a complete international geophys-ical observatory, with a seismometer (SEIS, France), a heat flux experiment (HP3, Germany), a geodesy experiment (RISE, US), a magnetometer and the APSS (US) suite of atmospheric sensors measuring wind (TWINS, Spain), atmospheric temperature, pressure and magnetic fields. SEIS is the primary instrument of the mission and consists of a 3-axis very-broad-band (VBB, France) instrument and a 3-axis short period (SP, UK) instrument, mounted on a Leveling system (LVL, Germany), connected to acquisition and control electronics (Ebox, Switzerland) by a Tether (US), and protected by a Wind and Thermal Shield (WTS, US). The SP noise floor is 3 10-9 m/s2/Hz1/2 between 0.1 and 6 Hz and significantly better than SP requirements (10-8 m/s2/Hz1/2 between 0.1 and 10Hz). The VBBs are en-closed in a vacuum thermal enclosure (EC) under JPL responsibility, which not only provides a high thermal pro-tection for the VBBs but also reduces their Brownian noise, enabling the VBBs to reach a very low noise floor of 3 10-10 m/s2/Hz1/2 between 0.1 and 1 Hz, which is also significantly better than VBBs requirements (10-9 m/s2/Hz1/2 between 0.01 and 1Hz). We describe first the SEIS experiment and present its science goals and performance demonstrated during the Flight Model characterization done during the 2017 Flight Model delivery activities, both in the clean rooms of CNES and LMA for the Flight Units and in the Black Forest Observatory seismic vault for the qualification unit. As SEIS is expected to provide the first seismic records of Mars, implementation of the science goals has been very challenging due to the lack of information on the deep seismic interior structure of Mars, as well as its level of seismic activity and surface seismic noise. Nevertheless and in parallel with the hardware technical developments made by the SEIS hardware team, the SEIS science team has developed sophisticated noise models, blind tests with synthetic data and field tests, including during activities of the HP3 mole system, which will be presented. We then summarize and review the most recent analysis made by the SEIS team for predicting the seismic per-formance of the SEIS experiment in the Martian environment, including pressure and magnetic decorrelations using APSS sensors. We present the most recent update estimates of seismic signals generated by quakes, impacts and the Martian dynamic atmosphere, as well as structure inversion and seismic catalogue perspectives. We conclude by describing the Public Outreach and Educational program of SEIS.

The ExoMars Trace Gas Orbiter (TGO) reached Mars orbit on October 19, 2016, and after aerobraking, it will begin its final science and operational data relay phase in April 2018 in a 400 km near-circular orbit. Tracking data from these mission phases are collected and analysed for TGO's Mars Atmosphere and Gravity Experiment investigation (MAGE).

MAGE will make use of ground infrastructure as well as spacecraft subsystems. During the orbital phase of the mission, X-band will be used for uplink for commanding, and downlink for telemetry return and tracking. Deep-space ground stations from ESA, NASA and Russia's Roscosmos will track TGO. Doppler shift in the radio communications signal can be used to determine the gravitational field of Mars. From the time variability of the gravity field one can derive and track seasonal changes in the location of carbon dioxide deposited on the surface. TGO's Doppler tracking data is also used for estimates of the neutral density of Mars thermosphere during the aerobraking passes.

ESA's Science Operations Centre (SOC) is responsible for science planning and operation for TGO, as well as low-level processing and archiving in the ESAC Planetary Science Archive (PSA) of the resulting data. We have created the Mars Atmosphere and Gravity Experiment

Working Group (MAGE WG) that acts as a liaison between the guest investigator and ESA. MAGE WG coordinates the process that ensures a proper data provision mechanism to the guest investigator, starting with the data requirements to conduct the MAGE investigation. The Data Processing pipeline receives raw telemetry from the Mission Operations Centre in ESOC and generates PDS4 products for inclusion in the PSA. Products for the archive are grouped into containers known as collections and these in turn are grouped into bundles of collections, following the PDS4 standard. For TGO there are bundles for each instrument plus a separate bundle for generic mission data, with a typical instrument bundle containing separate collections for different processing levels plus calibration, documentation, ancillary and other distinct data types.

In this paper we will give an overview of the TGO's MAGE investigation and ESA's support to provide the required products to the selected guest investigator and archiving for the working group.

ExoMars is a joint programme between the European Space Agency and ROSCOSMOS.

B4.1-0032-18 WATER ICE CLOUD PROFILES DURING THE APHELION SEASON ON MARS RETRIEVED FROM MARS CLIMATE SOUNDER FAR-INFRARED RADIANCE MEASUREMENTS

Armin Kleinboehl, armin.kleinboehl@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States
John Schofield, john.t.schofield@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States
David Kass, david.kass@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States

Limb sounding of thermal emission in the infrared wavelength range is a powerful technique for measuring aerosols in the martian atmosphere. It provides superior vertical resolution and, due to the long optical path, typically has a higher sensitivity compared with nadir viewing measurements. However, the limb path can become opaque in high aerosol conditions, preventing a limb sounding measurement from penetrating the atmosphere. This is a particular problem in the aphelion season on Mars, where water ice clouds reach opacities that make limb measurements at mid-infrared wavelengths challenging. This problem is greatly improved with measurements in the far-infrared wavelength region, where water ice opacities are much reduced.

The Mars Climate Sounder (MCS), a passive infrared radiometer onboard Mars Reconnaissance Orbiter (MRO), has been operating in Mars orbit since September 2006. With its 5 midinfrared, 3 far infrared, and one broadband visible/near-infrared channels it views the martian atmosphere in limb, nadir, and off-nadir geometries. Each spectral channel uses a linear detector array consisting of 21 elements, which provides -10 to 90 km altitude coverage with 5 km vertical sampling when pointed at the Mars limb. From the measured radiance profiles, atmospheric profiles of temperature, dust and water ice opacity are operationally retrieved using the midinfrared channels.

Here we present the first retrievals of water ice profiles from MCS limb measurements in the farinfrared. The retrievals combine detectors of the far-infrared channel centered at a frequency of 254 cm-1 in high water ice opacity conditions with detectors of the the mid-infrared channel centered at 843 cm-1 in low opacity conditions. The conversion between far-infrared and midinfrared opacities is based on extinction efficiency ratios obtained empirically from the MCS limb measurements [Kleinböhl et al., Sixth International Workshop on the Mars Atmosphere, 2017]. Limb retrievals of water ice in the far-infrared channel are typically possible at opacities a factor 2-3 higher than in the mid-infrared channel.

Initial results from these first retrievals indicate that the vertical structure of the water ice clouds in the equatorial cloud belt significantly changes between daytime and nighttime. During daytime water ice profiles exhibit a layered structure with peak opacities around 30 km altitude. During nighttime peak opacities tend to be lower but the ice is distributed over a larger vertical range. These first results suggest that the new capability of retrieving water ice profiles in the far-infrared will provide new insights into the structure of the equatorial cloud belt and its temporal evolution on diurnal to seasonal time scales.

S.C. Chakravarty, chakravarty08@gmail.com Bangalore University, Bangalore, India

The atmospheric composition data of Mars has been utilized from Mars Exospheric Neutral Composition Analyser (MENCA) experiment on board the Mars Orbiter Mission (MOM) during the period September 2014 through September 2016. The time series data has been processed to derive the corrected, calibrated and normalized parameters of various gaseous constituents along with the total atmospheric pressure of Mars. The time tagged data is further organised with reference to the satellite sub-point coordinates and its altitude from the surface using SPICE kernels of MOM with proper codes developed by us. The overall data is categorised for different orbits of MOM in order to select preferable data points, particularly near to the periareion of MOM. The total pressure values were analysed to study the characteristics of its variability with altitude, seasons and influence of solar activity. The results obtained were compared with a simple model developed for this purpose. Further analysis is carried out to compute the partial pressures of CO_2, Ar, (N_2+CO), H, N and O to derive their spatial and temporal variations. In addition, high resolution results are also obtained for selected data from MOM orbits for comparison with similar observations made by other missions of Mars. The results presented provide various points to validate the model developed by us and existing models elsewhere.

B4.1-0035-18 MARTIAN ACTIVE GULLY STUDIES AND WHAT THEY IMPLY ABOUT PRESENT AND RECENT SURFACE PROCESSES

Serina Diniega, serina.diniega@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Colin Dundas, cdundas@usgs.gov

United States Geological Survey, Flagstaff, Arizona, United States Alfred McEwen, mcewen@lpl.arizona.edu

University of Arizona, Tucson, Arizona, United States Candice Hansen, cjhansen@psi.edu

Planetary Science Institute, Tucson, United States Susan Conway, susan.conway@univ-nantes.fr University of Nantes, Nantes, France

Young martian gullies, first observed in 2000 by Malin et al., usually consist of an alcove, channel, and apron and are found on both sandy and rocky slopes, primarily through the mid-latitudes (e.g., Auld and Dixon, 2016; Harrison et al., 2015). Due to their morphological resemblance to terrestrial water-formed ravines (or large gullies), many of the early studies proposed water-driven mechanisms for their formation. Furthermore, due to their superposition over young geologic features, pristine features, and lack of superimposed craters, some of these features were interpreted as potential geomorphic evidence of recent surface liquid water flow and thus categorized as a potential ('uncertain') Special Region (as described by the Special Regions Science Analysis Groups (Beaty et al., 2006; Rummel et al., 2014) and adopted by COSPAR (Kminek et al., 2010)): regions within which conditions for replication of terrestrial organisms might be found, especially with regards to temperature and water availability. Proposed water-driven mechanisms for gully formation were questioned, however, when active martian gullies were observed within the southern mid-latitudes, on both dune and non-dune (e.g., crater walls) slopes (Diniega et al., 2010; Dundas et al., 2010; Malin et al., 2006). Based on the winter-timing and locations of activity, those studies showed that present-day gully activity was likely tied to a seasonal frost-driven process. Since those first investigations, the activity within the southern mid-latitudes has been quantified over several Mars years and timing has been constrained further to late winter/early springtime (possibly related to springtime sublimation-driven or initiated processes) (Dundas et al., 2012; 2015; in press: Geo Soc London). Furthermore, studies of north polar dune "gullies" (i.e., alcove-apron features, often lacking a channel - hence the quotation marks) show activity also constrained to the frosted periods of the martian year (although possibly not the same frosted period) (Diniega et al., 2017; Hansen et al., 2011; 2015). This has motivated efforts to identify possible CO_2-frost driven mechanisms and to constrain the exact form and quantity of frost needed to initiate activity. However, it is not yet clear if all gullies form through the same driving environmental conditions and/or mass-wasting processes. In particular, equatorial gullies, while smaller than those in the mid-latitudes, also exist in regions where CO_2 frost is not expected and some have shown activity (Dundas et al., 2015; McEwen, in press: From Habitability to Life on Mars). In this presentation, we will give an overview of martian active gully studies from 2010 through the present. Within these results, we will discuss present-day rates of gully activity that have been extrapolated by Dundas et al. (2015; in press: GSL) to constrain what older features may reflect about past environmental conditions and processes. We will identify the current, most pressing gully-related questions (and when possible, relate these to ongoing investigations) and compare our current understanding of gullies to the definition of potential Special Regions as outlined in the latest SR-SAG and COSPAR reports.

B4.1-0036-18 SLOPE STREAKS SEGMENTATION USING WAVE ATOMS AND MORPHOLOGICAL OPERATORS

Slope streaks are a form of down-slope mass-movements that typically occur on the surface of Mars. The study of slope streaks has become a hot topic in recent years, motivated especially by scientists and astronomers who seek to understand this phenomenon and its hypothetical relationship with transient water activity on Mars. Since detecting slope streaks plays an important role in most computer vision systems and cartographic products, in this work we propose a new approach to detect and segment slope streaks in Mars images. We combine a recent harmonic analysis tool called wave atoms with classical morphology operators as an effective and concise framework. The wave atoms-driven model is a variant of 2D wavelet packet that improves the sparse representation of specific stripe-like features in the image when compared to more popular expansions such as wavelets, Gabor atoms and curvelets. In fact, the wave atoms package has two main advantages when compared against others texture analysis tools: first, the ability to systematically capture a certain pattern at pre-selected scales, and second, it ensures high anisotropy when representing image features such as stripes and oscillatory textures. We show that the designed framework produces high scores in terms of quantitative quality metrics when assessed on various data sets of Mars surface.

Although the prime focus of the InSight lander is determining the interior structure of Mars, it will also carry out geology and physical properties investigations that will test surface materials and subsurface structure predicted by interpretations of remote sensing data used to select the landing site in western Elysium Planitia near 4.5°N, 135.9°E [1]. Mapping of platy and smooth lava flows indicates the plains surface on which the InSight ellipse is located is composed of Early Hesperian volcanics about 2 km thick [2]. A surficial layer of fragmented regolith 3-17 m thick is indicated by the presence of rocks in the ejecta of fresh craters 30-200 m in diameter (but not smaller craters), and exposures of relatively fine-grained regolith that grades with depth into coarse blocky breccia over strong, jointed bedrock in nearby Hephaestus Fossae in southern

Utopia Planitia [3]. The surface is dominated by smooth terrain with a homogeneous thermal inertia of 200 J m–2 K–1 s–1/2 consistent with a surface composed of dominantly cohesionless, fine sand (0.17 mm) or sandy soils with low cohesion (<few kPa). Rock abundance is very low (<6%) except near sparsely distributed rocky ejecta craters where it can be as high as 35%. The albedo and dust cover index of the landing site are similar to dusty and low-rock abundance portions of the Gusev cratered plains, and both sites have been dominantly shaped by impact and eolian processes [1,4].

The geology and physical properties investigations will also provide critical information for both placing the instruments

(seismometer and heat flow probe with mole) on the surface after landing and for understanding the nature of the shallow subsurface and its effect on transmitted seismic waves [2]. Two color cameras on the lander will obtain multiple, wideangle stereo images of the surface and its interaction with the spacecraft and instruments.

Images will identify the geologic materials and features present, quantify their areal coverage, help determine the basic geologic evolution of the area, and provide ground truth for orbital remote sensing data. Continuous measurements of wind speed and direction offer a unique opportunity to correlate dust devils and high winds with eolian changes imaged at the surface and to determine the threshold friction wind stress for grain motion on Mars. A radiometer will determine the hourly temperature of the surface in two spots, which will allow derivation of the thermal inertia of the surface materials present and their particle size and/or cohesion. During the first two weeks after landing, these investigations will support the selection of instrument placement locations that are relatively smooth, flat, free of small rocks and load bearing. Location of the lander in high-resolution orbital images and direct-to-Earth spacecraft tracking will yield the best located position on Mars in both inertial and cartographic space. Soil mechanics parameters and elastic properties of near surface materials will be determined from experiments with the arm and scoop of the lander (indentations, scraping/trenching, and piling), passive monitoring of seismic waves, mole penetration and thermal conductivity measurements from the surface to 3-5 m depth, and the measurement of seismic waves during mole hammering [2].

In this investigation we use MCC, Viking, HiRISE and MOLA elevation data to understand the geomorphology of Arsia Mons. Arsia Mon is located in the Tharsis rise. The features identified as 1) scrap, which is considered to be the displacement of the land surface due to the movement along faults during tectonic events; 2) lobate facies which are convex lobes and resembles like rock-glacier on earth; 3) Knobby Facies, this sedimentary deposition often interpreted as a sublimation till which is resulted from downwasting of ash-rich glacier ice; 4) shield of Arsia Mons; 5) Caldera Floor, which represents the surface of the bowl-like depression inside the magma chamber ; and 6) Caldera Wall, it represents the surrounding walls Arsia Mons volcano.

Slope streaks are typically dark, narrow and fan-shaped features that extend down slope on Mars surface. They are one of the most active and dynamic process observed on the Martian ground nowadays. Dry and wet processes have been suggested for causing their formation but their origin is still unclear. Moreover, the streaks tend to fade with time, providing clues about dust settling and material properties. Thus, the objective of this work was to quantify and to compare the temporal variation of slope streaks albedo. Therefore, was analysed 63 streaks obtained from 25 overlapping images (10 MOC e 15 CTX) distributed on equatorial regions of Mars (Arabia, Amazonis and Tharsis). The overlapping images were acquired between the years 2000 and 2013. The fading process quantification was determined by the albedo contrast ratio of the inside and neighborhood pixels of the each individual streak. The streaks were segmented automatically by a morphological algorithm in order to obtain the media digital number (DN) of the interior and exterior of each streak. Once defined the media DN, it was converted into albedo value, taking as reference the calibration documentation of the MOC and CTX cameras. This procedure was made for each streak on 25 images. In a global evaluation throughout 13 terrestrial years, all the 63 slope streaks have faded. However, during some short periods we observed a slight reversal to darkening, and then brightening over again on the three regions. We also observed that the speed of fading is higher on the streaks with lower contrast ratio. The full inside pixel analysis of the streaks along with albedo transformation provided by our method ensure a whole set of reliable data.

B4.1-0040-18 EQUATORIAL SUBSURFACE ICE DETECTION IN THE PLAINS OF SOUTHWEST OF OLYMPUS MONS, MARS

Mohd Anul Haq, anul.haq@niituniversity.in

NIIT UNIVERSITY, NEEMRANA, INDIA, Neemrana, India

Shahid Iqbal Ansari, shahid.nasa@gmail.com

NIIT UNIVERSITY, NEEMRANA, INDIA, Neemrana, India

The detection of subsurface ice in mid-latitudes using SHAllow RADar (SHARAD) sounder onboard the Mars Reconnaissance Orbiter (MRO) and the formation of North Polar Layered Deposits (NPLD) and South Polar Layered Deposits (SPLD) revealed the journey of planet from various axial tilts. Mars Paleoclimate have always been the curiosity for the researchers. In the same mission, Compact Reconnaissance Imaging Spectrometers for Mars (CRISM) also played a vital role for many successful missions onward MRO to choose their prolific study area. The terrain boundary of south of the Olympus Mons shows geologically Amazonian and Hesperian transition. Many studies suggested pyroclastic flow deposition process formed Medusae Fossae Formation (MFF) units, steep sided Yardangs and ridges seen in images of Mars Color Camera (MCC) onboard Mars Orbiter Mission (MOM). The region observed with High Resolution Imaging Science Experiment (HiRISE) images having centimeter to meter scale roughness and low near subsurface permittivity decreases the strength of radar echo, even some parts are totally fade-up and these are the stealth areas. In this study, we detected subsurface reflector of low permittivity (nearby water-ice) bearing materials along the rise of south terrain (10.12° N, 220.10° S) towards roughest surface of MFF southwest of Olympus Mons. The Recurring Slope Linea Identified by HiRISE in this area hypothetically brings a scenario that they may be feeding by shallow aquifer of melting ice lies under the stealth area of porous rocks.

B4.1-0041-18 IDENTIFICATION OF CHLOROBENZENE IN THE VIKING GAS CHROMATOGRAPHMASS SPECTROMETER DATA SETS: REANALYSIS OF VIKING MISSION DATA CONSISTENT WITH AROMATIC ORGANIC COMPOUNDS ON MARS

Universidad Nacional Autonoma de Mexico, Mexico D.F., Mexico

The twin 1976 Viking landers (VL-1 and VL-2) performed the first in situ search for organic compounds on the martian surface. Each lander carried a pyrolysis-gas chromatograph mass spectrometer (pyr-GCMS), which were used to search for organic molecules in regolith samples excavated with a robotic arm [1]. Chloromethane was detected by VL-1 at levels of 15 parts per billion (ppb) and dichloromethane was detected by VL-2 at levels of 2-40 ppb [2]. Both chlorinated hydrocarbons were attributed to either terrestrial contamination resulting from the pre-flight use of chlorinated cleaning-solvents, or from the reaction of absorbed traces of methanol and HCl [2]. After martian perchlorate was discovered by the Wet Chemistry Laboratory on the 2008 Phoenix lander [3], Navarro-Gonzalez et al. [4] suggested that parts per million (ppm) levels of indigenous martian organics may have provided the carbon source for the reaction with perchlorate in the Viking GCMS ovens that resulted in the formation of the detected level of chlorinated organics. Motivated by the recent detection of chlorobenzene by the Sample Analysis at Mars (SAM) instrument suite on the Curiosity rover, and the identification of its carbon source as indigenous to Mars [5], we reexamined the original, microfilm preserved, Viking pyr-GCMS data sets. Here we show evidence for the presence of chlorobenzene in VL-2 data at levels corresponding to 0.08-1.0 ppb (relative to sample mass), in runs when the sample was heated respectively to 350°C and 500°C. We considered possible sources of carbon that may have produced the chlorobenzene signal, by reaction with perchlorate during pyrolysis, including potential indigenous martian organics and previously unreported instrument contamination. We conclude that the chlorobenzene signal measured by VL-2 originated from martian chlorine sources, and its carbon source is consistent with a martian origin, though a carbon source contribution from the instrument background cannot yet be ruled out. Through this work we have demonstrated that the Viking pyr-GCMS experiment may have detected organic materials indigenous to Mars' surface for the first time, almost forty years before the Curiosity rover's SAM experiment detected indigenous martian organics.

B4.1-0042-18 MINERALOGY AND MORPHOLOGY OF EOS CHAOS REGION IN EASTERN VALLES MARINERIS, MARS: IMPLICATIONS FOR DIVERSE GEOLOGICAL PROCESSES

Asif Iqbal Kakkassery, asifiqbal.17@res.iist.ac.in

Indian Institute of Space Science & Technology, Thiruvananthapuram, India Presenting author: Rajesh V.J, rajeshvj@iist.ac.in

Indian Institute of Space Science and Technology, Trivandrum, India

Structural and compositional variations within various segments of Valles Marineris, Mars can provide significant information on diverse geological processes operated within this largest valley system. Eos chaos is Martian morphological feature with diverse lithological units and structural features located towards east of Valles Marineris and with the central latitude and longitude 16.82o and 313.48o respectively. Light toned layered deposits and mineralogical evidences for aqueous processes has been reported from nearby areas of Eos chaos including Capri chasma and Eos chasma. Hyperspectral data derived out of Compact Reconnaissance Imaging Spectrometer for Mars (CRISM) onboard NASA's Mars Reconnaissance Orbiter (MRO), Images of Mars Colour Camera (MCC) onboard ISRO's Mars Orbiter Mission (MOM 1), Context Camera (CTX), and High Resolution Imaging Science Experiment (HiRISE) instrument on board MRO have been utilized. Using MTRDR CRISM data hydrated sulphate minerals have been identified from the western part of Eos chaos region within the Valles Marineris. Light toned sedimentary rocks having strong spectral signatures of kieserite ($MgSO_4.H_2O$) provide evidences for past aqueous processes operated in this area. Hydrous sulphate minerals like szomolnokite ($FeSO_4.H_2O$) and romerite ($Fe^{2+}Fe^{3+}{}_2(SO_4)_4.14(H_2O)$) have also been detected from this area. Low-grade metamorphic mineral zoisite ($Ca_2Al_3(SiO_4)_3(OH)$) has been identified from south sloping eroded surface of the western Eos chaos based on a characteristic spectral absorption feature at 1.5μm. Zoisite hints for a hydrothermal condition favorable for the formation of low grade metamorphic mineral associations. Presence of metamorphosed plagioclase glass maskelyinte implies an impact origin. An impact generated hydrothermal or low-grade metamorphism on Eos chaos has been proposed for the formation of zoisite. Various morphological features such as eroded face of chaotic mount with distinct layering, mesas formed by fluvial erosion, light toned boulders having spectral signature of hydrated minerals, gullies and channels partially filled by eolian sediments of western Eos chaos also implies past aqueous processes. Landslip with lobate structure directing north has been identified from eastern segment of Eos chaos. This flow of terrain towards north indicates saturated nature of land. Terraced appearance of the terrain sheds light on a series of faults occurred here. A model for the faulting has been prepared after analyzing profile derived from the Digital Elevation Model (DEM) created using stereo CTX images of the study area.

B4.1-0043-18 VACUUM SOLUTION APPROACH FOR THE SEIS INSTRUMENT ON THE INSIGHT MISSION TO MARS

Olivier Grosjean, olivier.grosjean@cnes.fr

Centre National d'Etudes Spatiales, TOULOUSE, France Mihail Petkov, mihail.p.petkov@jpl.nasa.gov

Michel Gautherin, michel.gautherin@sodern.fr SODERN, Limeil-Brevannes, France

Antoine Lecocq, antoine.lecocq@sodern.fr SODERN, Limeil-Brevannes, France

Pierre-Alain Dandonneau, dandonneau.ipgp@gmail.com France

The SEIS seismometer on the NASA InSight mission to Mars is of paramount importance for the surface-based geophysical investigation of Mars. The instrument contains three VeryBroad-Band (VBB) sensors [1], which enable the determination of the origin and magnitude of earthquakes, and aid the understanding of the planet structure. Due to the low mass, which couples to the seismic waves, the instrument has an inherently high sensitivity to the ambient pressure, which causes viscous damping and increased noise through heat transfer. Vacuum of <0.01 mbar is required for optimum performance and 0.1 mbar is considered the end-of-life pressure limit. In 2015, the instrument encountered anomalies that prevented achieving such vacuum levels. An air leak was first discovered and, subsequently, the non-evaporative getters were found to have insufficient capacity to cope with the instrument outgassing rates. Due to the insufficient time to resolve these issues, the InSight launch was postponed for 2018 [2]. The Evacuated Container (EC), the housing of the SEIS instrument, was redesigned to address the vacuum anomalies. The vulnerability to physical leak was alleviated on component level. Mitigating the outgassing rate requirement necessitated the development of novel zeolite-loaded aerogel (ZLA) getters [3]. Such materials were devised, tested and implemented in place of the original non-evaporative getters. The getter adsorption requirements were derived from residual gas analysis (RGA) spectra, taken during the SEIS bakeout events in 2015, as well as from a VBB outgassing test conducted in 2016. At the 117 C bakeout temperature, the spectrum was dominated by volatile organic materials, originating from an incompletely outgassed adhesive with a 105 °C glass transition temperature, whereas water was the overwhelmingly dominant component of the constituents of the RGA spectra at room temperature. Therefore, water became the primary adsorbent target for the new getters. The other measured components, H_2, CO and CO_2, can also be explained by byproducts of water breakup at the hot tungsten filaments. However, CO_2 can also be a cross-linking byproduct of adhesives, and titanium and stainless steel alloys contribute H_2, albeit at extremely small rates, reduced through annealing. These adsorption needs were addressed as a precautionary measure. CO_2 adsorption capability was also implemented in lieu of a redundancy mechanism for the mitigation of a potential Mars atmospheric leak during the mission. Water and CO_2 adsorption capabilities were provided by custom-developed ZLA getters, made by incorporating Na^+ and Ca^+ ion-exchanged faujasite zeolite micron-sized particles into an aerogel matrix, which facilitated molecular transport of the adsorbent to the zeolite. The ZLA getters were prepared from a liquid precursor, solidified into six metal getter canisters, engineered into the space allowed for the six original SAES getters. The canisters were open to the EC volume through a 1 µum filter to eliminate particulate contamination form the getters.

Validation and verification tests with assembled canisters were done to assess the level of water desorption from the getters at the bakeout temperatures, as well as to evaluate the getter adsorption capacity. Accelerated test conditions utilized water vapor as a proxy for outgassing at significantly higher rates. Due to the inability to complete the testing of Pd^+ exchanged zeolite on time for InSight to be added to the ZLA mixture for H_2 adsorption, the latter was addressed by SAES Ti/Pd getter films, deposited on modified thermal shields, welded to the shells of the Evacuated Container. The capacity of the Ti/Pd getters was tested at the manufacturer. Details of the verification and validation program for ensuring a viable vacuum solution for InSight are presented. The SEIS crown, containing the three sensors and the six getter canisters was first baked to reduce the outgassing from fresh adhesives. After welding the shells, whose fabrication included a 320 °C anneal step to minimize H_2

outgassing, the hermeticity of the complete SEIS instrument has been tested and verified to the state-of-the-art level ($<1x10^{-10}$ mbar.L/s He) in the full temperature range from 105 °C to +60 °C. The final instrument bakeout was done at 100 °C for 10 days. A satisfactory initial pressure of $3x10^{-5}$ mbar, measured by the pressure rise method, was achieved at room temperature, and the instrument was separated from the ground pumping system by pinching off the connecting copper tube (queusot). After the pinch-off, there is no possibility for a direct pressure measurement inside the instrument for levels below 0.002 mbar; a heat-transfer method was developed by CNES to measure higher pressures. The most recent in situ pressure measurements have not yet detected a pressure increase. A worst-case SEIS pressure forecast, constructed on the basis of getters test data, exceeds the mission requirements. Given the SEIS thermal conditions during the mission, the expected vacuum operational VBB environment is, expectedly, $<10^{-5}$ mbar for a duration far exceeding that of the primary mission. Furthermore, the ZLA getters have the capacity to deal with a significant atmospheric leak on Mars should such a necessity arise.

B4.1-0044-18 IMPACT-SEISMIC INVESTIGATIONS PLANNED FOR THE INSIGHT MISSION

Ingrid Daubar, ingrid.daubar@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Philippe Lognonne, lognonne@ipgp.fr

Institut de Physique du Globe de Paris-Sorbonne Paris Cité, Université Paris Diderot, Saint Maur Des Fossés, France

InSight Science Team InSight Science Team

The InSight NASA Discovery mission (Banerdt et al. 2017) will study the interior of Mars using seismic signals. These will emanate from both interior tectonic sources as well as from meteoroid impacts. We are planning many impact-related investigations that will further the scientific goals of the mission. For one, measuring the rate of crater formation at the surface will achieve the mission goal of determining the impact flux at Mars. Additionally, impacts will inform the major goal of investigating the interior structure of Mars, as each impact located on the surface will provide known seismic ray paths through the interior. Impact-related scientific analyses also include the seismic source and waveform modeling of impact generated seismic signals; detection, localization, and characterization of impact sources; detection of meteors; modeling of meteor infrasound and acoustic source and shock signals; and comparative analyses between Mars, Earth and the Moon. Unlike the Moon, Mars has an atmosphere; thus we must consider the seismic effects of airbursts and fragmentation.

Differentiating impact signals in seismic data from those of marsquakes will be challenging. We plan to utilize a suite of discriminating features, including: positive first motions, relative energies of P and S waves, ratios of body to surface wave magnitudes, cutoff frequencies, and the presence or absence of surface reflection phases from depth. Once InSight detects an impact in seismic data and a rough location is derived, images will be requested from spacecraft orbiting Mars to search for the new impact feature. Identification of fresh crater(s) will provide a definitive source location, something that will most likely not be possible for tectonic seismic sources. This will be of high scientific importance, allowing for determination of the ray paths and calibrating interior structure models and seismic attenuation. Any successful impact detections will also constrain the seismic source parameters (moment; frequency cutoff; and seismic efficiency, the ratio of impact energy to radiated seismic energy). The latter value in particular is not well constrained, with values in the literature ranging from 106 to 102 (Pomeroy 1963; McGarr 1969; Latham et al. 1970a; 1970b; Patton and Walter 1993; Walker 2003; Shishkin 2007; Richardson Kedar 2013; Güldemeister Wünnemann 2017).

Predictions of detectable impacts are uncertain to several orders of magnitude because of unknown aspects of the seismic propagation properties of Mars, the current impact rate, and the background noise level. In general, the larger the impact, the farther away it will be possible to detect it. Small impacts will only be detectable within a very limited range of the InSight landing site; only rare impacts producing craters > 30-40 m in diameter will be detected at large distances. Given the uncertainties mentioned above, (Teanby 2015) estimated that between 0.1-30 impacts per Earth year will be detectable at moderate distances < 1,000 km, while (Lognonné Johnson 2015) estimated 10 total impacts/year. (Daubar et al. 2015) determined a similar estimate of 4-8 total impacts detected/year. Large events that could be detected globally only occur once every 1 to 10 years (Teanby Wookey 2011). With a few to tens of impact events detected, the impact-related scientific goals of InSight should be achievable within the timeframe of the prime mission (one Mars year).

B4.1-0045-18 THE COLOR CAMERAS ON THE INSIGHT MARS LANDER

Justin Maki, justin.n.maki@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States the InSight Science Team

A. Trebi-Ollennu, R. Deen, M. Golombek, H. Abarca, C. Sorice, B. Banerdt, M. Schwochert

The InSight spacecraft is scheduled for launch in May 2018 with a Mars landing six months later in November 2018 [1]. The key objective of the InSight mission is the investigation of the interior structure and processes of Mars using a seismometer [2] and heat flow probe [3]. A robotic arm [4] will lift these instruments off of the top deck of the lander and place them onto the ground at specific locations chosen by the InSight science and engineering teams. To assist in this deployment task, the lander is equipped with two cameras: an Instrument Deployment Camera (IDC) mounted on the robotic arm and an Instrument Context Camera (ICC) mounted on the lander body underneath the top deck.

The primary objectives of the IDC and ICC are to: 1) support terrain assessment for the selection of the SEIS and HP3 instrument deployment locations, 2) facilitate and document the deployment activities, and 3) monitor the location and state of the instruments postdeployment. In addition, images from the cameras will be used to investigate the geology and physical properties of the landing site [5]. These objectives are met by the acquisition of images of the lander deck and the deployment workspace, nominally located to the south of the lander.

Both InSight cameras are flight spare Mars Science Laboratory (MSL) engineering cameras

[6] which flew build-to-print copies of the Mars Exploration Rover (MER) cameras [7]. The InSight project has converted the MSL cameras from greyscale to RGB color by replacing the MSL detector with a Bayer color filter array (CFA) version of the same detector. The camera electronics and optical assemblies are otherwise unchanged from MSL. The cameras utilize frame transfer charge-coupled devices (CCDs) with a photosensitive area of 1024 by 1024 pixels digitized at 12 bits. Both cameras use identical detectors and readout electronics, differing only in the type of lens mounted to the camera head. The IDC field of view (FOV) is 45 x 45 degrees, and the angular resolution at the center of the FOV is 0.82 mrad/pixel. Because it is attached to the robotic arm near the elbow, the IDC field of regard can cover areas above and below the lander deck, including views of the lander footpads, equipment on top of the lander deck, the sky, and terrain not obscured by the lander. Stereo IDC images are acquired by moving the arm-mounted camera between images. The ICC, mounted to the lander, has a FOV of 124 x 124 degrees and an angular resolution at the center of the FOV of 2.1 mrad/pixel.

All onboard IDC/ICC image processing is done by the lander flight software running on the lander computer. After an image is read out from the camera, a shutter image is acquired and subtracted from the image of interest; this removes frame transfer readout smear and any dark current acquired during frame readout. The raw Bayer image is demosaicked into RGB triplets, color balanced onboard using preloaded color correction coefficients, and companded to 8 bits using a 12-to-8 bit square root lookup table (LUT). The resultant images are JPEG-compressed

[8] by the lander computer and packetized for downlink. Typical JPEG quality values used for deployment activities are 85, 90, and 95, which correspond approximately to compressed bit rates of 1, 2, and 3 bits/pixel, respectively, although the exact relationship between compression quality and bit rate is scene-dependent.

Once on the ground, images are processed by the JPL Multimission Image Processing Laboratory (MIPL) using heritage image processing software from the MER and MSL missions [9]. The resulting three-dimensional (3D) terrain maps will be scrutinized by the science and engineering teams, and after careful topographical evaluation the operations team will command the robotic arm to place the instruments at the selected locations. The ICC will provide a wide-angle view of the activities during the deployment and will also serve as a partial backup to the IDC.

A full color panorama is also planned, as well as surface change detection and atmospheric imaging investigations. All InSight camera images acquired during the mission will be archived to the NASA Planetary Data System (PDS).

For a more detailed description of the InSight cameras, see [10].

B4.1-0046-18 UNVEILING THE INTERIOR OF VENUS: USING TECTONIC DEFORMATIONS ALONG CANALI TO CONSTRAIN LITHOSPHERIC STRUCTURE & MANTLE CONVECTION

Abhinav Jindal, abhinavjindal93@gmail.com Cornell University, Ithaca, New York, United States Alexander Hayes, hayes@astro.cornell.edu

Cornell University, Ithaca, New York, United States Thomas Loredo, loredo@astro.cornell.edu

Cornell University, Ithaca, New York, United States

Venus is Earth's "sister planet;" they both have nearly identical sizes and densities. However, analysis of its surface and atmosphere reveals that it took a very diverse evolutionary path from Earth. Studying the interior of Venus can help us understand when the evolutionary paths of Earth and Venus diverged and what caused this divergence. With the massive interest in the search for life beyond Earth, understanding the evolution of Venus could also significantly contribute towards answering the timely and provocative question of what makes a planet habitable. Deformational features of various varieties and styles are ubiquitous on the surface of Venus, and many of these display characteristic scales (widths or spacings) of deformation that fall into distinct size classes. We are studying the mantle convection and lithospheric structure of Venus by analyzing tectonic deformations along canali. Canali-type channels are long lava channels with almost constant widths found in the Venusian plains. Stratigraphic evidence points towards the canali being old features on the plains that formed with the last phases of extensive plains volcanism possibly induced by the hypothesized global resurfacing event 300 Myr ago. When these channels formed, they must have had downhill gradients, but post-depositional tectonic deformations in the Venusian lithosphere have caused them to be interspersed with nearly periodic topographic relief. The dominant length scales associated with these nearly periodic deformation features can inform us on the lithospheric structure and mantle convection of Venus. We have mapped all major (longer than 300 km) canali on Venus and generated their topographic profiles. Since the canali are sinuous and may not always flow perpendicular to the deformation features, the characteristic length scales of tectonic deformations we obtain by studying the canali undulation profiles may have a path dependent error in them. We are applying statistical modeling methods to eliminate this sinuosity-induced error in an attempt to accurately determine the deformation length scales. Once we eliminate the errors in the deformation length scales, we will build on crustal-thickness models of Zuber and Parmentier (1990) and plume models of Kiefer and Hager (1992), to link the observed length scales to the lithospheric structure and mantle convection of Venus.

B4.2-0001-18 THE INSIGHT MISSION TO THE INTERIOR OF MARS

William Banerdt, bruce.banerdt@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Suzanne Smrekar, ssmrekar@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

InSight Team

Sue Smrekar, Sami Asmar, Don Banfield, Marco Bierwirth, Simon Calcutt, Ulrich Christensen, John Clinton, Véronique Dehant, Sébastien deRaucourt, Bill Folkner, Raphael Garcia, Domenico Giardini, Matt Golombek, Matthias Grott, Jurek Grygorczuk, Tom Hoffman, Troy Hudson, Judit Jänchen, Catherine Johnson, Günter Kargl, Sharon Kedar, Brigitte KnapmeyerEndrun, Philippe Laudet, Philippe Lognonné, Justin Maki, David Mimoun, Antoine Mocquet, Paul Morgan, Nils Mueller, Mark Panning, Tom Pike, Jose-Antonio Rodriguez-Manfredi, Chris Russell, Stuart Spath, Tilman Spohn, Nick Teanby, Jeroen Tromp, Renee Weber, Mark Wieczorek, Peter Zweifel

Introduction: InSight was selected by NASA to illuminate the fundamental processes of terrestrial planet formation and evolution by performing the first comprehensive surface-based geophysical investigation of Mars. It will provide key information on the composition and structure of an Earth-like planet that has gone through most of the evolutionary stages of the Earth up to, but not including, plate tectonics. The traces of this history are still contained in the basic structural parameters of the planet: the size, state and composition of the core, the composition and layering of the mantle, the thickness and layering of the crust, and the thermal flux from the interior.

Science Goals: The scientific goals of InSight are to understand the formation and evolution of terrestrial planets through investigation of the interior structure and processes of Mars and to determine its present level of tectonic activity and impact flux. These goals will be realized through a specific set of basic scientific objectives: 1) Determine the thickness and structure of the crust; 2) Determine the mantle's composition and structure; 3) Determine the size, composition, and physical state of the core; 4) Determine the thermal state of the interior;

5) Measure the rate and distribution of internal seismic activity; and 6) Measure the rate of meteorite impacts on the surface.

Instrumentation and Flight System: InSight will delineate these parameters for Mars with a focused set of investigations centered on seismology and supported by precision tracking and heat flow measurements. It carries two primary scientific instruments: SEIS, a six-component

(3 Short Period and 3 Very-Broad-Band sensors) seismometer with careful thermal control, shielding from martian wind and temperature variations, and a sensitivity comparable to the best terrestrial instruments across a frequency range of 1 mHz to 50 Hz; and HP3 (Heat Flow and Physical Properties Package), an instrumented self-hammering mole system that will penetrate as deep as 5 m below the surface, trailing a string of temperature sensors to measure the planetary heat flux through thermal gradient and conductivity measurements. A third investigation, RISE (Rotation and Interior Structure Experiment), uses the spacecraft X-band communication system to provide precision tracking measurements of variations in the rotational axis of Mars.

A key aspect of the mission is the use of a robotic arm and a set of cameras to deploy the seismometer and heat flow package to the ground, enabling these instruments of perform their precise geophysical measurements. In addition, InSight carries a set of environmental sensors to monitor the magnetic field ambient air temperature, pressure and wind in order to separate environmental noise from seismic signals.

The InSight flight system, built by Lockheed-Martin, is based on a near-copy of the proven Phoenix lander. It has been updated with modern avionics and includes power system upgrades (larger solar arrays and cold-temperature batteries) to support the baseline 2-year equatorial mission.

Mission Timeline: Originally scheduled for launch in 2016, InSight was forced to slip by one Mars launch opportunity (26 months) by a flaw that was uncovered late in testing in the seismometer's vacuum enclosure. The enclosure was redesigned and exhaustively tested, and by the time of this presentation InSight will have been launched twoard Mars in May 2018 from Vandenberg AFB. After a 6½ month cruise in a Type-1 trajectory, it will land in western Elysium Planitia on November 26, 2018. During a roughly 2-month deployment phase the seismometer, its wind and thermal shield, and the heat flow probe will be placed on the ground. Subsequently the mole will penetrate to its final depth and the lander will settle into a largely passive observation phase lasting at least one Mars year. Data will be relayed to Earth through orbiters (InSight can use any of MRO, Odyssey, MAVEN, Mars Express, or TGO). A lowrate X-band DTE channel is available for commanding and low-rate data return in case of emergency.

Summary and Conclusions: The InSight mission fills a longstanding gap in the scientific exploration of the solar system by performing an in-situ investigation of the interior of an Earth-like planet other than our own. It will provide unique and critical information about the fundamental processes of terrestrial planet formation and evolution.

United Arab Emirates (UAE) has entered the space exploration race with the announcement of Emirates Mars Mission (EMM), the first Emirati mission to another planet, in 2014. Through this mission, UAE is to send an unmanned probe, called Hope probe, to be launched in summer 2020 and reach Mars by 2021 to coincide with UAE's 50th anniversary. The mission should be unique, and should aim for novel and significant discoveries that contributed to the ongoing work of the global space science community.

EMM has passed its Mission Concept Review (MCR), System Requirements Review (SRR), System Design Review (SDR), and Preliminary Design Review (PDR) phases. The mission is led by the Mohammed Bin Rashid Space Centre (MBRSC), in partnership with the University of Colorado Laboratory for Atmospheric and Space Physics (LASP), University of California Berkeley Space Sciences Lab (SSL), and Arizona State University (ASU) School of Earth and Space Exploration. The mission is designed to answer the following three science questions:

How does the Martian lower atmosphere respond globally, diurnally, and seasonally to solar forcing?

How do conditions throughout the Martian atmosphere affect rates of atmospheric escape?

How does the Martian exosphere behave temporally and spatially?

Each question is aligned with three mission objectives and four investigations that study the Martian atmospheric circulation and connections through measurements done using three instruments that image Mars in the visible, thermal infrared and ultraviolet wavelengths. Data will be collected around Mars for a period of an entire Martian year to provide scientists with valuable understanding of the changes to the Martian atmosphere today. The presentation will focus on the overviews of the mission and science objectives, instruments and spacecraft, as well as the ground and launch segments.

B4.2-0003-18 STATUS REPORT ON THE NASA MARS 2020 MISSION

Kenneth Farley, farley@gps.caltech.edu

California Institute of Technology, Pasadena, California, United States

NASA's Mars 2020 mission has the twin goals of in-situ exploration of an ancient astrobiologically relevant site, and preparation and caching of samples for possible return to Earth by future missions. Mars 2020 will also test new technologies of potential value for future investigation of Mars.

The rover draws heavily on the design of the Mars Science Laboratory, with new instruments and capabilities for the mission's specific objectives. The science payload includes a high resolution stereo zoom camera (Mastcam-Z), an instrument for remote characterization of rock chemistry and mineralogy (Supercam), a high resolution microscopic imager (Watson), instruments for elemental, organic chemistry, and mineralogical mapping at the 100 m scale (PIXL, SHERLOC), a ground penetrating radar (RIMFAX), and an instrument to characterize environmental conditions (MEDA). An additional instrument (MOXIE) will demonstrate the conversion of atmospheric CO2 to O2 as a potential resource for future Mars exploration.

As the first mission in a possible Mars Sample Return (MSR) campaign, Mars 2020 has the capability to select, prepare, and cache about 35 rock core samples of about 15g each. To achieve very stringent organic, inorganic, and biologic contamination limits, the samples will be drilled using very clean hardware into ultraclean sample tubes. These tubes will be hermetically sealed immediately after collection. Eventually the rover will deposit these tubes at one or possibly more depots, accessible for individual retrieval at some time in the future. The sample tubes are designed to tolerate tens of years of environmental exposure on Mars and in orbit during the possible return journey.

The fundamental concept of this mission is that the in-situ investigations provide the geologic data that is necessary to understand the landing site and simultaneously to select and document samples worthy of return to Earth. In support of this ambitious undertaking the Mars 2020 project has improved rover autonomy and provided tools for faster decision making.

Three potential landing sites remain under consideration for Mars 2020. Jezero Crater is a crater lake site with a well-developed delta, Northeast Syrtis has evidence for shallow subsurface aqueous alteration, and a feature in the Columbia Hills may be a fossil hot spring. The final workshop leading to landing site selection will occur in early Fall, 2018.

The Mars 2020 mission is now transitioning into the integration stage. It is scheduled to be launched in July or August 2020, and arrive at Mars in February 2021. Its prime mission will be at least one Mars year.

B4.2-0004-18 SEARCHING FOR TRACES OF LIFE WITH EXOMARS

Jorge Vago, jorge.vago@esa.int

European Space Agency, Noordwijk, Netherlands Håkan Svedhem, hakan.svedhem@esa.int European Space Agency, Noordwijk, Netherlands Elliot Sefton-Nash, elliot.sefton-nash@esa.int European Space Agency, Noordwijk, Netherlands Daniel Rodionov, rodionov@iki.rssi.ru

(1) Space Research Institute (IKI) Russian Academy, Moscow, Russia ExoMars Team

The first ExoMars mission was launched on 14 March 2016 and arrived at the red planet on 19 October 2016. It included two elements: 1) the Trace Gas Orbiter (TGO) to study atmospheric trace gases and subsurface water with the goal to acquire information on possible on-going biological or hydrothermal rock alteration processes; and 2) Schiaparelli, a European Entry, Descent, and Landing (EDL) demonstrator to prove technologies for landing and perform measurements during descent and on the martian surface. TGO is performing well and will soon complete a one-year aerobraking phase to reach its science orbit-from where it will also provide data communication services for surface missions, nominally until end 2022. Unfortunately, the lander was lost during the last minute of the EDL sequence.

The second ExoMars mission is scheduled to launch on 25 July 2020. It will deliver an instrumented landed platform and a 310-kg mass rover to the martian surface. After the Rover will have egressed, the platform will carry out environment measurements at the landing site.

The rover will explore the local geology and search for signs of past and present life. A drill will allow the rover to collect and analyse samples from outcrops and at depth. The subsurface sampling capability will provide the best chance yet to access and analyse well-preserved sedimentary deposits, possibly containing molecular biosignatures.

The rover's Pasteur payload includes: panoramic instruments (wide-angle and high-resolution cameras, an infrared spectrometer, a ground-penetrating radar, and a neutron detector); a subsurface drill capable of reaching a depth of 2 m to acquire specimens; contact instruments for studying rocks and collected samples (a close-up imager and an infrared spectrometer in the drill head); a Sample Preparation and Distribution System (SPDS); and the analytical laboratory, the latter including a visual and infrared imaging spectrometer, a Raman spectrometer, and a Laser-Desorption, Thermal-Volatilisation, Derivatisation, Gas Chromatograph Mass Spectrometer (LD + Der-TV GCMS). The very powerful combination of mobility with the ability to access subsurface locations is unique to this mission.

This presentation will discuss both missions, but concentrate more on the ExoMars rover, its strategy to search for biosignatures, and the possible importance of its discoveries for Mars Sample Return.

The Mars Organic Molecule Analyzer (MOMA) is one among the 9 science instruments onboard the Exomars 2020 rover. This is a unique chemical laboratory fully devoted to the search of organic molecules in the soil samples collected by the rover drill. The clay-rich rock accessible in Oxia Planum, the current preferred landing site zone, will provide the opportunity to sample ancient material, which are known to trap and stabilize organic molecules for very long durations on Earth. Moreover, the capability for the drill to collect samples down to 2 m deep will allow collection of samples that are protected from the harsh radiation and chemical conditions at the surface, thus increasing the potential to detect ancient organic materials. To achieve its goal, MOMA is composed of four main subsystems: - a pulsed UV laser (=266 nm, 1 ns duration) for performing Laser Desorption/Ionization (LDI) of molecules from the solid samples collected by the rover. This sampling method is known as a soft ionization process producing large, intact ions from the sample - a set of ovens able to conduct sample pyrolysis up to 850°C, or chemical treatments (i.e. derivatization) of the sample to enhance the analysis of key organic species indicating biotic or prebiotic chemistry, such as amino acids. - a gas chromatograph (GC) devoted to separate the many volatile species that may be released by heating or chemical treatment of the solid samples in the ovens. To produce the separation, the GC is composed of 4 analytical channels, each one targeted for separating a specific class of organic compounds. One of them will perform enantiomeric separation in order to assess the enantiomeric excess of key organic molecules, a feature that is important for identifying the existence of prebiotic chemistry. - an ion trap mass spectrometer (MS) that will characterize the ions produced from LDI, or from ionization by electronic impact (EI) of the molecules eluting from the GC. The design of this new mass spectrometer allows for both LDMS and GCMS analyses and its performances can be tailored to the analytical mode. Basically, the MS is able to characterize the ions in the m/z 50-500 range in the GCMS mode, and the m/z 100-1000 range in the LDMS mode, thereby focusing on the expected mass ranges produced by each ionization technique. In this contribution, we present an overview of the MOMA and of its performances derived from various experiments carried out on subsystem modules, and on the engineering test unit of the instrument. We will thus show the capability for this instrument to detect organic materials in relation to biotic and prebiotic processes on Mars.

The objective of the ExoMars 2020 mission (ESA-Roscosmos) is to search for past or extant traces of life on the red planet. The originality of the mission is its drill, which will permit production of drill-cores (3 cm long for 1 cm diameter) from up to 2 meters in depth. The drill-cores will be observed before crushing by the CLUPI and by the HRC cameras. During the drilling phase, the CLUPI camera will also observe the pile of rock powder forming at the surface. On Earth, there is no need to observe rocks in powder form or as centimetric drillcores. Thus, to date, there has been no investigation to determine what geological information can be deduced from the observation of these kind of samples. The aim of the present study is thus to describe powders and drill-cores made from analogue samples in order to maximize the scientific data that can be deduced from these ExoMars 2020-specific observations.

The majority of rocks on the surface of Mars are volcanic [1,2] or derivatives of volcanics. Thus, for this study, relevant samples were selected from the Massif Central, in France, in order to cover a large range of volcanic rock types, as designated in the compositional TAS diagram (Total Alkali Silica). The samples were then crushed to less than 60 µm and displayed next to each other showing a large variety of colour. Although the preliminary observation shows differences in colour between the different samples, two main issues still remained to be tackled.

First, we observed that the main difference between the different powders was the brightness, the different powders having various tones of greys. Unfortunately, it also appears that decreasing grain size induces an increase in brightness. The powders must thus be compared after sieving to obtain a uniform grain size distribution. Nevertheless, this step remains relevant since experiments have shown that drill powders (fines) are characterised by a more or less similar grain size (<60 µm).

Secondly, the most important issue was the fact that the colour of a powder is totally dependent on the ambient luminosity. In order to solve the last issue, a new method called CaliPhoto® was developed that consists of adding a reference target to the field of view of the camera, close to the sample. An image processing algorithm is then used to calibrate the images and permit comparison of the different samples. Well characterized rocks were then crushed, sieved and photographed using a commercial camera equipped with a detector similar to that used by the ExoMars Close Up Imager, CLUPI, i.e. a digital Foveon® sensor, in order to create a database of the colours of rock powders.

Several tests were carried out. For rocks included in the database created so far, the method permits identification with good accuracy. More interestingly, for those rocks not included in the database, it was still possible to make a good match based on rocks of similar composition in the database. Moreover, rocks having similar elemental composition but very different bulk colours, such as rhyolite (light) and obsidian (dark), have a similar powder colour, permitting thus a good identification. At present, the method is being used to help the interpretation of the ExoMars 2020 drill-cores. The protocol is also adapted in order to free the method from additional targets to be fixed onto the rover. Finally, the CaliPhoto® method could be very useful on Mars to help identification of rocks during drilling without adding any new instrumentation.

Acknowledgements: We acknowledge the Maison du parc national des volcans d'Auvergne for permission to sample. We thank the CNES and the SATT Grand Centre for funding.

Martian Moon eXploration (MMX) is the 3rd Japanese sample return mission followed by Hayabusa and Hayabusa-2. The MMX spacecraft is scheduled to be launched in 2024, orbit both Phobos and Deimos (multi-flyby), and retrieve and return >10 g of Phobos regolith back to Earth in 2029. The origins of Phobos and Deimos are still a matter of significant debate: capture of asteroids versus in-situ formation by a giant impact on Mars. In either case, MMX will definitely provide clues about their origins and offer an opportunity to directly explore the satellite building blocks or juvenile crust/mantle components of Mars. MMX will also aim to understand physical processes in the circumplanetary environment of Mars. The new knowledge of Phobos/Deimos and Mars will be further leveraged to constrain the initial condition of the Mars-moon system and to gain vital insights regarding the sources and delivery process of water (and organics) into the inner rocky planets.

We select six nominal science payloads for the remote sensing observations: 1) telescope (TL) and wide-angle multi-band (WAM) cameras, 2) near-infrared spectrometer (MacrOmega), 3) gamma-ray and neutron spectrometer (MEGANE), 4) light detection and ranging (LIDAR), 5) circum-Martian dust monitor (CMDM), and 6) mass spectrum analyzer (MSA). The spacecraft also carries a sampler system equipped with a robotic manipulator and corers, which enables the acquisition of Phobos regolith >2 cm beneath the surface.

The spacecraft consists of propulsion, exploration, and return modules (total launch mass =

3,500 kg). The chemical propulsion system is utilized for Mars orbit injection and escape maneuver. The outward interplanetary flights take 1 year by the most efficient Hohmann-like transfer. The spacecraft stays at circum-Mars orbits 3 years for exploration followed by the 1 year homeward interplanetary flight to Earth. The Phobos exploration includes multiple landing/sampling operations; each takes 2.5 hours. The spacecraft employs ballistic descent to reach the space right above a landing site before the final free-fall descent without a thruster jet to prevent whirling wind from blowing regolith particles.

B4.2-0008-18 FORWARD PLANNING FOR MARS SCIENTIFIC EXPLORATION

Jeffrey Johnson, jeffrey.r.johnson@jhuapl.edu JHU/APL, Laurel, Maryland, United States MEPAG Executive Committee

D. Beaty, R. Zurek, W. Calvin, J. Eigenbrode, B. Bussey, L. Pratt, S. Hubbard, M. Meyer, D. Banfield

The last two decades of NASA's exploration of Mars has combined science-focused inquiry with cutting edge technology to provide detailed and comprehensive datasets whose analyses have revolutionized our scientific understanding of past and current Martian environments. Data from past and ongoing Mars missions will continue to make significant discoveries in the areas of life, origins, and workings, and raise new high-priority questions, many of which will inform and drive aspects of Mars Sample Return (MSR) missions. In turn, the findings from MSR will require the contextual information provided by these missions, and will motivate additional discovery-driven science investigations.

NASA has supported an outstanding community of Mars scientists and engineers with expert knowledge of the martian environment and the technological means by which to explore it. They represent a national asset, spanning the full-range of career levels, with irreplaceable experience working in the Martian system via orbital and landed science operations. This community is a critical cog in the cycle of advancing our understanding of the Mars system: research and analysis clarifies and expands key scientific questions that feed directly into the design and development of technologies and missions that provide data for subsequent analyses. For NASA to continue the study of Mars during and beyond sample return, retention and expansion of the present engineering and science expertise in the community will be critical. However, the range and number of addressable Mars science investigations are expected to decline within the "lean MSR" architecture, and thus preservation of this knowledge and experience is at risk.

New discoveries in Mars system science, Mars sample science, and future human exploration remain to be made, but only if appropriate funding is available to support analyses of the substantial amounts of under-analyzed data returned by Mars missions. The receipt of samples from Mars in the 2030 timeframe will require a large community of sample scientists and analysts. But full interpretation of these samples requires placing them into broader planetary geologic context, such that a community with a mixture of geologists, geophysicists, geochemists, and atmospheric scientists also will be needed from now through the end of the existing extended missions and into the Mars2020 era (2021-2030). A representative portion of this experienced workforce will be needed to efficiently and effectively identify and respond to discoveries from Mars missions and MSR, including the development of investigations after

MSR.

In summary, two main challenges face the Mars community: (1) How to maintain momentum in interpreting the large amounts of data to address key goals of the Mars exploration program, including maximizing the science content of each phase of the MSR mission arc; and (2) How to retain the critical expertise and knowledge of a vibrant Mars science and engineering community both during and after MSR, and leading up to human exploration of Mars, in part through the targeted implementation of mission concepts at all levels. These issues could be addressed by deliberately and systematically increasing the resources provided to data analysis and technology maturation programs and ensuring their ongoing effectiveness during and after this period.

B4.2-0009-18 THE NEXT 30 YEARS OF MARS EXPLORATION: A PERSPECTIVE FROM THE NASA VISION 2050 WORKSHOP

Bethany Ehlmann, ehlmann@caltech.edu

California Institute of Technology, Pasadena, California, United States

In February 2017, NASA convened a meeting to identify potential science goals and enabling technologies that can be implemented by the end of the 2040s that would support the next phase of Solar System exploration. Here I summarize the findings on Mars. This abstract focuses on the vision contributed by 19 leading earlyand mid-career scientists who will professionally have their entire careers in the period from now until 2050 [1]. Additional materials are derived from the Mars Exploration Program summary of goals [2] and a post-conference synthesis of these and all the Mars abstracts [3].

Organizing principle for Mars Exploration: The engine driving the Mars Exploration Program is and will remain fundamental science questions that can only be answered on Mars. Two questions "Is/was there life?" and "What sustains a habitable planet through time?" are crucial as we seek to understand the prevalence of inhabited terrestrial planets like our Earth. New discoveries of the last decade show that obliquity cycles periodically enhance Mars' habitability today and groundwaters were persistent through its history. Moreover, Mars is the only body in our solar system that provides the geologic record from its first billion years to access answers to questions about the response of a terrestrial planet (like Earth) to atmospheric change, loss of a magnetic field and heavy impact bombardment.

Synergies with human and commercial space: In 2018, we are at a point of natural HEOMD, SMD, and "new space" commercial synergy in questions and needed technologies. With well-thought out, continued coordination, this can be a tremendous boon to Mars science and exploration. Although many HEOMD and science-driven measurements overlap, some science questions are fundamentally different from those solely in service of exploration. For example, rather than only "what?" and "how much?", scientific questions about a rock unit with hydrated minerals on Mars are also "when?", "how?", and "why?". Measurements for understanding the timing and processes behind early planetary evolution fall largely within the province of science alone. As such, a science-driven robotic and sampling program at Mars can and should continue, independent of but complementary to HEOMD activities, incorporating the enhancements that human capabilities can provide as they become available.

Mission types and architectures: Robotic sample return should be performed at least once, as rapidly and cost-effectively as possible, by leveraging support from international, commercial partners, and HEOMD. This can happen in the 2020s. However, Mars is like Earth in terms of the diversity of environmental conditions in space and time. Interrogation of multiple locations are needed to determine the processes driving Mars environmental change, its timing, and to search for life. The current juncture in science must recognize Mars is diverse, requiring tens of science mission opportunities in 2020-2050, overall enabled by a return to the cost-saving paradigm of multiple small craft rather than solely single large missions.

B4.2-0010-18 THE POTENTIAL SCIENTIFIC VALUE OF RETURNED MARTIAN SAMPLES: THE 2018 IMOST STUDY

David Beaty, dwbeaty@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Elliot Sefton-Nash, elliot.sefton-nash@esa.int European Space Agency, Noordwijk, Netherlands Monica Grady, monica.grady@open.ac.uk

Open University Milton Keynes, Milton Keynes, United Kingdom Brandi Carrier, bcarrier@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Harry McSween, mcsween@utk.edu

University of Tennessee, Knoxville, Tennessee, United States

Introduction: The analysis of well-collected, properly documented Mars samples in Earth laboratories is of ex-tremely high interest to the international Mars exploration communities. As part of its goal to promote international cooperation in the exploration of Mars, the International Mars Exploration Working Group (IMEWG) recent com-missioned a major study (referred to as iMOST) to update the recommended scientific and engineering objectives for the potential 1st Mars sample return mission, the kinds of samples needed to achieve those objectives, and the measurements that would need to be performed on those samples. The iMOST analysis began in November 2017, and draft results are expected to be presented for initial public discussion in late April 2018 at the 2nd International Mars Sample Return Conference in Berlin, Germany.

Why Now?: There are two primary reasons why an updated analysis of the scientific potential of Mars sample return is appropriate:

1. The last major analysis of the specific scientific objectives of Mars sample return, and how they translate to sample types and sample quantities, was the Mars Exploration Program Analysis Group (MEPAG)'s End-to-End International Science Analysis Group (E2E-iSAG) work carried out in 2010-11 (and published in early 2012). Since then, there have been advances on several different fronts that may change the scientific priorities for Mars sample return: • The number of Mars meteorites in our collections on Earth grew to over 100 (this number was 55 in 2011), and includes one brecciated sample differing in age from all the other martian meteorites, and thus presumably rep-resenting a different region of Mars. Therefore, we ask the question "What has changed from prior investiga-tions into martian meteorites and how can those data inform MSR strategies?" • The Curiosity rover landed on Mars (Aug. 2012) after E2E-iSAG had completed

its work, and has since operat-ed successfully for more than five years. It has analyzed a number of solid samples (both rocks and regolith) as well as the martian atmosphere. In addition, scientific output from the wealth of data returned by orbiter missions since 2011 (e.g. NASA's Mars Reconnaissance Orbiter, Mars Odyssey, and ESA's Mars Express) funda-mentally shaped and improved our understanding of the martian surface. We need to evaluate whether any of these discoveries change the priority of Mars returned sample science. • Research on terrestrial analogs, especially in the general field of astrobiology, has blossomed. We have im-proved our understanding of how life adapted to extreme environments survives in those conditions through geologic time. • Our ability to handle and analyze very small samples has improved substantially. A highly visible example is the work conducted on the Hayabusa samples (JAXA). There have been many instrumentation developments around the world. Did these developments meaningfully change what could be learned from returned martian samples of constrained size? 2. To plan the potential investigations of samples after they arrive on Earth, we need to systematically ana-lyze and prioritize the measurements that could or should be performed on the samples. Successor teams can use this information to derive an instrument list and determine the logical sequence of analyses. Sample receiving and curation facilities should incorporate this vital input into planning strategies and key operational decisions.

Results: This presentation will summarize the results of the iMOST project.

B4.2-0011-18 MARS SAMPLE RETURN ARCHITECTURE DEVELOPMENT

Charles Edwards, chad.edwards@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

The most recent planetary science decadal survey places high scientific priority on the eventual return of samples from Mars, for investigation in terrestrial laboratories, enabling a breadth and depth of scientific analysis far beyond what can be achieved with in situ investigations, and allowing possible breakthrough discoveries regarding the geological, climatological, and astrobiological history of the planet. The Mars 2020 mission will take an important first step towards this goal, acquiring and caching a scientifically selected set of samples for potential return to Earth.

NASA and ESA are currently exploring options for follow-on missions that could complete the return of these samples to Earth. A Sample Retrieval Lander mission would deliver a landed platform to the same landing site as Mars 2020, carrying a Sample Fetch Rover (SFR) and a Mars Ascent Vehicle (MAV). The SFR would retrieve the Mars 2020 samples and transfer them to an Orbiting Sample (OS) canister, which would be placed in the MAV for launch into low Mars orbit. There, a second mission, the Earth Return Orbiter, would rendezvous with the OS, with a payload to capture, orient, and robustly contain the OS, transferring it to an Earth Entry Vehicle (EEV). After a return flight from Mars to Earth, the Earth Return Orbiter would release the EEV on a trajectory for landing at a selected Earth site.

This pair of mission concepts presents a rich architectural design trade space, with key interfaces between missions, demanding a rigorous, campaign-level systems engineering approach. We provide an overview of the current baseline MSR architecture, highlighting these cross-project interfaces, key design trades, and enabling technology developments.

(The information provided about possible Mars sample return architectures is for planning and discussion purposes only. NASA has made no official decision to implement Mars sample return.)

B4.2-0012-18 OVERVIEW AND RESULTS FROM CSA'S 2016 MARS SAMPLE RETURN ANALOGUE DEPLOYMENT

Victoria Hipkin, victoria.hipkin@canada.ca Canadian Space Agency, St Hubert, Canada David Beaty, dwbeaty@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Martin Picard, martin.picard@canada.ca Canadian Space Agency, St Hubert, Canada Timothy Haltigin, timothy.haltigin@canada.ca Canadian Space Agency, Saint-Hubert, Canada Gordon Osinski, gosinski@uwo.ca

University of Western Ontario, London, Canada

An overview and discussion of results is presented for the Canadian Space Agency (CSA) 2016 Mars Sample Return Analogue Deployment (MSRAD) which took place in Utah from November 2016.

CSA's objectives for this deployment were to (1) Develop and strengthen partnerships and position Canada for future contributions through collaboration with iMARS agencies (2) Advance MSR science operations and sample targeting through a Cache Mission simulation 'CanMars' (3)Advance selected rover autonomy and arm positioning technologies through a Fetch rover technology demonstration scenario (4) Inform the general public and inspire young Canadians to pursue careers in STEM (5) Provide valuable learning opportunities to students through partnership in University of Western Ontario's NSERC CREATE project to train students for roles in future planetary missions.

The 'CanMars' cache rover simulation was conducted in partnership with University of Western Ontario with the remote science operations team based at the university.

The 'CanMars' Science Plan was developed in partnership with University of Western Ontario, NASA and UKSA, following an invitation to iMARS agencies to participate in the deployment. Its objectives were: 1. To test the accuracy of selecting samples remotely using the partial context available to mission scientists using rover-based field operations, compared to the full context available to a traditional human field party. 2. To test the efficiency of remote science operations with periodic pre-planned strategic observations compared to including strategic and tactical considerations in the tactical plan 3. To assess the utility of realistic autonomous science capabilities to the remote science team, to understand how such autonomy improves the effectiveness and rate of progress of the science mission, and to learn which strategies of exploration emerge from the availability of these capabilities, including in a downlink-constrained environment 4. To make a preliminary determination of the factors that affect the quality of sample selection decision-making in light of returned sample analysis Science plan objectives 1 2 were based on agency considerations and recommendations from previous analogue work.

The Science Plan was implemented by assigning the same success criteria to the remote science team and an independent Field Validation Team (1) identify the highest total organic carbon sample at the site as a proxy for an astrobiologically significant sample (2) advance understanding of the history of water at the site through development of a depositional model. The extensive data set and results generated as a result of successful implementation of the analogue mission are documented in a special issue of Planetary and Space Science which is currently in review.

The Fetch Rover scenario and tests successfully demonstrated autonomous navigation to 'cache depots' of Mars 2020-like sample tubes lying on the ground, acquisition of 6 such sample tubes using a novel tool developed by the CSA robotics group, and transfer to a Mars Ascent Vehicle (MAV) mock up.

CSA's Mars Exploration Science Rover ground prototype was used for both elements of the deployment, built by MDA, Brampton, who are also contracted to build ESA's ExoMars locomotion system. Rover operations were conducted from CSA's HQ at St Hubert, Quebec. In addition, UKSA and DLR conducted independent rover tests at the site making use of CSA's infrastructure and with a view to potential future co-ordinated campaigns.

The results will be discussed with a focus on science operations and their relevance to future missions.

B4.2-0013-18 PREPARING TO RECEIVE SAMPLES FROM MARS: RECOMMENDATIONS FROM THE INTERNATIONAL MARS ARCHITECTURE FOR THE RETURN OF SAMPLES (IMARS) PHASE II WORKING GROUP

Caroline Smith, caroline.smith@nhm.ac.uk

The Natural History Museum, London, United Kingdom Timothy Haltigin, timothy.haltigin@canada.ca

Canadian Space Agency, Saint-Hubert, Canada Christian Lange, christian.lange@canada.ca Canadian Space Agency, St Hubert, Canada Raffaele Mugnuolo, raffaele.mugnuolo@asi.it ASI - Agenzia Spaziale Italiana, Rome, Italy

Background: While much of the effort in planning for a Mars Sample Return (MSR) campaign has been dedicated towards the flight mission elements, the programmatic challenges associated with MSR cannot be overlooked. Certainly, returning the samples in the first place would represent a significant technical achievement. However, it is apparent that managing those samples once they are returned will require extensive international coordination. To address some of these issues, the International Mars Exploration Working Group (IMEWG) chartered the International Mars Architecture for the Return of Samples (iMARS) working group in 2014. Building from the iMARS Phase I findings [1], the Phase II group comprised two panels of experts: (i) Engineering: to provide a status report on the technical planning for MSR architecture, and; (ii) Science / Earth Operations: to develop a proposed sample management plan. This abstract focuses on the findings and of the Science / Earth operations sub-team.

iMARS Report Structure and Topics: Following earlier recommendations [1], the iMARS Phase II team was tasked specifically to proposing the governance for sample science management plan. In doing so, three themes were central to the group's deliberations: (i) Sample Management Structure: determining an organizational structure outlining roles responsibilities for key stakeholders; (ii) Science Implementation Plan: outlining preliminary sample examination flow, sample allocation processes, and data policies, and; (iii) Curation Plan: including sample tracking and routing procedures, sample sterilization considerations, and long-term archiving perspectives.

A total of 21 recommendations were put forth by the working group, a selection of which are summarized below.

Programmatic Recommendations: MSR will be heavily dependent on international collaboration. It is thus inevitable that well-defined and agreed upon standards and regulations must be developed to ensure a successful campaign implementation. As such, the working group recommended that:

An international MSR Science Institute be established as soon as the commitment for conducting an MSR campaign is made

Detailed working groups will be required to establish guidelines and recommendations of standards to be implemented at the Sample Return Facility (SRF)

The minimum safety requirements for safely returning the samples must be clearly defined

The projected timeline for SRF design, construction, and operation could exceed a decade; SRF planning should commence immediately

Sample Management Recommendations: The interplay of science inquiry and safety requirements drove many of the working group's deliberations. Ensuring that world class science will be done as safely as necessary, the following recommendations were put forth:

A internationally-sanctioned Planetary Protection Protocol should be produced as soon as is feasible

The organization of science teams, sample allocation, and test protocol development should be specific to each sample suite returned by the mission

Scientific access to samples should be driven by scientific excellence, independent of the financial contributions of the bidder's home country

Extensive additional research is required on the methods and doses required to adequately sterilize the samples to ensure safe distribution outside of the SRF

PROGRESSING TOWARDS MSR In summary, the iMARS working group has produced a credible structure and process ensuring that the best possible science is performed on these invaluable samples, the Earth is protected from contamination, and public engagement and transparency drives decision-making. As the flight segments of MSR become an increasing reality, the community must ensure it is ready to receive the samples when they are safely returned. EURO-CARES (European Curation of Astromaterials Returned from Exploration of Space) was a three year (2015-2017) multinational project funded under the European Commission's Horizon 2020 research programme. The objective of EURO-CARES was to create a roadmap for the implementation of a European Extra-terrestrial Sample Curation Facility (ESCF) suitable for the curation of samples from all possible return missions, to the Moon, asteroids, Mars, and other bodies of the Solar System. Here we summarize the main recommendations from the final project report for design and infrastructure requirements to allow the curation of samples from restricted bodies such as Mars.

Over the course of the project, the team has visited various facilities and companies, to gather best practices, bring innovative ideas, and build a strong network with the international sample curation community. Visits were made to the astromaterials curation facilities of NASA and JAXA, and to related facilities from the nuclear, cleanroom and BSL-4 sectors. Two successful collaborations with architects (Space architecture department of the Technical University of Vienna (Austria), then Merrick and Co. in Kanata (Canada) [1]) resulted in the development of more refined requirements and tentative designs for a Mars Sample Return (MSR) facility.

All possible activities that would take place in a MSR facility were first identified. All activities related to receiving, assessing, and opening the Earth Return Capsule are performed in a Sample Receiving Facility. Further activities, such as curation, Sample Early Characterization, and storage would be performed in a Sample Curation Facility (SCF). The SCF would also include a suite of instruments necessary for analyses defined in a Biohazard Assessment Protocol and for Life Detection. In addition, an Analogue and Mock-Up Facility (to be constructed first) would be used to assemble an analogue material collection, to test instruments and building materials/techniques, and to train staff members.

A MSR facility needs to integrate both cleanliness and containment principles, to keep the samples pristine, and to fulfill the Planetary Protection requirement of having a probability of release $P<10^{-6}$ for an unsterilized particle larger than 0.1 μm [2]. Primary enclosures for restricted samples were considered: depending on the activities, it was recommended that cabinets similar to the ones used in BSL-4 laboratories, or Double-Wall Isolators should be used [3]. Laminar flow cleanrooms were recommended for limiting cross-contamination while allowing flexibility in the future.

Because of the European nature of the project, the facility should be located in Europe. Other parameters, such as limited natural hazards, countries with histories of BSL-4 laboratories and space exploration expertise, would also need to be taken into consideration. Owing to so many uncertainties and decisions to be taken (such as the possible widespread use of robotics), it is impossible to evaluate a precise financial cost for such a facility, however, we estimate that a fully fitted MSR facility would cost at least 200 M€. Location, use of robots, cleanroom regime, instrumentation capacities, etc. are amongst the parameters that can drive the costs for the initial construction, and during the life of the facility.

It is estimated that a minimum of 7 to 10 years would be necessary to define the requirements, design, build, and commission the facility, while training the necessary staff. It is highly probable that such a facility will have various funding partners (space agencies, institutions, countries, etc.); a complex financial arrangement takes time to come to completion.

A MSR facility is a complex project, not only for the engineering aspects but also for financial and political reasons. In view of the timeline of sample return missions from Mars, it is imperative to move forward with this project as soon as possible. The design we developed encompasses the principles of Flexibility, Modularity, and Adaptability.

European Space Agency, Harwell, United Kingdom Dayl Martin, dayl.martin@esa.int

European Space Agency, Harwell, United Kingdom

Introduction: Since 2014, the Natural History Museum (NHM) has been the prime contractor to the European Space Agency (ESA) for defining and initiating the development of an Exploration Sample Analogue Collection and Curation Facility in support of the Human Robotic Exploration mission preparation programme. The ESA Exploration Sample Analogue Collection (ESA2C) will support the ongoing or future technology development activities that are required for human and robotic exploration of Mars, Phobos, Deimos, C-Type Asteroids and the Moon. The long-term goal of this work is to produce a useful and useable resource for engineers and scientists developing technologies for ESA missions and for appropriately qualified international users as well. Sample Analogue Collection: The complex mission architectures and diverse target bodies of interest means that a variety of different analogue materials are required to test all systems that come into contact with, the target body, whether these be part of the spacecraft system, such as landing and/or roving systems (e.g. wheels), sample collection systems (e.g. drills or scoops) or scientific payload. The analogue materials must replicate as far as possible the expected 'geological' environment of the target body in terms of both physical/mechanical properties and chemical/mineralogical properties. Samples selected include a variety of aggregates from the olivine-rich basalts from the Upper Lava Formation of the Paleogene Antrim Lava Group of Northern Ireland and clay samples from Cyprus, Spain and Senegal. During 2016 and 2017 we carried out a detailed characterisation of the analogue samples' physical and chemical properties [1,2]: Chemical properties: Whole-rock chemistry major, minor and trace element analyses by ICP-AES and ICP-MS. Mineralogy - analytical SEM, EPMA and XRD (whole-rock). Physical and mechanical properties: Particle Size Distribution (PSD) (aggregate and granular samples) - sieving. Grain Size and Morphology - SEM, X-ray micro-CT and visual inspection. Density and porosity (all samples) - mass-volume measurement and helium pycnometry, X-ray micro-CT. Shear strength (aggregate, granular and powder samples) - shear box apparatus. Compressive and tensile strength (rock samples) - UCS testing and Brazilian indirect tensile method. As part of ongoing work, further samples have been acquired for the ESA2C - anorthosite from a Norwegian quarry, basaltic sand and basaltic/ hyaloclastite collected from the Askja Region in Iceland and volcaniclastic/sedimentary/clay masonry unit (CMU) analogues that will be used for system level testing of the ExoMars crushing station. ESA Sample Analogue Curation Facility: This unique venture will build on ESA's Human Robotic Exploration mission preparation programme by establishing methodologies and protocols/procedures for curating the ESA2C, as well as defining and validating the distribution mechanisms and information exchange protocols for the analogue materials. The overarching role of the Sample Analogue Curation Facility (SACF) is to:- Curate ESA2C samples and those identified and acquired for the Collection and associated data pertaining to those samples; make samples available for study and provide access to relevant data pertaining to those samples; carry out fundamental physical and chemical properties testing in the SACF (or testing via appropriately qualified external laboratories). All analogues in the ESA2C will undergo fundamental properties characterisation using procured (or outsourced) equipment in the SACF laboratory, which include the following: Mineralogical and Chemical Properties: X-ray diffraction (XRD) - bulk mineralogy; SEM - mineral chemistry by point analysis of dominant phases; X-ray fluo-rescence (XRF) - minor and trace element identification and quantification; fourier-transform infrared (FTIR) and raman - chemical/molecular bonding and fingerprinting. Physical and mechanical properties: soil PSD - sieving and laser particle analysis (latter outsourced); soil grain size and morphology - SEM and visual inspection; soil bulk density and rock dry density - mass-volume measurements; rock and soil particle density (for porosity) - gas pyc-nometry; soil shear strength (outsourced) - direct shearbox; rock UCS (outsourced) - uniaxial/ unconfined compression. Future Opportunities: The facility will formally open on the Harwell campus (UK) in 2018. Some level of operation is however already ensured by NHM and at present specimens from the ESA2C are being used by engineers and scientists in the United Kingdom, Hungary and the US to support planetary research, related technology developments and testing activities for a variety of missions and mission architectures. The global distribution of planetary analogue material which has been well characterised, i.e. has known fundamental physical/ mechanical and chemical/mineralogical properties, provides a vital resource for scientists and engineers to carry out comparative and collaborative investigations into the vast sector of space exploration. The ESA Sample Analogue Curation Facility hopes to spearhead and centralise access to these resources for many years to come. References: [1] Manick K. et al. (2017) LPSC XLVIII,

NASA robotic sample return missions designated Category V Restricted Earth Return by the NASA Planetary Protection (PP) Office require sample containment and biohazard testing upon return to Earth. Since the 1960s, sample containment from an unknown extraterrestrial biohazard have been related to the highest containment standards and protocols known to modern science. Today, this is Biosafety Level (BSL) 4 containment. In the U.S., the Biosafety in Microbiological and Biomedical Laboratories publication authored by the U.S. Department of Health and Human Services (HHS): Public Health Service, Centers for Disease Control and Prevention, and the National Institutes of Health houses the primary recommendations, standards, and design requirements for all BSL labs. Past mission concept studies for constructing a NASA Curation Receiving Laboratory with an integrated BSL-4 quarantine and biohazard testing facility have been estimated in the hundreds of millions of dollars (USD). As an alternative option, we have conducted a trade study for constructing a mobile and/or modular sample containment laboratory that would meet all BSL-4 and planetary protection standards and protocols at a fraction of the cost. Mobile and modular BSL-2 and 3 facilities have been successfully constructed and deployed world-wide for government testing of pathogens and pharmaceutical production. Our study showed that a modular BSL-4 construction could result in 90% cost reduction when compared to traditional BSL-4 construction methods without compromising the preservation of the samples or Earth. For the design/construction requirements of a mobile/modular BSL-4 containment, we used the established HHS document standards and protocols for manipulation of agents in Class III Biosafety Cabinets (BSC; i.e., negative pressure gloveboxes) that are currently followed in operational BSL-4 facilities in the U.S.

A mobile BSL-4 negative pressure ISO class 5 cleanroom containment facility could secure a sample return capsule at the landing site. After biocide decontamination procedures, the facility could be transported anywhere in the world by land, sea, or air. The mobile facility could attach to an existing BSL-4 laboratory that could be used to conduct biohazard analyses on a sample subset while the mobile lab could provide primary clean containment of the science samples awaiting biosafety results. A second usage scenario could attach the lab to a dedicated NASA receiving and curation facility that could conduct the primary containment and biohazard testing. Additionally, a third scenario could have the mobile facility remain at the landing site as primary containment and a small sample is transported to an existing BSL-4 facility for biohazard testing. After completion of biohazard testing, decisions could be made to sterilize the sample or transport all or portions to a brick and mortar quarantine storage facility.

A modular BSL-4 negative pressure ISO class 5 cleanroom sample receiving facility could be assembled into any shell building or high bay using the same construction methods as the mobile laboratory. The modular construction could use standard 40 ft (12.2 m) containers, assembled together to create a large lab space with Class III BSC glovebox chains. Manufacturing in a dedicated cleanroom can maintain better control of the engineering, fabrication, assembly, and integration of a facility. Testing and certification could also be conducted at the manufacturing cleanroom facility and then transported and assembled on-site. While a modular BSL-4 facility has never been built, several modular Animal BSL-3 facilities have been successfully constructed worldwide. With added system redundancies, these facilities could be reclassified as BSL-4 laboratories.

Currently, NASA PP Office classifies Category V Restricted Earth Return for robotic sample return missions from Mars, Europa, and Enceladus with the caveat that future proposed mission locations could be added or restrictions lifted on a case by case basis as scientific knowledge and understanding of biohazards progresses. This presentation focuses on the design of a mobile/modular BSL-4 Curation Receiving Facility that can meet all current PP and HHS standards and protocols, including redundant systems and critical biological containment/pressurization requirements for future restricted Earth return missions.

B4.2-0017-18 FUTURE HIGH-RESOLUTION ORBITAL RECONNAISSANCE WITH MRO/HIRISE

Alfred McEwen, mcewen@lpl.arizona.edu

University of Arizona, Tucson, Arizona, United States HiRISE Science and Operations Team about 50 people

The High Resolution Imaging Science Experiment (HiRISE) on the Mars Reconnaisance Orbiter (MRO) has been orbiting Mars since 2006 (McEwen et al., 2007, JGR 112, E05S02). More than 1,000 peer-reviewed publications utilize HiRISE data. HiRISE obtains the highest-resolution orbital images of Mars, ranging from 25-35 cm/pixel scale. To acquire such images with a high signal:noise ratio (SNR), HiRISE uses time delay integration (TDI), imaging each patch of ground up to 128 times and summing the signal. Producing sharp images over such a small instantaneous field of view (1 microradian/pixel) and with 128 TDI lines requires very stable pointing from the spacecraft. HiRISE has 14 CCD detectors: 10 in a broad-band (RED) channel that cover the 5-6 km wide image swath, plus 2 with a blue-green (BG) filter and 2 with a near-infrared (NIR) filter, producing 3-color imaging in a narrow central swath of each image. There have been a number of anomalies that affect image quality. 1. The electronics supporting RED9 was lost in 2011, narrowing the swath width. Fortunately there have been no further failures to date, but this remains a distinct possibility in the future. 2. Soon after launch we discovered bit flips in some image channels. This problem has affected more and more image channels (each CCD has 2 readout channels). Fortunately we can mitigate this problem by warming the focal plane electronics (FPE) prior to Mars imaging, but this results in shorter images. Early images had up to 120,000 lines at full resolution (no pixel binning), the maximum now is near 50,000 lines (or 150,000 lines with 2x2 binning). 3. The percentage of images with noticeable blur (0.3-1.5 pixels) increased from near 0% in early 2017 to about 70% of full-resolution images in the fall of 2017 (at aphelion), then decreased to <20% in February 2018. The cause of this blurring seems most likely to be high-frequency pointing jitter. If the problem continues to be significant, we may decide that it is no longer useful to acquire bin-1 (full resolution) images in some seasons.

MRO has been in a sun-synchromous (nearly polar) orbit at close to 3 PM Local Mean Solar Time (LMST), which is usually close to ideal for imaging. However, to attempt to keep MRO functioning for another decade, a number of changes are being made to prolong battery life, including a plan to move to a later LMST (near 4:30 PM). The change to 4:30 PM LMST will provide three disadvantages and one advantage to HiRISE. First, it complicates change detection because we cannot repeat older images with similar lighting conditions. Second, it limits the latitude range of useful imaging within each season, reducing the seasonal range for polar monitoring. Third, stereo pairs must be completed more rapidly to avoid large changes in shadow lengths and positions. An advantage is that relatively flat equatorial regions are better imaged later in the day, to accentuate subtle topographic shading.

In the future, expect more binned images for two main reasons: (1) the later LMST provides lower brightness levels, reducing SNR, mitigated by pixel binning; and (2) we do not gain much or any resolution advantage from blurred bin-1 images, which may be a cold-season problem. However, we can cover four times as much of Mars with bin-2 images compared to full-resolution, and 0.6 cm/pixel remains better than any other orbital imaging of Mars. Many science objectives will benefit from the greater coverage. Landing site reconnaissance and small-scale change detection will be degraded but still useful.

HiRISE-class imaging is highly recommended in a study of the next NASA Mars orbiter (https://mepag.jpl.nasa.gov/reports.cfm) and is essential for landing sites. Advances in detector and electronics technologies since 2002 would lead to significantly improved images.

B4.2-0018-18 UNLOCKING THE CLIMATE RECORD STORED WITHIN MARS' POLAR LAYERED DEPOSITS

Isaac Smith, ibsmith@psi.edu

Planetary Science Institute, Lakewood, Colorado, United States
Paul Hayne, paul.hayne@lasp.colorado.edu

LASP / University of Colorado, Boulder, Colorado, United States
Shane Byrne, shane@lpl.arizona.edu

University of Arizona, Tucson, Arizona, United States

The PLD contain an accumulation and erosion record of ice, dust, and other impurities, that acts as a climate archive waiting to be read by future exploration. Over the previous decade, Mars Polar Science has advanced significantly to the point where hypotheses testable with new missions have been generated about the climate record stored in the polar layered deposits (PLD). In 2017 we co-led a two-part workshop at the Keck Institute for Space Studies focused on missions to unlock the climate record stored in the north PLD. The first part of the workshop determined high-level science questions and priorities to address, and the second part developed mission concepts to answer these science questions. This talk will discuss those science questions and three mission concepts: a Discovery-class lander and orbiter, and small surface investigations called Mars Drop.

B4.2-0019-18 CAN WE OBSERVE ELECTROMAGNETIC RADIATION FROM ELECTRIC DISCHARGES IN THE MARTIAN DUST STORMS?

Ivana Kolmasova, iko@ufa.cas.cz

Institute of Atmospheric Physics, Prague, Czech Republic Ondrej Santolik, os@ufa.cas.cz

Institute of Atmospheric Physics, Prague, Czech Republic Alexander Skalsky, skalsky@iki.rssi.ru

Institute of Space Research, Russian Academy of Sciences, Moscow, Russia

Based on simulations and laboratory experiments, and according to an analogy with terrestrial volcanic and dust discharges, electric discharges are expected to develop in Martian dust storms. Numerical results indicate that it is possible to reach an electrical breakdown in a low-pressure carbon dioxide Martian atmosphere under specific particle density, particle composition and sufficiently high wind velocity. Laboratory experiments confirm the existence of visible electrical discharges in a cloud of Martian regolith simulant in a low-pressure carbon dioxide atmosphere. An ultra-low frequency magnetic radiation generated by terrestrial dust devils was also observed. Lightning discharges are frequently observed in many types of volcanic eruptions. Although these results may indicate the existence of atmospheric lightning discharges on Mars, there is no optical evidence of existence of Martian lightning discharges up to now. Impulsive radio signals originating in electric discharges from the Martian dust storms have also never been detected from space. Using the ExoMars 2020 plasma wave analyzer which is supposed to measure directly on the Martian surface we would like to help to solve the puzzle of Martian lightning.

B4.2-0020-18 MARS ANALOGUE SAMPLES LAB & FIELD SPECTRAL ANALYSIS

Bernard H. Foing, bernard.foing@esa.int ESA/ESTEC, Noordwijk, Netherlands EuroMoonMars Team 2016-2018

B.H. Foing1,2,3, G.A. van der Sanden1,2,3, E. Clavé1,2,3, H.C. Vos1,2,3, L.C. Dubois1,2,4, J.Vago1, M. Grulich1,2,6. J. Lousada6, C. Jonglez1,2,4, A. Lillo1,2,4, A. Kołodziejczyk5, C. Krainski1 & ILEWG EuroMoonMars 2016, 2017 & 2018 support teams, 1ESA/ESTEC, Postbus 299, 2200 AG Noordwik, NL, 2ILEWG, 3Vrije Universitet Amsterdam, 4ISAE Supaero, 5LunAres Space Garden, Poland, 6SGAC, 7ZARM

We have analysed a set of Mars Analogue samples from field campaigns and from a petrological collection. We have acquired samples from Utah Mars Desert Research station, Eifel volcano region, Iceland, Hawaii, La Reunion and Tenerife. Several spectroscopy analyses in the UV/VIS spectrum were performed using the remotely controlled USB4000 spectrometer in the laboratory and during field campaigns. The EuroMoonMars campaigns were rehearsed at ESTEC for feasibility. We also used other diagnostic techniques. Spectroscopy of rocks, water, organics in the lab: The focus of these analyses (Vos et al 2017) was the detectability of certain elements known to influence the UV/VIS spectrum such as transitional metals, but also the influence on the spectrum of minerals, water, organics and volatiles. The influence of water was measured in accordance with known water absorption bands at 739 and 836 nm, and mineral or rock analyses signatures. We also investigated spectral biomarkers. Background on ExoGeoLab lander: The field spectroscopy was also performed during a campaign in the Eifel volcanic area in Germany at an outcrop near the Laacher See. The outcrop consisted of volcanic deposits from the Laacher See eruption from approximatly 13,000 years ago. During the campaign four analogue EVAs were performed and we collected geological samples brought to the lander for remote spectrometry analyses. We thank participants and collaborators for ILEWG EuroMoonMars 2016, 2017 and 2018 campaigns.

B4.2-0021-18 CONSIDERATIONS RELATED TO PLANNING FOR THE EXPLORATION OF THE MARTIAN SUBSURFACE

Vlada Stamenkovic, vlada.stamenkovic@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States Luther Beegle, luther.w.beegle@jpl.nasa.gov

Jet Propulsion Laboratory, Pasadena, California, United States Kris Zacny, zacny@honeybeerobotics.com

Honeybee Robotics, Pasadena, California, United States

Abstract:

The Martian subsurface is of enormous interest for astrobiology, geochemistry, climatology, and In Situ Resource Utilization (ISRU) objectives, which cannot be addressed with surface missions alone. Specifically, subsurface data are needed to help complete the search for extinct of extant life started by the Viking landers more than forty years ago and to prepare for human exploration.

If Mars ever had life, whether it emerged on or below the surface, then as the atmosphere thinned and global temperatures dropped [1], life may have followed the groundwater table to progressively greater depths where stable liquid water could persist. At such depths, life could have been sustained by hydrothermal activity and rock-water reactions. Hence, the subsurface likely represents the longest-lived habitable environment on Mars. Moreover, while the preservation of ancient molecular biosignatures on Mars is debated, the consensus is that detection at depths greater than a few meters is favored because of the shielding from harmful radiation [e.g., 2, 3] and the possibility to preserve water/ice resources. On the other hand, if Mars hosts extant life, then the most likely place to find evidence of it may well be at depths of a few hundred meters to many kilometers, where groundwater could persist despite today's low geothermal gradients [e.g., 4, 5].

Beyond searching for signs of extinct or extant life, we also face today the need to determine the presence and accessibility of resources, the ISRU potential, and any hazards to human health within the Martian subsurface, as part of the process of planning future human missions to the Red Planet.

The need to explore the Martian subsurface for astrobiology/ science and resource purposes, with the support of national space agencies, academia, and the commercial sector, has motivated a Keck Institute of Space Studies workshop titled "MarsX: Mars Subsurface Exploration for

Life and Resources", held Feb. 12-16, 2018 in Pasadena, CA, with participants from NASA, JPL, ESA, SpaceX, Schlumberger, Honeybee Robotics, and various universities and research institutes. The goal of the workshop team was to identify, toward the search for life and resources, (a) scientific measurements, instruments, and technologies, as well as (b) mission concepts and strategies that would enable chemical characterization, mapping, and groundtruthing of subsurface volatiles, focusing on H2O, and the overburden over multiple spatial scales, from meters to multiple kilometers.

Here, we will report the outcome of this workshop, focusing on key subsurface measurements regions of interest, the feasibility of needed exploration technologies (drilling, sounding, analytic tools, and other methods), and goal-oriented mission ideas to chart a roadmap for Mars subsurface access as it applies to the search for life and resources.

Introduction: Planetary cave exploration is a topic of growing interest in the planetary science community as well as for human exploration. More than 200 lunar and 2000 Martian caverelated features have been identified. Vents and fissures associated with water ice plumes on Saturnian, Jovian, and Neptunian moons also represent possible cave systems. Lunar and Martian caves are most commonly associated with lava tubes, although some have been proposed to be present in karstic sulfate terrain (Mars) and cryovolcanic features (outer planet moons). Caves offer stable physio-chemical environments, may trap volatiles, enhance secondary mineral precipitation and microbial growth, are expected to preserve biosignatures, and provide record of past climate. Investigation of petrological sequences on skylight and cave walls can provide critical constraints on lava temperature and cooling history, leading to insights into Martian magmatic processes and differentiation. Caves also represent potential environment for future human exploration: they are believed to offer stable, UV-shielding environment and potential to act as volatile traps. Science Definition: Building on previous work, we identified that a future mission to Martian caves should provide reconnaissance both for scientific and human exploration. Key science objectives for this pathfinder mission would be: (1) map the cave geometry (cave diameter/ceiling height from entrance to >100 m depth), (2) determine traversability challenges for future missions (boulder distribution, unconsolidated material),

(3) document the cave environment (spatial and temporal variations in temperature and humidity and radiation), and (4) map the compositional and lithological diversity of the cave materials, in particular to characterize mineralogy and search for volatiles, and organics. These science goals led to identification of possible instruments and resource requirements. The payload leverages recent or emerging miniaturized instruments developed for CubeSat-class deep space missions. The mild radiation and thermal environment expected in caves justifies the use of CubeSat-class instruments while the multiple assets provide redundancy. Subsurface Explorer Concept: Resource analysis so far suggests that the science of interest for a reconnaissance mission could be carried out with small (10s kg) platforms. Yet, intrinsic to their sizes, these platforms have limited resources, science capability, and lifetime. The situation is exacerbated in the case of the present concept where the only power source comes from batteries (radioisotope heating units were not deemed valuable in terms of anticipated cost and complexity). Novel operational concepts are required to compensate for limited power, which are expected to include higher levels of autonomy and frequent communication among spacecraft for autonomous coordination. Managing the complex design space, and performing associated trade studies to find well-balanced solutions, requires appropriate computational methods and tools to support mission designers and systems engineers in their decision-making processes. These will be addressed in more detail in the poster. We have focused on utilizing a variety of assets and strategies to mitigate challenges related to communication and instrument operations while optimizing data acquisition and science data retrieval via an organized network. We studied heterogeneous architectures where responsibilities (science, telecom) are distributed among assets. Our study includes trade-offs between potential power sources, homogeneity and heterogeneity of the assets, as well as distribution of science instruments to optimize cost and achieved benefit.

B4.2-0023-18 SCIENCE CAN BE A POWERFUL GUIDESTAR FOR HUMAN SPACEFLIGHT

James Bell, jim.bell@asu.edu

Arizona State University, Tempe, Arizona, United States Casey Dreier, casey.dreier@planetary.org

The Planetary Society, Pasadena, California, United States Jason Callahan, jason.callahan@planetary.org

The Planetary Society, Pasadena, California, United States

The Planetary Society, in its report Humans Orbiting Mars: A Critical Step Toward the Red Planet (http://hom.planetary.org), recommended incorporating the goals of the scientific community starting from the earliest planning stages of NASA's future Mars exploration architecture. Here, we expand upon that recommendation and reinforce the fact that whether the evolving plan takes us directly to Mars, or first to the Moon and then eventually on to Mars, there will still be critical roles for science in the advocacy, planning, conduct, and ultimate success of that plan.

NASA frequently uses scientific discovery as a justification for national investment in human spaceflight, even though science has generally been given a relatively low priority in both mission planning and operations (e.g., in the planning of Apollo and the ISS). Concomitantly, much of the scientific community rarely discusses the potential utility (or even necessity) for astronauts in addressing the most pressing space science questions. There is a large community of lunar and Martian scientists, in particular, that could serve as a cornerstone of support within any coalition for the human exploration of the Moon and Mars, but this support is not a given, and at times is not even specifically sought out.

As NASA plans to potentially return astronauts to the Moon and engages in long-term planning for humans to Mars, we believe that science should be more openly used as one of the guiding forces in defining the goals of these endeavors, and that the scientific community should be more explicitly integrated in mission planning from the very earliest stages. Via the recent Planetary Decadal Survey and ongoing studies by groups like MEPAG and LEAG, the scientific community has already defined its top priority scientific goals for the Moon and Mars, and these goals can serve as helpful constraints when working to coalesce a broad coalition to support a focused program of human spaceflight. Indeed, the most recent Decadal did begin to explore the important ways that human exploration can contribute meaningfully to scientific advances. Such analyses will hopefully be expanded and amplified in the next Decadal.

Science should not be treated as an afterthought in human exploration missions, nor should science budgets compete with (and lose to) those for human exploration. Rather, NASA and the science community should focus the science objectives of human missions on areas best served by humans, rather than areas where robotic assets have proven capable and adequate. NASA can make significant steps toward this goal by providing focused research funding for the scientific community to study these opportunities, and by establishing cross-directorate planning committees between HEOMD and SMD that provide funding for scientific participation.

B4.2-0024-18 SCIENCE/RECON NEEDS TO ENABLE HUMAN EXPLORATION ON THE SURFACE OF MARS

Robert Collom, robert.b.collom@nasa.gov

NASA, Washington, District of Columbia, United States Richard Davis, richard.m.davis@nasa.gov

NASA, Washington, District of Columbia, United States Sydney Do, sydney.do@jpl.nasa.gov

California, United States

David Beaty, dwbeaty@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Brandi Carrier, bcarrier@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

As we prepare for the future of human exploration at Mars, it is becoming increasingly clear that there are a number of reconnaissance objectives that need to be addressed in the coming decades. This talk will summarize the key Mars system reconnaissance data needed to inform NASA's ongoing human Mars exploration planning activities, especially as they evolve from architecture studies, to landing site selection and mission planning, and ultimately to technology development and maturation for future flight.

Such data needs to include next generation orbital reconnaissance to better understand water feedstock options and to provide high-resolution imaging of potential landing sites, as well as surface reconnaissance to validate observations made from orbit. This is especially important for water feedstock options such as hydrated minerals and subsurface ice. Leveraging these feedstocks for in-situ use by human crews relies on the confirmation of their existence (establishment of proven reserves), ease of access, and safety for use.

Next generation weather monitoring and prediction capability, involving both orbital and landed observing platforms, is also required to support major mission dynamic events such as landing and ascent, as well as for ensuring safe surface operations. Furthermore, data will be needed to establish next generation planetary protection policy and to establish the basis for its compliance.

Finally, there is growing evidence that returned Martian samples are needed not only for Decadal Survey science priorities, but also to improve our understanding of the mechanical properties of the regolith/dust (i.e. its abrasiveness, oxidizing potential particle size

etc.) and potential human health hazards (toxicity, respiratory, extant life, etc.). This information is needed for the design and development of the surface habitat/laboratory systems, human-class rovers, Mars surface suits, and the Mars Ascent Vehicle. The criticality of these samples may necessitate redundant paths for sample return, the first of which will likely be with a robotic mission, rather than with human mission. Such an approach would allow for the earlier return and analysis of samples needed to inform the engineering development of Mars surface systems (e.g. suit design, hatch seals, etc.), while also providing a roundtrip demonstration of the mission before attempts are made with humans.

B4.2-0025-18 ACHIEVING, AFFORDING, AND SUSTAINING HUMAN MARS EXPLORATION: SCENARIOS FROM THE FIFTH COMMUNITY WORKSHOP

Harley Thronson, harley.a.thronson@nasa.gov

Goddard Space Flight Center, Greenbelt, United States John Connolly, john.connolly-1@nasa.gov

NASA Johnson Space Center, Houston, Texas, United States Chris Carberry, carberry@exploremars.org

Explore Mars, Inc, Beverly, Massachusetts, United States

Initiated in late 2013 and sponsored by Explore Mars, Inc. and the American Astronautical Society, five workshops have been held to date to assess how to achieve, afford, and sustain human exploration of Mars. The workshops featured broad participation by representatives of the professional communities deeply involved in human exploration: NASA, academia, industry, and research institutions, as well as non-US colleagues. Formal reports and back-up material from the five workshops may be found at https://www.exploremars.org/affording-mars. In this special COSPAR session, we will present the results from our most recent workshop, the fifth, which was held in Washington, D.C., 5 - 7 December, 2017.

The overarching goal of our fifth workshop (aka, AM V) was to architect credible - that is, technologically achievable and plausibly affordable - scenarios for human exploration of Mars that achieved three distinctly different “end states” and to identify common architectural threads throughout the three scenarios. The three end states were chosen on the basis of published work to represent three commonly discussed options for human missions and are discussed in the accompanying presentations: (1) an Apollo-like series of short-stay landings, (2) a “beachhead”- type scenario, roughly analogous to current exploration of Antarctica, and (3) sustained and, eventually, growing human occupation.

Approximately 60 “mission architects” participated in the workshop over the course of three days, which followed extensive preand post-workshop activities. After a series of plenary discussions, the participants self-organized around the three unique mission scenarios. Each team was charged with identifying major elements of each scenario, developing a time line, identifying major milestones and decision points, developing justification for each decision, and producing a cost estimate. An essential element of the workshop was that each scenario was reviewed and critiqued in plenary by all participants. This invaluable activity allowed the creators of each scenario to iterate toward improved design before the workshop ended, iteration which continued for a subsequent month. Moreover, this community engagement allowed the three teams to take advantage on-site of expertise very rarely brought together in one place. Finally, the three unique architectures were analyzed to identify decision points that were common to

all scenarios as well as architectural decisions that were unique to the three end points. Both provide valuable insight, with the common architectural decisions providing the initial basis for a broad amalgam of human Mars mission scenarios.

In addition to building the three Mars scenarios, additional topics were assessed, including political sustainability of human exploration, potential roles of human lunar missions as stepping stones to Mars, and technology priorities common among all three scenarios. This latter topic allows the final report to be used as a guide for technology investments that would have the broadest impact regardless of final choice of scenario for eventual human Mars exploration.

B4.2-0026-18 SORTIE-CLASS HUMAN MISSIONS TO MARS

Humphrey Price, humphrey.w.price@jpl.nasa.gov JPL, Pasadena, California, United States

Joe Cassady, joe.cassady@rocket.com

Aerojet Rocketdyne, Canoga Park, United States Gabe Merrill, raymond.g.merrill@nasa.gov

NASA Langley Research Center, Hampton, Virginia, United States

A community architecture was developed in a two-day workshop with participation by subject matter experts in the NASA and industry human spaceflight field. The concept is for initial Mars human exploration with a series of near-term missions to Mars orbit and sorties to the Martian surface with crews of four. The approach would utilize proven technologies and vehicles that are currently under development by NASA, U.S. commercial aerospace, and international partners.

An initial flight rate of a crewed Mars mission every four years could be achieved with no more than two Space Launch System (SLS) launches per year. The concept would take advantage of commercial cargo deliveries to high Earth orbit and/or cislunar space and also commercial deliveries to Mars.

The initial architecture would have a Mars transit stack assembled at the Deep Space Gateway (or in high elliptical Earth orbit) consisting of a Deep Space Habitat (DSH), Mars Orbit Insertion stage, Trans-Earth Injection stage, Earth Departure Stage (EDS), and an Orion vehicle with a crew of four. For surface access, a single lander with a fully-fueled Mars Ascent Vehicle (MAV) would be separately delivered by two SLS launches and aerocaptured into High Mars Orbit (HMO) to await the crew.

After transferring the crew from Earth to HMO, the stack would rendezvous with the lander for crew transfer. The lander would de-orbit and perform entry, descent, and landing, and the crew would conduct a two-week mission on the surface, similar in scope to an extended Apollo 17 type mission with an unpressurized rover and science equipment. At the conclusion of the surface mission, the MAV would launch the crew to Mars orbit and use a pre-positioned boost stage to transfer to the transit stack. The crew would spend the remainder of their stay in HMO, teleoperating assets on the surface, including the rover. Upon Earth return, the crew would perform direct entry with Orion.

This example program architecture has some attractive advantages. It could represent a nearterm, low-risk approach for human exploration of Mars in the 2030s. Cost estimates were performed that suggest this example of a program could be executed with an annual budget and a total budget similar to that of the International Space Station. Although the architecture was intended to be minimal in scope for the initial missions, it would

have the capability to evolve and expand to support extensive long-stay human exploration of Mars, the incorporation of more advanced technologies and in-situ resource utilization, and the eventual buildup of a semi-permanent international base on Mars.

B4.2-0027-18 ACHIEVING MARS V BREAKOUT SESSION #2 GROUP REPORT

Robert Collom, robert.b.collom@nasa.gov

NASA, Washington, District of Columbia, United States Sydney Do, sydney.do@jpl.nasa.gov

California, United States

Molly Anderson, molly.s.anderson@nasa.gov

NASA/Johnson Space Center, Houston, Texas, United States

AMV Breakout Session 2 COSPAR Abstract

Explore Mars, Inc.'s annual Achieving Mars Workshop, asked teams to develop draft mission architectures for Mars exploration scenarios. Breakout session 2 was assigned to consider human Mars missions with the goal of creating temporary research field stations on the surface of the planet. Team 2 leveraged the experience, insight, and expertise of its team members to define an architecture to enable the development of field stations on Mars capable of informing future human exploration objectives.

In framing our architecture and outcomes the team relied heavily on the policy guidance outlined in the bi-partisan NASA Authorization Act of 2010 as refined by the NASA Authorization Act of 2017 which mandates the Long Term Goals and Key Objectives of the NASA human spaceflight and exploration efforts. The three pillars of human exploration as recorded in the Authorization Act are: (1) To expand permanent human presence beyond LEO and to do so, where practical, in a manner involving international, academic, and industry partners;

(2) Crewed missions and progress toward achieving the goal in (1) to enable the potential for subsequent human exploration and the extension of human presence throughout the solar system; and (3) To enable a capability to extend human presence, including potential human habitation on another celestial body and a thriving space economy in the 21st Century.

Our architecture was also informed by the Strategic Principles for Sustainable Exploration established by NASA's Human Exploration and Operations Mission Directorate (HEOMD) - Fiscal Realism; Scientific Exploration; Technology Pull and Push; Gradual Build Up of Capability; Economic Opportunity; Architecture Openness and Resilience; Global Collaboration and Leadership; and Continuity of Human Spaceflight.

With the above principles in mind, our team outlined the following goals for our field station architecture. 1) Learn how to live and work sustainably on the surface of Mars, 2) Develop and test the technologies required for future human habitation on the surface of Mars, 3) Define the desirable characteristics of an exploration zone in preparation for future human activities,

4) evaluate the viability of biology (human, agricultural, or extant microbes) in the Martian environment, and 5) perform meaningful science to understand the Martian environment and the effects of long term habitation in space and at Mars on human health.

This work builds on the research carried out as part of the Evolvable Mars Campaign (EMC). NASA's EMC effort was directed toward a very similar endpoint, but performed under different constraints and optimized for slightly different goals. The AM V team re-examined this architecture in an attempt to incorporate more commercial/international participation and examine whether and how to integrate technology demonstration and operations development in cis-lunar space. We believe this architecture offers a sustainable path forward for humanity's future on the red planet.

B4.2-0028-18 PERMANENT HUMAN HABITATION SCENARIO

Robert Moses, robert.w.moses@nasa.gov NASA/LaRC, Hampton, Virginia, United States

As part of the Explore Mars, Inc. annual Achieving Mars workshops, one of the three teams in 2017 developing Mars exploration scenarios was assigned to approach the scenario from a permanent human habitation perspective. Team 3 combined the personal experiences and voluntary views of its team members to define a campaign of missions to enable permanent human habitation of Mars. To frame the discussions leading to a "community" derived mission scenario, the team strongly considered the policy guidance in the bi-partisan NASA Authorization Act of 2010 as refined by the NASA Authorization Act of 2017 which mandates the Long Term Goals and Key Objectives of the NASA human spaceflight and exploration efforts. Rolled up from a much larger set of guidance in the Long Term Goals and Key Objectives within the NASA Authorization Acts, the goal of the team is to select architectural features and mission elements that will: 1) Enable a capability for human habitation on Mars and a thriving space economy in the 21st Century; 2) Maximize the role that human exploration of space plays in advancing overall knowledge of the universe; and 3) Explore the viability of and lay the foundation for sustainable economic activities in space. The team also leveraged the Strategic Principles for Sustainable Exploration established by NASA's Human Exploration and Operations Mission Directorate (HEOMD). In short, those principles are Fiscal Realism; Scientific Exploration; Technology Pull and Push; Gradual Build Up of Capability; Economic Opportunity; Architecture Openness and Resilience; Global Collaboration and Leadership; and Continuity of Human Spaceflight. Key assumptions for a permanent human habitation scenario, which enable sustainability, include scaling the timeline to the available NASA budget and the involvement of international and commercial partner stakeholders and remaining flexible as the scenario builds up and starts to grow. Orbital missions and short stays may be key tools for managing technology development timelines, and subsequently budget outlays. A fundamental source of enterprise sustainability required for permanent human habitation is a critical mass and broad portfolio of international and commercial partner stakeholders. While it is hard to predict the exact contributions from each partner, their contributions increase sustainability by providing broad, diverse support for the mission campaign. The architecture needs to be designed to encourage partner stakeholders to contribute through open standards, flexibility, and a clear stable mission sequence. The campaign to reach an end state of permanent human habitation is broken into three phases that provide for intermediate evaluation and decision points on crew safety/mission success and affordability before proceeding to the next phase.

For each phase, the team identified key activities, plausible system upgrades, reusing assets, availability of resources, plausible technology and capability performance upgrades, required major technologies, major risks, the role of the ISS, cis-lunar space and lunar surface, and capabilities with the potential for partner contribution. The details presented herein repre- sent our initial attempt to define a campaign of missions towards achieving permanent human habitation of Mars. We believe that scenario three will not materially increase costs or risks over other options if appropriately sequenced and managed, and it will allow us to achieve the unimaginable - permanent human presence on another planet.

B4.2-0029-18 MARS HUMAN LANDING SITES STUDY (HLS2)

Robert Collom, robert.b.collom@nasa.gov

NASA, Washington, District of Columbia, United States Richard Davis, richard.m.davis@nasa.gov

NASA, Washington, District of Columbia, United States David B. Bussey, david.b.bussey@nasa.gov

NASA HQ, Washington, District of Columbia, United States

This talk will provide an overview of NASA's effort to select the location for the first human base on Mars. It builds on the lessons learned from the first ever Mars Human Landing Sites Study (HLS2) Workshop held in October 2015. Since the workshop the HLS2 community has continued to expand its knowledge of potential human landing sites. Assets at Mars are being used to obtain images and data on potential landing sites proposed at the first HLS2 workshop. A number of studies have either been completed or are underway, such as an examination of what it takes to produce water from different types of water feedstocks on Mars. Researchers are also producing enhanced maps of Martian water feedstocks by combining existing datasets in new and innovative ways. The results of this study are expected to be delivered in mid to late 2018. This talk will look at lessons learned and unanswered questions.

B4.2-0030-18 STATUS OF NASA HUMAN-SCALE MARS ENTRY, DESCENT AND LANDING (EDL)

Michelle Munk, michelle.m.munk@nasa.gov

NASA Headquarters, Hampton, Virginia, United States Alicia Dwyer Cianciolo, alicia.m.dwyercianciolo@nasa.gov

NASA Langley Research Center, Hampton, Virginia, United States Tara Polsgove, tara.polsgrove@nasa.gov

NASA Marshall Space Flight Center, Huntsville, Alabama, United States

Ensuring the capabilities are in place for humankind's future landing on the Mars surface requires careful planning. The atmospheric entry, descent and landing on Mars has been identified as the "longest of the long poles," in terms of engineering challenges, and will require a paradigm shift from the way EDL has been performed at Mars, thus far. The 20 metric ton payloads that are required in NASA's current human Mars architecture must be placed in precise locations relative to each other to form a safe and functional operations site. Early identification of the EDL technologies that are most effective at meeting these requirements is key to minimizing development schedule and cost. When large-scale testing is not affordable, analysis at a fidelity high enough to identify concept discriminators must be employed.

For the past three years, NASA has supported a small team to analyze the Mars EDL in-depth, in the context of its published human Mars architecture approach. The team is made of individuals from multiple NASA centers, and coordinates closely with the Mars Study Capabilities team. The study objective is two-fold-to establish a simulation capability that can be used to evaluate the end-to-end system from concept to flight, and to provide system performance data that can influence the architecture as well as be used in technology funding decisions. This presentation will describe the latest results of the study, which have helped narrow the hypersonic decelerator trade space to two concepts, from four in previous years. Current efforts and future plans to enhance the descent and landing segment of the simulation will also be presented.

B4.2-0031-18 SPACEX MARS DEVELOPMENT OVERVIEW

Paul Wooster, paul.wooster@spacex.com

Space Exploration Technologies, Hawthorne, California, United States Margarita Marinova, margarita.marinova@spacex.com

Space Exploration Technologies, Hawthorne, California, United States Joshua Brost, jb@spacex.com

Space Exploration Technologies, Hawthorne, California, United States

SpaceX was founded in 2002 to revolutionize space technology, with the ultimate goal of making life multi-planetary through enabling the establishment of human civilization on Mars. Fundamental to achieving this goal is to vastly decrease cost and improve the reliability of access to and transport through space.

The commercial development of the Falcon 9 and Falcon Heavy launch vehicles and our successes in introducing launch vehicle and spacecraft reusability offer increased launch capability at reduced cost. With the largest payload capability of any operational launcher since the Saturn V, the Falcon Heavy provides significant trans-Mars injection mass delivery at a very affordable price point which can be quite valuable in the context of near-term robotic and human-precursor Mars missions.

We have also initiated development of the Big Falcon Rocket (BFR) launch and in-space transportation system, which will become available in the 2020's and provide Mars transportation capabilities well in excess of those currently available or being developed elsewhere, while continuing to decrease transportation costs by being fully and rapidly reusable. With a fully reusable launch system, Earth orbit propellant transfer, and a fully-propulsive Mars landing, BFR is capable of delivering over 100 metric tons of useful mass to the surface of Mars in an affordable fashion. In the context of human missions, through use of in-situ propellant production the system is capable of returning over 50 tons of useful mass from Mars to Earth. The system also offers additional capabilities for a wide variety of mission types, including in Earth orbit and to the surface of the Moon, which can be leveraged to help build operational experience and spread costs in parallel with Mars missions.

More information regarding the overall BFR system architecture and mission plans is available at http://spacex.com/mars.

B4.2-0032-18 DESIGN FOR EARTH-MARS CYCLER TRAJECTORIES BASED ON AERO ASSISTED ORBITAL TRANSFER

Shijie Sun, 416955465@qq.com CALT, Beijing, China

Rogue planet

Shijie Sun, Hao Guo, Yechen Zhang, Xuan Chen, Shuwen Yang

Earth-Mars cycler trajectories is a promising scenario for sustaining Mars exploration. In this approach, a cycling vehicle is arranged in the Earth-Mars cycler trajectories, the cycling vehicle can be continuously transferred between the Earth and Mars. Using this flight scheme, we can keep the life-support systems or other structures that only for space missions in the circular orbit for a long time. This makes it possible that it is no longer necessary to consume fuel at the missions of getting that equipment into/out to orbit. In this paper, we have introduced the aero assisted orbital transfer base on the traditional Earth-Mars cycler trajectories. the aerodynamic force is used as an auxiliary way to make the modification method of cycler trajectories more flexible. For the traditional Earth-Mars cycler trajectories, the perturbations between the planets will gradually diverge the cycler trajectories, additional fuel consumption is needed to maintain the long-term operation of the cycler trajectories. Preliminary calculation and analysis illustrate that when the aero assisted is introduced, the maneuverability of cycling vehicle is effective increased, so, the situation of cycler trajectories divergence can be effectively avoided. With the gradual maturity of hypersonic flight technology, Earth-Mars Cycler Trajectories based on aero assisted orbital transfer will play an important role in the mission of Mars exploration in future.

B4.2-0033-18 ORBITAL SYNTHETIC APERTURE RADAR FOR SUBSURFACE ICE DETECTION ON MARS: SCIENTIFIC RATIONALE AND CANADIAN TECHNICAL CONCEPT

Timothy Haltigin, timothy.haltigin@canada.ca Canadian Space Agency, Saint-Hubert, Canada Gordon Osinski, gosinski@uwo.ca

University of Western Ontario, London, Canada Arthur Baylis, arthur.baylis@mdacorporation.com MDA, Sainte Anne De Bellevue, Canada

Ivor Barnard, ivor.barnard@mdacorporation.com MDA, Sainte Anne De Bellevue, Canada

SUBSURFACE ICE DEPOSITS ON MARS

Recent Mars exploration efforts have been largely focused on understanding the planet's history of water in all of its forms. From an environmental perspective, determining the presence and distribution of subsurface ice deposits can help reconstruct Mars's geological and climatic evolution [1]. Looking forward, it is inevitable that a human exploration architecture on the Martian surface will be heavily reliant on access to water resources [2].

Vast quantities of subsurface ice at midto high-latitudes have been relatively well-documented for some time [e.g. 3, 4]; in fact, some 1/3 of the Martian subsurface is believed to be underlain by ground ice [5]. Given, however, that future human landing sites are most likely to be equatorward of 50 degrees [2], identifying the presence, quantity, and locations of putative resource deposits at lower latitudes will be critical.

GROUND ICE DETECTION METHODS

Techniques for detecting near-surface ice are varied. At the global scale, surface hydrogen abundance has been used as a proxy for the presence of water ice [3]. At local scales, in rare cases ground ice bodies have been made visible at the surface through very recent impacts [6] or exposures of eroding slope faces [5]. Also, the Mars Phoenix lander directly identified a shallow water ice table at its landing site [4].

At intermediate scales, orbital ground penetrating radar has served as a useful tool. Data from both the MARSIS and SHARAD instruments have been used to infer ground ice in a variety of locales [e.g. 7, 8]. However, neither of these instruments are capable of detecting ice within 10m of the surface [9], and thus cannot be relied upon for identifying resource deposits that could be reasonably accessible to humans.

THE CASE FOR SYNTHETIC APERTURE RADAR

A variety of previous studies have suggested that a Synthetic Aperture Radar (SAR) instrument may be capable of locating ice resources at depths of 1-10 m [10-12]. Such findings were echoed in the MEPAG Next Orbiter Science Analysis Group (NEX-SAG) report, which stated that a polarimetric SAR payload could meet the high priority science objective of mapping and quantifying shallow ground ice deposits [13].

CANADIAN MARS SAR CONCEPT

Canada is considered a world-leader in Earth observing SAR technologies, based primarily on it successful Radarsat and Radarsat 2 programs. In 2017 the Canadian Space Agency issued a contract to MDA Corporation, in conjunction with a science team led by the University of Western Ontario, to develop a concept for a Mars SAR for a potential future orbital mission.

While the work remains ongoing, preliminary observation and instrument requirements have been developed. A series of important trades between penetration depth, resolution, antenna size, power consumption, and data rate are ongoing. At present, both P-band (500MHz) and L-Band (1GHz) center frequencies are being studied, as is a dual frequency solution. In SAR imaging mode, both fully polarimetric (quad-pol) and compact-pol options were considered. The primary benefit of the compact-pol is it potential to use the circular polarization ratio (CPR) as a proxy for ice presence [12] without the associated increase in data rate generated by the full polarization mode. In sounder mode, the current preferred configuration is a nadirlooking mode with a vertical resolution of 1m and along track sampling of < 50m.

FORWARD WORK

The requirements listed above are presently in draft form, and the concept is still evolving. Future efforts will be devoted to further expanding the investigation's scientific objectives (i.e. beyond ice detection), tightly defining observation requirements that satisfy the objectives, and refining the technical concept to ensure an efficient instrument design. Input from the community is welcomed.

B4.2-0034-18 MOXIE, ISRU, AND THE CO2 ECONOMY

Michael Hecht, mhecht@haystack.mit.edu

Massachusetts Institute of Technology Haystack Observatory, Westford, Massachusetts, United States

Manifested for flight on NASA's 2020 Mars Rover, the Mars Oxygen In Situ Resource Utilization Experiment (MOXIE) is a 1% scale model of an oxygen processing plant that is intended to support a human expedition sometime in the 2030s. Like the "Oxygenator" in Andy Weir's "The Martian," MOXIE ingests the thin CO2 that comprises 96% of the Martian air, and produces O2 and CO as products. Such a process would produce 30 metric tons of liquid oxygen (LOx) for ascent vehicle propellant in the 16 months preceding launch of a human crew to Mars, representing 78% of the propellant mass needed for a CH4/O2 propulsion system. To bring this amount of oxygen from Earth would otherwise require 4 to 5 heavy lift launches [1]. At Caltech's Jet Propulsion Laboratory the MOXIE Project is now assembling and testing flight hardware. In the MOXIE enclosure, a scroll pump developed by Air Squared, Inc. collects and compresses the CO2 for conversion to O2 by MOXIE's solid oxide electrolysis (SOXE) stack, which is built by Ceramatec, Inc. [2]. The stack is constructed from scandia-stabilized zirconia electrolyte-supported cells with thin screen-printed electrodes, coated with a catalytic cathode on one side and an anode on the other. When CO2 flows over the catalyzed cathode surface at 800°C under an applied electric potential, it is electrolyzed to produce CO and oxygen ions. The ions are electrochemically drawn through the solid oxide electrolyte to the anode, where they combine to produce gaseous O2. On Mars, MOXIE will generate a minimum of 6 g/hr high purity oxygen from the Martian atmosphere in at least 15 separate runs, sampling different environmental conditions on Mars, in the 2.5 years following landing of the Mars 2020 rover in February, 2021 [3]. Oxygen production is expected to be limited both by the compressor capacity and by the external conditions that determine the density and quantity of air that can be drawn in. While MOXIE stands on its own as a means to perform the specific function of fueling an ascent vehicle, it is also an exemplar of the direction in situ resource utilization (ISRU) is likely to take in the exploration of a new world. On Earth, the single most important resource is sunlight, the ultimate source of all the energy to support life. Arguably, our atmosphere is the second most significant, followed by water. While the air serves many mechanical functions, from windmills to the expansion medium in hot air balloons, its most important role is as a source of oxygen, an oxidant for chemical reactions that include our own metabolical respiration. Instead of oxygen, Mars offers us carbon dioxide as an oxidant. MOXIE takes a decidedly Earth-centric view of this resource, using it as a source of the more familiar O2 and either discarding the CO as an unwanted byproduct or using it as a feedstock to produce methane fuel in combination with a to-be-determined source of hydrogen. In a Mars-centric viewpoint, we might instead consider burning the CO and O2 byproducts directly, closing the cycle by producing CO2. We might also consider bypassing oxygen production entirely and directly using CO2 as an oxidant with lithium or other reactive metals.

B4.2-0035-18 RADIATION SHIELDING FOR MANNED MISSION TO MARS: CHALLENGES AND PROBABLE DESIGN

Ankita Vashishtha, ankita_vashishtha@yahoo.co.in India

NASA has postponed the manned mission to Mars by 2030 and even unlikely to be certain by then also. One of the major constraints for manned mission to mars is the radiation shielding. A round trip to mars will make astronauts susceptible to 100 REM of radiation which is of course a biologically dangerous radiation level for a human body. So, to sort out this constraint an effective radiation shielding is required. This technology may be inspired from earth's radiation shielding. Earth is protected from cosmic radiation and solar flares by the virtue of its atmosphere and magnetic radiation. Moreover one other point which is required to be considered is that radiation shielding is required not only in the free space but also on the martian surface as Mars is having very thin atmosphere. So a two level protection is to be developed for a prototype radiation shielding for future manned mission. First level protection is in the free space by making a prototype design inspired from earths shielding and second level protection is on the martian surface by settling the base in the local magnetic field which could provide some radiation shielding. This paper deals with these key issues in solving a major technological constraint for manned mission to Mars i.e Radiation Shielding.

B4.2-0036-18 THE POTENTIAL IMPACT OF MARS' ATMOSPHERIC DUST ON FUTURE HUMAN EXPLORATION OF THE RED PLANET

Daniel Winterhalter, daniel.winterhalter@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

With the increasing focus by NASA and other space agencies on a crewed mission to Mars in the 2039 time-frame, many Mars-specific environmental factors are now starting to be considered by NASA and other engineering teams. Learning from NASA's Apollo Missions to the Moon, where lunar dust turned out to be a significant challenge to mission and crew safety, attention is now turning to the dust in Mars' atmosphere and regolith. To start the process of identifying possible dust-caused challenges to the human presence on Mars, and thus aid early engineering and mission design efforts, the NASA Engineering and Safety Center (NESC) Robotic Spacecraft Technical Discipline Team organized and conducted a Workshop on the "Dust in Mars' Atmosphere and Its Impact on the Human Exploration of Mars", held at the Lunar and Planetary Institute (LPI), Houston, TX, June 13-15, 2017. The workshop addressed the following general areas:

What is known about Mars' dust in terms of its physical and chemical properties, its local and global abundance and composition, and its variability.

What is the impact of Mars atmospheric dust on human health.

What is the impact of Mars atmospheric dust on surface mechanical systems (e.g., spacesuits, habitats, mobility systems, etc.).

We present the top priority issues identified in the workshop.

B4.2-0037-18 SURVEYING MARTIAN SURFACE USING BALLOONS: AN OPEN-ARCHITECTURE MISSION CONCEPT

Joseph Wang, josephjw@usc.edu

University of Southern California, Los Angeles, California, United States Chen Cui, cuichen@usc.edu

University of Southern California, Los Angeles, United States Joseph Wyer, wyer@usc.edu

University of Southern California, Los Angeles, California, United States Mike Gruntman, mikeg@usc.edu

University of Southern California, Los Angeles, United States Neil Siegel, siegel.neil@gmail.com

University of Southern California, Los Angeles, California, United States Thomas Heinsheimer, thomas.heinsheimer@aero.org

Aerospace Corporation, El Segundo, United States

Surface mobility is one of the primary limiting factors in planetary exploration. Current roverbased technology precludes the possibility of surveying large areas of Martian surface. Recent advances in materials and miniature instrumentation increase the attractiveness of using suggest that balloons to explore much larger areas of the, once thought not suitable for application on Martian surface, may provide a viable alternative to rovers in a Mars mission.

We present a feasibility study conceptual design to enable the exploration on a concept to survey of the Martian surface utilizing Martian balloons. Solar-heated balloons can autonomously select an operating altitude in order to find wind moving in a direction of interest to the mission. Using a weighted guide rope, the balloon can "land", enabling closer inspection, and even the dispatch of small rovers to gather samples. Samples can thus be returned from a wide area of Mars to a single area, facilitating eventual Mars sample return to the Earth.

A physics based simulation model was developed to simulate Martian balloon flight. Utilizing parameters from the Mars Climate database, simulations were carried out for various payloads and climate conditions. We find that a balloon with a volume of 105m3 (balloon mass 30kg) can be designed to carry a 10kg payload for longrange flight on Mars. This capability is sufficient to allow one to develop a balloonbased Mars surface survey and sample-collection mission. A mission concept for in-situ Martian surface characterization using balloons and a new miniature Gamma-Ray/Neutron Spectrometer will also be discussed.

B4.2-0038-18 OPPORTUNISTIC BISTATIC RADAR WITH TELECOMMUNICATIONS SYSTEMS ON PLANETARY HELICOPTERS: MARS RECURRING SLOPE LINEA AND BEYOND

David Bell, david.j.bell@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology/ NASA, Pasadena, California, United States

Abigail Fraeman, abigail.a.fraeman@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Joseph Lazio, joseph.lazio@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Julie Castillo-Rogez, julie.c.castillo@jpl.nasa.gov

California Institute of Technology, Pasadena, CA, United States

Bistatic radar is a technique that utilizes the telecommunication system to obtain science data about a target body. The New Horizons mission used this technique to probe the atmosphere of Pluto via transmissions from the Deep Space Network, the Cassini-Huygens mission used this technique to characterize the surface of Titan, and the Rosetta mission (with the CONSERT instrument) used this technique between the Philae lander and the Rosetta orbiter. In opportunistic bistatic radar, the technique is applied by taking advantage of required transmissions that are not otherwise planned for science purposes.

In the case of a helicopter flying in the atmosphere of another planet, a straightforward data transfer scenario is that the helicopter would relay its data through another surface asset, such as a rover. The transmissions from the helicopter to the surface asset would have not only a direct path, but a portion of the transmitted energy would be reflected from the (sub)surface. Interference between the direct and reflected signals can be used to probe the (sub)surface between the helicopter and the rover, with the depth of penetration depending upon the wavelength (or frequency) used for the telecommunications.

We have constructed a field deployable model of the telecommunications system (900 MHz) for the Mars Helicopter Scout, which is under consideration for flying with Mars 2020 rover at the time of this abstract's submission. We describe a series of tests designed to characterize the performance of this system. As a motivating scenario, we consider the extent to which the bistatic radar technique would be able to probe into recurring slope linea (RSLs) on Mars, specifically whether a helicopter-surface asset system would be capable of distinguishing between "wet" RSLs, i.e., those originating from the flow of a brine, and "dry" RSLs. An attractive aspect of the bistatic radar technique is that it would allow remote sensing of potentially sensitive RSLs.

Finally, while the focus of this work has been a helicopter on Mars, the bistatic radar technique would be more generally applicable to any aerial vehicle at a planet with an atmosphere.

Some of the information presented is pre-decisional, for information and discussion purposes only. Part of this research was carried out at the Jet Propulsion Laboratory, California Institute of Technology, under a contract with the National Aeronautics and Space Administration.

B4.2-0039-18 WAVE ANALYZER MODULE OF THE MAIGRET INSTRUMENT ONBOARD SURFACE PLATFORM OF THE EXOMARS 2020 MISSION

Ondrej Santolik, os@ufa.cas.cz

Institute of Atmospheric Physics, Prague, Czech Republic Ivana Kolmasova, iko@ufa.cas.cz

Institute of Atmospheric Physics, Prague, Czech Republic Jan Soucek, soucek@ufa.cas.cz

Institute of Atmospheric Physics, ASCR, 14131, Czech Republic Ludek Uhlir, uhlir@ufa.cas.cz

Institute of Atmospheric Physics, Prague 4, Czech Republic Radek Lan, rl@ufa.cas.cz

Institute of Atmospheric Physics, Prague, Czech Republic Alexander Skalsky, skalsky@iki.rssi.ru

Institute of Space Research, Russian Academy of Sciences, Moscow, Russia

The wave analyzer module of the MAIGRET instrument will be placed on the ExoMars 2020 Surface platform. The module is dedicated to the measurement of magnetic field fluctuations in the frequency band from 100 Hz to 20 kHz. The scientific objectives of the wave analyser module will mainly concentrate on electromagnetic emissions of atmospheric origin and possible wave activity originated in electrical discharges in dust storms. The wave activity linked to the interactions of interplanetary plasma medium with Martian ionosphere and Martian magnetic anomalies at the surface and the ionosphere-atmosphere-lithosphere interactions on Mars related to space weather effects will be also investigated. The scientific questions which we plan to address have never been answered by measurements of the fluctuating magnetic fields in the appropriate range of frequencies directly on the surface of the planet. The immediate questions related to these targets are: i) Can we observe electromagnetic radiation propagating from the interplanetary space down to the surface of the planet? ii) Can we observe electromagnetic radiation from electric discharges in the Martian dust storms?

B4.2-0040-18 OVERVIEW AND STATUS REPORT ON THE UPCOMING SUPERCAM INVESTIGATION FOR THE MARS 2020 MISSION

Peter Willis, peter.a.willis@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Roger Wiens, rwiens@lanl.gov

SuperCam Team

_

BACKGROUND Our exploration of Mars began with ground-based observations, followed by flyby missions, then orbiters, and then landed spacecraft capable of making up-close measurements of the composition of matter on its surface. Through a series of rover-based missions, we have discovered a rich variety of Martian micro-environments, some of which may have been conducive to life. The upcoming Mars 2020 mission will seek out and explore such microenvironments at the highest level of spatial and compositional detail possible, with the goal of searching for potential biosignatures, and assembling a cache of samples for return to Earth [1]. The SuperCam instrument suite, which will be capable of making a host of elemental, mineralogical, and textural measurements using remote sensing techniques, will play a central role in this search. SuperCam will also provide highly efficient means for rapidly searching the area around the rover for compositional fingerprints (including vibrational spectral signatures of organic compounds) that warrant further investigation using the rover-arm-mounted instruments SHERLOC and PIXL. And finally, after the very most promising material has been identified and sampled for return to Earth, SuperCam can then also make detailed chemical and mineralogical measurements of the walls of the drill holes that remain after samples are removed.

OVERVIEW OF THE SUPERCAM SUITE SuperCam is a suite of co-boresighted remote optical instruments comprising 1) Laser Induced Breakdown Spectroscopy (LIBS), 2) Raman and time-resolved luminescence spectroscopy (TRLS), 3) visible and near-infrared spectroscopy (VISIR), and 4) high resolution color remote micro-imaging (RMI) [2]. Additionally, SuperCam includes a microphone capable of recording sounds associated with LIBS impacts (useful in determining surface properties) as well as recording sounds from the environment and rover

itself. SuperCam hardware is distributed among three modules on the Mars2020 rover: a mastmounted unit provided by CNES (containing the laser, telescope, imager, IR spectrometer, and microphone), a rover body-mounted unit provided by LANL (containing LIBS/Raman/VIS spectrometers and data processing hardware), and a calibration target assembly near the back of the rover provided by UVA (containing geological samples of primary interest to Mars exploration, targets specifically for calibration of trace element composition, and geometric and color targets for imager and IR reflectance calibration.) Although SuperCam's LIBS, VIS, and RMI capabilities rely heavily on ChemCam instrument heritage from the MSL mission, SuperCam's Raman and IR capabilities are entirely new, providing critical mineralogical observations that complement textural and elemental chemistry data. In the overall context of multi-mission Mars exploration in general, these new capabilities are especially noteworthy, as SuperCam measurements of mineralogy can be compared to IR data acquired from orbit. This data comparison will provide critical ground-truthing of global mineralogical maps of Mars such as those produced by the Mars Reconnaissance Orbiter's CRISM instrument or the Mars Express mission's OMEGA instrument. And in areas where samples are obscured by Mars dust, SuperCam can use its LIBS laser to remove dust prior to analysis.

SUPERCAM OPERATION ON MARS Each of the SuperCam co-boresighted measurement modes function over distinct but overlapping distance ranges. LIBS measurements can be made up to 7 m away from the rover mast, by focusing the SuperCam laser's 1064 nm output to spots approximately 0.3-0.6 mm in diameter on the surface of a sample. And since the LIBS process physically removes sample from a surface (a few microns depth per laser pulse) it is possible to probe sample composition as a function of depth by repeatedly firing the laser up to a thousand times at a single spot. Raman and TRLS measurements can be made at greater distances, up to 10 m, by utilizing the 532 nm output of the SuperCam laser in a collimated 8mm diameter spot. Measurements from both of these "active" laser illumination modes have an 0.67 mrad angular field of view, defined by instrument collection optics (in other words, they collect light from a 1.3 mm spot at 2 m distance, or a 2.6 mm spot at 4 m distance, etc.). SuperCam "passive" measurements that do not require laser illumination (VISIR and RMI) can be performed at even more remote targets, as far away as the horizon. These modes have larger fields of view than the laser measurement modes (1.2mrad for IR and 20mrad for RMI). RMI images are in color, and are higher resolution (pixel FOV 20 µrad) than the corresponding panchromatic ChemCam RMI images.

CURRENT STATUS AND FUTURE OUTLOOK At the time of writing, the SuperCam instrument suite is currently in the final stages of development, following the successful completion of instrument CDR in December 2016. The Engineering Qualification Model (EQM) is currently being assembled at LANL and instrument calibration of the full range of instrument suite functionality will soon begin. Flight instrument delivery is scheduled for November 2018. In this presentation we will provide an updated summary of the latest status and developments in the SuperCam investigation, including information on planned instrument operation on Mars as well as associated mission system and data analysis tools.

B4.2-0041-18 PLANETARY X-RAY DIFFRACTION BEYOND THE CHEMIN INSTRUMENT.

Philippe Sarrazin, psarrazin@seti.org

SETI Institute, Mountain View, California, United States David Blake, david.blake@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States Thomas Bristow, thomas.f.bristow@nasa.gov

NASA Ames Research Center, Moffett Field, California, United States

X-ray diffraction (XRD) is a reference laboratory analytical technique for mineral identification and quantitative mineralogy. It has been deployed in robotic planetary exploration for the first time with the CheMin instrument in MSL. CheMin established the quantitative mineralogy of the Mars soil, characterized the first habitable environment on another planet, and provided the first in-situ evidence of Martian silicic volcanism. CheMin is now employed in the characterization of the depositional and diagenetic environments of lacustrine mudstones that comprise the lower strata of Mt. Sharp. Powder XRD typically requires samples comprised of small grains (<10 µm) packed in random orientations. In CheMin, vibrated sample cells cause internal flows in a bed of loose powder, improving particle statistics and relaxing the requirement for fine-grained samples. Analysis of soils collected by the scoop or rock powders produced by the percussion drill is possible without any sample preparation other than screening. Nonetheless, CheMin still relies on a complex sample collection and delivery facility, which limits its deployment potential on smaller missions.

XTRA (Extraterrestrial Regolith Analyzer) is miniaturized derivative of CheMin, intended to analyze fines in as-delivered surface regolith. Fine-grained regolith coats the surfaces of most airless bodies in the solar system, and because this fraction is comminuted from the rocky regolith, it can often be used as a proxy for the surface as a whole. Like CheMin, XRD uses a CCD in direct illumination for the collection of XRD and XRF signals. XTRA can be configured either in transmission geometry like CheMin using thin vibrated sample cells, requiring screening to <150 µm, or in reflection geometry using thick vibrated sample cells for as-delivered powders, allowing direct analysis of materials scooped at the surface, and simpler sample delivery. All critical components of XTRA have been developed to high TRL in collaboration with industrial partners: CCD detector in cooled packages, FPGA electronics for low noise CCD operation and embedded data processing, micro-focused X-ray tube, controller and high voltage power supply. XTRA will be proposed for upcoming landed missions targeting remote mineralogical analysis, collection, selection and caching of return-samples, or in-situ resources characterization.

Other XRD concepts are under development. Hybrid-XRD (HXRD) is intended to analyze rocks or soils without sample preparation. Fine grained materials are analyzed with a powder XRD method in reflection geometry using the characteristic K emission of the X-ray tube target, while coarse-grained crystals are analyzed using single crystal Laue patterns obtained from the wide spectrum bremsstrahlung emission. Unlike typical Laue applications, HXRD analyzes the energy of each Laue spot which enables mineral identification. Proof of concept prototypes and dedicated crystallographic software have been developed for this method. Another XRD concept under development aims at improving the capability to resolve complex mineralogies: a Guinier camera powder XRD is used in a compact geometry capable of high 2ϑ resolution normally only achievable in laboratory instruments. This design hinges on the use of a curved 2D detector to cover the angular range of interest. A substantial gain in resolution has been demonstrated. Both reflection and transmission geometries can be developed with this concept and are being explored as part of a PICASSO funded effort.

B4.2-0042-18 A MINIATURIZED VARIABLE PRESSURE SCANNING ELECTRON MICROSCOPE (MVP-SEM) FOR MARS

Jessica Gaskin, jessica.gaskin@nasa.gov

NASA Marshall Space Flight Center, Huntsville, Alabama, United States Jennifer Edmunson, jennifer.e.edmunson@nasa.gov

Jacobs Technology, Huntsville, Alabama, United States Technical and Science Team

Technical Team: William Mackie and Gerald (Bud) Magera (Applied Physics Technologies, Inc.); Bob Kline-Schoder (Creare LLC); Jurij Simcic and Mathieu Fradet (NASA JPL); Gregory Jerman and Michael Effinger (NASA MSFC) Garasimos Danilatos (ESEM Research Laboratory)

Science Team: Ivria Doloboff, Kenneth Williford and Aaron Noell (NASA JPL); Nina Lanza (Los Alamos National Lab); Horton Newsom and Zach Gallegos (University of New Mexico);

J.R. Skok (SETI Institute); Hunain Alkhateb (University of Mississippi); Debra Needham and Caleb Fassett (NASA MSFC); Andrew Needham (USRA); Amy Williams (Towson University); Mark Salvatore (Northern Arizona University)

A scanning electron microscope is the "go-to" instrument for petrologists, geochemists, and astrobiologists to make an initial assessment of the types of minerals, glasses, metals, and potential forms of life present in a sample. The MVP-SEM is under development to eventually provide this instrument for the surface of Mars. This development is funded by the NASA Planetary Instrument Concepts for the Advancement of Solar System Observations (PICASSO) Research Opportunities in Space and Earth Sciences (ROSES) and is based on previous miniaturized SEM designs and advancements in the miniaturization of vacuum systems and detectors for low vacuum sample chambers. The variable pressure aspect of the SEM allows for unprepared (uncoated) samples to be analyzed by utilizing the carbon dioxide-rich Mars atmosphere for the neutralization of sample charging from the electron beam. This property of the MVP-SEM makes it ideal for use in locations where complex sample preparation is not desirable, such as the surface of Mars. In addition, the lack of sample preparation needed here simplifies the sample acquisition process and allows caching of the samples for future complementary payload use or eventual delivery to Earth.

The MVP-SEM team is comprised of an Instrument Development Team and a Science Team. The Instrument Development Team is led by NASA Marshall Space Flight Center and its members include the Jet Propulsion Laboratory (JPL), Applied Physics Technologies, and Creare LLC. The MVP-SEM Science Team members include planetary scientists, astrobiologists, members of ongoing Mars rover mission science teams, and research engineers.

Science requirements for the instrument include: 1) an imaging system capable of resolving uncoated objects or phases 100nm in size or better, 2) determination of the geochemistry of uncoated samples to a precision of 2 weight percent per major element, 3) capability to analyze materials with little to no sample preparation, 4) the ability to analyze multiple samples with a reusable sample holder, 5) production of images capable of being downlinked to Earth, and 6) ability to operate on a Mars-landed spacecraft.

The Instrument Development Team constrained the operational conditions of the instrument for imaging by testing with terrestrial SEMs using carbon dioxide gas for the appropriate electron scattering and charge neutralization conditions. Prototype development is nearing completion; testing of the instrument will be completed using a Mars environment chamber at the JPL. The instrument development process and results of testing to date will be presented.

B4.2-0043-18 INTERPLANETARY DUST ENVIRONMENT AROUND MARS AND PARTICLE DETECTION FROM FUTURE ORBITER

Jayesh Pabari, jayesh@prl.res.in

Physical Research Laboratory, Ahmedabad, Ahmedabad, India MODEX Team

Acharyya, S. A. Haider, V. Sheel, A. Bhardwaj, S. Nambiar, D. Patel, S. Jitarwal, R. K. Singh, A. Kumar and B. M. Pandya

Interplanetary dust in the inner solar system is expected mainly to be originated from asteroid belt beyond Mars and it travels inward towards Sun. On its way, it encounters various planets, which causes incoming dust environment in upper atmosphere of the planet. Mars, being the first in the travel path of Interplanetary Dust Particles (IDPs) from asteroid belt, more particles are expected at Mars than those predicted from existing model. Two plausible sources of incoming dust at Mars are envisaged, viz., first is IDP travelling from beyond the Mars and other is dust which might be originated from Phobos/Deimos. Recently, very high altitude dust from 150-1000 km has been observed by MAVEN mission. However, the source of such dust particles is not understood and their measurements are necessary to explain the possible origination. Further, the existing hypothesis that dust could be in the form of a thin ring around Mars may be confirmed due to long term observations and satellite orbit information. To study origin, abundance, distribution, flux and seasonal variation of IDP at Mars, a Mars Orbit Dust Experiment (MODEX) is proposed and the development of impact ionization dust detector has been initiated at PRL. This presentation discusses the dust at Mars, scientific motivation for dust measurements and developmental aspects of a dust detector along with initial results. The further work is underway.

The Natural History Museum, London, United Kingdom EURO-CARES consortium

Joseph Michalski, John Robert Brucato, Ernesto Palomba, Alessandra Rotundi, Andrea Meneghin, Andrea Longobardo, Ludovic Ferrière, Aurore Hutzler, Jérôme Aléon, Matthieu Gounelle, Yves Marrocchi, Lucy Berthoud, John Vrublevskis, Mike Guest, Stefano Matussi, Monica Grady, Ian Franchi, Ben Dryer, Petra Rettberg, Stefan Leuko, John Holt, Allan Bennett, Thomas Pottage, Katherine Joy, Martin Lee, Jesus Martinez Frias, Penny Wozniakiewicz, Nicolas Bost, Mike Zolensky, Hajime Yano, Hilde Schroeven-Deceuninck, Gerhard Kminek, Matthias Van Ginneken and Michel Viso.

The objective of the H2020-funded EURO-CARES project (grant agreement n° 640190) was to create a roadmap for the implementation of a European Extraterrestrial Sample Curation Facility (ESCF) that would be suitable for the curation of samples from all possible return missions likely over the next few decades, i.e. from the Moon, asteroids and Mars.

The return of extraterrestrial samples brought to Earth will require specific storage conditions and handling procedures, in particular for those coming from Mars. For practical reasons and sterility concerns it might be necessary for such a facility to have its own collection of analogue samples permitting the testing of storage conditions, and to develop protocols for sample prepartion and analyses. Within the framework of the EURO-CARES project, we have created a list of the different types of samples that would be relevant for such a curation facility.

The facility will be used for receiving and opening of the returned sample canisters, as well as for handling and preparation of the returned samples. Furthermore, it will provide some analysis of the returned samples, i.e. early sample characterisation, and is expected to provide longterm storage of the returned samples. Each of these basic functions requires special equipment. Equipment, handling protocols and long-term storage conditions will strongly depend on the characteristics of the materials, and on whether returned samples are from the Moon, Mars or an asteroidal body. Therefore the different types and aspects of analogue samples one need to be considered, i.e. the nature of the materials, which analogues are needed for what purpose, what mass is needed, and how should the analogue samples be stored within the facility.

We distinguished five different types of anologue samples: analogue (s.s.), witness plate, voucher specimen, reference sample, and standard. Analogues are materials that have one or more physical or chemical properties similar to Earth-returned extraterrestrial samples. Reference samples are well-characterised materials with known physical and chemical properties used for testing. They may not necessarily be the same materials as the analogues defined above. Standards are internationally recognised, homogeneous materials with known physical and chemical properties that are used for calibration. They can also be used as reference samples in certain circumstances. They may be made of natural materials but are often produced artificially. A voucher specimen is a duplicate of materials used at any stage during sample acquisition, storage, transport, treatment etc., e.g. spacecraft materials (including solar panels), lubricants, glues, gloves, saws, drills, and others. In addition, Earth landing site samples (from the touch down site) would be necessary in case of doubtful analysis, even if normally this type of contamination is not expected. Finally, a witness plate is defined as material left in an area where work is being done to detect any biological, particulate, chemical, and/or organic contamination. It is a spatial and temporal document of what happens in the work area.

Analogue materials could be solids (including ices), liquids or gases. These could contain biological (extant and/or exinct) and/or organic components. They could be natural materials, e.g. rocks or minerals, or could be manufactured, such as mixtures of different components, which may be biologically and/or organically doped. Analogues with appropriate sample size and nature will be well-suited for testing and training of sample handling procedures, and for transport protocols. The training of science and curation teams also requires reference samples and standards. Long-term storage needs special witness plates and voucher specimes. Developing and testing sample preparation protocols needs all sample types.

B4.2-0045-18 A MODEL OF ATMOSPHERIC DRAG EFFECT ON MARS MISSION ORBITER DURING GEOCENTRIC, HELIOCENTRIC AND AREOCENTRIC TRAJECTORIES

Victor U.J. Nwankwo, victornwankwo@yahoo.com Anchor University, Lagos, Nigeria

Sandip Kumar Chakrabarti, chakraba@bose.res.in

S.N. Bose National Centre for Basic Sciences, Kolkata, India

Interplanetary missions are susceptible to gravitational and non-gravitational perturbing forces at every trajectory phase (e.g., geocentric, heliocentric and Martian trajectories/areocentric phases). In this study, we analyzed such perturbing forces and their possible effects on interplanetary and/or Mars mission satellites, before Orbit Insertion. We also model the significance of atmospheric drag force on Mangalyaan Mars orbiter mission around/during perigee passage, as a function of solar and geomagnetic parameters during its 28 days in Earth's orbit, 300 days of heliocentric and 100 days of Martian trajectory, based on Earth-Mars atmosphere density ratio.

B4.2-0046-18 EFFECT OF SOLAR ENERGETIC ELECTROMAGNETIC AND PARTICLE RADIATIONS ON THE UPPER ATMOSPHERE OF MARS AND ITS IMPLICATIONS ON ROBOTIC MISSIONS

Praveen Kumar Kuttanpillai, praveenisro@gmail.com Indian Space Research Organization, Bangalore, India Nagaraja Kamsali, kamsalinagaraj@bub.ernet.in Bangalore University, Bengaluru, India

Praveen Kumar Basuvaraj, praveenkumarbasuvaraj@gmail.com Bangalore University, Bengaluru, India

S.C. Chakravarty, chakravarty08@gmail.com Bangalore University, Bangalore, India

A number of robotic missions have been planned in the near future by international space agencies to study various geological/ atmospheric phenomena including the search for indicators/ signatures of microbial or other forms of life on Mars. Spacecraft pressed for such autonomous pursuits followed up, later by possible manned Mars missions would have to be designed to withstand the total integrated as well as specific solar and cosmic event based radiation environment. While the heavy ion GCR flux and solar proton events (SPE) contribute to the bulk of the radiation doses, the solar activity constitutes an important control parameter of these fluxes which are oppositely correlated with the variations of sunspot numbers. A power law fit of the differential flux provides for the spectral hardness of these energetic radiations and a higher spectral coefficient contributes considerable radiation doses even behind the shielding. Hence the hazards of severe space radiation in deep space particularly for long duration planetary missions need to be appropriately assessed. The possible safeguards from the exposures to the ionising radiations of GCR and SPE are to be built in the design of the shielding and related subsystems of the spacecraft. In order to achieve a better optimisation with respect to the specific materials and structural elements of the shielding technology, it is essential that accurate model to predict GCR and SPE fluences be available around the survey region of Mars specific to a robotic mission. In this paper we develop an integrated GCR/SPE model to provide predicted total radiation environment on Mars. The solar energetic particle radiation and GCR data are obtained from many spacecraft observations during different periods of solar activity to develop the model by using neural networks. Further the partial absorption and attenuation of these radiations by the atmosphere of Mars is also taken into account using the data from MOM, MAVEN and other missions. The model results are validated with available experimental observations.

B4.2-0047-18 IN-SITU LUMINESCENCE DATING OF MARTIAN SEDIMENTS

Debabrata Banerjee, deba@prl.res.in

Physical Research Laboratory, Ahmedabad, India

D. K. Panda, pdipak@prl.res.in

Physical Research Laboratory, Ahmedabad, India

Recent discoveries have revealed that Mars possesses a record of diverse surfaces created as a result of geological processes occurring prior to 3 Ga, and recent volcanism, weathering events during the last few 100 Million years. This geological record is yet to be found on Moon or the Earth, and new Mars missions provide an opportunity to address questions regarding planetary evolutionary processes, how and whether life arose elsewhere in the solar system, and the interplay between geological and possible biological history. At present, Mars is too cold with a very thin atmosphere to support the existence of liquid water on its surface. However, images from Mariner 9 and later by Viking orbiters suggested the presence of geomorphic features which might have formed in the past by the action of liquid water flowing along the Martian surface. Further, Mars Global Surveyor images indicated the existence of young, fluvial landforms at latitudes above 30o in both hemispheres. These features might be younger than 1 Million years, as they appear to be relatively fresh, and because of the absence of impact craters on surrounding terrain and their association with young (< few Million years) sand dunes. It is important to study the above mentioned features as the fossil remains of extinct life on Mars, if existing, are likely to be found in areas where there was a source of water. Other important repositories for water on Mars consist of the polar regions, comprising perennial ice, overlain by seasonal CO2 frost caps, and underlain by layered deposits. These deposits are believed to preserve a record of variations in CO2, H2O and dust concentrations over the last 100 million years and are the best archives of recent climatic changes on Mars. Thus, sedimentary deposits are likely to provide important records of paleoclimatic change on Mars. Establishment of a Martian paleoclimatic history requires the development of absolute dating techniques. This presentation proposes determination of a chronology for Martian sediments over the last 2 Million years using optically stimulated luminescence (OSL) dating techniques. Luminescence dating has revolutionized terrestrial Quaternary studies as these methods can be used for dating a variety of earth surface processes and sediments that were conventionally considered undatable. On Mars, OSL dating will provide high-precision age estimates for the laminated polar deposits, aeolian activation periods, and fluvial and lacustrine sedimentation periods.

B4.2-0049-18 NASA'S ASTROMATERIALS ACQUISITION AND CURATION OFFICE: ENABLING 50 YEARS OF LUNAR AND PLANETARY RESEARCH, NOW HEADING TO MARS

The NASA Astromaterials Acquisition and Curation Office at the NASA Johnson Space Center curates all of NASA's extraterrestrial samples, including 10 unique collections: (1) Apollo lunar samples (1969); (2) Antarctic meteorites from asteroids, the Moon, and Mars (1976); (3) Cosmic dust particles collected in the stratosphere (1981); (4) Microparticle Impact Collection (1985); (5) Genesis solar wind atoms (2004); (6) Comet Wild 2 particles from the Stardust mission (2006); (7) Stardust interstellar particles (2006); (8) Hayabusa asteroid particles (2010);

(9) OSIRIS-REx spacecraft coupons and witness plates (2015); and (10) Mars2020 spacecraft contamination knowledge. The broad range of samples in NASA collections have resulted in growing capabilities to curate large rock samples (Apollo, Meteorite), bulk regolith and coresmixtures of particles ranging from submicron to 1 cm (Apollo), micron-scale particles (Cosmic Dust, Hayabusa), micron-scale particles embedded in aerogel (Stardust), solar wind atoms implanted in various materials (Genesis), carbon-rich samples (Meteorite), spacecraft pieces with embedded astromaterials (Microparticle Impact Collection), and materials that capture contamination knowledge for extraterrestrial samples (Genesis, Stardust, OSIRIS-Rex, Mars2020). The standards of Astromaterials Curation are described by NASA Policy Directive 7100.10F and derivative documents that specifically direct the NASA Curation Office at JSC to implement the ". curation of all extraterrestrial material under NASA control, including future NASA missions", and defines curation to include documentation, preservation, preparation, and distribution of samples for research, education, and public outreach. This policy ensures the proper curation of current and future astromaterials collections, including future samples from Mars, at the Johnson Space Center. Based on this policy, the NASA Astromaterials Curation Office has built an experience base spanning 50 years that encompasses curation facility planning, research and development of sample handling and contamination control protocols, partnering with mission teams, and continuous daily operations [1,2]. The resulting product is the world's most diverse, extensive, best-documented, and least-contaminated extraterrestrial sample collection that supports planetary research by hundreds of researchers around the globe. An average of 1500 samples are allocated to scientists every year. These allocations result in 100s of papers annually, fundamental discoveries about the evolution of the solar system (e.g. [3]), and serve as ground truth for robotic missions such as NASA's Dawn mission to Vesta and Ceres, OSIRIS REx mission to Bennu [1,3], and the rovers on Mars.

Advances in Astromaterials Curation: Today's advanced curation initiatives build on decades of NASA experience developing and executing astromaterials curation facilities and protocols. Lessons from the Apollo missions formed the foundation of NASA's curation effort, including the need for early involvement of curation scientists in mission planning [1], have been applied to all subsequent sample return campaigns. The 2013 National Academy of Sciences report

[4] noted: "Curation is the critical interface between sample return missions and laboratory research. Proper curation has maintained the scientific integrity and utility of the Apollo, Antarctic meteorite, and cosmic dust collections for decades. Each of these collections continues to yield important new science." Today, a large part of NASA Curation's efforts includes planning for samples returned from future missions, including samples from locations designated "restricted Earth return" such as Mars. Key areas of research include: 1) detecting and monitoring all forms of contamination and achieving increasingly high levels of cleanliness (inorganic and organic [5]) in our facilities to enable analysis for all elements and relevant organic species; 2) development of new high precision cleaning and validation techniques for sampling materials and witness plates; 3) continued research on sample handling and containment technologies including cross contamination and robotic sample handling solutions, and concepts for restricted samples (see Calaway et al, this session); 4) development of requirements for cold curation that will enable preservation and handling of samples, including volatiles collected at extremely low temperatures. We are also enhancing sample databases

and documentation of data derived from NASA's astromaterials samples, restoring legacy data sets, collecting and serving high resolution imagery, developing 3D imaging techniques and have established an X-ray CT laboratory [6], and upgrading labs with web-based communication enabling remote access for investigators from around the world. These advances support the continued curation of Apollo samples, our other astromaterials collections, and the future curation of samples from challenging exploration destinations such as the south polar region of the Moon, icy moons of outer planets, comets, and the surface of Mars.

B4.2-0050-18 MAXIMUM SAMPLE TEMPERATURE FOR MARS SAMPLE RETURN: A HISTORICAL PERSPECTIVE

Marc Fries, marc.d.fries@nasa.gov

NASA Johnson Space Center, Houston, Texas, United States
Michael Calaway, michael.calaway@nasa.gov

Jacobs/Johnson Space Center, Houston, Texas, United States

Since the first Mars Sample Return (MSR) report published by the Jet Propulsion Laboratory (JPL) in 1974 [1], a series of panels, reports, and white papers have recognized the importance of sample temperature and offered an informed sample maximum temperature (henceforth SMT) limit for returning martian samples to Earth. The Mars Sample Handling and Requirements Panel (MSHARP, 1999) stated that "[t]he main issue in sample preservation is temperature" [2]. More recently, the Mars Exploration Program Analysis Group (MEPAG)'s "Science Priorities for Mars Sample Return" report (2008), declared that "[s]ignificant loss, particularly to biological studies, occurs if samples reach +50°C for three hours", whereby "scientific objectives related to life goals could be seriously compromised" [3]. By contrast, the Mars 2020 mission has adopted a SMT of +60°C as spelled out in Beaty et al., 2016 [4]. Samples will be collected and then deposited on the surface in sealed tubes for possible retrieval and return to Earth. Beaty et al. [4] calculates that the samples will experience maximum temperatures of +30 to +60°C, depending on latitude. At present, there is no mission requirement for the measurement/data logging of sample temperature during this period. We will explore the history of martian SMTs, as they have been recorded since 1974 [1], effectively representing input across multiple generations of Mars scientists. Ten separate publications present SMTs for MSR samples [1-10]. One report [10] is for a mission concept specifically designed to exclude life detection investigations, and recommended an SMT of 50°C. Another did not specify a temperature, recommending "Mars ambient temperature" [5]. Of the remaining eight, SMTs are given as: -30°C [1], -20°C [3], 60°C [4], -73 to 41°C depending on sample type [6], -40°C [7], -43 to 13°C depending on type [2,8], and -33°C [9]. If we restrict the temperatures to samples highlighted in the Mars 2020 mission goals, i.e. organics-bearing and sedimentary rocks, then the average SMT is -28±39°C (n=8). Applying a Dixon's Q Test at P=0.05 (two-tailed), the 60°C SMT [4] fails with Q=0.602 versus Qcrit=0.526. Excluding the outlier produces an average SMT of -40±17°C (n=7). Therefore, the average SMT expressed by the Mars science community over the past 44 years (two generations) is a sample temperature no greater than -40°C. The difference in chemical reaction rates between this average SMT and Beaty et al [4] can be estimated using the Arrhenius equation. Assuming a generic chemical reaction with an activation energy of 50 kJ/mol and a pre-exponential factor invariant with temperature, this reaction will proceed 2300x faster at 60°C than at -40°C. To illustrate the effects of the increased reaction rate, consider 10 ppb of alanine in a Mars 2020 cache, and assume that it becomes unmeasurable if it degrades to 1 ppb, as per the Mars 2020 Organic Contamination

Panel contamination limits [11]. If we illustrate the effect with an arbitrary degradation rate such that the alanine will become undetectable in ten years at -40°C, then the same 10 ppb alanine degrades beyond detectability in only 38 days at 60°C. Further research is required to quantify expected analyte losses in the cached samples due to thermal processing. [1] Jaffe, L.D., et al 1974. JPL Internal Rept., (760-101). The Emirates Mars Infrared Spectrometer (EMIRS) is one of three scientific instruments abroad the Emirates Mars Mission (EMM) spacecraft named "Hope". EMM will launch in 2020 and is designed to explore the diurnal and seasonal dynamics of the martian atmosphere on a global scale. EMM has three scientific instruments that provide an improved understanding of climate and weather in the martian lower and middle atmosphere as well as the thermosphere and exosphere. The Emirates eXploration Imager (EXI) and EMIRS instruments will focus on the lower atmosphere constituents, constraining dust and water ice optical depths, while determining the ozone and water vapor column abundances and the thermal structure up to 50 km altitude. The Emirates Mars Ultraviolet Spectrometer (EMUS) will make complementary observations, enabling important links between the lower atmospheric dynamics and the thermosphere and exosphere of the planet.

The EMIRS instrument is an interferometric thermal infrared spectrometer developed by Arizona State University (ASU) and Mohammed Bin Rashid Space Centre (MBRSC). It builds on a long heritage of thermal infrared spectrometers designed, built, and managed by ASU's Mars Space Flight Facility, including the Thermal Emission Spectrometer (TES), Miniature

Thermal Emission Spectrometer (Mini-TES), and the OSIRIS-REx Thermal Emission Spectrometer (OTES). EMIRS collects spectral

data from 6-40+ µm at 5 cm-1 spectral sampling, which is enabled by a diamond beamsplitter and digital servo interferometer control electronics. EMIRS has a 3×3 array of pyroelectric DLaTGS detectors and a scan mirror that enable it make high-precision infrared radiance measurements over a martian hemisphere in 1/2 an hour of observing. The EMIRS instrument performance, spectral coverage, and spatial sampling are optimized to capture the integrated, lower and middle atmospheric dynamics, collecting 60 observations per week (20 images per orbit) at a resolution of 100-300 km/pixel. EMIRS contributes heavily to the scientific objectives of EMM and will provide a new view of the martian lower and middle atmosphere, capturing the sub-seasonal and diurnal evolution of key atmospheric constituents over the entire globe during the EMM two year primary mission.

B4.2-0052-18 SCIENTIFIC PAYLOAD OF THE EMIRATES MARS MISSION: EMIRATES EXPLORATION IMAGER (EXI) OVERVIEW

LASP / University of Colorado, Boulder, Colorado, United States

The Emirates eXploration Imager (EXI) instrument is one of three scientific instruments abroad the Emirate Mars Mission (EMM) spacecraft, “Hope”. The planned launch window opens in the summer of 2020, with the goal of this United Arab Emirates (UAE) mission to explore the dynamics of the Martian atmosphere through global spatial sampling which includes both diurnal and seasonal timescales. A particular focus of the mission is the improvement of our understanding of the global circulation in the lower atmosphere and the connections to the upward transport of energy of the escaping atmospheric particles from the upper atmosphere. This will be accomplished using three unique and complementary scientific instruments. The subject of this presentation, EXI, is a multi-band, camera capable of taking 12 megapixel images, which translates to a spatial resolution of better than 8 km with a well calibrated radiometric performance. EXI uses a selector wheel mechanism consisting of 6 discrete bandpass filters to sample the optical spectral region: 3 UV bands and 3 visible (RGB) bands. Atmospheric characterization will involve the retrieval of the ice optical depth using the 300-340 nm band, the dust optical depth in the 205-235nm range, and the column abundance of ozone with a band covering 245-275 nm. Radiometric fidelity is optimized while simplifying the optical design by separating the UV and VIS optical paths. The instrument is being developed jointly by the Laboratory for Atmospheric and Space Physics (LASP), University of California, Boulder, USA, and Mohammed Bin Rashid Space Centre (MBRSC), Dubai, UAE.

The Emirates Mars Ultraviolet Spectrometer (EMUS) instrument is one of three science instruments on board the "Hope Probe" of the Emirates Mars Mission (EMM). EMM is a United Arab Emirates' (UAE) mission to Mars, launching in 2020, to explore the global dynamics of the Martian atmosphere, while sampling on both diurnal and seasonal timescales. The EMUS instrument is a far-ultraviolet imaging spectrograph that measures emissions in the spectral range 100-170 nm. Using a combination of its one-dimensional imaging and spacecraft motion, it will build up two-dimensional far-ultraviolet images of the Martian disk and near-space environment at several important wavelengths: the Lyman beta atomic hydrogen emission (102.6 nm), the Lyman alpha atomic hydrogen emission (121.6 nm), two atomic oxygen emissions (130.4 nm and 135.6 nm), and the carbon monoxide fourth positive group band emission (140 nm-170 nm). Radiances at these wavelengths will be used to derive the column abundance of atomic oxygen, and carbon monoxide in the Martian thermosphere, and the density of atomic oxygen and atomic hydrogen in the Martian exosphere both with spatial and sub-seasonal variability. The EMUS instrument consists of a single telescope mirror feeding a Rowland circle imaging spectrograph with selectable spectral resolution (1.3 nm, 1.8 nm, or 5 nm), and a photon-counting and locating detector (provided by the Space Sciences Laboratory at the University of California, Berkeley). The EMUS spatial resolution of less than 300 km on the disk is sufficient to characterize spatial variability in the Martian thermosphere (100-200 km altitude) and exosphere (>200 km altitude). The instrument is jointly developed by the Laboratory for Atmospheric and Space Physics (LASP) at the University of Colorado Boulder and Mohammed Bin Rashid Space Centre (MBRSC) in Dubai, UAE.

Optical microscopy in transmitted light is one of the most standard techniques in geology and has been used for more than 150 years. Indeed, atlases of microscopic images of rocks and their characteristic mineralogy and textures are widely used in geological departments [1]. Observation in transmitted light permits identification of rocks having similar chemical and mineralogical compositions but different mineral textures (basalt vs. gabbro for instance). Using polarized light, it permits identification of most rock-forming minerals in thin section [2]. Observation in transmitted light is also essential for micropaleontology since it is the only way to observe individual microfossils or colonies of microfossils, if they are large enough, and to document the mineralogical and textural context in which the biosignatures occur. Nevertheless, optical observation in transmission has never been carried out on Mars. Indeed, although optical microscopes are used in space exploration (e.g. on Mars), thin section preparation in situ on an extraterrestrial body is not easy to do. In particular, on Earth it requires several human manipulations that are difficult to automate.

The aim of the LithoSpace project, supported by the CNES since 2014, is to work on the development of an automated system permitting preparation of petrographic thin sections on extraterrestrial bodies, in particular, on Mars. Several studies and tests have been conducted and most of the problems solved. The final protocol follows the process from obtaining a standardized drill core to observation of a thin section in a fully automated way.

The project is an excellent way to raise student awareness of space science and technology, helped by the fact that it is possible to develop a model for a relatively limited cost. Thus, a preliminary numerical model of the system was designed by fifth year students at the engineering school Polytech'Orléans, University of Orléans, France. They also proposed smart solutions for different critical steps of the preparation. Subsequently, it was decided to constructed the model with the help of students in the BTS (two-year technical degree) course "conception of industrial products", from the Benjamin Franklin high school of Orléans. In this way a group of five students, helped by their teachers, have started the development of a physical demonstration model to be presented during the COSPAR 2018 meeting.

In situ thin section preparation would be an important improvement for the geological and astrobiological exploration of the solar system in general, for Mars as well as for other planetary bodies. The proposed instrument could incorporate new high resolution techniques, such as Raman mapping or micro-LIBS as well as optical microscopic observation in transmitted light.

The Juno spacecraft was launched in 2011 and arrived at Jupiter on July 4, 2016. Juno's scientific objectives include the study of Jupiter's interior, atmosphere and magnetosphere with the goal of understanding Jupiter's origin, formation and evolution. The baseline mission utilizes thirty-two polar orbits to effectively map Jupiter both inside and out. Each perijove provides Juno's nine instrument payload a close pass over Jupiter at altitudes as close as 3500 km above the cloud tops. With its unique orbit and unique viewing geometry, Juno peers into Jupiter's deep atmosphere, deep interior and hovers over the polar magnetosphere to reveal for the first time the physics of giant planets. The results have fundamentally changed our understand- ing of Jupiter and are providing a new approach to solar system investigation. An extensive campaign of Earth based observations of Jupiter and the solar wind were orchestrated to complement Juno measurements during Juno's approach to Jupiter and during its orbital mission around Jupiter. This presentation provides an overview of results from the Juno measurements and the collaborative campaign. Scientific results include Jupiter's interior structure, magnetic field, deep atmospheric dynamics and composition, and the first in-situ exploration of Jupiter's polar magnetosphere and aurorae.

Since its arrival in July of 2016, NASA's Juno spacecraft continues to return invaluable observations regarding Jupiter's dynamic magnetosphere. The polar orbiting spacecraft has an orbital period of 53.5 days, which takes it from just a few thousand kilometers above Jupiter's one-bar "surface" outward to over 100 jovian radii - cutting through Jupiter's polar region as well as its equatorial region. Although these regions are inherently coupled, in this talk we compartmentalize Juno's observations into the auroral and magnetospheric regions and briefly discuss their connections. One of Juno's primary science goals is to investigate the nature of Jupiter's aurora - the most powerful aurora in the solar system. Outfitted on the space- craft are a suite of instruments dedicated to measuring the in situ plasma waves and magnetic fields, charged particles as well as remote sensing the ultraviolet and infrared signatures of the aurora. In concert, these observations have and continue to paint a fundamentally different view of the mechanisms producing the Jovian auroras. Juno's instruments are also sending back new and compelling observations of Jupiter's magnetospheric regions. Examples include: the discovery of a belt of heavy ions residing inside the main ring, new details regarding the magnetopause structure and dynamics, and a more comprehensive survey of the plasma sheet particle populations and dynamics. In this presentation we will briefly summarize some of the major findings from both the auroral and magnetospheric regions and discuss new mysteries and future anticipated observations from Juno.

Thanks to Juno's very eccentric orbit (apojove 110 Rj, perijoe 1.05 Rj), JADE observes plasma populations throughout the Jovian magnetosphere: the magnetosheath through the magnetopause; the outer, middle, and inner magnetosphere; and close-in down to the ionosphere. We present here some of the highlights of the JADE observations from the first to the most recent orbits.

Plasma disk crossings in the middle and inner magnetosphere show a mixture of heavy and light ions. A novel analysis technique allows us to separate O+ from S2+ in the TOF spectra. During perijove crossings at high latitudes when Juno was connected to the Io torus JADE-I observed heavy ions with energies consistent with a co-rotating pickup population. At sub-auroral and equatorial latitudes, low energy (<100 eV) ionospheric ion distributions are observed that are distinct from the Io torus population.

The electron pitch angle distributions on field lines connected to the auroral regions change as a function of radial distance. For example, the higher energy electrons (30-100 keV) are mostly isotropic at large distances and mostly trapped closer to Jupiter, while the lower energies (<3 keV) are mostly field aligned at most distances.

Over the polar and auroral regions, JADE observed bi-directional electron beams having broad energy distributions interspersed between beams of upward electrons with narrow, peaked energy distributions, regions void of these electrons, and regions dominated by penetrating radiation. In most instances the electrons show evidence of acceleration via stochastic processes (broad energy distributions) and sometimes via parallel electric fields (inverted-V structures). One of the most surprising and still puzzling results is that the upward energy flux of the electron distributions is typically greater than the downward energy flux, except when Juno is connected to the diffuse aurora equatorward of the main auroral emission.

B5.1-0004-18 JUNO WAVES OBSERVATIONS AT JUPITER

William Kurth, william-kurth@uiowa.edu

The University of Iowa, Iowa City, IA, Iowa, United States Juno Waves Team

G. B. Hospodarsky, M. Imai, S. S. Elliott, D. A. Gurnett, S.-Y. Ye, A. Sulaiman, P. Louarn,

P. Valek, F. Allegrini, J. E. P. Connerney, B. H. Mauk, S. J. Bolton, S. M. Levin, A. Adriani,

G. R. Gladstone, D. J. McComas, P. Zarka, I. Kolmasova, and O. Santolik

The Juno spacecraft successfully entered Jupiter orbit on 5 July 2016. One of Juno's pri- mary objectives is to explore Jupiter's polar magnetosphere. An obvious major aspect of this exploration includes remote and in situ observations of Jupiter's auroras and the processes responsible for them. To this end, Juno carries a suite of particle, field, and remote sensing instruments. One of these instruments is a radio and plasma wave instrument called Waves, designed to detect one electric field component of waves in the frequency range of 50 Hz to 41 MHz and one magnetic field component of waves in the range of 50 Hz to 20 kHz. Juno has now made scientific observations on several perijove passes beginning with Perijove 1 on 27 August 2016. This paper presents an update of some of the results from the Juno Waves instrument. Among radio emissions, kilometric, hectometric, and decametric emissions have been observed. We present observations suggesting Juno has flown through or close to several sources of these auroral radio emissions. Remote observations provide source locations for broadband kilometric radiation that are consistent with auroral field lines. Waves observes whistler-mode hiss on auroral field lines and over the polar cap. The hiss sometimes exhibits quasi-periodic intensity fluctuations in the range of a few to a few tens of minutes, similar to that of quasi-periodic (QP) radio bursts and temporal variations in some UV auroral emissions and X-ray hot spots poleward of the main oval. The hiss intensity exhibits a good correlation with upgoing energetic electrons observed by the Jupiter Energetic particle Detector (JEDI). It is enticing to consider the possibility that the hiss and energetic electrons are associated with the quasi-periodic emissions. Juno's perijove passes carry it over mid-latitudes where lightning is known to exist and, consequently, copious numbers of lightning whistlers have been observed, significantly increasing our understanding of lightning occurrence on Jupiter. Proton whistlers have also been observed on a few occasions, a first for this phenomenon in a non-terrestrial locale. Near perijove the Waves instrument observes whistler mode hiss whose upper cutoff is likely at the local electron plasma frequency providing in situ observations of Jupiter's topside ionosphere. Dust is also observed near the jovigraphic equator through hypervelocity impacts with Juno. It is thought that the grains are micron-sized and are the result of material moving inward from Jupiter's ring.

An intense electromagnetic impulse induced by Jupiter's lightning propagates through the magnetized plasma in the ionosphere and inner magnetosphere producing a low-frequency dispersed whistler emission and a non-dispersed sferic pulse. Jupiter's whistlers were observed by Voyager 1 in a frequency range of a few tens of Hz to 20 kHz, having the restriction of propagation below either the local electron cyclotron frequency or local electron plasma frequency, whichever is lower. A non-dispersed sferic was first captured at Jupiter by the Galileo Probe in a magnetic field waveform between 10 Hz and 100 kHz. Sferic signals at frequencies above 100 kHz were conjectured but no detections of this kind were reported in the Jovian inner magnetosphere using Voyager radio observations in a frequency range from 20 kHz to 41 MHz. Another opportunity to examine the nature of Jupiter lightning is provided by the Juno polar-orbiting spacecraft that arrived at Jupiter on 5 July, 2016. Since then, Juno has maintained a 53-day eccentric polar orbit about Jupiter. During Juno's eight perijove surveys from 27 August, 2016, through 24 October, 2017, we have investigated all waveform snapshots in 122.88-ms intervals from

50 Hz to 20 kHz and in 16.384-ms intervals from 10 kHz to 150 kHz collected by the Waves instrument. We found copious, new types of electromagnetic waves related to lightning at frequencies below 150 kHz, including whistlers below 5 kHz at extremely short time scales and dispersed millisecond pulses below 150 kHz (Jupiter dispersed pulses or JDPs). The number of detected whistlers and JDPs have respectively reached over 1600 and 400 detections, which comprise the largest dataset for Jovian lightning. We have also attempted to compare these observations below 150 kHz with some of high-frequency observations from 600 MHz to 22 GHz made independently by the MWR instrument onboard Juno. In this talk, we highlight our findings and interpretations of the lightning-induced electromagnetic waves detected at Jupiter.

Ultra-relativistic electrons trapped by Jupiter's very strong magnetic field near the equator and close to planet (RJ< 4), release energy via synchrotron emission. Over the course of Juno's 53-day polar orbit, the Microwave Radiometer experiment (MWR) on the spacecraft observes the Jovian radiation environment from a wide range of viewing angles, at 6 wavelengths from 2 cm to 50 cm. At large wavelengths the synchrotron emission dominates the planetary radiation signature. Synchrotron data collected with the MWR is used to improve and provide new constraints on existing synchrotron emission models, in particular in refining the electron energy distribution parameters utilized in empirical models.

B5.1-0007-18 CAN JUNO DETECT THE GRAVITATIONAL SIGNATURE OF JUPITER'S MERIDIONAL FLOWS AND FREQUENCY-DEPENDENT TIDAL RESPONSE?

Università degli Studi di Roma "La Sapienza", Roma, Italy

On 7 February 2018, Juno completed its fifth orbit devoted to gravity measurements. The current data set acquired through Juno's state-of-the-art radio system provided insight into the internal structure of the gas giant by suggesting the presence of a diluted core and revealing that the surface zonal winds extend to a depth of thousands of kilometres. The extremely accurate gravity measurements are carried out by measuring the Doppler shift of two-way radio links established at Ka-band (32.5-34 GHz).

The nominal mission will end on 30 July 2021, after a total of 25 gravity orbits. The extended data set will reveal components of the gravity field that are currently not accessible. The fine effects of the wind dynamics can be assessed with the broader coverage in longitude. Meridional variations of the zonal flows, associated with Jupiter's vortices, may be revealed by analysing the tesseral component of the gravity field. The magnitude of the tesseral harmonics provides information on the depth of the non-zonal atmospheric circulation. A larger number of gravity passes will also allow to observe the frequency-dependent response of Jupiter to tidal effects induced by the Galilean satellites and obtain indications on the non-equilibrium response of the planet to external forcing fields. We report on numerical simulations of the gravity experiment and discuss the expected results at the end of the mission.

B5.1-0008-18 A NEW MODEL OF JUPITER'S MAGNETIC FIELD FROM JUNO'S FIRST NINE PERIJOVES

John Connerney, jack.connerney@nasa.gov

Space Research Corporation, Annapolis, Maryland, United States John Jørgensen, jlj@space.dtu.dk

DTU Space, Lyngby, Denmark

Characterizing the planetary magnetic field of Jupiter is one of the primary science objectives of the Juno Mission. Juno's 53.5-day capture orbit trajectory carries her science instruments from pole to pole in approximately 2 hours, with a closest approach to within 1.06 Rj of the center of the planet (one Rj = 71,492 km), just a few thousand km above the clouds. Observations acquired during 8 of Juno's first 9 orbits provide the first truly global coverage of Jupiter's magnetic field with a coarse longitudinal separation of 45 degrees between perijoves. Juno measures the vector magnetic field with two magnetometer sensor suites, located 10 and 12 m from the center of the spacecraft. Each contains a vector fluxgate magnetometer (FGM) sensor and a pair of co-located star trackers, providing accurate attitude for the FGM sensors. Observations acquired within 7 Rj of Jupiter during the first 9 polar passes are used to characterize the planetary magnetic field with extraordinary spatial resolution. The magnetic field is represented with a degree 20 spherical harmonic model for the planetary field, combined with an explicit model of the magnetodisc. Partial solution of the underdetermined inverse problem using generalized inverse techniques yields a model ("JRM09") of the planetary magnetic field with spherical harmonic coefficients determined through degree and order 10, providing the first detailed view of a planetary dynamo beyond Earth's. The Jovian magnetic field is unlike anything previously imagined, evidencing a complexity that portends great insight into the dynamo process in general and the dynamics of Jupiter's interior in particular. We present a degree 10 spherical harmonic model of the Jovian magnetic field and illustrate its characteristics via a set of maps of the surface field, and consider implications for particle motion, auroral emissions, and the dynamo.

The Juno Microwave Radiometer (MWR) has frequencies in six channels ranging from 0.6 to 22 GHz (1.37-50 cm). The sensor was designed to understand the composition and dynamics of the Jovian atmosphere to pressures greater than 100 bars. The microwave channels are primarily sensitive to the ammonia and water vapor concentration with depth in the atmosphere. We will provide an overview of the findings from the Juno Microwave Radiometer though the first twelve orbits focusing on the unexpected results from the atmospheric observations. Our original finding from the first orbits was that ammonia is not uniformly mixed beneath its saturation level in the atmosphere, but enhanced in a band near the equator and depleted in the north and south equatorial belts. This is observed to be persistent with longitude and time over the nearly two years of observations. We will discuss the first detection of high-frequency sferic signals from Jovian lightning and the inferred distribution of moist convection on the planet. Sferic signals from Jovian lightning were previously undetected, despite search with instruments on Voyager and Galileo. These results suggest lightning discharges on Jupiter may be more like terrestrial lightning than previously thought. We find lightning to be strongest and most prevalent in the northern middle to high latitudes. It is preferentially concentrated toward both poles and absent near the equator. We will also show several cases of MWR lightning data overlaid on JunoCam visible imagery revealing types of cloud features associated with lighting at various latitudes. Finally, we will highlight the newest polar maps of multi-spectral brightness temperature constructed from data taken in orbits where the spacecraft spin vector is oriented such that the MWR antenna beam is scanned over the polar cap.

B5.1-0010-18 CONVECTION BELOW THE CLOUDS: WHAT JUNO DIDN'T SEE

Data from the Juno Microwave Radiometer (MWR) were made into latitude-altitude maps of ammonia abundance down at least to the 100 bar level, which is well below the water cloud base at 5-8 bars and the ammonia cloud base at 0.6-0.8 bars. There were several surprises in these maps: An ammonia-rich band extends around the planet at 0-5°N; its mixing ratio is nearly constant from 1 bar to 100 bars, although there a hint of a local maximum at 2 bars. Outside the band from 0-5°N there is a low-ammonia layer with a local minimum at 6 bars. The mixing ratio at the local minimum is about one-half that at the local maximum in the 0-5°N band. From these maps, Ingersoll et al. (2017) [Geophys. Res. Lett. 44, doi:10.1002/2017GL074277] posed three questions: How is the low-ammonia layer maintained? Why is the belt-zone structure barely evident in the ammonia distribution outside the region from 0-20°N? And how is the internal heat transported upward through the low-ammonia layer to the ammonia cloud base? Here we argue that the answers all contain ultra-fast updrafts and downdrafts that balance the ammonia budgets in the vertical. Because the velocities in the updrafts and downdrafts are much greater than those outside, they occupy much less space than the air outside and are much less visible. Without these hidden convection currents, the vertical transports of ammonia, water, and energy cannot be maintained.

B5.1-0011-18 DETECTION OF DEEP JOVIAN DYNAMICS BY THE JUNO GRAVITY EXPERIMENT

William Hubbard, hubbard@lpl.arizona.edu University of Arizona, Tucson, Arizona, United States Hubbard_coauthors

Y. Kaspi, E. Galanti, D. J. Stevenson, S. J. Bolton, L. Iess, T. Guillot, J. Bloxham, J. E. P. Connerney, H. Cao, D. Durante, W. M. Folkner, R. Helled, A. P. Ingersoll, S. M. Levin, J. I.

Lunine, Y. Miguel, B. Militzer, M. Parisi, S. M. Wahl

"How deep Jupiter's zones, belts, and other features penetrate is one of the most outstanding fundamental questions in Jovian atmospheric dynamics. " - This is a key mission goal stated in the Juno Phase A Concept Study Report (2005). In this talk we report major progress in answering this question, based on radio science data from the ongoing Juno Jupiter orbiter mission. The Juno spacecraft is designed for precision measurements of Jupiter's external gravitational potential. Juno is equipped with radio links at Xand Ka-band and a special Ka-band translator system, permitting highly accurate measurement of spacecraft accelerations, which, after extensive modeling of data taken during Juno's periapse passes within a few thousand kilometers of Jupiter's cloud tops, reveal milligal gravity anomalies with good signal/noise. These anomalies are with respect to an a priori model based on classical theory for rapidly-spinning bodies in hydrostatic equilibrium. In strict hydrostatic equilibrium, the jovian external gravity potential should have axial symmetry (no tesseral harmonics apart from tidal distortions), and north-south symmetry (no odd zonal harmonics). Less than midway through the 32 orbit primary mapping mission, symmetry-breaking terms in Jupiter's multipole gravity expansion have been clearly detected by Juno, and correlate with large-scale zonal currents in the observed cloud deck. Despite the north-south extent of jovian zonal wind patterns (thousands of km) and the large surface gravity (over two thousand gal), shallow dynamics-produced gravity anomalies would be undetectable by Juno. The observed anomalies imply that the zonal currents entrain so much mass that they must have very great vertical extent (thousands of km). This is because of a characteristic of the equation of state of compressed hydrogen: its density increases roughly linearly with depth in Jupiter, smoothly transitioning from gaseous densities at the cloudtops to liquid densities as pressures approach megabars.

B5.1-0012-18 JUNO'S CHARACTERIZATION OF JUPITER'S DEEP ROTATION AND STRUCTURE

Tristan Guillot, tristan.guillot@oca.eu Observatoire de la Côte d'Azur, Nice, France Juno IWG

Y. Miguel, B. Militzer, W.B. Hubbard, Y. Kaspi, E. Galanti, H. Cao, R. Helled, S.M. Wahl,

L. Iess, W.M. Folkner, D.J. Stevenson, J.I. Lunine, D.R. Reese, A. Biekman, M. Parisi, D. Durante, J.E.P. Connerney, S.M. Levin, S.J. Bolton

Juno's extremely accurate mapping of Jupiter's gravity field and its detection of a north-south asymmetry enables us to characterize the depth of the atmospheric zonal flow and the state of the deeper interior. The combination of thermal wind models and interior models matching both odd and even gravitational moments shows that below about 3000km from the cloud tops, Jupiter's interior rotates nearly as a rigid body. This corresponds to the level at which the electric conductivity becomes large and magnetic drag should suppress differential rotation.

This has several consequences: Owing to its smaller mass, Saturn should have a differentially rotating at least three times more extended than that of Jupiter. Conversely, massive giant planets and brown dwarfs should have smaller differentially regions.

But most importantly, the characterization of differential rotation in the planet should enable us to fully exploit the accuracy of the gravity field determination to better constrain Jupiter's internal structure and composition.

B5.1-0013-18 FROM GALILEO TO JUNO: AN ATMOSPHERIC COMPOSITION PERSPECTIVE

"Flyby, orbit, land" has been the guiding philosophy of NASA's planetary exploration in order to address such fundamental questions as the origin and evolution of the solar system. This led to the Galileo entry probe at Jupiter to determine the abundances of the heavy elements (mass>helium), their isotopic ratios as well as the abundance of helium, which is a tracer of the interior processes in the multi-megabar pressure region. While only the topmost clouds of ammonia ice have ever been identified spectrally [1], thermochemical models predict a multicomponent, multi-layer cloud structure extending down to 5-10 bars of pressure [2] with the clouds of ammonium hydrosulfide (or ammonium sulfide) solid, water ice and aqueous-ammonia solution lying below the ammonia cloud layer. Thus, in principle, the heavy elements can all be determined below approximately the 10-bar level, the expected region of well-mixed atmosphere. The Galileo probe met its objective of measuring the heavy elements and isotopes, except for oxygen. This was derived from the abundance of water, where bulk of Jupiter's oxygen is sequestered and was found to be sub-solar even at 22 bars, but rising. The oxygen elemental abundance is a critical missing piece of the puzzle of Jupiter's formation models, however, as water was presumably the original carrier of the heavy elements and could have made up one-half to two-thirds of Jupiter's core mass. Since Juno's arrival at Jupiter in July 2016, its microwave radiometer (MWR) instrument [3] has been carrying out observations to measure and map the composition, particularly the water and ammonia abundances, to deep atmosphere. Serendipitous data on lightning collected by the MWR have significantly extended the statistics on the known lightning in Jupiter's atmosphere [4] and support the assertion that the global water abundance in Jupiter is at least 1x solar [5], not the sub-solar value measured in the entry site of the Galileo probe. The global distribution of ammonia measured by the MWR reveals a complex structure extending to more than 100 bars, not just the comparatively shallow pressure levels sensed by the Galileo probe and the VLA, and reveals that Jupiter's well-mixed region is much deeper than 10 bars [6,7]. Like ammonia, atmospheric dynamics [8] is expected to govern the distribution of water as well, which implies that it is essential to probe much deeper than was possible before Juno in order to measure the well-mixed abundance of water, hence the oxygen elemental abundance in Jupiter. The MWR observations are in fact sensing down to several hundred bars of pressure. This talk will elaborate on the above perspectives of Jupiter's composition and how Juno has challenged our thinking of the formation of Jupiter and its atmosphere.

Jupiter's formation in the protoplanetary disk of our solar system had a primary impact on the disk's subsequent evolution and the formation of the other planets. Jupiter must have formed early, within the first few million years when the gaseous disk was present, but how early is not understood. Thanks to its large gravitational field, Jupiter also played a primary role in the scattering of bodies up to Mars size in the inner solar system during the formation of the terrestrial planets, which occurred during and after the depletion of the nebular gas according to isotopic evidence.

The Juno mission provides clues to Jupiter's formation via several key pieces of evidence, including the global abundance of water, the size and nature of the core, and the total amount of non-hydrogen and -helium elements in the interior. In each case, the parameter value does not need to be precise to provide significant information. For example, it is useful to know whether water is above or below the protosolar value, and if the former, is it mildly (2-5 times) or grossly (exceeding 5 times) solar? A global fit of all the key measurements by Juno (total heavy-element abundance, core mass, O enrichment) along with Galileo probe data provide constraints on the physical and chemical conditions for Jupiter's formation. This includes constraining planetesimals/pebbles composition, the growth history, and discriminating among disk and nucleated instability.

Finally, comparing the enrichment of the major elements (C,O) in Jupiter (relative to the protosolar value) to the equivalent in giant exoplanets will be possible thanks to several observing programs planned for JWST. Understanding the relation between stellar and planetary heavyelement enrichments for multiple giant planets would provide an unprecedented opportunity to determine the uniqueness of Jupiter's origin.

The Jovian InfraRed Auroral Mapper (JIRAM) [1] on board the Juno [2,3] spacecraft, is equipped with an infrared camera and a spectrometer working in the spectral range 2-5 m. JIRAM was built to study the infrared aurora of Jupiter and to map the planet's atmosphere in the 5 μm spectral region. Its spectroscopic observations in the 2-5 μm range can be used for studying atmospheric dynamics, clouds and measuring the abundance of certain trace species that are important to atmospheric chemistry, microphysics and dynamics such as water, ammonia and phosphine and for the formation of the infrared aurora like the ion H3+. The instrument has operated during most of the Jupiter flybys since science mission started in August 2016 performing several observations of the of the planet from the equator to poles. Unprecedented views of the polar atmospheric structures and auroras have been observed for the first time thanks special nature of Juno's orbit. We present an overview of the most significant observations done by the instrument since the start of the mission.

The Ultraviolet Spectrograph (UVS) on Juno observes Jupiter's northern and southern auroras for several hours each during every perijove pass. On each pass the 7°-long slit of UVS is used to observe the jovian aurora in a series of swaths, with one swath for each 30-s spin of the Juno spacecraft. During these perijove periods, the range of Juno to the aurora drops from 6 RJ to 0.3 RJ (or less) in the north - and then reverses this in the south - so that spatial resolution and coverage change dramatically. A scan mirror points the UVS boresight at up to 30° from the Juno spin plane to enable targeting of different features or to build up context images by rastering over the auroral region. In addition, during the time period between observations of the northern and southern auroral regions, low-latitude airglow observations are possible. Since Juno perijove altitudes are only 3500-8000 km above the cloud tops, UVS is able to study Jupiter's airglow from

within Jupiter's upper atmosphere. A variety of auroral forms and activity levels can be identified in the Juno-UVS data; some of these have been described before with HST observations, but others are new. One new result is that a large expanse of polar emissions may be excited by low-energy ionospheric electrons (and thus would be unrelated to precipitating particles). Recent results and comparisons with simultaneous Chandra observations at x-ray wavelengths will be presented here. In addition, we will also report on UVS airglow observations to date, with special attention to the Lyα emissions of atomic hydrogen.

The Juno mission to Jupiter carries a visible imager on its payload primarily for outreach, and also very useful for jovian atmospheric science. Lacking a formal imaging science team, members of the public have volunteered to process JunoCam images. Lightly processed and raw JunoCam data are posted on the JunoCam webpage at https://missionjuno.swri.edu/junocam/processing. Citizen scientists download these images and upload their processed contributions.

JunoCam images through broadband red, green and blue filters and a narrowband methane filter centered at 889 nm mounted directly on the detector. JunoCam is a push-frame imager with a 58 deg wide field of view covering a 1600 pixel width, and builds the second dimension of the image as the spacecraft rotates. This design enables capture of the entire pole of Jupiter in a single image at low emission angle when Juno is 1 hour from perijove

(closest approach). At perijove the wide field of view images are high-resolution while still capturing entire storms, e.g. the Great Red Spot.

Juno's unique polar orbit yields polar perspectives unavailable to earth-based observers or most previous spacecraft. The first discovery was that the familiar belt-zone structure gives way to more chaotic storms, with cyclones grouped around both the north and south poles [1, 2]. Time-lapse sequences have enabled measurement of the rotation rates and wind speeds of these circumpolar cyclones [3].

Other topics are being investigated with substantial, in many cases essential, contributions from citizen scientists. These include correlating the high resolution JunoCam images to storms and disruptions of the belts and zones tracked throughout the historical record. A phase function for Jupiter is being developed empirically to allow image brightness to be flattened from the subsolar point to the terminator. We are studying high hazes and the stratigraphy of the upper atmosphere, utilizing the methane filter, structures illuminated beyond the terminator, and clouds casting shadows. Numerous high altitude clouds have been detected and we are investigating small-scale dynamics that could be their cause.

A network of Earth-based observations of the Jovian environment continues to expand and enhance the science return of the Juno mission. This report focuses on joint discoveries made using thermal-emission observations by Juno instruments: the Microwave Radiometer (MWR) and the Jupiter Infrared Auroral Mapper (JIRAM), together with supporting thermal-infrared ground-based observations made from the Infrared Telescope Facility (IRTF), the Subaru Telescope, the Very Large Telescope (VLT) and the Gemini North Telescope. These results are supported by observation of Jupiter's cloud field from the JunoCam instrument and Earth-based observations from the Hubble Space Telescope, the IRTF and the Gemini North Telescope. The thermal observations are capable of determining the spatial and temporal variability of temperatures, clouds or gaseous constituents. Examples of results include the following. Earth-based measurements of the temperature field in Jupiter's polar regions show a remarkable coincidence of the boundaries of a cold polar vortex, extending from the troposphere through the stratosphere, with the

boundaries of polar haze layers. Measurements of auroral-related stratospheric heating show that they are completely enclosed within the classical auroral oval and coincide with UV emission by particles associated with open field lines of the magnetosphere. Ground-based mid-infrared observations of the Great Red Spot (GRS) support the assertion that the variability in radiance detected by the MWR near the 0.7-bar level arises as much from variability in temperatures as from variability in the NH3 humidity. To date, we find a high but incomplete correlation of radiances associated with Jupiter's 5-μm hot spots, with no measurements to date of radiances we would expect from the extremely desiccated conditions in the Galileo probe entry site; this is most likely due to incomplete MWR resolution of the hot-spot features.

B5.1-0019-18 DEVELOPMENT OF THE JOVIAN MAGNETODISK ANALYTICAL MODELS WITH DIFFERENT DEPENDENCES OF THE CURRENT DENSITY ON THE DISTANCE FROM THE PLANET.

Alexander Lavrukhin, lavrukhin@physics.msu.ru

Lomonosov Moscow State University, SINP, Moscow, Russia Igor Alexeev, alexeev@dec1.sinp.msu.ru

Skobeltsyn Institute of Nuclear Physics, MSU, Moscow, Russia

A large-scale structure in the form of a thin current disk exists in the Jovian magnetosphere. This structure, called magnetodisk, or plasmadisk, is arises due to the Io plasma production and the fast Jupiter's rotation, and is located close to the dipole magnetic equator. Inside the radial distance 20RJ, plasma almost rigidly corotates with the planet. Behind this radial distance, which coincides with the Alfven radius, the Jovian magnetospheric plasma begins to lag behind the corotation due to the radial outflow, which leads to the magnetic field lines stretching. At a radial distance of 50 60RJ, the current sheet becomes non-rigid and begins to respond to changes in the solar wind conditions.

In general, the mechanism for the magnetodisk formation can be described as follows: an increased plasma density near the Io orbit leads to the interchange instability development and to the plasma radial drift from the inner magnetosphere to the outer magnetosphere. Corotation electric field, which is generated due to the daily rotation of the ionosphere, leads to the plasma acceleration in the azimuthal direction to the velocity which is close to the angular velocity of Jupiter's rotation, J. The centrifugal force acting on the plasma leads to the field lines stretching until the moment, when the tension of the field lines balances the centrifugal force. Then, beyond the Alfven radius, the kinetic energy of plasma begins to dominate over the energy of the Jovian internal magnetic field, which leads to the formation of radial expansion of the plasma in a relatively thin current disk.

We have developed and compared with observations the analytical models of the magnetodisk having different spatial scales and different dependences of the current density azimuthal component on the distance. To develop these models we have used a spherical coordinate system with Z axis, parallel to the Jovian dipole axis, polar angle ϑ and azimuthal angle ϕ, which was measured in the direction of the planetary rotation. We consider simple models of an infinitely thin current disk azimuthally symmetric with respect to the magnetic dipole axis. Magnetodisk in the models is located in the magnetic equatorial plane. Its magnetic field depends on the distances to the inner and outer edges and on two parameters, which determine the current density radial profile in the disk. We consider the linear and square dependences j 1/r and j 1/r2, and also their linear combination:

j a 1/r + b 1/r2, where a and b are coefficients, defining the total current in the disk. The current, proportional to j 1/r, is related to the interchange instability, while in the case of j 1/r2, the flux of the magnetic field of the disk BMDr 2πr2 is conserved in the northern and southern hemispheres, which corresponds to the free plasma expansion. We assumed, that the magnetodisk current has only azimuthal component jMDϕ. This assumption simplifies the development of the models, because in this case the magnetic vector-potential of the magnetodisk AMD has only one nonzero component - AMDϕ.

The radial profiles of the magnetic field latitudinal component Bϑ obtained in calculations were compared with Juno as well as Ulysses and Galileo magnetometer data.

Juno's Radiation Monitoring (RM) Investigation measures the high-energy particle environment at Jupiter by making use of noise signals from penetrating high-energy particles as an in situ observable. The implementation approach was born out of knowledge gained during the development of Juno's instruments and spacecraft which must withstand the incredibly harsh radiation environment at Jupiter. Images and housekeeping data from several of Juno's heavily shielded instruments are actively planned, retrieved, and analyzed to extract the characteristic signatures of penetrating high-energy electrons and ions during each of Juno's science orbits. Collaborative observation campaigns are performed to simultaneously collect "radiation images" and penetrating particle counts from multiple instruments in previously unexplored regions of the magnetosphere [Becker, H.N., et al. (2017), Space Sci Rev, doi: 10.1007/s11214- 017-0345-9; Becker, H.N. et al. (2017), Geophys. Res. Lett., 44, doi:10.1002/2017GL073091].

This presentation will provide a summary overview of the Investigation's key findings since Juno's arrival at Jupiter in 2016.

Since August 2016, the Juno MicroWave Radiometer (MWR) has continuously measured the radiation emitted by Jupiter and the surrounding environment, over a frequency range from 0.6 to 22 GHz, from Juno's highly elliptical 53-day polar orbit about Jupiter. The contributors to the strongest radio signals at the shorter frequencies are the thermal, cosmic microwave background, and synchrotron emission produced by the inner electron belt. Weaker but perceptible signatures in MWR are also reported at the shortest frequency during perijove 1 (PJ1) and PJ3-PJ11. Some of them are identified as a source of synchrotron emission produced by downward field-aligned MeV electrons in the middle magnetosphere. In this paper, we present a synthesis of the spatial distributions of the microwave radiation observed at six wavelengths. We focus on synchrotron emissions originating from regions beyond Io's plasma torus that we believe to be linked to auroral activity. To support our findings, we discuss the results of a multi-instrument analysis of radio (MWR, WAVES), field (Juno magnetometer), extreme and far-ultraviolet auroral emission (Juno/UVS), plasma and energetic electron (JADE, JEDI) datasets, and background radiation signatures in Juno's ASC instrument for PJ1. Our data analysis raises the question how electrons with energies of 10's of MeV are populating, transported, and accelerated within the middle magnetosphere to become part of the auroral current circuit at Jupiter.

As part of Juno mission support, we monitored Jovian synchrotron emission at 2.3 GHz (13 cm) using the NASA Deep Space Network. NASA's DSN is a sensitive network of ground based radio telescopes, either 70m or 34m in diameter, dedicated to tracking spacecraft that are exploring deep space. The network telescopes are also available for use in radio astronomy. This DSN, with complexes in the USA, Australia and Spain, is capable of monitoring sources uninterrupted for an entire day. We used this unique ability to monitor Jupiter continuously for 30 hours.

Our Jupiter monitoring program is linked with the Jupiter Patrol observations currently being performed by the educational programs GAVRT, STARS, and PARTNeR, based in the USA, Australia and Spain, respectively. The DSN partially supports these education programs by providing time on the network's 34m telescopes, thereby involving students in space research and exploration. Students contribute to Juno science and the radiation environment modelling by providing the necessary microwave radiometer data, and by participating in June science lessons.

B5.1-0023-18 RETRIEVAL ACCURACY OF JOVIAN CONSTITUENT PROFILES DEVELOPED USING A NEURAL NETWORK SURROGATE APPLIED TO DATA FROM THE JUNO MWR

The Juno Microwave Radiometer (MWR) has six channels ranging from 1.36-50 cm and has the ability to peer deep into the Jovian atmosphere. A two step retrieval algorithm has been developed using a surrogate neural network for Jovian constituent profiles using Juno MWR data. An artifical neural network algorithm is used as the surrogate for the Juno Atmospheric Microwave Radiative Transfer (JAMRT) model in this minimization. The neural network is trained by simulating emissions at the six wavelengths computed using JAMRT. By exploiting the speed of this surrogate model, retrievals for Jovian constituents profiles, such as ammonia, can be rapidly and accurately performed. Retrieved abundance profiles for the first eight perijoves during which the Juno MWR was operational will be presented. Additionally a detailed analysis of uncertainties in the retrievals will be discussed.

This work was supported by NASA Contract NNM06AA75C from the Marshall Space Flight Center supporting the Juno Mission Science team, under Subcontract 699054X from the Southwest Research Institute.

The Jupiter Infrared Auroral Mapper (JIRAM) instrument, onboard the NASA's Juno mission, is composed of a camera in the L and M bands, and a spectrometer covering the 2-5 µm region. During the period from August 2016 to March 2017, when five mission flybys were completed, it was possible to observe with JIRAM the Jupiter's atmosphere in a very slant perspective, allowing sampling the stratosphere at different altitudes. We took advantage of H+ emissions in the 3-4 µm spectral band, observed with JIRAM in the above reported period, to retrieve the H3+ densities and temperatures, through the inversion method described in Dinelli et al. (2017), at altitudes from 200 to 700 km above the 1-bar level, and in the latitude region from 60° equatorward, in both hemispheres. Retrieved volume mixing ratios are on average higher in the Southern hemisphere than in the Northern, in accordance with previous observations in the auroral region (Adriani et al. 2017). Temperature values increase quite uniformly with altitude in both hemispheres, and are generally in agreement with temperature fields retrieved with Cassini/CIRS at 200-300 km (Sinclair et al. 2017). Finally, H3+ concentrations decrease from about 106 mol/cm3 at 200-300 km to 3x105 mol/cm3 at 600 km.

Although the coverage of analysed data does not allow investigating the H+ variability with respect to local time, the available data potentially allow to retrieve a 3-dimensional structure of the atmosphere in the 200-700 km altitude range, which has not been well addressed by previous ground-based and space observations.

Acknowledgments The project JIRAM is funded by the Italian Space Agency.

B5.1-0025-18 JUNO AND THE NEW RENAISSANCE

Theodore Clarke, tcclarke@earthlink.net

Project Juno, Altadena, California, United States

There is an intangible societal need to connect with the universe. This is why the space program is so popular. Through the space program the people of the world can touch the universe, touch infinity. Spacecraft reconnaissance of our solar system continues a legacy of exploration ingrained in our psyches. As a human race, we explore. We ask, Who am I and where do I come from? In the process of this exploration the aura and soul of NASA's Juno mission to the planet Jupiter, like the Medici of the Renaissance, has inspired, facilitated and embodied a broad spectrum of human creativity, including not only science and technology, but also history and literature, art and music, and visualization and public engagement. Indeed, through Juno the world is witness to a remarkable convergence of art and science, witness to a New Renaissance. Juno is an ambassador to the universe of this New Renaissance. In my paper I will unveil Juno's intimate link to history, literature, music, art, and stunning visualization experiences, and to its public engagement program called Science in a Fishbowl. The Science in a Fishbowl program encourages public participation in processing, in often artistic ways, imaging data taken of Jupiter by JunoCam, the camera on Juno. I will show some of the best of these citizen scientist works of art. I will also assemble and describe a 3-D scale model of the orbital mission of Juno at Jupiter. The scale of the model is 1" = 2 RJ. In summary, I will unveil a dimension of the Juno mission to the planet Jupiter that will appeal to a broad sector of the global public.

B5.2-0001-18 NEW DISCOVERIES IN CASSINI'S GRAND FINALE YEAR

Linda Spilker, linda.j.spilker@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Scott Edgington, scott.g.edgington@jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

The Cassini-Huygens mission ended in a science-rich blaze of glory on September 15, 2017. Covering a period of roughly ten months, the Grand Finale and Ring Grazing orbits marked the final phases of Cassini's 13-year mission, ending with the first time in-situ exploration of the region between the rings and planet. On its final orbit, Cassini plunged into Saturn's atmosphere at 126,000 km/hr (35 km/sec), vaporizing and satisfying planetary protection requirements, while sending back its final bits of unique science data.

Ring Grazing Orbits. On November 29, 2016, a single Titan flyby sent Cassini into a series of 20 highly inclined, elliptical Ring Grazing orbits with peripases just outside Saturn's main rings at distances within 10,000 km of Saturn's F ring. These orbits provided high-resolution views of Saturn's F and A rings, providing prime viewing conditions of fine scale ring structures such as propellers, and included the closest flybys of tiny ring moons.

Grand Finale Orbits. A final close flyby of Titan on April 22, 2017 propelled Cassini across Saturn's main rings. In its 22 Grand Finale orbits, the spacecraft repeatedly dove between Saturn's innermost rings and upper atmosphere to answer fundamental questions that were unattainable earlier in the mission. The Grand Finale was like a brand-new mission, exploring a region of the Saturn system that was unexplored by any previous outer planet spacecraft.

Saturn's gravitational and magnetic fields were measured to unprecedented accuracy, providing information from which constraints on the interior structure of the planet, mass distribution in the rings, and the structure of the internal magnetic field could be obtained. The Grand Finale orbits provided the highest resolution observations ever of both Saturn's C and D rings and Saturn's atmospheric weather layer. Direct in-situ sampling of the ring particle composition, upper atmosphere and the innermost radiation belts was also achieved.

Cassini's Final Orbit. During the final plunge into Saturn, Cassini became the first atmospheric probe with all of fields and particle instruments gathering data for as long as possible.

This talk will present key science findings and new mysteries gleaned from the Ring Grazing and Grand Finale orbits. The research described in this paper was carried out in part at the Jet

Propulsion Laboratory, California Institute of Technology, under a contract with the National Aeronautics and Space Administration.

B5.2-0002-18 HUYGENS AND TITAN'S EXPLORATION: MAIN SCIENTIFIC RESULTS

Francois Raulin, francois.raulin@lisa.u-pec.fr Université Paris Est Créteil, Créteil Cedex, France Jean-Pierre Lebreton, jean-pierre.lebreton(at)esa.int ESA/ESTEC, 2200 AG Noordwijk, Netherlands Nicolas Altobelli, nicolas.altobelli@esa.int ESA/ESAC, Villanueva De La Ca, Spain

Niemann† and the GCMS team, M. Tomasko and the DISR team, J. Zarnecki and the SSP team, D. Gautier and J. Lunine

On January 14, 2005, Huygens, the first atmospheric probe designed to explore Titan, successfully entered in its atmosphere and descended to its surface where it smoothly landed and continued working for more than three hours. The four hours of measurements done by the six scientific instruments (2 ½ hours of descent and 72 minutes on the surface), relayed to Earth via Cassini, provided a unique data set complementary to the one obtained by Cassini at Titan during its 144 flybys. The Huygens scientific payload provided in situ results concerning the atmosphere - from the exosphere to the low troposphere - of Titan, its surface and even its subsurface and internal water ocean. This paper presents some of the key scientific results obtained by the Huygens probe on Titan, their complementarity to the Cassini orbiter observations and their implications on the vision we now have of Titan, the largest satellite of Saturn.

B5.2-0003-18 CASSINI'S GRAND FINALE GRAVITY AND RING HIGHLIGHTS

Richard French, rfrench@wellesley.edu

Wellesley College, Wellesley, Massachusetts, United States Cassini Radio Science Team

Aseel Anabtawi, John Armstrong, F. Michael Flasar, Luciano Iess, Essam Marouf, Colleen McGhee-French, Andrew Nagy, Nicole Rappaport, Paul Schinder, Paolo Tortora

During Cassini's Grand Finale orbits, the spacecraft repeatedly dove between the rings and Saturn, providing an unprecedented opportunity to measure the gravitational field of Saturn and its rings, and to probe the rings by radio occultations at very close range. Acquiring these observations was a remarkable feat in its own right, involving careful planning, precise navigation, and international engineering support involving NASA's Deep Space Network and the European Space Agency's ESTRACK network. This presentation will review the extraordinary scientific and engineering highlights of Cassini's Grand Finale gravity and ring experiments.

B5.2-0004-18 CASSINI UVIS TOP TEN DISCOVERIES

Larry W. Esposito, larry.esposito@lasp.colorado.edu University of Colorado, Boulder, Colorado, United States

Enceladus icy jets spew 200kg/sec of water, with no significant variations over the mission. The strongest jets are more variable, though.

Titan's airglow is primarily from sunlight and photoelectrons, but the weak night airglow is from magnetospheric particle impacts.

An atomic oxygen torus surrounds Saturn, peaking at its source, Enceladus.

The Europa atmosphere is dominated by atomic oxygen at low density, inconsistent with water plume activity at the time of the Cassini Jupiter flyby. The Enceladus plumes are significantly different from those found at Europa.

UVIS observations of propellers, gaps, ghosts, kittens, self-gravity wakes indicate ongoing aggregation in Saturn's rings; ring statistics, wavelet analysis, haloes, small particles show aggregation/disaggregation on an orbital time scale; we can understand this with an analogy to a predator-prey ecosystem.

UVIS and VIMS comparisons find small particles in the outer A ring, and other regions that are strongly perturbed by moon resonances.

The UV spectrum of Saturn's rings can be matched by pure water ice polluted over the age of the solar system by material having the reflectance of Comet 67P (as measured by Rosetta's Alice). Using Cassini results for the ring mass from RSS and the polluting flux from CDA, we constrain the ring age to less than about 200 million years.

A solitary wave is excited by the Janus-Epimetheus swap, when Janus moves inward every 8 years. This is evidence for non-linear dynamics, and may limit the application of previous conclusions based on a linear theory.

UVIS star and solar occultations quantify the profiles of aerosols, nitriles and organics in Titan's atmosphere; and show that Saturn's thermosphere breathes in and out. It was 'in' at the Grand Finale.

UVIS sees the auroral 'footprint' of Enceladus and also time varying arcs and spots that indicate magnetospheric variations. Bombarding charged particle radiation may explain the dark color of the polar hexagon.

B5.2-0005-18 WHAT CASSINI HAS TAUGHT US ABOUT SATURN'S RINGS

Matthew Hedman, mhedman@uidaho.edu

University of Idaho, Moscow, ID, Idaho, United States

Saturn's rings are not only among the most beautiful structures in the Solar System, but are also powerful tools that can help address a wide variety of questions in planetary science and astrophysics. Cassini's extensive observations of Saturn's rings have revealed many ring structures that can either be used to probe the rings' dynamical environment or examine processes operating in other, more remote astrophysical disks. For example, certain features in Saturn's rings appear to be generated by asymmetries and normal-mode oscillations inside Saturn itself, and so are yielding novel insights into the planet's internal structure .At the same time, objects have been found embedded within the rings whose orbits vary over time in a manner that is likely analogous to planetary migration in protoplanetary disks. More than anything, the rings illustrate just how complicated astrophysical disk systems can be. Indeed, the end of the Cassini mission revealed a surprisingly rich array of fine scale structures whose origins are just beginning to be explored, while new measurements of the ring's total mass have implications for the rings' age and origins.

The Grand Finale of the Cassini spacecraft with its unique proximal orbits allowed fantastic scientific discoveries between April and September 2017. Cassini crossed the ring plane 22 times at a distance which was so close, that it touched the clouds of Saturn. The Cosmic Dust Analyzer observed unexpected high densities of tiny dust grains. On the other hand, larger grains above one micrometer were found to be highly depleted. The mass distribution of the grains detected peaks well below 70 nm and is cut off by the calibrated mass threshold. The dust density varied along the trajectory with overall consistent results during different ring plane crossings. Significant number of particles were detected above the ring plane, in the ring plane and below the ring plane at latitudes between +/-45 degrees. The measured density profiles are compared with latest models of nanograins ejected by the B and C ring. This paper summarizes the current understanding of this "Ring Rain", starting at Saturn's main ring and ending in Saturn's atmosphere. Density profiles, mass distributions and early compositional variations are reported.

B5.2-0007-18 CASSINI GRAND FINALE PERIAPSE RADIO OCCULTATIONS OF SATURN'S RINGS

Essam Marouf, essam.marouf@sjsu.edu

Cassini's final and daring 22 orbits ("Grand Finale") provided opportunities for capturing radio occultations of Saturn's rings of unprecedented observation geometry. The closest approach period of 6 of the 22 orbits (May to July 2017) were dedicated to Cassini Radio Science observations of Saturn's gravity field and companion occultations of the main ring system, the latter are the focus of this presentation. On each of the 6 orbits and for about 26 minutes starting immediately after orbit periapse, roughly the time Cassini plunged through a "free-space" gap separating Saturn's upper atmosphere from the D Ring, three radio signals transmitted from Cassini back to Earth (0.94, 3.6, and 13 cm-wavelength) swept radially through the main ring system from the inner D Ring to well beyond the F Ring. These "periapse" ring occultations were the closest (about 0.2 to 1.5 Rs) throughout the Cassini mission lifetime and were among the fastest (about 35 to 55 km/s radial velocity). The relatively small spacecraft distance to the rings implies small Fresnel scale of diffraction and small high-gain antenna (HGA) footprint, hence high spatial resolution measurements of both the direct and forward scattered signals. The large radial velocity limits achievable SNR, however. The occultations nicely complement in geometry an optimal set of diametric ring occultations implemented near the beginning of the Cassini mission (March to August 2005). Both sets were acquired when the rings opening angle was relatively large (20 to 27°), making them especially valuable for characterizing structure and physical properties of optically thick ring regions, the B and A Rings in particular. The 12-year time separation provides an opportunity to search for potential time variability.

Particularly striking in spectrograms of the observed near-forward scattered 3.6 cm-wavelength signal (X-band) of the 6 periapse occultations is the clear signature of 100 to 200 m wavelength quasi-periodic ring structure, likely due to gravitational overstability. Acting like a giant diffraction grating that spatially modulates the background optical depth, diffraction diverts part of the incident signal power into grating lobes the strongest of

which are observed in spectra of the Earth received radio signal as modulation side-bands centered on the carrier component. The measured frequency separation from the carrier and knowledge of the occultation geometry determine the structure wavelength. The gravitational overstability structure is clearly detectable in the inner A Ring, and in regions B1 and B2 of the B Ring. It is marginally detectable in region B4. The structure was first identified in spectrograms of the 2005 diametric ring occultations (Thomson et al., GRL, Dec 2007), however, the large radial velocity of the periapse ring occultations, hence large Doppler spread, and the proximity of the spacecraft to the rings, hence large incident power per unit ring area, appear to enhance prominence of the overstability structure in the 2017 periapse ring occultations. We use the measured spectrograms to characterize variability of structure wavelength and other properties with ring radius and optical depth, and compare with the 2005 results to search for potential variability of structure properties with time. We carry out similar comparison of optical depth morphology and scattering properties of other prominent ring features of various spatial scales across the ring system.

B5.2-0008-18 CLUMPS AND HOLES IN SATURN'S RINGS FROM CASSINI UVIS STELLAR OCCULTATIONS

Joshua Colwell, josh@ucf.edu

University of Central Florida, Orlando, Florida, United States James Cooney, james.cooney@ucf.edu

University of Central Florida, Orlando, Florida, United States Larry W. Esposito, larry.esposito@lasp.colorado.edu University of Colorado, Boulder, Colorado, United States

Observations of star occultations by Saturn's rings with the Cassini Ultraviolet Imaging Spectrograph (UVIS) High Speed Photometer (HSP) provide direct measurements of ring structure at small spatial scales. Depending on the geometry of the occultation and star brightness, this can provide direct measurements of self-gravity wakes and viscous instabilities in the rings with spatial scales as small as 10 meters. In addition to this direct measurement of clumps and gaps in the rings, the occultation data provide additional insights into the small-scale structure of the rings through higher-order moments of the time series of the observed stellar signal through the rings. The variance of the data can be related to the probability that two independent measurements of light passing through the rings are correlated, which in turn depends on the size of a shadow cast by ring particles. Larger shadows, due to larger individual particles or to agglomerations or overlapping ring particle shadows, results in a larger, or excess, variance in the occultation data than would be observed if the ring particle sizes were vanishingly small. The excess variance thus provides a measure of the largest clumps or particles in the rings. This measure varies widely across the ring system, sometimes with abrupt transitions at ring boundaries, and other times varies quite gradually even over large gradients in ring optical depth. The next higher moment of the data, the skewness, provides additional information that can help identify whether the rings are punctuated by large clumps or large holes in the spatial distribution of particles. This measure also shows that different ring regions have different clumping characteristics, something that is also seen in the highest resolution images of the rings. We will explore the distribution and properties of ring clumps and holes throughout the ring system as revealed from Cassini UVIS occultation observations and discuss implications for ring dynamics and evolution.

B5.2-0009-18 RINGAND MOON-ASSOCIATED ENERGETIC PARTICLE DROPOUTS OBSERVED BY MIMI-LEMMS DURING CASSINI'S RING-GRAZING ORBITS

Applied Physics Laboratory, Laurel, Maryland, United States

During December 2016-April 2017, the Cassini spacecraft performed 19 orbits with periapses just outside Saturn's main rings. These ring plane crossings allowed magnetic field lines threading the outer regions of the main ring system to be sampled close to the equatorial plane. Trapped energetic particles have been previously shown to provide valuable information on the presence of moons, rings, and incomplete ring arcs that complements the data provided by remote sensing instruments. We report on observations of this region by the LEMMS sensor of Cassini's Magnetospheric Imaging System, MIMI. We concentrate on results relevant to the region surrounding the moons Janus and Epimetheus at 2.4 to 2.8 Saturn radii from the planet's centre. We present the inferences that can be drawn about this region from absorption signatures due to those moons plus the ring material that orbits near to them, slightly complicated by the northward offset of Saturn's magnetic equator.

B5.2-0010-18 CIRS HIGH-RESOLUTION THERMAL SCANS AND THE STRUCTURE OF SATURN'S B RING

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California, United States

Cassini's 126th flyby of Titan on 29 November 2016, sent the spacecraft on a trajectory that would take it within 10,000 kilometers of Saturn's F ring before a subsequent encounter on 22 April 2017 would send it on ballistic trajectory carrying it between Saturn's cloud tops and the planet's D ring. This geometry has proven very beneficial for high-resolution studies of the rings, not just because of Cassini's proximity to the rings, but also because of the spacecraft's high elevation angle above the rings, which reduces the foreshortening that tends to degrade resolution in the ring plane.

We will report on several observations made by Cassini's Composite Infrared Spectrometer of Saturn's main rings at the high spatial resolutions enabled by the end-of-mission geometry, particulary the B ring, during the F-ring and proximal orbits. CIRS' three infrared detectors cover a combined spectral range of 10 to 1400 cm−1 (1 mm down to 7 μm). We focus on data from Focal Plane 1, which covers the 10 to 600 cm−1 range (1 mm to 16 μm). The apodized spectral resolution of the instrument can be varied from 15 to 0.5 cm−1 (Flasar et al. 2004). FP1's wavelength range makes it well-suited to sensing thermal emission from objects at temperatures typical of Saturn's rings.

Correlating temperatures retrieved from scans of that face of the rings exposed to direct solar illumination (the lit face) and the opposite (unlit) face with ring optical depth suggests differences in ring structure or particle transport between the lit and unlit rings in different regions of the B ring. We find that the temperature differential between the lit and unlit faces of the rings varies from 2-3 K in the most optically thin sections of the B ring's B1 region (ring radii of 92,000-99,000 km) up to 20 K in the optically thick portions of the B2 region of the B ring (ring radii of 99,000-104,500

km). Moreover, temperatures on the unlit side of the B ring's B3 region vary (ring radii of 104,500-110,000 km) by 5-6 K and are correlated with slight optical depth variations. There are no such correlated temperature variations on the lit side of the B3 region for reasons that are not yet clear. Ferrari et al. (2013) and Pilorz et al. (2015) published thorough analyses of the thermal throughput across this optically thick ring. We will discuss these recent CIRS rings observations and their implications in the context of such work. (B ring region definitions are taken from Colwell et al. (2009).)

This research was carried out at the Jet Propulsion Laboratory, California Institute of Technology, under contract with NASA.

B5.2-0011-18 SCIENCE HIGHLIGHTS FROM THE CASSINI MAGNETOMETER INSTRUMENT

Michele K. Dougherty, m.dougherty@imperial.ac.uk

The Blackett Laboratory, Imperial College, London, United Kingdom The Cassini Magnetometer Team there are 40 + members of the team based in UK, USA, Germany, Hungary and France.

Highlights from the Cassini magnetic field observations made during the orbital tour at the Saturn system will be described. These discoveries encompass topics including the magnetosphere and its aurora, Saturn's internal dynamo magnetic field, the icy satellites of Saturn (and Enceladus in particular), as well as the large moon Titan.

B5.2-0012-18 MAGNETOSPHERIC HIGHLIGHTS FROM CASSINI

Chris Paranicas, chris.paranicas@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Contributors from Cassini MAPS

N. Achilleos, A. Coates, F. Crary, M. Dougherty, S. Edgington, T. Gombosi, D. Gurnett, G. Hospodarsky, N. Krupp, W. Kurth, D. G. Mitchell, K. Khurana, P. Kollmann, L. Lamy, A. Masters, E. Roussos, L. Spilker, M. Thomsen, J.-E. Wahlund, J. H. Waite

The Cassini spacecraft entered Saturn orbit in 2004 and for many particles-and-field sensors made nearly continuous measurements until 2017. In this talk, we will describe some of the highlights of magnetospheric discoveries made by Cassini. The talk will be organized by advances in our knowledge of structure: such as radiation belts, boundaries, corotating plasma, high latitude regions, warped current sheet, and tail, and of dynamics: such as periodicities, largeand small-scale injections, and pulsations. Other subjects that received considerable attention by the MAPS community were Saturn's ionosphere and aurora, interactions between magnetospheric populations and rings, moons, and neutrals, interactions of Saturn's magnetosphere with the highly variable solar wind, the Enceladus source and its consequences, the interaction with Titan, the effects of solar cycle and seasons and coordination with remote studies.

B5.2-0013-18 INSIGHTS INTO COUPLING BETWEEN SATURN AND ITS MAGNETOSPHERE FROM RADIO AND PLASMA WAVE OBSERVATIONS DURING CASSINI'S GRAND FINALE

William Kurth, william-kurth@uiowa.edu

A. M. Persoon, A. Sulaiman, J.-E. Wahlund, S.-Y. Ye, and P. Zarka

In its Grand Finale phase, Cassini traversed a region of the Saturnian system not explored in the preceding 12 years in orbit. These high inclination, highly eccentric orbits took Cassini through the source regions of Saturn kilometric radiation (SKR) on auroral magnetic field lines, across field lines that tie the planet to its magnetosphere, the ring system, and through the topside ionosphere near the sub-solar equator just below the ring system. The Radio and Plasma Wave Science (RPWS) instrument studied the conditions in the SKR source region that had only been traversed twice in the entire preceding mission. Near 5 kHz intense narrowband emissions are observed in the Z mode at latitudes above about 10°. Plasma wave phenomena known as VLF saucers were observed on field lines threading both Enceladus and the ring system, providing evidence of electron beams and quite possibly currents connecting these members of the Saturnian system to the planet. The RPWS found only very small numbers of micronsized dust grains in the region between the rings and the atmosphere. Perhaps some of the most important measurements were of plasma densities and temperatures in Saturn's equatorial topside ionosphere, providing important information for understanding how the ring system and the ionosphere interact. These observations revealed small-scale structures in the ionospheric densities and large-scale asymmetries associated with ring shadowing. The ionosphere revealed a new plasma wave phenomenon apparently driven by a lower hybrid instability. This paper will summarize evidence of coupling between Saturn, the rings, and the more distant magnetosphere afforded by Cassini's Grand Finale orbits.

Understanding the generation of planetary auroral radio emissions, the powerful non-thermal radiations produced by all the magnetized planets explored so far, and actively searched from exoplanets and more massive objects, requires in situ measurements from within their source region. During the ring-grazing high-inclination orbits spanning late 2016 to early 2017, the Cassini spacecraft sampled at three occasions the top of Saturn's Kilometric Radiation (SKR) emission region, whose intensifications have long been used as a sensitive proxy of large-scale magnetospheric dynamics. The narrow-banded radio sources were crossed at frequencies of 10-20 kHz, all in the northern dawn-side sector. They hosted extraordinary mode emission, radiated quasi-perpendicularly to the local magnetic field from 6-12 keV electron-beams consistent with the Cyclotron Master Instability and embedded within regions of upward currents themselves coincident with the main auroral oval. Overall, the SKR low frequency sources appear to be strongly controlled by time-variable electron densities.

B5.2-0015-18 SURPRISES FROM SATURN: CAPS ELS RESULTS ON MAGNETOSPHERE, MOONS AND RINGS

Andrew Coates, a.coates@ucl.ac.uk

MSSL, University College London, Dorking, United Kingdom

The Cassini mission at Saturn has provided many surprises on Saturn's rapidly rotating magnetosphere and its interaction with the diverse moons, as well as its interaction with the solar wind. One of the early discoveries was the water-rich composition of the magnetosphere. Its structure and dynamics indicate remarkable injections, periodicities and interchange events. Enceladus, orbiting at 4 Rs, was found to have plumes of water vapour and ice which are the dominant source for the inner magnetosphere. Charged water clusters, charged dust and photoelectrons provide key populations in the 'dusty plasma' seen here, as well as chemical complexity in the plume material. Direct pickup is seen near Enceladus and field aligned currents create a spot in Saturn's aurora. At Titan, orbiting at 20 Rs, one of the significant surprises of the mission was heavy negative and positive ions seen in the ionosphere, as well as neutrals, all of which have surprising chemical complexity. These provide the source for Titan's haze. Ionospheric plasma is seen in Titan's tail, enabling ion escape to be estimated at 7 tonnes per day. Saturn's ring ionosphere was seen early in the mission, which was oxygen rich and produced photoelectrons. At Rhea, pickup positive and negative ions indicated weak atmospheres sustained by energetic particle impact, seen in the neutrals also. A weak atmosphere was also seen at Dione. The exosphere production process operates at Jupiter's moons also. At Hyperion, surface charging was seen on a body beyond our Moon for the first time. Here we review some of the key results from CAPS, concentrating on key ELS contributions, and discuss the implications for other solar system contexts.

During six of the 22 Grand Finale orbits, Cassini acquired Doppler data for the determination of the gravity field of the gas giant. In addition, the unique geometry of the last phase of the mission, when the spacecraft flew between the planet and its rings, broke the correlation between the weak gravitational signal from the rings and Saturn's even zonal harmonics, thus enabling a dynamical determination of their mass.

The gravity field measurements were carried out by establishing two-way radio links with NASA's and ESA's ground antennas at X-band (7.2-8.4 GHz). The tracking of Cassini was established continuously for 24-36 hours around the closest approach. The analysis revealed that Saturn's gravity deviates significantly from earlier theoretical expectations and requires a strong differential rotation extending deep into the planet.

In addition, Cassini revealed an unexpected component of Saturn's gravity, possibly ascribable to a time-varying field. The physical phenomena that could provide such a time-variable field include axially asymmetric deep flows and oscillation modes of the entire planet. Some of these modes have already been observed through the analysis of the perturbations induced on Saturn's rings. We discuss the magnitude of the unexplained accelerations and relate them to possible geophysical sources.

Titan observations during the F-Ring and Proximal Orbits that brought the Cassini mission to a close provided key insights into this enigmatic moon. Here we highlight observations of the surface and atmosphere and interpretations and implications thereof for understanding Titan as a system.

Cassini ISS and VIMS documented seasonal cloud distributions, morphologies, behavior, and altitudes from late southern summer in 2004 through early northern summer in 2017 (e.g., Corlies et al. 2017; Kelland et al. 2017; Rodriguez et al. 2011; Turtle et al. 2011). Atmospheric circulation models predicted cloud activity would increase at high northern latitudes as early as 2010 as northern summer approached (e.g., Schneider et al. 2012), similar to activity at high southern latitudes upon Cassini's arrival. Elongated cloud streaks began to appear frequently at 55°N in 2016, and small clouds appeared 15-40°N, a few years later than predictions. However, only small isolated cells were observed near Titan's North Pole through the end of the mission in 2017. The stronger preference for clouds at midrather than high-northern latitudes is consistent with recent models that include polar wetland methane reservoirs

beyond concentrations in the maria (Faulk et al. 2017; Mitchell Lora 2016; Lora et al. 2015), suggesting that a broader subsurface polar methane table is accessible to the atmosphere.

A surprise in 2016-2017 north-polar observations was VIMS detection at 2.1 µm of apparent cloud features that were not seen at 2.0 or 5.0 µm or by ISS at 0.94 µm (Turtle et al. 2016), spectral characteristics that differ from typical clouds and are currently unexplained.

Cassini's final observations of Titan's surface also brought important insights and completed ISS and VIMS maps. Photometric analysis of the entire ISS equatorial (±30°) dataset has improved the signal-to-noise ratio by a factor of 4-5, along with the effective resolution, and produced calibrated surface albedos (Karkoschka et al. 2011). VIMS' global-scale hyperspectral mosaic is empirically corrected for the atmospheric contribution and improves coverage and resolution of the northern lake district (Le Mouélic et al. 2018). RADAR observations of high northern latitudes on Cassini's final close flyby of Titan provided altimetry and bathymetry measurements of Titan's lakes, constraining depths to be >100 m (Mastrogiuseppe et al. 2017) and demonstrating that lakes are hydrologically connected but perched hundreds of meters higher than the equipotential surface of the maria (Hayes et al. 2017). SAR observations of Ligeia Mare did not detect the transient "magic islands" observed previously, leaving the most likely explanation to be waves, bubbles, or floating or suspended solids (Hofgartner et al. 2017). Comparison of all three datasets suggests shallow ponds may have desiccated during the Cassini mission (MacKenzie et al. 2018).

Our understanding of Titan has been completely revolutionized by Cassini-Huygens, nevertheless, there remain many unanswered questions about the surface and atmosphere (Nixon et al. 2018).

We have monitored Titan's seasonal evolution in the neutral atmosphere, during the CassiniHuygens mission. We present here an analysis of nadir spectra acquired by Cassini/CIRS (Jennings et al., 2017, App. Opt. 56, 5274) at high resolution in the past years and describe the temperature and composition variations. During the first years of the mission, Titan's stratosphere was still enhanced in the North. The equatorial and mid-latitudes do not show a lot of variation. In 2010, we have returned to the same season as for the Voyager 1 encounter with Titan in 1980. We will discuss the data comparison between CIRS and V1/IRIS. Since 2010, with CIRS, we have observed at Titan's south pole a strong temperature decrease and the onset of a strong enhancement of several trace species such as complex hydrocarbons and nitriles (Coustenis et al. 2016,Icarus 270, 409 and references therein). This is due to the transition of Titan's seasons from northern winter in 2002 to summer in 2017 and the advent of winter in the south pole. During this transition period species with longer chemical lifetimes linger in the north undergoing slow photochemical destruction, while those with shorter lifetimes decrease and reappear in the south. An opposite effect was expected in the north, but was not observed until recently. From 2013 until 2016, the northern temperature increased by 10 K, while the south has shown a more significant decrease (up to 25 K). While the south polar region is continuously enhanced since about 2012, the chemical content in the north is finally showing a clear depletion for most molecules only since 2015 (Coustenis et al., 2018, submitted). This can set constraints on photochemical and GCM models.

B5.2-0019-18 A POST-CASSINI VIEW OF TITAN'S METHANE-BASED HYDROLOGIC CYCLE

Alexander Hayes, hayes@astro.cornell.edu

Cornell University, Ithaca, New York, United States Ralph Lorenz, ralph.lorenz@jhuapl.edu

Johns Hopkins University Applied Physics Laboratory, Laurel, Maryland, United States Jonathan Lunine, jlunine@astro.cornell.edu

Cornell University, Ithaca, New York, United States

The methane-based hydrologic cycle on Saturn's largest moon, Titan, is an extreme analog to Earth's water cycle. Titan is the only planetary body in the solar system, other than Earth, that is known to have an active hydrologic cycle. With a surface pressure of 1.5 bar and temperatures of 90-95 K, methane and ethane condense out of a nitrogen-based atmosphere and flow as liquids on moon's surface. Exchange processes between atmospheric, surface, and subsurface reservoirs produce methane and ethane cloud systems, as well as erosional and depositional landscapes that have strikingly similar forms to their terrestrial counterparts. Over its thirteen-year exploration of the Saturn system, the Cassini-Huygens mission revealed that Titan's hydrocarbon-based hydrology is driven by nested methane cycles that operate over a range of timescales, including geologic, orbital (e.g., Croll-Milankovitch cycles), seasonal, and that of a single convective storm. We will review the discoveries made by the CassiniHuygens mission, including several new findings derived from Cassini's final flyby of Titan, and present a post-Cassini view of Titan's methane-based hydrologic system, describing the dominant exchange processes that operate over season, orbital, and geologic timescales.

Titan's methane-based hydrologic cycle is a complex, diverse, and multifaceted system that is both similar to and distinct from Earth's water-based hydrologic cycle. A fast physical (phasechange) cycle drives active weather and fluvial processes over seasonal to orbital timescales, a medium-paced chemical cycle siphons off methane for photochemical synthesis, depositing the products on the surface, over timescales of millions of years, while a geologic cycle may sporadically inject methane into the system from Titan's interior over the age of the solar system. Although the Cassini mission's exploration of Titan's methane cycles has ended, ground-based observations can continue to monitor Titan's weather until future missions map fluvial features at a higher resolution and characterize the composition of surface material (including the lakes and seas) through in-situ exploration.

Understanding Titan's methane-based hydrologic system also provides us with a potential window into Earth's distant future and, despite being based on methane as opposed to water, is a useful analog for understaning the climate evolution of the terrestrial planets in general. Titan's methane is essentially free to diffuse into the stratosphere where it is either photolyzed or escapes the atmosphere. This is in contrast to the Earth's modern water cycle, in which the very cold tropopause traps water vapor and limits diffusion into the stratosphere. As the Sun's luminosity increases over the next billion years or so, however, the final state of Earth's hydrologic cycle might resemble the current state of Titan's in that Earth's ocean would be largely gone with only some polar water remaining.

B5.2-0020-18 COMPOSITION AND DEPTHS OF TITAN HYDROCARBONS LAKES REVEALED BY THE CASSINI RADAR ALTIMETER

During the last fly-by of Titan (April 22, 2017) Cassini made a unique observation of the Northern polar terrains in an area rich of small - medium size (10 - 50 km) hydrocarbon lakes previously imaged by the Cassini RADAR. A dedicated processing procedure previously applied to altimetric data acquired over Ligeia Mare where the radar revealed the bathymetry and composition of the sea is exploited to demonstrate that these liquid bodies can exceed one-hundred meters of depth. We present detailed investigation of their depth and liquid composition. The analysis of the backscattering shows that all the observed lakes have similar composition to each other and Ligeia Mare, being methane dominated.

Saturn's largest moon, Titan, possesses a thick atmosphere composed of nitrogen and methane and is the only other place in the solar system to have an active hydrologic cycle. As one of the few direct observables of this cycle, clouds have long been monitored, both with Cassini and from Earth, however, only a small number of these systems have been modelled in detail.

We present a complete analysis of the characteristics of 150+ clouds observed on Titan with the Visual and Infrared Mapping Spectrometer (VIMS) aboard the Cassini-Huygens spacecraft. Understanding the location, frequency, and characteristics of clouds can place important constraints on general circulation models (GCMs), inform about the transport of volatile material in Titan's atmosphere, and provide glimpses into the nature of atmosphere/surface interactions on Titan. We find that clouds generally reside at 5-25 km in altitude, which is in agreement with altitudes expected from convective formation. Cloud optical depths are found to follow an exponential distribution, suggesting that the strongest storms are rare. We find no significant dependence of cloud properties on either location or season, suggesting a universal formation mechanism for clouds on Titan. Assuming convective formation, cloud altitude can provide constraints on the convective available potential energy (CAPE) necessary for formation, which can then place constraints on local surface humidity. Furthermore, combining the sizes and optical depths allows for estimates of the mass (and therefore volatile content) in the cloud. Together these estimates place constraints on the intensity of storms on Titan and can inform the likelihood of precipitation, which in turn influences the surface as well as the local dynamics that drive the cloud formation.

Although clouds have long been observed, to date, only few clouds have been modelled in detail. We employ here a radiative transfer code developed to model Titan's atmosphere, PyDISORT, built around the discrete ordinates method (DISORT), which allows for fast atmospheric retrievals. Clouds are modelled by inserting an additional atmospheric layer into the model. To simulate self-consistent scattering properties, Mie scattering is used to determine the phase function, single scattering albedo, and optical depth for the cloud layer. Free parameters include the optical depth assigned at a reference wavelength (typically 2.0 m) and altitude at which the layer is inserted. The drop size distribution is modelled using a log-normal distribution with an average drop radius of 100 m. We employ a combination of systematic and gradient-minimization search algorithms to quickly and accurately find the best-fit parameters for each cloud.

The analysis here can be tied to and constrain models at both mesoscales and global scales. Multiple observations of cloud systems allow for the evolution to be monitored, which can place further constraints on the mechanisms that influence cloud formation (e.g. surface interactions, winds, etc.) in mesoscale models. Comparison of the modelled clouds (e.g. location, frequency, and characteristic) throughout the datasets can also place valuable constraints on GCMs such as local humidity, wind profiles, and the net transport of volatile material in Titan's atmosphere.

B5.2-0022-18 TITAN CLOUDS OBSERVABLE ONLY IN THE NEAR-INFRARED

Christian Tate, cdt59@cornell.edu

Cornell University, Brooktondale, New York, United States Paul Corlies, pmc232@cornell.edu

Cornell University, Ithaca, New York, United States Alexander Hayes, hayes@astro.cornell.edu

Cornell University, Ithaca, New York, United States

In Cassini's fourteen-year mission, several rare clouds were observed in Titan's methane and nitrogen atmosphere that bring new insights to both the chemistry of Titan's atmospheric circulation and the radiation balance through its thick troposphere. These clouds in Titan's atmosphere were detected by Cassini's Visible and Infrared Imaging Spectrometer (VIMS) but not in its Imaging Subsystem (ISS). Closer analysis shows that these clouds are novel for both their atmospheric properties and for constraining the particular observational synergy between VIMS and ISS. This study constrains these clouds to high altitudes and low opacities where Cassini's instruments can detect them only in the near-infrared.

Designated "Now You See Them, Now You Don't" clouds (NYSTNYD), these clouds appear in the near-infrared methane bands at 1.6, 2.1, 2.8, and 4.9 microns while they are absent in ISS's photometric bands between 0.8 and 1.0 microns. This is not typical for the clouds on Titan observed thus far. These discrepancies between Cassini instruments are opportunities to explore the particular cloud properties and viewing geometries that lead to clouds observable only in the near-infrared. We implement a detailed signal-to-noise model in combination with a radiative transfer model to constrain the cloud opacities and altitudes at which a cloud is observable in either VIMS or ISS but not the other.

In this study, we fit the NYSTNYD cloud properties and model the signal-to-noise ratio (SNR) for the cloud detection that the VIMS and ISS instruments would observe. We fit the VIMS spectra using a chi-squared minimization in an opacity-altitude parameter space generated by libRadtran's DISORT radiative transfer model (Mate, et al. 2016, Icarus). After we constrain the haze, opacity, chemical abundances, and altitude for the NYSTNYD clouds in their particular viewing geometry, we find the sigma of detection for these clouds at various altitudes and thicknesses. The discernable parameter space detectable for both VIMS and ISS wavelengths is quantized and compared to show relative blind-spots in ISS's photometry bands given the modeled cloud spectra. These results have implications for future missions to Titan where it will be crucial to optimize the wavelengths of photometry cameras and spectrometers to resolve the fine structure of Titan's atmosphere.

B5.2-0023-18 THE WEIRD AND WONDERFUL ICY MOONS OF SATURN

Carly Howett, howett@boulder.swri.edu

Southwest Research Institute, Boulder, Colorado, United States Cassini Team

Everyone who contributed to the success of Cassini

From the moment it arrived in the Saturn system Cassini began to reveal the wonder of Saturn's moons, and the results are both numerous and astonishing. The answer to the long held question as to whether Enceladus is active was spectacularly answered by observations of plumes erupting into space and high heat flow on its surface. While in contrast evidence is mounting against the long-held belief that Dione is active too. Although there is evidence to suggest both Dione and Mimas, like Enceladus, might have oceans deep beneath their surface.

Evidence for ancient rings was discovered on the surface of Iapetus (in the form of a 20-km high equatorial ridge), and perhaps on Rhea too (blueish markings along high promontories along Rhea's equator). Images of Iapetus brought its color dichotomy into sharp focus, and the composition of its dark material (and that on Phoebe) was discovered to be a mixture of hydrated iron oxides and space weathered nano-metallic iron mixed with crystalline water ice. Strange surface colorations were found on Tethys, in the form of still unexplained redstreaks that appear to cut across a multitude of geological features. "PacMan" color and thermal anomalies were discovered on Mimas and Tethys, while contrary Dione showed hints at a similar anomaly but only in the thermal analysis. The cause of the "PacMan" anomalies is believed to be surface alteration by high-energy elections, which preferentially bombard the anomalous regions.

Cassini's final gift to us was a chance to observe Saturn's ring moons (some of which were only discovered using Cassini images earlier in its mission) in unprecedented detail. The images showed they were not to be outdone by their larger neighbors, and that these small icy moons were intriguing too! Their densities are all low enough to be consistent with the accretion of ring particles, but their appearances vary wildly. Some appear smooth with seemingly gravity-defying "aprons" around their equator, while others appear more rounded and heavily cratered. Coloration variations were also observed, particularly between 0.35 and 0.55 microns, probably due to differences in the relative amounts of surface contamination from the reddish chromophore (from the ring system itself) and the bright icy E-ring grains. Measurements of the radiation environment of these moons also had some surprises; they showed that some moons have times in their orbit where surface bombardment by energetic electrons actually ceases.

We will discuss the details, context and implications of these results from Cassini, and more!

B5.2-0024-18 THE SEARCH FOR ACTIVITY ON DIONE AND TETHYS WITH THE CASSINI VISIBLE INFRARED MAPPING SPECTROMETER (VIMS)

Bonnie Buratti, bonnie.buratti@jpl.nasa.gov

California Institute of Technology, Pasadena, California, United States Phillip Nicholson, nicholso@astro.cornell.edu

Cornell University, Ithaca, New York, United States

One of the major open questions towards the end of the Cassini mission was whether there was any type of residual geologic activity on Dione or Tethys. The discovery of intriguing red streaks on Tethys, which seemed to be painted onto its surface (Schenk et al., 2015) suggested some sort of recent or ongoing outgassing. But the bulk of the remaining mission resources was focused on Dione, because of the number of hints at low-level activity on this moon coming from a variety of instruments. Burch et al. (2007) found evidence for the injection of plasma streams into the Saturnian magnetosphere from both Tethys and Dione. Khurana et al. (2007) presented magnetometer data that were consistent with a mass loading of 0.72 kg/s neutrals from Dione, about 0.3% of that from Enceladus; this amount could not be explained by sputtering from the surface alone. Three of the five targeted flybys of Dione were devoted to gravity analysis, and two independent teams inferred a subsurface ocean (Beuthe et al., 2016; Hemingway et al., 2016). Another significant result was the detection in December of 2004 of an atmospherelike aura surrounding Dione that was detected by VIMS (Clark et al., 2008) and by CAPS in October 2005 (Simon et al., 2011). Also compelling is the existence of possible cyrovolcanic features on Dione surrounding by regions that appear to be volcanic deposits. Finally, fossilized "tiger stripes" appear to crisscross parts of the moon.

Because no clear evidence of activity was detected during the mission, in spite of these several lines of evidence for it, time was devoted during the F-ring and Proximal orbits in the last year of the mission to obtain high-phase observations of Dione, during which any plume, jet, or atmosphere on the moon would be emphasized in forward-scattered radiation. We overview the results of these observations from the VIMS measurements, as well as a close inspection of

VIMS images of Dione to search for the reappearance of a transient atmosphere similar to the one observed in 2004.

B5.2-0025-18 THE SEASONAL EVOLUTION OF TITAN'S STRATOSPHERIC ICE CLOUDS AS OBSERVED BY CASSINI CIRS

Carrie Anderson, carrie.m.anderson@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States Robert Samuelson, robert.e.samuelson@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States Delphine Nna-Mvondo, delphine.nnamvondo@nasa.gov

NASA Goddard Space Flight Center - USRA, Greenbelt, Maryland, United States Richard Achterberg, richard.k.achterberg@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States

Over the course of Cassini's 13-year mission, the Composite InfraRed Spectrometer (CIRS) observed numerous ice clouds in Titan's stratosphere. This includes the v6 band of HC3N near 506 cm−1 [Anderson et. al. (2010) Icarus, 207, 914-922], as well as the v8 band of C4N2 at 478 cm−1, in which solid-state photochemistry was invoked as a plausible formation mechanism

[Anderson et. al. (2016) Geophys. Res. Lett., 43, 3088-3094]. CIRS also observed geometrically thin ice clouds spanning latitudes 85°N to 60°S during northern winter, which we call the 160 cm−1 ice clouds, with broad spectral dependences peaking at 160 cm−1 [Anderson and

Samuelson (2011) Icarus, 212, 762-778]. Laboratory experiments indicate that these ice clouds are spectrally compatible with co-condensed mixtures of HCN and HC3N. As Titan transitioned into northern spring/southern fall, these ice clouds vanished, and eventually, a massive cloud system developed in Titan's mid stratosphere at high southern latitudes. This is the ice cloud we have named the High-Altitude South Polar (HASP) cloud, which is at least an order of magnitude more intense than the 160 cm−1 ice cloud system, with a different spectral signature.

Laboratory experiments show the HASP cloud is spectrally compatible with an HCN-C6H6 cocondensed ice mixture.

CIRS also observed a spectrally broad and intense unidentified emission feature in Titan's stratosphere that spectrally peaks at 221 cm−1, which we call the Haystack. The Haystack was observed to persevere during northern winter at latitudes poleward of 50°N, with diminishing emission at high northern latitudes as Titan transitioned out of northern winter. During Titan's mid southern fall season, CIRS then observed the Haystack's reappearance at high southern polar latitudes [Jennngs et. al. (2012), ApJ Letters, 761:L15].

In this presentation, we will review the numerous time varying physical and chemical characteristics of Titan's CIRS-observed stratospheric ice clouds. A companion paper (21314) by

Nna-Mvondo et al. will detail our dedicated laboratory efforts to identify their chemical compositions, structural characteristics, and formation mechanisms.

B5.2-0026-18 THE ENIGMATIC CIRS-OBSERVED TITAN'S STRATOSPHERIC ICE CLOUDS STUDIED IN THE LABORATORY

Delphine Nna-Mvondo, delphine.nnamvondo@nasa.gov

NASA Goddard Space Flight Center - USRA, Greenbelt, Maryland, United States Carrie Anderson, carrie.m.anderson@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States Robert Samuelson, robert.e.samuelson@nasa.gov

NASA Goddard Space Flight Center, Greenbelt, Maryland, United States

Stratospheric ice clouds have been repeatedly observed in Titan's atmosphere by the Cassini Composite InfraRed Spectrometer (CIRS) since the Cassini spacecraft entered into orbit around Saturn in 2004. Most of these stratospheric ice clouds form as a result of vapor condensation processes, composed of a combination of pure and mixed nitriles and hydrocarbons. So far, the crystalline cyanoacetylene (HC3N) v6 band at 506 cm−1 (Anderson et al., 2010) and a co-condensed nitrile ice feature at 160 cm−1, dominated by a mixture of HCN and HC3N ices

(Anderson and Samuelson, 2011), have been identified in the CIRS limb spectra. However, the presence of other CIRS-observed stratospheric ice emission features, such as the v8 band of dicyanoacetylene (C4N2) at 478 cm−1 and the unidentified Haystack emission feature at 220 cm−1, are puzzling since they have no associated observed vapor emission features. As well, recently, a massive stratospheric ice cloud system, called the High-Altitude South Polar (HASP) cloud, was discovered in Titan's early southern winter stratosphere at high southern latitudes, with an emission feature peaking near 210 cm−1 (Anderson et al., 2017). We are investigating in laboratory these perplexing observed stratospheric ices to better understand their formation mechanisms, identify their chemical compositions, and determine their optical properties. We have performed transmission spectroscopy of thin films of pure and mixed nitrile ices, as well as -CN ices combined with benzene, from the nearto far-infrared spectral region (50 cm−1 to 11700 cm−1), using the SPECTRAL high-vacuum chamber. Their respective vapors were deposited at low temperatures from 30 K to 150 K and the resulting ices were analyzed at different times after deposition, from immediately after dosing to up to 24 hours post-dosing. Their spectral evolution with time and temperature were studied, the ice phase formation identified, and their optical constants computed. The first surprising yet significant result reveals that the libration mode of HCN (166 - 169 cm−1) is drastically altered by the surrounding molecules when mixing occurs in a co-condensed phase. For propionitrile ice, we observe peculiar temperature and time-driven ice phase transitions, revealed by significant spectral changes in the midand far-IR until a stable crystalline phase is achieved. Comparing our laboratory spectra to the CIRS data, we found that a HCN-C6H6 mixed ice is a good match for the HASP cloud emission feature. We present a summary of our findings obtained so far.

B5.2-0027-18 THE GEOMORPHOLOGY AND COMPOSITION OF TITAN'S SURFACE: COMBINING THE SPATIAL INFORMATION OF CASSINI RADAR WITH THE SPECTRAL INFORMATION OF CASSINI VIMS

Nicholas Kutsop, nwk25@cornell.edu

Cornell University, Ithaca, New York, United States Alexander Hayes, hayes@astro.cornell.edu

Cornell University, Ithaca, New York, United States Kenneth J. Lawrence, kjl@mipl.jpl.nasa.gov

Jet Propulsion Laboratory, California Institute of Technology/ NASA, Pasadena, California, United States

Operating from 2004 to 2017, the Cassini-Huygens mission acquired compositional information and high resolution images of the surface of Saturn's largest moon, Titan, by using the Visual and Infrared Mapping Spectrometer (VIMS) and RADAR instrument. VIMS took more than 36,000 spectral cubes of Titan at 16nm resolution from 0.9 to 5 microns, though it mapped

<5% of the surface at spatial scales > 5km. RADAR mapped 45% of Titan at a resolution of 350m and 75% at 2km or below, though only at a single wavelength (2.1cm) and with low temporal cadence. In this work, we combine the spatial information from the Cassini RADAR with the spectral information and temporal coverage of VIMS to investigate the correlation between geomorphologic and compositional signatures on Titan. We do this by clustering atmospherically corrected VIMS data [1] into RADAR defined geomorphologic units [2-4] and statistically determining the degree of compositional separability [5,6] of the same processed defined units. By utilizing the entire VIMS data regardless of resolution and collecting them into physically significant groups, we achieve global compositional coverage of Titan with a high temporal cadence to examine ongoing processes on Titan's surface. Using this methodology, we investigated whether the same geomorphologic units defined in the northern and southern polar terrain showed similar degrees of compositional separability regardless of hemisphere. Atmospheric haze formed

through photolysis, will sediment out of Titan's atmosphere and accumulate unless washed into drainage basin by rain or swept into dunes by wind [7,8]. In older, drier areas the depth of the deposited hazes could become substantially optically thick in the IR. Therefore, we searched for morphologic units which show separation in one hemisphere but not in the other which may be caused by an optically thick layer of deposited haze which transcends morphologic boundaries. We connect our findings with the conclusion of Birch 2017 that the north and the south were formed through similar process, but that the paucity of fluvial features and the abundance of mountainous features in the south compared to the north is explained by pole-to-pole fluid transport which follows Titan's 100,000-year apsidal precession [2,9,10].

B5.2-0028-18 ASTROBIOLOGY OF TITAN & ENCELADUS: OBSERVATIONS, SIMULATION EXPERIMENTS AND SPECULATIONS

Francois Raulin, francois.raulin@lisa.u-pec.fr Université Paris Est Créteil, Créteil Cedex, France

The Cassini-Huygens mission has unveiled many new aspects of Titan confirming the huge astrobiological importance of the largest satellite of Saturn. The mission has also discovered a new body of prime interest for Astrobiology: Enceladus. However, many questions of astrobiological importance still remain, such as: 1) Complex organic chemistry is one of the many astrobiologically important aspects, of Titan. Solid atmospheric particles seem to play a key role in this chemistry, allowing the formation and evolution of complex organics. What is the chemical nature of these aerosols and their potential evolution after sedimentation on Titan's surface? Laboratory simulation experiments based on Cassini-Huygens observation try to answer these questions. How pertinent are their answer, to which extent can we extrapolate the results obtained from laboratory analogues to the Titan's case? 2) Titan's lakes are mainly made of liquid methane and other low molecular weight hydrocarbons. The possibility of an exotic life in these lakes, involving a biochemistry without O-atoms has been speculated. What are the pros and cons of such an hypothesis and what is the scientific pertinence of such speculation? 3) Both satellites have an internal water ocean. Titan's internal ocean is sandwiched between two layers of ice, but may have been resting on a rocky bottom in its early history. Enceladus's internal ocean is still today in this rocky configuration, which has frequently been considered as privileged for the emergence and development of life. Now new scenarios on the origin of life on Earth imply the involvement of UV radiations, incompatible with deep seas and internal oceans environments. Thus the question of life in these internal oceans must be reexamined taking into account these new scenarii. This presentation will discuss these three points of important astrobiological consequences.

B5.2-0029-18 TITAN AS A SEDIMENTARY WORLD

We performed a detailed mapping and analysis of Titan's geomorphological units to determine the sources and sinks of Titan's sediment cycle. Our global mapping is consistent with past work that suggests that Titan's equatorial dune sands are made from organic material derived from atmospheric photochemistry. The dune sands are transported away from the equator to form the vast mid-latitude plain deposits, possibly as a loess-like terrain unit derived from fragmented dune materials. Some materials deposited in the lower polar latitudes/high mid-latitudes also migrate equatorward to converge with the mid-latitude plains deposits of organic materials. The lack of observed, large high-order collective channels and extensive liquid-filled basins in the equatorial zone and mid-latitudes suggests that surface liquids either evaporate, or percolate into a porous regolith over timescales shorter than the timescale to form a stable channel. The overprinting of eolian deposits is consistent with the mid-latitudes and equatorial region of Titan being dominated by eolian compared to fluvial processes. In the polar regions, there is little evidence for eolian morphology; most of the geomorphology is best explained by fluvial, lacustrine, and even karstic dissolution processes. The enigmatic labyrinthic terrains found mostly in the high latitudes are testament to the production of thick stacks of presumed organic materials that have been deposited and later eroded through eolian, fluvial, or dissolution processes. Our overall synthesis is that Titan is a sedimentary world where the original icy crust has been mantled by organics and eroded to create sediments that were transported and modified by eolian, fluvial, dissolution, and even tectonic processes.

Saturn's largest moon Titan is the second known solar system body on which standing bodies liquid are maintained, the first being Earth. Under Titan's current climatic conditions, stable surface liquids (predominantly a methane-ethane-nitrogen ternary mixture) are restricted to the polar regions. There, liquids pond within two distinct type of depressions: open basins like Kraken Mare or Jingpo Lacus, where evaporation/infiltration is counter-balanced by surface runoff. These larger basins appear to have developed through inundation of a preexisting well-drained landscape, and their formation is relatively straightforward.

The remainder of liquids are contained within sharp edged depressions (SEDs) form topographically closed depressions with no evidence, at the 300-m resolution of SAR images, of terrain features that would suggest inflow or outflow of fluid on the surface, and presumably retain a filled state via subsurface infiltration. SAR images have shown that SEDs are found throughout both polar regions, and show no obvious planview orientation or spatial patterns. Further, the floors of many SEDs are relatively smooth, while the curvature of their perimeters is consistent with growth via uniform scarp retreat. Compared to the larger seas, SED formation is poorly understood. New topographic data, however, is now allowing for more detailed studies of their 3-dimensional forms, and permits more detailed models of formation.

Dissolution of a soluble substrate, as noted in previous studies of Titan's SEDs, can successfully explain all the above observations, and remains a particularly attractive model for their formation. However, new topographic data has revealed the presence of hundred-meter high raised rims around the perimeters of a

subset of these features that defy explanation, and add serious complications that cannot be explained by dissolution erosion alone. Here, we perform a comprehensive study of the rims of Titan's SEDs using a combination of SAR image, and high-resolution topographic data.

Cassini topographic data is available through 3 different processes, with the altimeter being the most useful because of its order-of-magnitude better vertical (<35 m) resolution. This resolution is further increased by another factor of 2 through super-resolution processing of the returned signal, providing the best possible topographic data on Titan available from the Cassini mission. For the 8 flybys where Cassini acquired altimetry data over the polar regions, we can compare directly these topographic profiles to the SAR images. Specifically, the T30, T91, and T126 profiles all crossed one or more SEDs and thus allowed us to investigate the topographic profiles of these features in the highest detail possible. For the 15 SEDs that had a topographic profile, all but 2 had elevated rims. For many of these, a peculiar pattern also appeared, where the elevated portion repeatedly exhibits a distinctive bright-dark pairing, suggestive of elevated topography.

The high probability, albeit with a limited sample size, of SEDs with rims in topographic data, along with the repeated correlation of elevated topography with a visible feature necessitated an inspection of the remainder of Titan's SEDs. To do this, and remain confident that identified features are in fact real, we restricted ourselves to SEDs that have been imaged at least twice from different azimuth and/or incidence angles. By using multiple images, of the same SED, and at differing viewing geometries, we can observe how the bright-dark pairing changes.

For example, if we look at the same SED from two opposing azimuth angles (180° different), then the bright-dark pairing should invert itself. Similarly, for higher incidence angle observations, the pattern should differ from more nadir observations. For high incidence angle observations, the returned power from the leeward side (closer to the spacecraft) of a rim should be relatively high compared to a more nadir observation, where a rim is less obvious. Therefore, if a given feature appears exactly same even though viewing geometries change drastically, then we conclude that the given SED does not have a rim. The opposite is true if the bright-dark pairing does change. For intermediate cases, where geometries are similar, the pattern should remain self-consistent, in which case we also conclude that a SED has a rim.

Using the criterion described above, we found 191 SEDs that were covered by multiple SAR swaths with varying viewing geometries. This represents 30% of Titan's north polar SEDs. Of these, 75% have an observable rim, with a preference for larger SEDs to have more observable (larger) rims. This pattern is consistent with the altimetry statistics, indicating that most SEDs have rims, and that rims may be constructional.

B5.2-0031-18 RIVERS ON TITAN - NUMERICAL MODELLING OF SEDIMENTARY STRUCTURES

On Titan surface one can expect a few geomorphological forms, e.g. fluvial valley and river channels. In our research we use numerical model of rivers to determine the limits of different fluvial parameters that play important roles in evolution of the rivers on Titan and on the Earth. We have found that transport of sediments as suspended load is the main way of transport on Titan [1]. We also determined the range of the river parameters for which a braided river is developed rather than a meandering river. Similar, parallel simulations for rivers deltas are presented in [2].

Introduction

Titan is a very special body in Solar System. It is the only moon that has dense atmosphere and flowing liquid on its surface. The Cassini-Huygens mission has found meandering rivers on Titan and indicated processes of erosion, transport of solid material and its sedimentation. This work is aimed to investigate the similarity and differences between these processes on Titan and on the Earth.

Numerical model

The dynamical analysis of the considered rivers is performed using the package CCHE adapted for the specific conditions on Titan. The package is based on the Navier-Stokes equations for depth-integrated two dimensional, turbulent flow and three dimensional convection-diffusion equation of sediment transport. For more information about equations see [1]-[4].

Parameters of the model
